3:2	RW	0x0	FS1_FS0: Frame List Size. (Read/Write). 000 = Default. This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one. Hence this field is Read/Write for this implementation. This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index. Note that this field is made up from USBCMD bits 15, 3, and 2. 000 = 1024 elements (4096 bytes) Default value 001 = 512 elements (2048 bytes) 010 = 256 elements (1024 bytes) 011 = 128 elements (512 bytes) 100 = 64 elements (256 bytes) 101 = 32 elements (128 bytes) 110 = 16 elements (64 bytes) 111 = 8 elements (32 bytes) Only the host controller uses this field.
1	RW	0x0	RST: Controller Reset. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Host Controller: When software writes a one to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller results in undefined behavior. Device Controller: When software writes a one to this bit, the Device Controller resets its internal pipelines, timers, counters, state machines, etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. Writing a one to this bit in device mode is not recommended. 0 = CLEAR 1 = SET
0	RW	0x0	RS: Run/Stop: Host Controller: When set to a 1, the Host Controller proceeds with the execution of the schedule. The Host Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HCHalted bit in the status register indicates when the Host Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the host controller is in the Halted state (i.e., HCHalted in the USBSTS register is a one). Device Controller: Writing a one to this bit will cause the device controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to

Bit	R/W	Reset	Description
			prevent an attach event before the device controller has been properly initialized. Writing a 0 to this will cause a detach event. 0 = STOP 1 = RUN

19.13.4.19 USB2_CONTROLLER_1_USB2D_USBSTS_0

USB2D USB Status Register

Offset: 0x134 | Read/Write: R/W | Reset: 0b00000000000000000x100x0000x0000

Bit	R/W	Reset	Description
31:16	RW	0x0	PPCI: Port-n Change Detect - RW. Default = 0000h. The definition for each bit is identical to the Port Change Detect field (bit 2 of this register) except these bits are specific to a given port, where bit 16 = Port 1, 17 = Port 2, etc. For example, if bit 17 is set to a one then a port change event was detected on Port 2. The N_PORTS field in HCSPARAMS specifies how many ports are exposed by the host controller and thus how many bits in this field are valid.
15	RW	0x0	AS: Asynchronous Schedule Status. This bit reports the current status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. If AS = ASE: 1= Enable Asynchronous Schedule. 0= Disable Asynchronous Schedule. Only used by the host controller. 0 = DISABLE 1 = ENABLE
14	RW	0x0	PS: Periodic Schedule Status. This bit reports the current status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. If PS = PSE:: 1 = Periodic Schedule is enabled. 0 = Periodic Schedule is disabled. Only used by the host controller. 0 = DISABLE 1 = ENABLE
13	RO	X	RCL: Reclamation. This is a read-only status bit used to detect an empty asynchronous schedule. Only used by the host controller. 0 = DISABLE 1 = ENABLE
12	RW	0x1	HCH: HCHalted. 1 = Default. This bit is a zero whenever the Run/Stop bit is a one. The Host Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Host Controller hardware (e.g., internal error). Only used by the host controller. 0 = UNHALTED 1 = HALTED
11	RW	0x0	UALT_INT: ULPI alt_int Interrupt. 0 = Default. This interrupt bit is set when an RXCMD is received through the ULPI interface with bit 7 set (alt_int). The alt_int bit is set when an unmasked event occurs on any bit in the Carkit Interrupt Latch Register, in the ULPI PHY. The software should read the Carkit Interrupt Latch Register (Read to Clear) through the ULPI Viewport to check the source of the interrupt. Only present in designs where configuration constant VUSB_HS_PHY_ULPI = 1. 0 = NOT_ULPI_ALT_INT 1 = ULPI_ALT_INT
10	RW	0x0	ULPI_INT: ULPI Interrupt. This bit is set whenever an interrupt is received from ULPI PHY. Software writes 1 to clear it. 0 = NOT_ULPI_INT 1 = ULPI_INT

Bit	R/W	Reset	Description
8	RW	0x0	SLI: DCSuspend. When a device controller enters a suspend state from an active state, this bit will be set to a 1. The device controller clears the bit upon exiting from a suspend state. Only used by the device controller. 0 = NOTSUSPEND 1 = SUSPENDED
7	RW	0x0	SRI: SOF Received. When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When an SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125 µs in HS mode and will be synchronized to the actual SOF that is received. Since device controller is initialized to FS before connect, this bit will be set at an interval of 1ms during the prelude to the connect and chirp. In host mode, this bit will be set every 125 µs and can be used by host controller driver as a time base. Software writes a 1 to this bit to clear it. This is a non-EHCI status bit. 0 = SOF_NOT_RCVD 1 = SOF_RCVD
6	RW	0x0	URI: USB Reset Received. When the device controller detects a USB Reset and enters the default state, this bit is set to a 1. Software can write a 1 to this bit to clear the USB Reset Received status bit. Only used by the device controller. 0 = NO_USB_RESET 1 = USB_RESET
5	RW	0x0	AAI: Interrupt and Asynchronous Advance. System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the USBCMD register. This status bit indicates the assertion of that interrupt source. Only used by the host controller. 0 = NOT_ADVANCED 1 = ADVANCED
4	RO	X	SEI: System Error. This bit is not used in this implementation and will always be set to "0". 0 = NO_ERROR 1 = ERROR
3	RW	0x0	FRI: Frame List Rollover. The Host Controller sets this bit to a 1 when the Frame List Index rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [1 3] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a 1 every time FHINDEX [12] toggles. Only used by the host controller. 0 = NO_ROLLOVER 1 = ROLLOVER
2	RW	0x0	PCI: Port Change Detect. The Host Controller sets this bit to a 1 when on any port a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port. The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operational states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively. This bit is not EHCI compatible. 0 = NO_PORT_CHANGE 1 = PORT_CHANGE
1	RW	0x0	UEI: USB Error Interrupt. This bit gets set by the Host/Device controller when completion of a USB transaction results in an error condition. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also ad its interrupt on complete (IOC) bit set. 0 = NO_ERROR 1 = ERROR
0	RW	0x0	UI: USB Interrupt. This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) as an interrupt on complete (IOC) bit set. This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes. 0 = NO_INT 1 = INT

19.13.4.20 USB2_CONTROLLER_1_USB2D_USBINTR_0

USB2D USB Interrupt Enable Register

Offset: 0x138 | Read/Write: R/W | Reset: 0b0000000000000000xxxx00x000000000

Bit	Reset	Description
31:16	0x0	PPCE: Port-n Change Detect Enable - RW. Default = 0000h. The definition for each bit in this field is identical to bit 2 of this register (Port Change Interrupt Enable) except these bits are specific to a given port, where bit 16 = Port 1, 17 = Port 2, etc. For example, if bit 17 is set (1b) then a port change event was detected on Port 2. When a bit in this field is a one, and the corresponding Port-n Change Detect bit in the USBSTS register is a one, the host controller will issue an interrupt. The interrupt is acknowledged by software clearing the Port-n Change Detect bit.
11	0x0	UALTIE: ULPI alt_int Interrupt Enable. 1 = USB controller issues an interrupt if the ULPI_ALT_INT bit in the USBSTS register transitions. The interrupt is acknowledged by software writing a 1 to the ULPI_ALT_INT bit. 0 = DISABLE 1 = ENABLE
10	0x0	ULPIE: ULPI Interrupt Enable. 1 = USB controller issues an interrupt if ULPI_INT bit in USBSTS register transitions. The interrupt is acknowledged by software by writing a 1 to the ULPI_INT bit. 0 = DISABLE 1 = ENABLE
8	0x0	SLE: Sleep Enable. 1 = Device controller issues an interrupt if DCSuspend bit in USBSTS register transitions. The interrupt is acknowledged by software by writing a 1 to the DCSuspend bit. Only used by the device controller. 0 = DISABLE 1 = ENABLE
7	0x0	SRE: SOF Received Enable. 1 = Device controller issues an interrupt if SOF Received bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the SOF Received bit. 0 = DISABLE 1 = ENABLE
6	0x0	URE: USB Reset Enable.1 = Device controller issues an interrupt if USB Reset Received bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the USB Reset Received bit. Only used by the device controller. 0 = DISABLE 1 = ENABLE
5	0x0	AAE: Interrupt on Asynchronous Advance Enable. 1 = the host controller issues an interrupt at the next interrupt threshold if the Interrupt on Async Advance bit in the USBSTS register = 1. The interrupt is acknowledged by software clearing the Interrupt on Async Advance bit. Only used by the host controller. 0 = DISABLE 1 = ENABLE
4	0x0	SEE: System Error Enable. 1 = Host/device controller issues an interrupt if the System Error bit in the USBSTS register = 1. The interrupt is acknowledged by software clearing the System Error bit. 0 = DISABLE 1 = ENABLE
3	0x0	FRE: Frame List Rollover Enable. 1 = Host controller issues an interrupt if the Frame List Rollover bit in the USBSTS register = 1. The interrupt is acknowledged by software clearing the Frame List Rollover bit. Only used by the host controller. 0 = DISABLE 1 = ENABLE
2	0x0	PCE: Port Change Detect Enable. 1 = Host/device controller issues an interrupt if Port Change Detect bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the Port Change Detect bit. 0 = DISABLE 1 = ENABLE
1	0x0	UEE: USB Error Interrupt Enable. 1 = Host controller issues an interrupt at the next interrupt threshold if the USBERRINT bit in USBSTS = 1. The interrupt is acknowledged by software clearing the USBERRINT bit in the USBSTS register. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
0	0x0	UE: USB Interrupt Enable. 1 = Host/device issues an interrupt at the next interrupt threshold if the USBINT bit in USBSTS = 1. The interrupt is acknowledged by software clearing the USBINT bit. 0 = DISABLE 1 = ENABLE

19.13.4.21 USB2_CONTROLLER_1_USB2D_FRINDEX_0

USB2D USB Frame Index Register

Offset: 0x13c | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
13:0	X	FRINDEX: Frame Index. The value in this register increments at the end of each time frame (micro-frame). Bits [N: 3] are used for the Frame List current index. Each location of the frame list is accessed 8 times (frames or micro-frames) before moving to the next index. The following illustrates values of N based on the value of the Frame List Size field in the USBCMD register, when used in host mode. USBCMD [Frame List Size] Number Elements N 000b (1024) 12 001b (512) 11 010b (256) 10 011b (128) 9 100b (64) 8 101b (32) 7 110b (16) 6 111b (8) 5 In device mode, the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode, bits 2:0 indicate the current micro-frame.

19.13.4.22 USB2_CONTROLLER_1_USB2D_PERIODICLISTBASE_0

USB2D Host Controller Frame List Base Address Register

Offset: 0x144 | Read/Write: R/W | Reset: 0b00000000000000000000xxxxxxxxxxxx

Bit	Reset	Description
31:25	0x0	USBADR: Device mode. The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET_ADDRESS request.
24	0x0	USBADRA: Device Address Advance. Default=0. When this bit is 0, any writes to USBADR are instantaneous. When this bit is written to a 1 at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0). Note: After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD cannot write of the device address within 2ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.
31:12	0x0	BASEADR: Host mode: This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence. Base Address (Low). These bits correspond to memory address signals [31:12], respectively. Only used by the host controller.

19.13.4.23 USB2_CONTROLLER_1_USB2D_ASYNCLISTADDR_0

USB2D Next Asynchronous List Address Register

Offset: 0x148 | Read/Write: R/W | Reset: 0b00000000000000000000000000xxxxx

Bit	Reset	Description
31:11	0x0	EPBASE: Device mode. This register contains the address of the top of the endpoint list in system memory. These bits correspond to memory address signals [31:11], respectively. This field will reference a list of up to 32 Queue Heads (QH). Only used by the device controller.
31:5	0x0	ASYBASE: Host mode. This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Link Pointer Low (LPL). These bits correspond to memory address signals [31:5], respectively. This field may only reference a Queue Head (OH). Only used by the host controller.

19.13.4.24 USB2_CONTROLLER_1_USB2D_ASYNCTTSTS_0

USB2D Asynchronous Buffer Status for Embedded TT Register

Offset: 0x14c | Read/Write: R/W | Reset: 0bx0000000xxxxxxxxxxxxxxxxxxxxxx0x

Bit	R/W	Reset	Description
30:24	RW	0x0	TTHA: Internal TT Hub Address representation. This field is used to match the Hub Address field in QH (queue head) and siTD to determine if the packet is routed to the internal TT for directly attached FS/LS devices. If the Hub Address in the QH or siTD does not match this address, then the packet will be broadcast on the High-Speed ports destined for a downstream High Speed hub with the address in QH/siTD.
1	RW	0x0	TTAC: Embedded TT Async Buffers Clear. (Read/Write to set). This field will clear all pending transactions in the embedded TT Async Buffer(s). The clear will take as much time as necessary to clear buffer without interfering with a transaction in progress. TTAC will return to zero after being set by software only after the actual clear occurs.
0	RO	X	TTAS: Embedded TT Async Buffers Status. (Read Only). This read-only bit will be 1 if one or more transactions are being held in the embedded TT Async. Buffers. When this bit is a zero, then all outstanding transactions in the embedded TT have been flushed.

19.13.4.25 USB2_CONTROLLER_1_USB2D_BURSTSIZE_0

USB2D Burst Size register

Offset: 0x150 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx0000100000001000

Bit	Reset	Description
15:8	0x8	TXPBURST: Programmable TX Burst Length. (Read/Write). This register represents the maximum length of a burst in 32-bit words while moving data from system memory to the USB bus.
7:0	0x8	RXPBURST: Programmable RX Burst Length. (Read/Write). This register represents the maximum length of a burst in 32-bit words while moving data from the USB bus to system memory.

19.13.4.26 USB2_CONTROLLER_1_USB2D_TXFILLTUNING_0

USB2D Transmit Fill Tuning Register

Offset: 0x154 | Read/Write: R/W | Reset: 0bxxxxxxxxxx000010xxx0000000000000

Bit	Reset	Description
21:16	0x2	TXFIFOTHRES: FIFO Burst Threshold. (Read/Write). This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2, and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO

Bit	Reset	Description
		may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in USBMODE register is set.
12:8	0x0	TXSCHHEALTH: Scheduler Health Counter. (Read/Write To Clear) [Default = 0] This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max out at 31.
7:0	0x0	TXSCHOH: Scheduler Overhead. (Read/Write) [Default = 0] This register adds an additional fixed offset to the schedule time estimator described above as Tff. As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267 µs when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333 µs when a device is connected in Low/Full Speed Mode

19.13.4.27 USB2_CONTROLLER_1_USB2D_ICUSB_CTRL_0

USB2D ICUSB Control Register

This register enables and controls the ICUSB FS/LS transceiver.

Offset: 0x15c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000

Bit	Reset	Description
3	0x0	IC_ENB1: ICUSB transceiver enable. This bit enables the ICUSB transceiver. To enable the interface, the PTS bits must be set to 11 in the PORTSCx. Writing a '1' to this bit selects the IC_USB interface. 0 = DISABLE 1 = ENABLE
2:0	0x0	IC_VDD1: ICUSB voltage select. It selects which voltage is being supplied to the ICUSB peripheral. 000= No voltage 001 = 1.0V - reserved 010= 1.2V - reserved 011= 1.5V - reserved 100 = 1.8V 101 = 3.0V 110 = reserved 111 = reserved The Voltage negotiation should happen between enabling port power (PP) and asserting the run/stop bit.

19.13.4.28 USB2_CONTROLLER_1_USB2D_ULPI_VIEWPORT_0

This register provides indirect access to the ULPI PHY register set. Although the USB controller performs access to the ULPI PHY register set, there may be extraordinary circumstances where software may need direct access.

Note: WRITES TO THE ULPI THROUGH THE VIEWPORT CAN SUBSTANTIALLY HARM STANDARD USB OPERATIONS. CURRENTLY NO USAGE MODEL HAS BEEN DEFINED WHERE SOFTWARE SHOULD NEED TO EXECUTE WRITES DIRECTLY TO THE ULPI PHY. SEE EXCEPTION REGARDING OPTIONAL FEATURES BELOW.

Note: EXECUTING READ OPERATIONS THROUGH THE ULPI VIEWPORT SHOULD HAVE NO HARMFUL SIDE EFFECTS TO STANDARD USB OPERATIONS.

There are two operations that can be performed with the ULPI Viewport-- wakeup and read /write operations.

The wakeup operation is used to put the ULPI interface into normal operation mode and re-enable the clock if necessary. A wakeup operation is required before accessing the registers when the ULPI interface is operating in low power mode, serial mode, or Carkit mode.

The ULPI state can be determined by reading the sync state bit (ULPI_SYNC_STATE). If this bit is a one, then ULPI interface is running in normal operation mode and can accept read/write operations. If the ULPI_SYNC_STATE indicates a 0 then then read/write operations will not be able to execute. Undefined behavior will result if ULPI_SYNC_STATE = 0 and a read or write operation is performed.

To execute a wakeup operation, write all 32 bits of the ULPI Viewport where ULPI_PORT is constructed appropriately and the ULPI_WAKEUP bit is a 1 and ULPI_RUN bit is a 0. Poll the ULPI Viewport until ULPI_WAKEUP is zero for the operation to complete.

To execute a read or write operation, write all 32 bits of the ULPI Viewport where ULPI_DATA_WR, ULPI_REG_ADDR, ULPI_PORT, ULPI_RD_WR are constructed appropriately and the ULPI_RUN bit is a 1. Poll the ULPI Viewport until ULPI_RUN is zero for the operation to complete. Once ULPI_RUN is zero, the ULPI_DATA_RD will be valid if the operation was a read.

The polling method above can be changed to interrupt driven using the ULPI interrupt defined in the USBSTS and USBINTR registers. When a wakeup or read/write operation is complete, the ULPI_INT interrupt will be set.

There are several optional features that may need to be enabled or disabled by system software as part of system configuration. These bits are contained in the Interface and OTG Control registers of the ULPI PHY register set. These registers also contain bits which are controlled by the link dynamically and therefore should be only modified by system software using the Set/Clear access method. Direct writes to these registers could have harmful side effects to the standard USB operations. The optional bits are as follows: Bits 3 through 7 in the Interface Control register and Bits 6 and 7 in the OTG Control register.

Please refer to the ULPI Specification Revision 1.1 for further information on the use of the optional features.

USB2D ULPI Viewport Register

Offset: 0x160 | Read/Write: R/W | Reset: 0b000xx00000000000xxxxxxxx00000000

Bit	R/W	Reset	Description
31	RW	0x0	ULPI_WAKEUP: ULPI Wakeup. Writing the 1 to this bit will begin the wakeup operation. The bit will automatically transition to 0 after the wakeup is complete. Once this bit is set, the driver cannot set it back to 0. Note: The driver must never execute a wakeup and a read/write operation at the same time. 0 = CLEAR 1 = SET
30	RW	0x0	ULPI_RUN: ULPI read/write Run. Writing the 1 to this bit will begin the read/write operation. The bit will automatically transition to 0 after the read/write is complete. Once this bit is set, the driver cannot set it back to 0. Note: The driver must never execute a wakeup and a read/write operation at the same time. 0 = CLEAR 1 = SET
29	RW	0x0	ULPI_RD_WR: ULPI read/write control. (0) Read; (1) Write. This bit selects between running a read or write operation. 0 = READ 1 = WRITE
27	RO	X	ULPI_SYNC_STATE: ULPI sync state. (1) Normal Sync. State. (0) In another state (i.e., Carkit, serial, low power). This bit represents the state of the ULPI interface. 0 = NOT_NORMAL 1 = NORMAL
26:24	RW	0x0	ULPI_PORT: ULPI PHY port number. This field should be always written as 0.
23:16	RW	0x0	ULPI_REG_ADDR: ULPI PHY register address. When doing a read or write operation to the ULPI PHY, the address of the ULPI PHY register being accessed is written to this field.
15:8	RO	X	ULPI_DATA_RD: ULPI PHY data read. The data from the ULPI PHY register can be read from here after the read operation completes.
7:0	RW	0x0	ULPI_DATA_WR: ULPI PHY data write. The data to write to the ULPI PHY register is written

Bit	R/W	Reset	Description
			here.

19.13.4.29 USB2_CONTROLLER_1_USB2D_PORTSC1_0

USB2D Port Status/Control 1 Register

Offset: 0x174 | Read/Write: R/W | Reset: 0b0000000xx0000000xxx1xx00x0xx010x

Bit	R/W	Reset	Description
31:25	RW	0x0	DA: Device Address. Default = 0000000b. The 7-bit USB device address for the device attached to an immediately downstream of the associated root port. A value of zero indicates no device is present or software support for this feature is not present. This is used by the Controller when sending the LPM token. This field is only valid when the core is operating in host mode. If in device mode it will be read only and always equal to 0000000b.
24:23	RO	X	SSTS: Suspend Status. Default = 00b. These two bits are used by software to determine whether an L1-based suspend request was successful, specifically: 00b - L1 state entered with success. ACK received from peripheral. 01b - NYET received from peripheral. It was not able to enter L1 state this time. 10b - L1 state not supported by peripheral. STALL received. 11b - Peripheral did not respond or an error occurred. The value of this field is only valid when the port resides in the L0 state - that is, the meaning of these bits is invalid whenever bit 7 of this register (SUSP) is one. Ideally, the Controller driver should read this register if it receives an interrupt after issuing a suspend using L1 support. In case of a non-success a port change interrupt will be fired and this field should be checked for a possible L1 failure. This field is only valid when the core is operating in host mode. If in device mode it will be always equal to 00b. 0 = L1STATE_ENTERED 1 = NYET_PERIPH 2 = L1STATE_NOT_SUPPORTED 3 = PERIPH_NORESP_ERR
22	RW	0x0	WKOC: Default = 0b. Wake on Over-current Enable: Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. This field is zero if Port Power (PP) is zero. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behavior. 0 = DISABLE 1 = ENABLE
21	RW	0x0	WKDS: Wake on Disconnect Enable: Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if Port Power (PP) is zero or in device mode. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behavior. This bit should not be written to 1 if there is no device connected. After the device disconnect is detected, this bit should be cleared to 0. 0 = DISABLE 1 = ENABLE
20	RW	0x0	WKCN: Wake on Connect Enable: Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if Port Power (PP) is zero or in device mode. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behavior. This bit should not be written to 1 while the device is connected. After the device connection is detected, this bit should be cleared to 0. 0 = DISABLE 1 = ENABLE
19:16	RW	0x0	PTC: Port Test Control: Any value other than zero indicates that the port is operating in test mode. Value Specific Test. 0000b Not enabled. 0001b J_ STATE. 0010b K_STATE.

Bit	R/W	Reset	Description
			0011b SEQ_NAK. 0100b Packet. 0101b FORCE_ENABLE. 0110b to 1111b Reserved. Refer to Chapter 7 of the USB Specification Revision 2.0 for details on each test mode. 0 = NORMAL_OP 1 = TEST_J 2 = TEST_K 3 = TEST_SE0_NAK 4 = TEST_PKT 5 = TEST_FORCE_ENABLE
15:14	RO	X	PIC: Port Indicator Control: This field is not supported in the current implementation. Please use a GPIO if you wish to use Port Indicators.
13	RO	X	PO: Port Owner. Port owner handoff is not implemented in this design, therefore this bit will always be 0.
12	RW	0x1	PP: Port Power: The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows: PPC PP Operation 0b 0b Read Only. A device controller with no OTG capability does not have port power control switches. 1b 1b/0b RW. Host/OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (i.e., PP equals a 0), the port is non-functional and will not report attaches, detaches, etc. When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitioned by the host controller driver from a one to a zero (removing power from the port). 0 = NOT_POWERED 1 = POWERED
11:10	RO	X	LS: These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. The encoding of the bits is: 00b = SE0 10b = J-state 01b = K-state 11b = Undefined The value of this field is undefined if Port Power (PP) is zero in host mode. In host mode, the use of line state by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS. In device mode, the use of line state by the device controller driver is not necessary. 0 = SE0 1 = K_STATE 2 = J_STATE 3 = UNDEFINED
9	RW	0x0	SLP: Suspend using L1 - RW. Default = 0b. When this bit is set to '1' and a non-zero Device Address (DA) is specified Controller will instigate L1 entry during suspend (bit 7) and L1 exit during resume (bit 6). When set to zero the Controller will use the legacy (L2) mechanism. Software should only set this bit when the device attached immediately downstream supports L1 transitions. When acting as device, this bit is read-only and set to '1' by the hardware when the Controller enters is L1 state (LPM token received and accepted). Note: HSP is redundant with PSPD(27:26). This bit is not defined in the EHCI specification.
8	RW	0x0	PR: This field is zero if Port Power (PP) is zero. In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. When software writes a one to this bit, the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver. In Device Mode: This bit is a read-only status bit. Device reset from the USB bus is also indicated in the USBSTS register. 0 = NOT_USB_RESET 1 = USB_RESET

Bit	R/W	Reset	Description
7	RO	X	SUSP: Port suspend. 1=Port in suspend state. 0=Port not in suspend state. In Host Mode: Read/Write. Port Enabled bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0x Disable 10 Enable 11 Suspend When in the suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. The host controller will unconditionally set this bit to zero when software sets the Force Port Resume bit to zero. A write of zero to this bit is ignored by the host controller. If host software sets this bit to a one when the port is not enabled (i.e., Port enabled bit is a zero), the results are undefined. This field is zero if Port Power (PP) is zero in host mode. In Device Mode: Read Only. This bit is a read-only status bit. 0 = NOT_SUSPEND 1 = SUSPEND
6	RW	0x0	FPR: Force Port Resume. 1= Resume detected/driven on port. 0=No resume (K state) detected/driven on port. In Host Mode: Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to one. This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver. Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit remains a one until the port has switched to the high-speed idle. Writing a zero has no effect because the port controller will time the resume operation to clear the bit when the port control state switches to HS or FS idle. This field is zero if Port Power (PP) is zero in host mode. This bit is not-EHCI compatible. In Device mode: After the device has been in Suspend State for 5 ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to one. Software should ensure that the PHY clock is operational before writing a 1 to this bit to start the resume sequence. This is true for both Device and Host modes. 0 = NO_RESUME 1 = RESUME
5	RO	X	OCC: Over-current Change: Not supported 0 = NO_CHANGE 1 = CHANGE
4	RO	X	OCA: Over-current Active: Not supported 0 = NO_OVER_CURRENT 1 = OVER_CURRENT
3	RW	0x0	PEC: Port Enable/Disable Change: 1=Port enabled/disabled status has changed. 0=No change. In Host Mode: For the root hub, this bit gets set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is zero if Port Power (PP) is zero. In Device mode: The device port is always enabled. (This bit will be zero) 0 = NO_CHANGE 1 = CHANGE
2	RW	0x1	PE: Port Enabled/Disabled: 1=Enable. 0=Disable (default) In Host Mode: Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b)

Bit	R/W	Reset	Description
			downstream propagation of data is blocked except for reset. This field is zero if Port Power (PP) is zero in host mode. In Device Mode: The device port is always enabled. (This bit will be one) 0 = PORT_DISABLED 1 = PORT_ENABLED
1	RW	0x0	CSC: Connect Status Change: 1 =Change in Current Connect Status. 0=No change (default) In Host Mode: Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (i.e., the bit will remain set). Software clears this bit by writing a one to it. This field is zero if Port Power (PP) is zero in host mode. This bit is undefined in device controller mode. 0 = NO_CHANGE 1 = CHANGE
0	RO	X	CCS: Current Connect Status. In Host Mode: 1=Device is present on port. 0=No device is present (default). This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change bit (Bit 1) to be set. This field is zero if Port Power (PP) is zero in host mode. In Device Mode: 1=Attached. 0=Not Attached (default). A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended. 0 = NOT_CONNECTED 1 = CONNECTED

19.13.4.30 USB2_CONTROLLER_1_USB2D_HOSTPC1_DEVLC_0

USB2D Device Mode LPM Behavior and Control Register

This register controls the LPM behavior and controls the behavior of each USB port. Only available when in device mode. This register shares the same address with the HOSTPC1 register (which is used only in host mode).

USB2D Host Mode LPM Behavior and Control Register

This register controls the LPM behavior and controls the behavior of each USB port. Only available when in host mode. This register shares the same address with the DEVLC register (which is used only in device mode).

Offset: 0x1b4 | Read/Write: R/W | Reset: 0b0000xxx0000000000000xxxxxxxxxxx0

Bit	R/W	Reset	Description
31:29	RW	0x0	PTS: Parallel transceiver select. This bit is not defined in the EHCI specification. 0 = UTMI 1 = RESERVED 2 = ULPI 3 = ICUSB_SER
28	RW	0x0	STS: Serial transceiver not selected. This is the only value supported. This bit is not defined in the EHCI specification. 0 = PARALLEL_IF 1 = SERIAL_IF
27	RO	X	PTW: Parallel Transceiver Width. Fixed to 0. This bit is not defined in the EHCI specification. 0 = EIGHT_BIT 1 = RESERVED

Bit	R/W	Reset	Description
26:25	RO	X	PSPD: This register field indicates the speed at which the port is operating. 00 = Full Speed 01 = Low Speed 10 = High Speed. This bit is not defined in the EHCI specification. 0 = FULL_SPEED 1 = LOW_SPEED 2 = HIGH_SPEED 3 = RESERVED
24	RW	0x0	ALPD: Auto Low Power While Disconnect - RW. Default = 0b. If set, this feature will be enabled, and every time the port enters the disconnect state, it will also enter in low power state, disabling the transceiver clock. The behavior will be same as if the PHCD bit was enabled (in fact this bit will be set to 1 as soon as low power mode is enabled).When this field is set the WKCN field of PORTSCx register (Wake on Connect Enable) will also be set. This way the core will wake up in case a connect is detected. There will be a delay between the detection of a disconnect and actually enter in low power mode. This delay can be controlled by writing to the ALPDD field in the register USBMODE 0 = DONT_AUTO_LOW_POWER_WHILE_DISCONNECT 1 = AUTO_LOW_POWER_WHILE_DISCONNECT
23	RW	0x0	PFSC: Port Force Full Speed Connect - RW. Default = 0b. Writing this bit to a '1b' will force the port to only connect at Full Speed. It disables the chirp sequence that allows the port to identify itself as High Speed. This is useful for testing FS configurations with an HS host, hub or device. This bit is not defined in the EHCI specification. 0 = DONT_FORCE_FULL_SPEED 1 = FORCE_FULL_SPEED
22	RW	0x0	PHCD: PHY Low Power Suspend - Clock disable: Writing this bit to a 1 will disable the PHY clock. Writing a 0 enables it. Reading this bit will indicate the status of the PHY clock. NOTE: The PHY clock cannot be disabled if it is being used as the system clock. In device mode, the PHY can be put into Low Power Clock Disable when the device is not running (USBCMD RS=0b) or the host has signaled suspend (PORTSCx SUSP=1b). Low Power Clock Disable will be cleared automatically when the host has signaled resume. Before forcing a resume from the device, the Controller driver must clear this bit. In host mode, the PHY can be put into Low Power Suspend Clock Disable when the downstream device has been put into suspend mode or when no downstream device is connected. Low Power Clock Disable is completely under the control of software. 0 = DISABLE 1 = ENABLE
21:20	RW	0x0	LPMX: Auto LPM set - RW. Default = 00b. This bit field is valid during Host Mode Only. For Device Mode this is reserved. Value Meaning 00b Disables auto LPM. 01b If there is no activity for a certain number of SOFs the controller will send an LPM token, enter in suspend and issue a port change interrupt. 10b Same as above but without issuing an interrupt. 11b Reserved for futures LPM enhancements. The detection of no activity is based on the absence of response from the downstream device. Because of this limitation this feature should not be used if ISO OUT endpoints are being used (as no handshake is expected).
17	RW	0x0	ASUS: Auto Low Power - RW. Default = 0b. This bit field is valid during Device Mode Only. In Host Mode it is part of ELPM field. This bit is used to control the auto low power feature. If set, the auto low power feature will be enabled and every time the port enters in suspend state it will also enter in low power state, disabling the transceiver clock. The behavior will be the same as if the PHCD bit was enabled (in fact this bit will be set to '1' as soon as low power mode is enabled). 0 = DISABLE 1 = ENABLE
19:16	RW	0x0	EPLPM: Endpoint for LPM token - RW. Default = 0000b. This bit field is valid during Host Mode only. For Device Mode [19:18] is reserved and 17 is ASUS, while 16 is STL. This sets the endpoint number to which the LPM token will be sent. It will be directly mapped to the ENDP field in the LPM token with the EXT PID.
16	RW	0x0	STL: STALL reply to LPM token - RW. Default = 0b. This bit field is valid during Device Mode Only. In Host Mode it is a part of ELPM field. When this bit is set to '1', the Controller will reply always with STALL to all incoming LPM tokens. This bit overrides the LPM NYET bit (NYT).

Bit	R/W	Reset	Description
			0 = DISABLE 1 = ENABLE
15:12	RW	0x0	LPMFRM: Auto LPM SOF Threshold - RW. Default = 0000b. This bit field is valid during Host Mode Only. For Device Mode this is reserved. This holds the SOF counter threshold. When the number of SOFs with no activity in between reaches this threshold and the auto LPM is enabled, an LPM token is sent and the port enters the suspend state. The SOF counter for this threshold is incremented each 125 µs, even if the port is not in HS operation.
11:1	RO	X	BA: bmAttributes - RO. Default = 00000000000b. This holds the bmAttributes field of the LPM sub-token received, after the EXT PID token.
0	RW	0x0	NYT_ASUS: NYET reply to LPM token - RW. Default = 0b. This bit is NYT during Device Mode. When this bit is '1', the device controller will NYET all the LPM tokens. When this bit is set to '0', the Controller will ACK all the LPM tokens if the STALL bit (STL) is also set to '0'. This bit is ASUS in Host Mode. This bit is used to control the auto low power feature. If set, the auto low power feature is enabled and every time the port enters the suspend state, it also enters the low power state, disabling the transceiver clock. The behavior is the same as if the PHCD bit was enabled (this bit is set to '1' as soon as low power mode is enabled). 0 = DISABLE 1 = ENABLE

19.13.4.31 USB2_CONTROLLER_1_USB2D_OTGSC_0

USB2D On-The-Go (OTG) Status and Control Register

Offset: 0x1f4 | Read/Write: R/W | Reset: 0bx0000000x0000000xxxxxxxxxx100x00

Bit	R/W	Reset	Description
30	RW	0x0	DPIE: Data Pulse Interrupt Enable. Setting this bit enables the Data pulse interrupt. 0 = DISABLE 1 = ENABLE
29	RW	0x0	ONEMSE: 1 millisecond timer Interrupt enable. Setting this bit enables the 1 millisecond timer interrupt. 0 = DISABLE 1 = ENABLE
28	RW	0x0	BSEIE: B Session End Interrupt Enable. Setting this bit enables the B session end interrupt 0 = DISABLE 1 = ENABLE
27	RW	0x0	BSVIE: B Session Valid Interrupt Enable. Setting this bit enables the B session valid interrupt 0 = DISABLE 1 = ENABLE
26	RW	0x0	ASVIE: A Session Valid Interrupt Enable. Setting this bit enables the A session valid interrupt 0 = DISABLE 1 = ENABLE
25	RW	0x0	AVVIE: A VBus Valid Interrupt Enable. Setting this bit enables the A VBus valid interrupt 0 = DISABLE 1 = ENABLE
24	RW	0x0	IDIE: USB ID Interrupt Enable. Setting this bit enables the USB ID interrupt 0 = DISABLE 1 = ENABLE
22	RW	0x0	DPIS: Data Pulse Interrupt Status. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC(0). PortPower = Off (0). Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
21	RW	0x0	ONEMSS: 1 millisecond timer Interrupt Status: This bit is set once every millisecond. Software writes a 1 to clear it. 0 = INT_CLEAR 1 = INT_SET

Bit	R/W	Reset	Description
20	RW	0x0	BSEIS: B Session End Interrupt Status. This bit is set when VBus has fallen below the B session end threshold. Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
19	RW	0x0	BSVIS: B Session Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the B session valid threshold (0.8 VDC). Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
18	RW	0x0	ASVIS: A Session Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the A session valid threshold (0.8 VDC). Software writes a one to clear this bit. 0 = INT_CLEAR 1 = INT_SET
17	RW	0x0	AVVIS: A VBus Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the VBus valid threshold (4.4 VDC) on an A device. Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
16	RW	0x0	IDIS: USB ID Interrupt Status. This bit is set when a change on the ID input has been detected. Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
14	RO	X	DPS: Data Bus Pulsing Status. A 1 indicates data bus pulsing is being detected on the port. 0 = STS_CLEAR 1 = STS_SET
13	RO	X	ONEMST: 1 millisecond timer toggle. This bit toggles once per millisecond 0 = STS_CLEAR 1 = STS_SET
12	RO	X	BSE: B session End. Indicates VBus is below the B session end threshold 0 = STS_CLEAR 1 = STS_SET
11	RO	X	BSV: B Session Valid. Indicates VBus is above the B session valid threshold 0 = STS_CLEAR 1 = STS_SET
10	RO	X	ASV: A Session Valid. Indicates VBus is above the A session valid threshold 0 = STS_CLEAR 1 = STS_SET
9	RO	X	AVV: A VBus Valid. Indicates VBus is above the A VBus valid threshold 0 = STS_CLEAR 1 = STS_SET
8	RO	X	ID: USB ID: 0 = A-device 1 = B-device 0 = A_DEV 1 = B_DEV
5	RW	0x1	IDPU: USB ID Pullup 0 = CLEAR 1 = SET
4	RW	0x0	DP: Data Pulsing. Setting this bit causes the pull-up on DP to be asserted for data pulsing during SRP. 0 = NO_DATA_PULSE 1 = DATA_PULSE
3	RW	0x0	OT: OTG Termination. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM. 0 = NO_OTG_TERM 1 = OTG_TERM
1	RW	0x0	VC: VBUS Charge. Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP. 0 = NO_VBUS_CHRG 1 = VBUS_CHRG

Bit	R/W	Reset	Description
0	RW	0x0	VD: VBUS_Discharge. Read/write. Setting this bit causes Vbus to discharge through a resistor. 0 = NO_VBUS_DISCHRG 1 = VBUS_DISCHRG

19.13.4.32 USB2_CONTROLLER_1_USB2D_USBMODE_0

USB2D USB Device Mode Register

Offset: 0x1f8 | Read/Write: R/W | Reset: 0b00000000000000000xxxxxxxx0xxxxx

Bit	R/W	Reset	Description
31:16	RW	0x0	ALPDD: Auto Low Power While Disconnect Delay. Used when the ALPD field of the HOSTPCx register is set. Defines the delay between disconnect detection and entering in low power mode. The delay is <this register value>*64*100/3 in milliseconds. The maximum value is 65535*64*100/3 = 139,808 ms. The minimum value is 0. Only used in Host mode.
15	RW	0x0	SRT: Shorten USB Reset Time. Software should never set this to 1.
5	RW	0x0	VBPS: VBUS Power Select This can be used by logic that selects between an on-chip Vbus power source (charge pump) and an off-chip source in systems when both are available. Only to be used in Host Mode. Software should not use this.
4	RO	X	SDIS: Stream disable: 1 Streaming is disabled - helpful to avoid overruns/underruns when system load is too high. 0 = STREAM_ENABLE 1 = STREAM_DISABLE
3	RO	X	SLOM: Setup Lockout Mode: In device mode, this bit controls the behavior of the setup lockout mechanism. 0 - Setup lockout is ON (default) 1 Setup lockout is OFF. Firmware requires the use of setup tripwire semaphore in USB2D_USBCMD register. 0 = LOCKOUT_ON 1 = LOCKOUT_OFF
2	RO	X	ES: Endian Select: Note: For this implementation, this should be always set to 0 (little endian). 0 = LITTLE_ENDIAN 1 = RESERVED
1:0	RO	X	CM: Controller Mode: The controller mode will default to an idle state and will need to be initialized to the desired operating mode after reset. This register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the RESET bit in the USBCMD register before reprogramming this register. 00 = Idle [Default]. 01 = Reserved. 10 = Device Controller. 11 = Host Controller. 0 = IDLE 1 = RESERVED 2 = DEVICE_MODE 3 = HOST_MODE

19.13.4.33 USB2_CONTROLLER_1_USB2D_ENDPTNAK_0

USB2D Endpoint NAK register

Offset: 0x200 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	EPTN: TX Endpoint NAK R/WC. Each TX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received IN token for the corresponding endpoint. 0 = CLEAR 1 = SET
15:0	0x0	EPRN: RX Endpoint NAK R/WC. Each RX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received OUT or PING token for the corresponding endpoint. 0 = CLEAR 1 = SET

19.13.4.34 USB2_CONTROLLER_1_USB2D_ENDPTNAK_ENABLE_0

USB2D Endpoint NAK Enable Register

Offset: 0x204 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	EPTNE: TX Endpoint NAK Enable R/W. Each bit is an enable bit for the corresponding TX Endpoint NAK bit. If this bit is set and the corresponding TX Endpoint NAK bit is set, the NAK Interrupt bit is set. 0 = DISABLE 1 = ENABLE
15:0	0x0	EPRNE: RX Endpoint NAK Enable R/W. Each bit is an enable bit for the corresponding RX Endpoint NAK bit. If this bit is set and the corresponding RX Endpoint NAK bit is set, the NAK Interrupt bit is set. 0 = DISABLE 1 = ENABLE

19.13.4.35 USB2_CONTROLLER_1_USB2D_ENDPTSETUPSTAT_0

USB2D Endpoint Setup Status Register

Offset: 0x208 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx0000000000000000

Bit	Reset	Description
15	0x0	ENDPTSETUPSTAT15: Endpoint 15 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
14	0x0	ENDPTSETUPSTAT14: Endpoint 14 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
13	0x0	ENDPTSETUPSTAT13: Endpoint 13 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
12	0x0	ENDPTSETUPSTAT12: Endpoint 12 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
11	0x0	ENDPTSETUPSTAT11: Endpoint 11 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
10	0x0	ENDPTSETUPSTAT10: Endpoint 10 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total

Bit	Reset	Description
		response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
9	0x0	ENDPTSETUPSTAT9: Endpoint 9 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
8	0x0	ENDPTSETUPSTAT8: Endpoint 8 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
7	0x0	ENDPTSETUPSTAT7: Endpoint 7 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
6	0x0	ENDPTSETUPSTAT6: Endpoint 6 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
5	0x0	ENDPTSETUPSTAT5: Endpoint 5 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
4	0x0	ENDPTSETUPSTAT4: Endpoint 4 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
3	0x0	ENDPTSETUPSTAT3: Endpoint 3 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
2	0x0	ENDPTSETUPSTAT2: Endpoint 2 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD

Bit	Reset	Description
1	0x0	ENDPTSETUPSTAT1: Endpoint 1 Setup Status: For every setup transaction that is received, this bit is set to 1. 19.13.4.36 USB2_CONTROLLER_1_USB2D_ENDPTPRIME_0

USB2D Endpoint Initialization Register

Offset: 0x20c | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31	0x0	PETB15: Prime Endpoint Transmit Buffer: This bit is used to request that a buffer prepared for a transmit operation in order to respond to a USB IN/INTERRUPT transaction on this endpoint. Software should write a "1" to this bit when posting a new transfer descriptor to this endpoint. Hardware will automatically use this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware will clear this bit when this endpoint is successfully primed. This is only used in device mode. 0 = DONT_PRIME 1 = PRIME
30	0x0	PETB14: Prime Endpoint Transmit Buffer: This bit is used to request that a buffer prepared for a transmit operation in order to respond to a USB IN/INTERRUPT transaction on this endpoint. Software should write a "1" to this bit when posting a new transfer descriptor to this endpoint. Hardware will automatically use this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware will clear this bit when this endpoint is successfully primed. This is only used in device mode. 0 = DONT_PRIME 1 = PRIME
29	0x0	PETB13: Prime Endpoint Transmit Buffer: This bit is used to request that a buffer prepared for a transmit operation in order to respond to a USB IN/INTERRUPT transaction on this endpoint. Software should write a "1" to this bit when posting a new transfer descriptor to this endpoint. Hardware will automatically use this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware will clear this bit when this endpoint is successfully primed. This is only used in device mode. 0 = DONT_PRIME 1 = PRIME
28	0x0	PETB12: Prime Endpoint Transmit Buffer: This bit is used to request that a buffer prepared for a transmit operation in order to respond to a USB IN/INTERRUPT transaction on this endpoint. Software should write a "1" to this bit when posting a new transfer descriptor to this endpoint. Hardware will automatically use this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware will clear this bit when this endpoint is successfully primed. This is only used in device mode. 0 = DONT_PRIME 1 = PRIME
27	0x0	PETB11: Prime Endpoint Transmit Buffer: This bit is used to request that a buffer prepared for a transmit operation in order to respond to a USB IN/INTERRUPT transaction on this endpoint. Software should write a "1" to this bit when posting a new transfer descriptor to this endpoint. Hardware will automatically use this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware will clear this bit when this endpoint is successfully primed. This is only used in device mode. 0 = DONT_PRIME 1 = PRIME

Bit	Reset	Description
26	0x0	PETB10: Prime Endpoint Transmit Buffer: This bit is used to request that a buffer prepared for a transmit operation in order to respond to a USB IN/INTERRUPT transaction on this endpoint. Software should write a "1" to this bit when posting a new transfer descriptor to this endpoint. Hardware will automatically use this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware will clear this bit when this endpoint is successfully primed. This is only used in device mode. 0 = DONT_PRIME 1 = PRIME

2	0x0	FERB2: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
1	0x0	FERB1: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
0	0x0	FERB0: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH

19.13.4.38 USB2_CONTROLLER_1_USB2D_ENDPTSTATUS_0

USB2D Endpoint Status Register

Offset: 0x214 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	X	ETBR15: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY

Bit	Reset	Description
30	X	ETBR14: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
29	X	ETBR13: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
28	X	ETBR12: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
27	X	ETBR11: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
26	X	ETBR10: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
25	X	ETBR9: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
24	X	ETBR8: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY

Bit	Reset	Description
23	X	ETBR7: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
22	X	ETBR6: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
21	X	ETBR5: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
20	X	ETBR4: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
19	X	ETBR3: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
18	X	ETBR2: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
17	X	ETBR1: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY

Bit	Reset	Description
16	X	ETBR0: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
15	X	ERBR15: Endpoint Receive Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
14	X	ERBR14: Endpoint Receive Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
13	X	ERBR13: Endpoint Receive Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
12	X	ERBR12: Endpoint Receive Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
11	X	ERBR11: Endpoint Receive Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
10	X	ERBR10: Endpoint Receive Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY

Bit	Reset	Description
9	X	ERBR9: Endpoint Receive Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
8	X	ERBR8: Endpoint Receive Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. 19.13.4.39 USB2_CONTROLLER_1_USB2D_ENDPTCOMPLETE_0

USB2D Endpoint Complete Register

Offset: 0x218 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31	0x0	ETCE15: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
30	0x0	ETCE14: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
29	0x0	ETCE13: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
28	0x0	ETCE12: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE

Bit	Reset	Description
27	0x0	ETCE11: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
26	0x0	ETCE10: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
25	0x0	ETCE9: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
24	0x0	ETCE8: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
23	0x0	ETCE7: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
22	0x0	ETCE6: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
21	0x0	ETCE5: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
3	0x0	ERCE3: Endpoint Receive Complete Event: Each bit indicates a received event (OUT/SETUP) occurred and software should read the corresponding endpoint queue to determine the transfer status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
2	0x0	ERCE2: Endpoint Receive Complete Event: Each bit indicates a received event (OUT/SETUP) occurred and software should read the corresponding endpoint queue to determine the transfer status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
1	0x0	ERCE1: Endpoint Receive Complete Event: Each bit indicates a received event (OUT/SETUP) occurred and software should read the corresponding endpoint queue to determine the transfer status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
0	0x0	ERCE0: Endpoint Receive Complete Event: Each bit indicates a received event (OUT/SETUP) occurred and software should read the corresponding endpoint queue to determine the transfer status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE

19.13.4.40 USB2_CONTROLLER_1_USB2D_ENDPTCTRL0_0

USB2D Endpoint Control 0 Register

Offset: 0x21c | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23	X	TXE: TX Endpoint Enable. Endpoint 0 is always enabled. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
19:18	X	TXT: TX Endpoint Type. Endpoint 0 is fixed as a Control Endpoint. 0 = CTRL 1 = ISO 2 = BULK 3 = INTR
16	X	TXS: TX Endpoint Stall: Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue returning STALL until the bit is cleared by software or it will automatically be cleared upon receipt of a new SETUP request. 0 = EP_OK 1 = EP_STALL
7	X	RXE: RX Endpoint Enable. Endpoint 0 is always enabled. 0 = DISABLE 1 = ENABLE
3:2	X	RXT: RX Endpoint Type. Endpoint 0 is fixed as a Control Endpoint. 0 = CTRL 1 = ISO 2 = BULK 3 = INTR
0	X	RXS: RX Endpoint Stall: Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue returning STALL until the bit is cleared by software or it will automatically be cleared upon receipt of a new SETUP request. 0 = EP_OK 1 = EP_STALL

19.13.4.41 USB2_CONTROLLER_1_USB2D_ENDPTCTRLn_0

USB2D Endpoint Control n Register

USB2D Endpoint Control 1 through 15 registers have the same field definitions and reset value. In the register offset, the value n is the register number (1 through 15).

Offset: 0x220 + (n – 1) * 0x04 | Read/Write: R/W | Reset: 0bxxxxxxxx000x00x0xxxxxxxx000x00x0

Bit	R/W	Reset	Description
23	RW	0x0	TXE: TX Endpoint Enable. An Endpoint should be enabled only after it has been configured. 0 = DISABLE 1 = ENABLE
22	RW	0x0	TXR: TX Data Toggle Reset: Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PIDs between the Host and device. 0 = KEEP_GOING 1 = RESET_PID_SEQ
21	RW	0x0	TXI: TX Data Toggle Inhibit: This bit is only used for test and should always be written as zero. Writing a one to this bit will cause this endpoint to ignore the data toggle sequence and always transmit DATA0 for a data packet. 0 = DIS_PID_SEQ 1 = ENB_PID_SEQ
19:18	RW	0x0	TXT: TX Endpoint Type: 00 = Control. 01 = Isochronous. 10 = Bulk. 11 = Interrupt. 0 = CTRL 1 = ISO 2 = BULK 3 = INTR
17	RO	X	TXD: This bit is fixed to 0.
16	RW	0x0	TXS: TX Endpoint Stall: This bit will be set automatically upon receipt of a SETUP request if this Endpoint is not configured as a Control Endpoint. It will be cleared automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint. Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue to returning STALL until this bit is either cleared by software or automatically cleared as above.

Bit	R/W	Reset	Description
			0 = EP_OK 1 = EP_STALL
7	RW	0x0	RXE: RX Endpoint Enable. An Endpoint should be enabled only after it has been configured. 0 = DISABLE 1 = ENABLE
6	RW	0x0	RXR: RX Data Toggle Reset: Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PIDs between the host and device. 0 = KEEP_GOING 1 = RESET_PID_SEQ
5	RW	0x0	RXI: RX Data Toggle Inhibit: This bit is only used for test and should always be written as zero. Writing a one to this bit will cause this endpoint to ignore the data toggle sequence and always accept data packet regardless of their data PID. 0 = DIS_PID_SEQ 1 = ENB_PID_SEQ
3:2	RW	0x0	RXT: RX Endpoint Type: 00 = Control. 01 = Isochronous. 10 = Bulk. 11 = Interrupt. 0 = CTRL 1 = ISO 2 = BULK 3 = INTR
1	RO	X	RXD: This bit is fixed to 0.
0	RW	0x0	RXS: RX Endpoint Stall: This bit will be set automatically upon receipt of a SETUP request if this Endpoint is not configured as a Control Endpoint. It will be cleared automatically upon receipt a SETUP request if this Endpoint is configured as a Control Endpoint. Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue to returning STALL until this bit is either cleared by software or automatically cleared as above, 0 = EP_OK 1 = EP_STALL

19.13.5 USB2 Controller Interface Registers

These are used to generate the actual RTL registers for USB2 controller interface.

ULPIS2S resets to be used as follows:

- Assert ULPIS2S_SLV0_CLAMP_XMIT to ensure that the signals between SLV0 and the line simulator are clean.
- Assert ULPIS2S_SLV0_RESET
- Do a functional asynchronous reset of the ChipIdea controller
- Deassert ULPIS2S_SLV0_RESET
- Deassert ULPIS2S_SLV0_CLAMP_XMIT

NULPI_SLV1_RESET should be used in the same way if there is some explicit way to reset the external ULPI controller (which is not necessarily the case). There is usually no reason to assert ULPIS2S_LINE_RESET.

19.13.5.1 USB2_IF_USB_SUSP_CTRL_0

This register controls the suspend and resume behavior of the USB controller/PHY.

USB Suspend Control Register

Offset: 0x400 | Read/Write: R/W | Reset: 0bxxxxx00111110000x1001000xx000000

Bit	R/W	Reset	Description
26	RW	0x0	FAST_WAKEUP_RESP: Enable Fast Response from UTMIP PHY for a Remote Wakeup request from device. This is used only for cases where wakeup response needs to be within 1ms of spec. Used for Host mode ONLY.

Bit	R/W	Reset	Description
			0 = DISABLE 1 = ENABLE
25	RW	0x0	UTMIP_SUSPL1_SET: Enable SuspendL1 for UTMIP PHY Enabling this will only cutoff clocks to the UTMIP logic. The USB PLLs, PllU and UTMIP PLL will still be running. 0 = DISABLE 1 = ENABLE
24	RW	0x1	ULPI_PADS_CLKEN_RESET: Async reset for the synchronizers that are used in the external and loopback ULPI 60 MHz clock. 0 = DISABLE 1 = ENABLE
23	RW	0x1	ULPI_PADS_RESET: Async reset for trimmers and line state logic that is implemented in the pad macros. 0 = DISABLE 1 = ENABLE
22	RW	0x1	ULPIS2S_LINE_RESET: Async reset of the line simulator logic that sits between the two virtual PHYs (active high). The ULPI PHY registers should be programmed while ULPI is in reset. 0 = DISABLE 1 = ENABLE
21	RW	0x1	ULPIS2S_SLV1_RESET: Async reset of the SLV1 ULPI logic. This corresponds to resetting the virtual PHY that is connected to the internal ULPI controller (active high). The ULPI PHY registers should be programmed while ULPI is in reset. 0 = DISABLE 1 = ENABLE
20	RW	0x1	ULPIS2S_SLV0_RESET: Async reset of the SLV0 ULPI logic. This corresponds to resetting the virtual PHY that is connected to the external ULPI controller. (active high). The ULPI PHY registers should be programmed while ULPI is in reset. 0 = DISABLE 1 = ENABLE
19	RW	0x0	UHSIC_PHY_ENB: Enable UHSIC PHY mode. Set this to 1 if using UHSIC PHY. Otherwise set this to 0. 0 = DISABLE 1 = ENABLE
18:16	RW	0x0	USB_WAKEUP_DEBOUNCE_COUNT: USB PHY wakeup debounce counter USB will debounce any wakeup event by the number of clocks programmed in this counter. A value of 0 results in no debounce.
14	RW	0x1	UHSIC_RESET: Reset going to UHSIC PHY (active high). This should be set to 1 whenever programming the UHSIC config registers. It should be cleared to 0 after the programming of UHSIC config registers is done. UHSIC config registers should be programmed only once before doing any transactions on UHSIC. The UHSIC PHY registers should be programmed while UHSIC is in reset. 0 = DISABLE 1 = ENABLE
13	RW	0x0	ULPI_PHY_ENB: Enable ULPI PHY mode. Set this to 1 if using null or link ULPI PHY. Otherwise set this to 0. 0 = DISABLE 1 = ENABLE
12	RW	0x0	UTMIP_PHY_ENB: Enable UTMIP PHY mode Set this to 1 if using UTMIP PHY. Otherwise set this to 0. 0 = DISABLE 1 = ENABLE
11	RW	0x1	UTMIP_RESET: Reset going to UTMIP PHY (active high). This should be set to 1 whenever programming the UTMIP config registers. It should be cleared to 0 after the programming of UTMIP config registers is done. UTMIP config registers should be programmed only once before doing any transactions on UTMIP. The UTMIP PHY registers should be programmed while UTMIP is in reset. 0 = DISABLE 1 = ENABLE
10	RW	0x0	USB_SUSP_POL: Polarity of the suspend signal going to UHSIC PHY.

Bit	R/W	Reset	Description
			0 = Active low (default) 1 = Active high. This should not be changed by software. 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
9	RW	0x0	USB_PHY_CLK_VALID_INT_ENB: USB PHY clock valid interrupt enable. If this bit is enabled, interrupt is generated whenever USB clocks are resumed from a suspend. 0 = DISABLE 1 = ENABLE
8	RO	0x0	USB_PHY_CLK_VALID_INT_STS: USB PHY clock valid interrupt status. This bit is set whenever USB PHY clock is woken up from suspend. Software must write a 1 to clear this bit. 0 = UNSET 1 = SET
7	RO	X	USB_PHY_CLK_VALID: USB PHY clock valid status. This bit indicates whether the USB PHY is generating a valid clock to the USB controller. If USB PHY clock is running, this bit is set to 1, else it is set to 0. 0 = UNSET 1 = SET
6	RO	X	USB_CLKEN: USB AHB clock enable status. Indicates whether the AHB clock to the USB controller is enabled or not. If AHB clock to USB controller is enabled, this bit is set to 1, else it is set to 0. NOTE: even when this is set to 0, all essential blocks that are required to resume USB clocks from suspend will be active and their AHB clock will not be suspended. 0 = UNSET 1 = SET
5	RW	0x0	USB_SUSP_CLR: Suspend Clear Software must write a 1 to this bit to bring the PHY out of suspend mode. This is used when the software stops the PHY clock during suspend and then wants to initiate a resume. Software should also write 0 to clear it. NOTE: It is required that software generate a positive pulse on this bit to guarantee proper operation. 0 = UNSET 1 = SET
4	RW	0x0	USB_WAKE_ON_DISCON_EN_DEV: Wake on Disconnect Enable (device mode). When enabled (1), USB device will wake up from suspend on a disconnect event. This is only valid when USB controller is in device mode, it is not applicable when USB controller is in host mode. 0 = DISABLE 1 = ENABLE
3	RW	0x0	USB_WAKE_ON_CNNT_EN_DEV: Wake on Connect Enable (device mode). When enabled (1), USB device will wake up from suspend on a connect event. This is only valid when USB controller is in device mode, it is not applicable when USB controller is in host mode. 0 = DISABLE 1 = ENABLE
2	RW	0x0	USB_WAKE_ON_RESUME_EN: Wake on resume enable. If this bit is enabled, the USB will wake up from suspend whenever a resume event is detected on USB. This is valid for both USB device and USB host modes. 0 = DISABLE 1 = ENABLE
1	RW	0x0	USB_WAKEUP_INT_ENB: USB wakeup interrupt enable. If this bit is enabled, interrupt is generated whenever USB wakeup event is generated. 0 = DISABLE 1 = ENABLE
0	RO	0x0	USB_WAKEUP_INT_STS: USB wakeup interrupt status. This bit is set whenever the USB wakes up from suspend (a wakeup event is generated). Software must write a 1 to clear this bit. Note that during the wakeup sequence, PHY clocks will be resumed from suspend. Software can check when the PHY clocks are resumed by reading the bit USB_PHY_CLK_VALID. There is also a separate interrupt generated when PHY clock is resumed if USB_PHY_CLK_VALID_INT_EN is set. During the wakeup sequence, first USB_WAKEUP_INT_STS will be set, and it will take some time for the PHY clock to resume, which can be detected by checking USB_PHY_CLK_VALID. 0 = UNSET 1 = SET

19.13.5.2 USB2_IF_USB_PHY_VBUS_SENSORS_0

This register controls the OTG VBUS sensors in the USB PHY. There are 4 VBUS sensors:

- A_VBUS_VLD
- A_SESS_VLD
- B_SESS_VLD
- B_SESS_END

The debounced status of each sensor can be read from the corresponding _STS bit field of the sensor in this register. The _CHG_DET field is set to 1 whenever a change is detected in the value of the _STS bit field of the corresponding sensor. If _INT_EN is set, then an interrupt is generated to the processor. This interrupt can be routed to CPU/AVP by appropriately writing the USBD bits in the interrupt controller registers.

In case software wants to override the value for a sensor, it can set the corresponding _SW_EN to 1, and set the corresponding sensor _SW_VALUE to 1 or 0 as per the requirement.

There are two debouncers for each sensor - DEBOUNCE_A and DEBOUNCE_B. The debounce values for them are controlled by the register UTMIP_DEBOUNCE_CFG0, fields UTMIP_BIAS_DEBOUNCE_A and UTMIP_BIAS_DEBOUNCE_B. For each sensor, we can select whether to use DEBOUNCE_A or DEBOUNCE_B by setting the field _DEB_SEL_B to the appropriate value (SEL_A or SEL_B).

Note: Do not set either UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

USB PHY VBUS SENSORS Control Register

Offset: 0x404 | Read/Write: R/W | Reset: 0bx0000x00x0000x00x0000x00x0000x00

Bit	R/W	Reset	Description
30	RW	0x0	A_VBUS_VLD_WAKEUP_EN: A_VBUS_VLD wakeup enable. If this bit is enabled, USB will wake up from suspend whenever a change is detected on A_VBUS_VLD. 0 = DISABLE 1 = ENABLE
29	RW	0x0	A_VBUS_VLD_DEB_SEL_B: A_VBUS_VLD debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
28	RW	0x0	A_VBUS_VLD_SW_VALUE: A_VBUS_VLD software value. Software should write the appropriate value (1/0) to set/unset the A_VBUS_VLD status. This is only valid when A_VBUS_VLD_SW_EN is set. 0 = UNSET 1 = SET
27	RW	0x0	A_VBUS_VLD_SW_EN: A_VBUS_VLD software enable. Enable Software Controlled A_VBUS_VLD. Software sets this bit to drive the value in A_VBUS_VLD_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE
26	RO	X	A_VBUS_VLD_STS: A_VBUS_VLD status. This is set to 1 whenever A_VBUS_VLD sensor output is 1. 0 = UNSET 1 = SET
25	RO	0x0	A_VBUS_VLD_CHG_DET: A_VBUS_VLD change detect. This field is set by hardware whenever a change is detected in the value of A_VBUS_VLD. software writes a 1 to clear it 0 = UNSET 1 = SET

Bit	R/W	Reset	Description
24	RW	0x0	A_VBUS_VLD_INT_EN: A_VBUS_VLD interrupt enable. If this field is set to 1, an interrupt is generated whenever A_VBUS_VLD_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
22	RW	0x0	A_SESS_VLD_WAKEUP_EN: A_SESS_VLD wakeup enable. If this bit is enabled, USB will wake up from suspend whenever a change is detected on A_SESS_VLD. 0 = DISABLE 1 = ENABLE
21	RW	0x0	A_SESS_VLD_DEB_SEL_B: A_SESS_VLD debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
20	RW	0x0	A_SESS_VLD_SW_VALUE: A_SESS_VLD software value. Software should write the appropriate value (1/0) to set/unset the A_SESS_VLD status. This is only valid when A_SESS_VLD_SW_EN is set. 0 = UNSET 1 = SET
19	RW	0x0	A_SESS_VLD_SW_EN: A_SESS_VLD software enable. Enable Software Controlled A_SESS_VLD. Software sets this bit to drive the value in A_SESS_VLD_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE
18	RO	X	A_SESS_VLD_STS: A_SESS_VLD status. This is set to 1 whenever A_SESS_VLD sensor output is 1. 0 = UNSET 1 = SET
17	RO	0x0	A_SESS_VLD_CHG_DET: A_SESS_VLD change detect. This field is set by hardware whenever a change is detected in the value of A_SESS_VLD. software writes a 1 to clear it 0 = UNSET 1 = SET
16	RW	0x0	A_SESS_VLD_INT_EN: A_SESS_VLD interrupt enable. If this field is set to 1, an interrupt is generated whenever A_SESS_VLD_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
14	RW	0x0	B_SESS_VLD_WAKEUP_EN: B_SESS_VLD wakeup enable. If this bit is enabled, USB will wake up from suspend whenever a change is detected on B_SESS_VLD. 0 = DISABLE 1 = ENABLE
13	RW	0x0	B_SESS_VLD_DEB_SEL_B: B_SESS_VLD debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
12	RW	0x0	B_SESS_VLD_SW_VALUE: B_SESS_VLD software value. Software should write the appropriate value (1/0) to set/unset the B_SESS_VLD status. This is only valid when B_SESS_VLD_SW_EN is set. 0 = UNSET 1 = SET
11	RW	0x0	B_SESS_VLD_SW_EN: B_SESS_VLD software enable. Enable Software Controlled B_SESS_VLD. Software sets this bit to drive the value in B_SESS_VLD_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE
10	RO	X	B_SESS_VLD_STS: B_SESS_VLD status. This is set to 1 whenever B_SESS_VLD sensor output is 1. 0 = UNSET 1 = SET

Bit	R/W	Reset	Description
9	RO	0x0	B_SESS_VLD_CHG_DET: B_SESS_VLD change detect. This field is set by hardware whenever a change is detected in the value of B_SESS_VLD. software writes a 1 to clear it 0 = UNSET 1 = SET
8	RW	0x0	B_SESS_VLD_INT_EN: B_SESS_VLD interrupt enable. If this field is set to 1, an interrupt is generated whenever B_SESS_VLD_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
6	RW	0x0	B_SESS_END_WAKEUP_EN: B_SESS_END wakeup enable. If this bit is enabled, USB will wake up from suspend whenever a change is detected on B_SESS_END. 0 = DISABLE 1 = ENABLE
5	RW	0x0	B_SESS_END_DEB_SEL_B: B_SESS_END debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
4	RW	0x0	B_SESS_END_SW_VALUE: B_SESS_END software value. Software should write the appropriate value (1/0) to set/unset the B_SESS_END status. This is only valid when B_SESS_END_SW_EN is set. 0 = UNSET 1 = SET
3	RW	0x0	B_SESS_END_SW_EN: B_SESS_END software enable. Enable Software Controlled B_SESS_END Software sets this bit to drive the value in B_SESS_END_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE
2	RO	X	B_SESS_END_STS: B_SESS_END status. This is set to 1 whenever B_SESS_END sensor output is 1. 0 = UNSET 1 = SET
1	RO	0x0	B_SESS_END_CHG_DET: B_SESS_END change detect. This field is set by hardware whenever a change is detected in the value of B_SESS_END. software writes a 1 to clear it 0 = UNSET 1 = SET
0	RW	0x0	B_SESS_END_INT_EN: B_SESS_END interrupt enable. If this field is set to 1, an interrupt is generated whenever B_SESS_END_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE

19.13.5.3 USB2_IF_USB_PHY_VBUS_WAKEUP_ID_0

This register controls the battery charger (VDCD_DET, VDAT_DET), VBUS_WAKEUP and ID sensors. The following sensors are in this register:

- VBUS_WAKEUP
- ID
- VDAT_DET
- VDCD_DET

The debounced status of each sensor can be read from the corresponding _STS bit field of the sensor in this register. The _CHG_DET field is set to 1 whenever a change is detected in the value of the _STS bit field of the corresponding sensor. If _INT_EN is set, then an interrupt is generated to the processor. This interrupt can be routed to CPU/AVP by appropriately writing the USBD bits in the interrupt controller registers.

In case software wants to override the value for a sensor, it can set the corresponding _SW_EN to 1, and set the corresponding sensor _SW_VALUE to 1 or 0 as per the requirement.

There are two debouncers for each sensor - DEBOUNCE_A and DEBOUNCE_B. The debounce values for them are controlled by the register UTMIP_DEBOUNCE_CFG0, fields UTMIP_BIAS_DEBOUNCE_A and UTMIP_BIAS_DEBOUNCE_B. For each sensor, we can select whether to use DEBOUNCE_A or DEBOUNCE_B by setting the field _DEB_SEL_B to the appropriate value (SEL_A or SEL_B).

Note: Do not set either UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

There are debouncers for VDAT_DET and VDCD_DET. These use separate debouncers -CHRG_DEBOUNCE_PERIOD_A and CHRG_DEBOUNCE_PERIOD_B. The debounce values for them are controlled by the register UTMIP_CHRG_DEB_CFG0, fields UTMIP_CHRG_DEBOUNCE_PERIOD_A and UTMIP_CHRG_DEBOUNCE_PERIOD_B. For each sensor, we can select whether to use CHRG_DEBOUNCE_PERIOD_A or CHRG_DEBOUNCE_PERIOD_B by setting the field _DEB_SEL_B to the appropriate value (SEL_A or SEL_B).

Note: Do not set either UTMIP_CHRG_DEBOUNCE_PERIOD_A or UTMIP_CHRG_DEBOUNCE_PERIOD_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

USB2 PHY VBUS Wakeup and ID Control Register

Offset: 0x408 | Read/Write: R/W | Reset: 0b00000x00xx000x00xx000x00x1000x00

Bit	R/W	Reset	Description
31	RW	0x0	DIV_DET_EN: Battery charger divider detection enable. This goes to the USB2OTG pad. 0 = DISABLE 1 = ENABLE
30	RW	0x0	VBUS_WAKEUP_WAKEUP_EN: VBUS_WAKEUP wakeup enable. If this bit is enabled, USB will wake up from suspend whenever a change is detected on VBUS_WAKEUP. 0 = DISABLE 1 = ENABLE
29	RW	0x0	VDCD_DET_DEB_SEL_B: VCDT_DET debounce A/B select. Selects the debounce value from UTMIP_CHRG_DEBOUNCE_PERIOD_A or UTMIP_CHRG_DEBOUNCE_PERIOD_B from the register UTMIP_CHRG_DEB_CFG0. 0 = SEL_A 1 = SEL_B
28	RW	0x0	VDCD_DET_SW_VALUE: VDCD_DET software value. Software should write the appropriate value (1/0) to set/unset the VDCD_DET status. This is only valid when VDCD_DET_SW_EN is set. 0 = UNSET 1 = SET
27	RW	0x0	VDCD_DET_SW_EN: VDCD_DET software enable. Enable Software Controlled VDCD_DET. Software sets this bit to drive the value in VDCD_DET_SW_VALUE to the USB controller 0 = DISABLE 1 = ENABLE
26	RO	X	VDCD_DET_STS: VDCD_DET status. This is set to 1 whenever VDCD_DET sensor output is 1. 0 = UNSET 1 = SET
25	RO	0x0	VDCD_DET_CHG_DET: VDCD_DET change detect. This field is set by hardware whenever a change is detected in the value of VDCD_DET. software writes a 1 to clear it 0 = UNSET 1 = SET
24	RW	0x0	VDCD_DET_INT_EN: VDCD_DET interrupt enable. If this field is set to 1, an interrupt is generated whenever VDCD_DET_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
23	RO	X	VOP_DIV2P7_DET:This read-only status bit from battery charging divider circuit of USB2OTG pad 0 = UNSET

Bit	R/W	Reset	Description
			1 = SET
22	RO	X	VOP_DIV2P0_DET:This read-only status bit from battery charging divider circuit of USB2OTG pad 0 = UNSET 1 = SET
21	RW	0x0	VDAT_DET_DEB_SEL_B: VDAT_DET debounce A/B select. Selects between the two debounce values UTMIP_CHRG_DEBOUNCE_PERIOD_A or UTMIP_CHRG_DEBOUNCE_PERIOD_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
20	RW	0x0	VDAT_DET_SW_VALUE: VDAT_DET software value. Software should write the appropriate value (1/0) to set/unset the VDAT_DET status. This is only valid when VDAT_DET_SW_EN is set. 0 = UNSET 1 = SET
19	RW	0x0	VDAT_DET_SW_EN: VDAT_DET software enable. Enable Software Controlled VDAT_DET. Software sets this bit to drive the value in VDAT_DET_SW_VALUE to the USB controller 0 = DISABLE 1 = ENABLE
18	RO	X	VDAT_DET_STS: VDAT_DET status. This is set to 1 whenever the VDAT_DET sensor output is 1. 0 = UNSET 1 = SET
17	RO	0x0	VDAT_DET_CHG_DET: VDAT_DET change detect. This field is set by hardware whenever a change is detected in the value of VDAT_DET. software writes a 1 to clear it 0 = UNSET 1 = SET
16	RW	0x0	VDAT_DET_INT_EN: VDAT_DET interrupt enable. If this field is set to 1, an interrupt is generated whenever VDAT_DET_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
15	RO	X	VON_DIV2P7_DET:This read-only status bit from battery charging divider circuit of USB2OTG pad 0 = UNSET 1 = SET
14	RO	X	VON_DIV2P0_DET:This read-only status bit from battery charging divider circuit of USB2OTG pad 0 = UNSET 1 = SET
13	RW	0x0	VBUS_WAKEUP_DEB_SEL_B: VBUS_WAKEUP debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
12	RW	0x0	VBUS_WAKEUP_SW_VALUE: VBUS wakeup software value. Software should write the appropriate value (1/0) to set/unset the VBUS_WAKEUP status. This is only valid when VBUS_WAKEUP_SW_EN is set. 0 = UNSET 1 = SET
11	RW	0x0	VBUS_WAKEUP_SW_EN: VBUS wakeup software enable. Enable Software Controlled VBUS_WAKEUP. Software sets this bit to drive the value in VBUS_WAKEUP_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE
10	RO	X	VBUS_WAKEUP_STS: VBUS wakeup status. This is set to 1 whenever VBUS_WAKEUP sensor output is 1. 0 = UNSET 1 = SET
9	RO	0x0	VBUS_WAKEUP_CHG_DET: VBUS wakeup change detect. This field is set by hardware whenever a change is detected in the value of VBUS_WAKEUP. software writes a 1 to clear it 0 = UNSET 1 = SET

Bit	R/W	Reset	Description
8	RW	0x0	VBUS_WAKEUP_INT_EN: VBUS wakeup interrupt enable. If this field is set to 1, an interrupt is generated whenever VBUS_WAKEUP_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
7	RO	X	STATIC_GPI: Static GPI status 0 = UNSET 1 = SET
6	RW	0x1	ID_PU: ID pullup enable. Set to 1. 0 = DISABLE 1 = ENABLE
5	RW	0x0	ID_DEB_SEL_B: ID debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
4	RW	0x0	ID_SW_VALUE: ID software value. Software should write the appropriate value (1/0) to set/unset the ID status. This is only valid when ID_SW_EN is set. 0 = UNSET 1 = SET
3	RW	0x0	ID_SW_EN: ID software enable. Enable Software Controlled ID. Software sets this bit to drive the value in ID_SW_VALUE to the USB controller 0 = DISABLE 1 = ENABLE
2	RO	X	ID_STS: ID status. This is set to 1 whenever ID sensor output is 1. 0 = UNSET 1 = SET
1	RO	0x0	ID_CHG_DET: ID change detect. This field is set by hardware whenever a change is detected in the value of ID. software writes a 1 to clear it 0 = UNSET 1 = SET
0	RW	0x0	ID_INT_EN: ID interrupt enable. If this field is set to 1, an interrupt is generated whenever ID_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE

19.13.5.4 USB2_IF_USB_PHY_ALT_VBUS_STS_0

USB PHY Alternate VBUS Status Register

Offset: 0x40c | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
8	X	VDCD_DET_ALT: VDCD_DET alternate status 0 = UNSET 1 = SET
7	X	VDAT_DET_ALT: VDAT_DET alternate status 0 = UNSET 1 = SET
6	X	A_SESS_VLD_ALT: A_SESS_VLD alternate status 0 = UNSET 1 = SET
5	X	B_SESS_VLD_ALT: B_SESS_VLD alternate status 0 = UNSET 1 = SET
4	X	ID_DIG_ALT: ID alternate status 0 = UNSET

Bit	Reset	Description
		1 = SET
3	X	B_SESS_END_ALT: B_SESS_END alternate status 0 = UNSET 1 = SET
2	X	STATIC_GPI_ALT: Static GPI alternate status 0 = UNSET 1 = SET
1	X	A_VBUS_VLD_ALT: A_VBUS_VLD alternate status 0 = UNSET 1 = SET
0	X	VBUS_WAKEUP_ALT: Vbus wakeup alternate status 0 = UNSET 1 = SET

19.13.5.5 USB2_IF_USB_ULPIS2S_CTRL_0

This register is used to set up parameters for ULPI null PHY mode.

Note: Current ULPI configuration registers use settings that support NV software drivers and should NOT be modified. If designing custom drivers, consult your NV representative prior to modifying these registers

ULPI NULL PHY Control Register

Offset: 0x418 | Read/Write: R/W | Reset: 0bxxxxxxxx0000xx0000000000xxxx0000

Bit	Reset	Description
23:20	0x0	ULPIS2S_CLAMP_LINE_DRIVE: The line drive value that should be sent into the line simulator during transmit clamping. The suggested value is 0x1: tri-state.
17	0x0	ULPIS2S_SLV1_CLAMP_XMIT: When set to 1, the outputs of the SLV1 transmit state machine are clamped to 0. This bit should be set before the SLV0 async reset is asserted to prevent meta-stability issues in the line simulator.
16	0x0	ULPIS2S_SLV0_CLAMP_XMIT: When set to 1, the outputs of the SLV0 transmit state machine are clamped to 0. This bit should be set before the SLV0 async reset is asserted to prevent meta-stability issues in the line simulator.
15	0x0	ULPIS2S_DISABLE_STP_PU: When set to 1 and in ULPIS2S mode, the pullup on the STP pin will NOT be active, even if the remote LINK asks to do so. In this case, an external pullup resistor would be required to ensure valid levels when the remote link is not powered.
14	0x0	ULPIS2S_SUPPORT_HS_KEEP_ALIVE: When enabled, the PHY will support HS KeepAlive packets. In that case, this would be the only thing that is supported in Opmode3. All other Opmode3 generate packets are not supported under any circumstances. 0 = DISABLE 1 = ENABLE
13	0x0	ULPIS2S_DISCON_DONT_CHECK_SE0: When enabled, the disconnect detection logic will only check that that the other side is 'driving' tri-state. It will not check whether or not the local side is driving SE0. 0 = DISABLE 1 = ENABLE
12	0x0	ULPIS2S_FORCE_ULPI_CLK_OUT: When enabled and ULPIS2S_ENA is ENABLED, the external ULPI_CLOCK pad will always carry the internal 60MHz clock, even if the interface is in shutdown mode. 0 = DISABLE 1 = ENABLE
11:8	0x0	ULPIS2S_SPARE: Reserved bits.
3	0x0	ULPIS2S_PLLU_MASTER_BLASTER60: When enabled, the PLLU 60MHz clock will be forced on. 0 = DISABLE 1 = ENABLE
2	0x0	ULPIS2S_SUPPORT_DISCONNECT: When disabled, the PHY will never detect a Disconnect.

Bit	Reset	Description
		0 = DISABLE 1 = ENABLE
1	0x0	ULPIS2S_SLV1_FORCE_DEVICE: When disabled, the slave port that is connected to the pins can be programmed to be host or a device depending on the value of the DpPulldown and DmPulldown bits in the OTG_CTRL ULPI register. When enabled, the values of those bits in the OTG_CTRL register is ignored and the port will always behave like a device. 0 = DISABLE 1 = ENABLE
0	0x0	ULPIS2S_ENA: When enabled, the ULPI link interface coming out of the USB2 controller enters a NULL PHY with two slaves. As a result the external pins will have a slave ULPI interface. When disabled, the ULPI link interface coming out of the USB2 controller go straight to the pins. 0 = DISABLE 1 = ENABLE

19.13.5.6 USB2_IF_USB_ULPIS2S_SLV1_ID_0

This register controls the product and vendor ID fields for ULPI null PHY presented to external ULPI master.

Note: Current ULPI configuration registers use settings that support NV software drivers and should NOT be modified. If designing custom drivers, consult your NV representative prior to modifying these registers

Offset: 0x41c | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	ULPIS2S_SLV1_VENDOR_ID: PHY vendor_id as seen by the external ULPI master
15:0	0x0	ULPIS2S_SLV1_PRODUCT_ID: PHY product_id as seen by the external ULPI master

19.13.5.7 USB2_IF_USB_INTER_PKT_DELAY_CTRL_0

Inter Packet Delay Control

This register controls the interpacket delay between two consecutive transmit packets in HS mode. This only applies to host mode as device never transmits two packets in a row.

Offset: 0x420 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxx0010010

Bit	Reset	Description
6:0	0x12	IP_DELAY_TX2TX_HS: HS Tx to Tx inter-packet delay. This is valid only for UHSIC PHY. Software should not change this.

19.13.5.8 USB2_IF_USB_RSM_DLY_0

USB Controller Resume Signalling Delay

Offset: 0x490 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx0110100101111000

Bit	Reset	Description
15:0	0x6978	TIME_TO_RESUME: Send the resume back in number of 60 MHz cycles. Default gives 900 µs delay. Only applicable in host mode.

19.13.5.9 USB2_IF_SPARE_0

For ICUSB PADCTLS

Spare Register

Offset: 0x498 | Read/Write: R/W | Reset: 0b11111111111111110000000000000000

Bit	Reset	Description
31:16	0xffff	SPARE_HI: Spare register bits, defaulted to 1. SPARE_HI[0] - usb_port_reset_fix_en. Enable port-reset fix SPARE_HI[1] - hsic_conn_det_feature_enable. Enable HSIC connect detection
15:0	0x0	SPARE_LO: Spare register bits, defaulted to 0. SPARE_LO[4] - usb_hs_rsm_eop_fix_en. Enable HS_RESUME EOP fix SPARE_LO[5] - usb_port_suspend_fix_en

19.13.5.10 USB2_IF_ULPI_DIR_OVERRIDE_0

ULPI Override

Offset: 0x49c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1

Bit	Reset	Description
0	0x1	ULPI_DIR_OVERRIDE: By default, this bit is set. This will override ulpi_dir; i.e., when this bit is set, ulpi_dir is always asserted. Software needs to explicitly clear this bit, once slv1 Lp0 context is restored.

19.13.5.11 USB2_IF_USB2_NEW_CONTROL_0

USB Coherency and Memory Alignment Controls

Offset: 0x4c0 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx00001111xxxxxx00

Bit	Reset	Description
15:8	0xf	REQUEST_EXPIRY_COUNTER: Time to wait for coalescing the request.
1	0x0	MEM_ALIGNMENT_MUX_EN: Mux to select between Tegra 3 style (0) and Tegra K1 style (1) DMA request generation mechanism 0 = DISABLE 1 = ENABLE
0	0x0	COHERENCY_EN: Enable fence mechanism. 0 = DISABLE 1 = ENABLE

19.13.6 USB2 UTMIP Configuration Registers

Note: Current UTMIP configuration registers use settings that support NV software drivers and should NOT be modified. If designing custom drivers, consult your NV representative prior to modifying these registers

19.13.6.1 UTMIP REGISTER: PLL_CFG0

This register was used to configure PLL inside UTMIP block prior to Tegra K1 devices. This has been de-featured from UTMIP space and moved to CAR space. This register is used to configure the PHY PLL contained in the UTMIP module. Refer to the Clock and Reset Controller section for details on this register.

Note: This register has been moved to the Clock and Reset section of this document. PROGRAMMING THIS REGISTER HERE WILL HAVE NO EFFECT!

19.13.6.2 USB2_UTMIP_PLL_CFG1_0

UTMIP PLL and PLLU Configuration Register 1

Note: This register has been moved to the Clock and Reset section of this document. PROGRAMMING THIS REGISTER HERE WILL HAVE NO EFFECT!

This register was used to configure the PLL inside the UTMIP block prior to Tegra K1 devices. This register has been defeatured from UTMIP space and moved to CAR space. Refer to the Clock and Reset Controller section for details on this register.

19.13.6.3 USB2_UTMIP_XCVR_CFG0_0

UTMIP Transceiver Cell Configuration Register 0

Offset: 0x808 | Read/Write: R/W | Reset: 0b00100000001001010110010100000000

Bit	Reset	Description
31:25	0x10	UTMIP_XCVR_HSSLEW_MSB: Most significant bits of HS_SLEW.
24:22	0x0	UTMIP_XCVR_SETUP_MSB: Most significant bits of SETUP.
21	0x1	UTMIP_XCVR_LSBIAS_SEL: Low speed bias selection method for USB transceiver pad
20	0x0	UTMIP_XCVR_DISCON_METHOD: Disconnect method on the USB transceiver pad
19	0x0	UTMIP_FORCE_PDZI_POWERUP: Force PDZI input into power up.
18	0x1	UTMIP_FORCE_PDZI_POWERDOWN: Force PDZI input into power down. (Overrides FORCE_PDZI_POWERUP.)
17	0x0	UTMIP_FORCE_PD2_POWERUP: Force PD2 input into power up.
16	0x1	UTMIP_FORCE_PD2_POWERDOWN: Force PD2 input into power down. (Overrides FORCE_PD2_POWERUP.)
15	0x0	UTMIP_FORCE_PD_POWERUP: Force PD input into power up.
14	0x1	UTMIP_FORCE_PD_POWERDOWN: Force PD input into power down. (Overrides FORCE_PD_POWERUP.)
13	0x1	UTMIP_XCVR_TERMEN: Enable HS termination.
12	0x0	UTMIP_XCVR_HSLOOPBACK: Internal loopback inside XCVR cell. Used for IOBIST.
11:10	0x1	UTMIP_XCVR_LSFSLEW: LS falling slew rate control.
9:8	0x1	UTMIP_XCVR_LSRSLEW: LS rising slew rate control.
7:6	0x0	UTMIP_XCVR_FSSLEW: FS slew rate control.
5:4	0x0	UTMIP_XCVR_HSSLEW: HS slew rate control. The two LSBs.
3:0	0x0	UTMIP_XCVR_SETUP: SETUP[3:0] input of XCVR cell. HS driver output control. 4 LSBs.

19.13.6.4 USB2_UTMIP_BIAS_CFG0_0

UTMIP Bias Cell Configuration Register 0

Offset: 0x80c | Read/Write: R/W | Reset: 0bx00000001100000000000110000000000

Bit	Reset	Description
30	0x0	UTMIP_IDDIG_C_VAL: See IDDIG_C_SEL.
29	0x0	UTMIP_IDDIG_C_SEL: 0: IdDig_c = IdDig_c.

Bit	Reset	Description
		1: IdDig_c = IDDIG_C_VAL.
28	0x0	UTMIP_IDDIG_B_VAL: See IDDIG_B_SEL.
27	0x0	UTMIP_IDDIG_B_SEL: 0: IdDig_b = IdDig_b. 1: IdDig_b = IDDIG_B_VAL.
26	0x0	UTMIP_IDDIG_A_VAL: See IDDIG_A_SEL.
25	0x0	UTMIP_IDDIG_A_SEL: 0: IdDig_a = IdDig_a. 1: IdDig_a = IDDIG_A_VAL.
24	0x0	UTMIP_HSDISCON_LEVEL_MSB: Most significant bit of UTMIP_HSDISCON_LEVEL, bit 2
23	0x1	UTMIP_IDPD_VAL: See IDPD_SEL.
22	0x1	UTMIP_IDPD_SEL: 0: Reserved. Refer to the PMC registers for this feature.
21	0x0	UTMIP_IDDIG_VAL: See IDDIG_SEL.
20	0x0	UTMIP_IDDIG_SEL: 0: IdDig = IdDig. 1: IdDig = IDDIG_VAL.
19	0x0	UTMIP_GPI_VAL: See GPI_SEL.
18	0x0	UTMIP_GPI_SEL: 0: StaticGpi = IdDig. 1: StaticGpi = GPI_VAL.
17:15	0x0	UTMIP_ACTIVE_TERM_OFFSET: Active termination control offset.
14:12	0x0	UTMIP_ACTIVE_PULLUP_OFFSET: Active 1.5K pullup control offset.
11	0x1	UTMIP_OTGPD: Power down OTG circuit.
10	0x1	UTMIP_BIASPD: Power down bias circuit.
9:8	0x0	UTMIP_VBUS_LEVEL_LEVEL: Vbus detector level.
7:6	0x0	UTMIP_SESS_LEVEL_LEVEL: SessionEnd detector level.
5:4	0x0	UTMIP_HSCHIRP_LEVEL: HS chirp detector level.
3:2	0x0	UTMIP_HSDISCON_LEVEL: HS disconnect detector level.
1:0	0x0	UTMIP_HSSQUELCH_LEVEL: HS squelch detector level.

19.13.6.5 USB2_UTMIP_HSRX_CFG0_0

UTMIP High Speed Receive Config 0

Offset: 0x810 | Read/Write: R/W | Reset: 0b10010001011001010011010000000000

Bit	Reset	Description
31:30	0x2	UTMIP_KEEP_PATT_ON_ACTIVE: Keep the stay alive pattern on active
29	0x0	UTMIP_ALLOW_CONSEC_UPDN: Allow consecutive ups and downs on the bits, debug only, set to 0.
28	0x1	UTMIP_REALIGN_ON_NEW_PKT: Realign the inertia counters on a new packet
27:24	0x1	UTMIP_PCOUNT_UPDN_DIV: The number of (edges-1) needed to move the sampling point
23:21	0x3	UTMIP_SQUELCH_EOP_DLY: Limit the delay of the squelch at EOP time
20	0x0	UTMIP_NO_STRIPPING: Do not strip incoming data
19:15	0xa	UTMIP_IDLE_WAIT: Number of idle cycles to declare IDLE.

Bit	Reset	Description
14:10	0xd	UTMIP_ELASTIC_LIMIT: Depth of elastic input store
9	0x0	UTMIP_ELASTIC_OVERRUN_DISABLE: Do not declare overrun errors until overflow of FIFO
8	0x0	UTMIP_ELASTIC_UNDERRUN_DISABLE: Do not declare underrun errors
7	0x0	UTMIP_PASS_CHIRP: When in Chirp Mode, allow chirp RX data through
6	0x0	UTMIP_PASS_FEEDBACK: Pass through the feedback, do not block it.
5:4	0x0	UTMIP_PCOUNT_INERTIA: Retime the path.
3:2	0x0	UTMIP_PHASE_ADJUST: Based on incoming edges and current sampling position, adjust phase
1	0x0	UTMIP_THREE_SYNCBITS: Sync pattern detection needs 3 consecutive samples instead of 4
0	0x0	UTMIP_USE4SYNC_TRAN: Require 4 sync pattern transitions (01) instead of 3

19.13.6.6 USB2_UTMIP_HSRX_CFG1_0

UTMIP High Speed Receive Config 1

Offset: 0x814 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxx010011

Bit	Reset	Description
5:1	0x9	UTMIP_HS_SYNC_START_DLY: How long to wait before start of sync launches RxActive
0	0x1	UTMIP_HS_ALLOW_KEEP_ALIVE: Allow Keep Alive packets

19.13.6.7 USB2_UTMIP_FSLSRX_CFG0_0

UTMIP Full and Low Speed Receive Config 0

Offset: 0x818 | Read/Write: R/W | Reset: 0b11111101010101001000010000101001

Bit	Reset	Description
31	0x1	UTMIP_FSLS_SE1_DRIBBLE_FILTER: One SE1, do not allow dribble
30	0x1	UTMIP_FSLS_SE1_FILTER: Filter SE1
29	0x1	UTMIP_FSLS_SERIAL_SE0_RCV
28:26	0x7	UTMIP_FSLS_UPR_DRIBBLE_SIZE: Do not allow <= dribble bits
25:23	0x2	UTMIP_FSLS_LWR_DRIBBLE_SIZE: Do not allow >= dribble bits
22	0x1	UTMIP_FSLS_EOP_ENDS_AT_SE0: Only look for transitioning out of EOP
21:16	0x14	UTMIP_FSLS_KCOUNT_MAX: Number of K bits in question
15	0x1	UTMIP_FSLS_KCOUNT_LIMIT: Limit the number of bit times a K can last
14	0x0	UTMIP_FSLS_ACTIVE_ON_FULL_SYNC: Require a full sync pattern to declare the data received
13:8	0x4	UTMIP_FSLS_IDLE_WAIT_MAX: 4 bits of SEO should exceed the time limit
7	0x0	UTMIP_FSLS_IDLE_WAIT_LIMIT: Enable the reset of the state machine on extended SE0
6:1	0x14	UTMIP_FSLS_IDLE_COUNT_MAX: 20 bits of idle should end the packet if FsLsIdleCountLimitCfg=1.
0	0x1	UTMIP_FSLS_IDLE_COUNT_LIMIT: Give up on packet if a long sequence of J

19.13.6.8 USB2_UTMIP_FSLSRX_CFG1_0

UTMIP Full and Low Speed Receive Config 1

Offset: 0x81c | Read/Write: R/W | Reset: 0bxxxxx01000100110011101000000000

Bit	Reset	Description
26	0x0	UTMIP_EARLY_LINE_STATE_FILTER: Assumes line state filtering table is inclusive, not exclusive
25:23	0x4	UTMIP_LS_BOUNCE_LENGTH: Number of clock cycle of LS stable
22:17	0x13	UTMIP_LS_EXTRACTION_COUNT: Phase count on which LS bits are extracted
16:11	0xe	UTMIP_LS_EOP_START_COUNT: Number of SEO clock cycles to block bit extraction
10:5	0x20	UTMIP_LS_SE0_COUNT: Only for this number of 60MHz of SEO and Idle to end packet
4	0x0	UTMIP_LS_LENIENT_DRIBBLE: Allow for large dribble in low speed mode
3	0x0	UTMIP_FS_LENIENT_DRIBBLE: Allow for large dribble in full speed mode
2	0x0	UTMIP_FS_WEAK_SYNC: Only look for a KK pattern, instead of KJKK
1	0x0	UTMIP_FS_DEBOUNCE: Whether full speed uses debouncing
0	0x0	UTMIP_FS_EOP_LENGTH: Whether full speed EOP is determined within 3 or 4 60MHz cycles 0: 3 60 MHz cycles 1: 4 60 MHz cycles

19.13.6.9 USB2_UTMIP_TX_CFG0_0

UTMIP Transmit Config Signals

Offset: 0x820 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxx00010000001000000000

Bit	Reset	Description
19	0x0	UTMIP_FS_PREAMBLE_J: Output enable sends an initial J before sync pattern
18	0x0	UTMIP_FS_POSTAMBLE_OUTPUT_ENABLE: Output enable turns off 1/2 cycle after
17	0x0	UTMIP_FS_PREAMBLE_OUTPUT_ENABLE: Output enable turns on 1/2 cycle before
16	0x1	UTMIP_FSLS_ALLOW_SOP_TX_STUFF_ERR: Allow SOP to be source of transmit error stuffing
15	0x0	UTMIP_HS_READY_WAIT_FOR_VALID
14:10	0x0	UTMIP_HS_TX_IPG_DLY
9	0x1	UTMIP_HS_DISCON_EOP_ONLY: Only check during EOP
8	0x0	UTMIP_HS_DISCON_DISABLE: Disable high speed disconnect
7	0x0	UTMIP_HS_POSTAMBLE_OUTPUT_ENABLE: Output enable turns off 1 cycle after
6	0x0	UTMIP_HS_PREAMBLE_OUTPUT_ENABLE: Output enable turns on 1 cycle before
5	0x0	UTMIP_SIE_RESUME_ON_LINESTATE: SIE, not macrocell, detects LineState change to resume
4	0x0	UTMIP_SOF_ON_NO_STUFF: SOF when OpMode 3 -- perhaps, when sending controller made packets
3	0x0	UTMIP_SOF_ON_NO_ENCODE: SOF when OpMode 2 -- not likely, for Chirp
2	0x0	UTMIP_NO_STUFFING: No bit stuffing, static programming
1	0x0	UTMIP_NO_ENCODING: No encoding, static programming
0	0x0	UTMIP_NO_SYNC_NO_EOP: Do not send SYNC or EOP

19.13.6.10 USB2_UTMIP_MISC_CFG0_0

UTMIP Miscellaneous Configurations

Offset: 0x824 | Read/Write: R/W | Reset: 0bx00000111110000000000000001111000

Bit	Reset	Description
30:27	0x0	UTMIP_DPDM_OBSERVE_SEL: Select DP/DM obs signals
26	0x0	UTMIP_DPDM_OBSERVE: Use DP/DM as obs bus
25	0x1	UTMIP_KEEP_XCVR_PD_ON_SOFT_DISCON
24	0x1	UTMIP_ALLOW_LS_ON_SOFT_DISCON
23	0x1	UTMIP_FORCE_FS_DISABLE_ON_DEV_CHIRP
22	0x1	UTMIP_SUSPEND_EXIT_ON_EDGE: Suspend exit requires edge or simply a value.
21	0x1	UTMIP_LS_TO_FS_SKIP_4MS: Do not block changes for 4 ms when going from LS to FS (should not happen)
20:19	0x0	UTMIP_INJECT_ERROR_TYPE: Force error insertion into RX path. (Used for IOBIST.) 0 = DISABLE 1 = BIT_ERR 2 = RX_ERR 3 = BIT_RX_ERR
18	0x0	UTMIP_FORCE_HS_CLOCK_ON: Force HS clock always on.
17	0x0	UTMIP_DISABLE_HS_TERM: Force HS termination inactive.
16	0x0	UTMIP_FORCE_HS_TERM: Force HS termination active.
15	0x0	UTMIP_DISABLE_PULLUP_DP: Force DP pullup inactive. (Overrides FORCE_PULLUP_DP.)
14	0x0	UTMIP_DISABLE_PULLUP_DM: Force DM pullup inactive. (Overrides FORCE_PULLUP_DM.)
13	0x0	UTMIP_DISABLE_PULLDN_DP: Force DP pulldown inactive. (Overrides FORCE_PULLDN_DP.)
12	0x0	UTMIP_DISABLE_PULLDN_DM: Force DM pulldown inactive. (Overrides FORCE_PULLDN_DM.)
11	0x0	UTMIP_FORCE_PULLUP_DP: Force DP pullup active.
10	0x0	UTMIP_FORCE_PULLUP_DM: Force DM pullup active.
9	0x0	UTMIP_FORCE_PULLDN_DP: Force DP pulldown active.
8	0x0	UTMIP_FORCE_PULLDN_DM: Force DM pulldown active.
7:5	0x3	UTMIP_STABLE_COUNT: Number of cycles of crystal clock of signal not changing to consider stable.
4	0x1	UTMIP_STABLE_ALL: Determines if all signal need to be stable to not change a config.
3	0x1	UTMIP_NO_FREE_ON_SUSPEND: Do not use free running terminations during suspend.
2	0x0	UTMIP_NEVER_FREE_RUNNING_TERMS: Ignore free-running terminations, even when no clock
1	0x0	UTMIP_ALWAYS_FREE_RUNNING_TERMS: Use free-running terminations at all time
0	0x0	UTMIP_COMB_TERMS: Use combinational terminations or synced through CLKXTAL

19.13.6.11 USB2_UTMIP_MISC_CFG1_0

UTMIP Miscellaneous Configurations

Offset: 0x828 | Read/Write: R/W | Reset: 0bx10000000001100110000000000100100

Bit	Reset	Description
30	0x1	UTMIP_PHY_XTAL_CLOCKEN: Selects whether to enable the crystal clock in the module.

Bit	Reset	Description
29	0x0	UTMIP_LINESTATE_BYPASS: Bypass LineState reclocking logic
28	0x0	UTMIP_LINESTATE_NEG: Use negative edge sync for line state
27	0x0	UTMIP_LINESTATE_XCVRSEL3: 0: Use FS filtering on line state when XcvrSel=3 1: Use LS filtering on line state when XcvrSel=3
26:25	0x0	UTMIP_OBS_SEL
24	0x0	UTMIP_FSLS_TDM
23	0x0	UTMIP_FORCE_IOBIST_CLK_ON
22:18	0x6	UTMIP_PLL_ACTIVE_DLY_COUNT: Reserved. Config moved to the Clock and Reset space.
17:6	0x600	UTMIP_PLLU_STABLE_COUNT: Reserved. Moved to the Clock and Reset space.
5	0x1	UTMIP_RX_ERROR_CNT_CLR
4	0x0	UTMIP_RX_ERROR_CNT_EN
3	0x0	UTMIP_FLIP_FSLS_POLARITY
2	0x1	UTMIP_SUSPEND_TERMSEL
1:0	0x0	UTMIP_XCVRSEL3: Bit 0: 0: 0xa5 -> treat as KeepAlive 1: treat as regular packet Bit 1: 0: Turn on FS EOP detection 1: Turn off FS EOP detection

19.13.6.12 USB2_UTMIP_DEBOUNCE_CFG0_0

UTMIP Avalid and Bvalid Debounce

Debounce values IdDig, Avalid, Bvalid, VbusValid, VbusWakeUp, and SessEnd. Each of these signals has its own debouncer. For each of those, one out of two debouncing times can be chosen (BIAS_DEBOUNCE_A or BIAS_DEBOUNCE_B.)

The values of DEBOUNCE_A and DEBOUNCE_B are calculated as follows:

0xffff -> No debouncing at all

ms = *1000 / (1/19.2MHz) / 4

So to program a 1 ms debounce for BIAS_DEBOUNCE_A:

BIAS_DEBOUNCE_A[15:0] = 1000 * 19.2 / 4 = 4800 = 0x12c0

Offset: 0x82c | Read/Write: R/W | Reset: 0b11111111111111111111111111111111

Bit	Reset	Description
31:16	0xffff	UTMIP_BIAS_DEBOUNCE_B: simulation value -- Used for interrupts
15:0	0xffff	UTMIP_BIAS_DEBOUNCE_A: simulation value -- Used for interrupts

19.13.6.13 USB2_UTMIP_BAT_CHRG_CFG0_0

UTMIP Battery Charger Configuration

Offset: 0x830 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxx000000xx000001

Bit	Reset	Description
13:8	0x0	UTMIP_CHRG_DEBOUNCE_TIMESCALE: Debouncer time scaling, factor-1 to slow down debouncing by. So 0 is 1, 1 is 2, etc.
5	0x0	UTMIP_OP_I_SRC_EN
4	0x0	UTMIP_ON_SRC_EN
3	0x0	UTMIP_OP_SRC_EN
2	0x0	UTMIP_ON_SINK_EN
1	0x0	UTMIP_OP_SINK_EN
0	0x1	UTMIP_PD_CHRG: Power-down charger circuit

19.13.6.14 USB2_UTMIP_SPARE_CFG0_0

UTMIP Spare Configuration Bits

Offset: 0x834 | Read/Write: R/W | Reset: 0b11111111111111111000000011111000

Bit	Reset	Description
31:0	-65288	UTMIP_SPARE: Spare register bits 0: HS_RX_IPG_ERROR_ENABLE 1: HS_RX_FLUSH_ALAP. Flush as late as possible 2: HS_RX_LATE_SQUELCH. Delay Squelch by 1 CLK480 cycle. 31 to 3: Reserved

19.13.6.15 USB2_UTMIP_XCVR_CFG1_0

UTMIP Transceiver Cell Configuration Register 1

Offset: 0x838 | Read/Write: R/W | Reset: 0bxxxx00000001100010000001000010101

Bit	Reset	Description
27:26	0x0	UTMIP_XCVR_RPU_RANGE_ADJ: 1.5k pull-up resistor range shift.
25:24	0x0	UTMIP_XCVR_HS_IREF_CAP: High-speed Iref cap control for bias current stability.
23:22	0x0	UTMIP_XCVR_SPARE: Spare bits for USB transceiver pad.
21:18	0x6	UTMIP_XCVR_TERM_RANGE_ADJ: Range adjustment on terminations.
17	0x0	UTMIP_RCTRL_SW_SET: Use a software override on RCTRL instead of automatic bias control.
16:12	0x8	UTMIP_RCTRL_SW_VAL: Encoded value to use on RCTRL when software override is enabled, 0 to 16 only.
11	0x0	UTMIP_TCTRL_SW_SET: Use a software override on TCTRL instead of automatic bias control
10:6	0x8	UTMIP_TCTRL_SW_VAL: Encoded value to use on TCTRL when software override is enabled, 0 to 16 only.
5	0x0	UTMIP_FORCE_PDDR_POWERUP: Force PDDR input into power up.
4	0x1	UTMIP_FORCE_PDDR_POWERDOWN: Force PDDR input into power down. (Overrides FORCE_PDDR_POWERUP.)
3	0x0	UTMIP_FORCE_PDCHRP_POWERUP: Force PDCHRP input into power up.
2	0x1	UTMIP_FORCE_PDCHRP_POWERDOWN: Force PDCHRP input into power down. (Overrides FORCE_PDCHRP_POWERUP.)
1	0x0	UTMIP_FORCE_PDDISC_POWERUP: Force PDDISC input into power up.
0	0x1	UTMIP_FORCE_PDDISC_POWERDOWN: Force PDDISC input into power down. (Overrides

Bit	Reset	Description
		FORCE_PDDISC_POWERUP.)

19.13.6.16 USB2_UTMIP_BIAS_CFG1_0

UTMIP Bias Cell Configuration Register 1

Offset: 0x83c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxx00000000101101

Bit	Reset	Description
13:8	0x0	UTMIP_BIAS_DEBOUNCE_TIMESCALE: Debouncer time scaling. Slows down debouncing by a factor-1. So 0 is 1, 1 is 2, etc.
7:3	0x5	UTMIP_BIAS_PDTRK_COUNT: Control the BIAS cell power down lag. The lag should be 20 µs. For a crystal clock of 13 MHz, it should be set to 5.
2	0x1	UTMIP_VBUS_WAKEUP_POWERDOWN: Reserved. See the PMC registers for this functionality.
1	0x0	UTMIP_FORCE_PDTRK_POWERUP: Force PDTRK input into power up.
0	0x1	UTMIP_FORCE_PDTRK_POWERDOWN: Force PDTRK input into power down. (Overrides FORCE_PDTRK_POWERUP.)

19.13.6.17 USB2_UTMIP_BIAS_STS0_0

UTMIP Bias Cell Status Register 0

Offset: 0x840 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	UTMIP_TCTRL: Thermal encoding output from USB bias pad.
15:0	X	UTMIP_RCTRL: Thermal encoding output from USB bias pad.

19.13.6.18 USB2_UTMIP_CHRG_DEB_CFG0_0

UTMIP VDcd_Det and VDat_Det Debounce

Debounce values VDcd_Det and VDat_Det. Each of these signals has its own debouncer. For each of those, 1 out of 2 debouncing times can be chosen (CHRG_DEBOUNCE_PERIOD_A or CHRG_DEBOUNCE_PERIOD_B).

The values of DEBOUNCE_PERIOD_A and DEBOUNCE_PERIOD_B are calculated as follows:

0xffff -> No debouncing at all

ms = *1000 / (1/19.2MHz) / 4

So to program a 1 ms debounce for CHG_DEBOUNCE_PERIOD:

CHG_DEBOUNCE_PERIOD[15:0] = 1000 * 19.2 / 4 = 4800 = 0x12c0

Offset: 0x844 | Read/Write: R/W | Reset: 0b11111111111111111111111111111111

Bit	Reset	Description
31:16	0xffff	UTMIP_CHRG_DEBOUNCE_PERIOD_B: simulation value -- Used for interrupts
15:0	0xffff	UTMIP_CHRG_DEBOUNCE_PERIOD_A: simulation value -- Used for interrupts

19.13.6.19 USB2_UTMIP_MISC_STS0_0

UTMIP MISC Status Register

Offset: 0x848 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
21	X	UTMIP_FS_DRV_EN: Indicates when the controller is driving on the bus
20:0	X	UTMIP_SPARE_FUSES: Spare fuses value to keep the connections preserved

19.13.6.20 USB2_UTMIP_PMC_WAKEUP0_0

UTMIP PMC Wakeup value

Offset: 0x84c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0

Bit	R/W	Reset	Description
1	RO	X	UTMIP_LINE_WAKEUP_EVENT_INT_STS: Indicates the status of the PMC wakeup event
0	RW	0x0	UTMIP_LINE_WAKEUP_EVENT_INT_ENB: Interrupt mask for the PMC wakeup event

19.13.7 UHSIC Configuration Registers

Note: Current HSIC configuration registers use settings that support NV software drivers and should NOT be modified. If designing custom drivers, consult your NV representative prior to modifying these registers

19.13.7.1 USB2_UHSIC_MISC_STS0_0

UHSIC SPARE Fuse Value

Offset: 0xc30 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
0	X	UHSIC_TX_HS_VLD: Indicates when the controller is driving on the bus

19.13.7.2 USB2_UHSIC_PMC_WAKEUP0_0

UHSIC PMC Wakeup Value

Offset: 0xc34 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0

Bit	R/W	Reset	Description
1	RO	X	UHSIC_LINE_WAKEUP_EVENT_INT_STS: Indicates the status of the PMC wakeup event
0	RW	0x0	UHSIC_LINE_WAKEUP_EVENT_INT_ENB: Interrupt mask for the PMC wakeup event

19.13.7.3 USB2_QH_USB2D_QH_EP_n_OUT_0

USB2D Queue Head for OUT Endpoint n

There are 16 USB2D Queue Head for OUT Endpoint registers, where n = 0 through 15.

Offset: 0x1000 + (n * 0x80) | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint n. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint n.

19.13.7.4 USB2_QH_USB2D_QH_EP_n_IN_0

There are 16 USB2D Queue Head for IN Endpoint registers, where n = 0 through 15.

USB2D Queue Head for IN Endpoint n

Offset: 0x1040 + (n * 0x80) | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint n. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint n.

19.13.8 USB3 Controller Registers

19.13.8.1 USB2_CONTROLLER_2_USB2D_ID_0

USB2D Identification Register

Offset: 0x0 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:29	X	CIVERSION: Identifies the CI version
28:25	X	VERSION: Identifies the version of the core
24:21	X	REVISION: Revision number of the USB controller. This is set to 0x0.
20:16	X	TAG: Identifies the tag of the core
15:8	X	NID: One's complement version of ID. This field is set to 0xF9.
7:0	X	ID: Configuration number. This field is set to 0x06

19.13.8.2 USB2_CONTROLLER_2_USB2D_HW_HOST_0

USB2D Hardware Host Register

Offset: 0x8 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
3:1	X	NPORT: VUSB_HS_NUM_PORT-1: This host controller has only 1 port. So this field will always be 0.
0	X	HC: VUSB_HS_HOST: Indicates support for host mode. Set to 1.

19.13.8.3 USB2_CONTROLLER_2_USB2D_HW_DEVICE_0

USB2D Hardware Device Register

Offset: 0xc | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
5:1	X	DEVEP: VUSB_HS_DV_EP: Number of endpoints supported by this device controller. Set to 16. This includes control endpoint 0.

Bit	Reset	Description
0	X	DC: Device capable: Set to 1 indicating support for device mode.

19.13.8.4 USB2_CONTROLLER_2_USB2D_HW_TXBUF_0

USB2D Hardware TX Buffer Register

Offset: 0x10 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	TXCHANADD: VUSB_HS_TX_CHAN_ADD: Total number of address bits for the transmit buffer of each transmit endpoint. Set to 7. Each transmit buffer is 128 words deep.
15:8	X	TXADD: VUSB_HS_TX_ADD: Total number of address bits for the transmit buffer. Set to 11. The total depth of the transmit buffer is 2048 words.
7:0	X	TCBURST: VUSB_HS_TX_BURST: Maximum burst size supported by the transmit endpoints for data transfers. Set to 8.

19.13.8.5 USB2_CONTROLLER_2_USB2D_HW_RXBUF_0

USB2D RX Buffer HW Parameters Register

Offset: 0x14 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:8	X	RXADD: VUSB_HS_RX_ADD: Total number of address bits for the receive buffer. Set to 7. The total depth of the receive buffer is 128 words.
7:0	X	RXBURST: VUSB_HS_RX_BURST: Maximum burst size supported by the receive endpoints for data transfers. Set to 8.

19.13.8.6 USB2_CONTROLLER_2_USB2D_GPTIMER0LD_0

The host/device controller drivers can measure time-related activities using these timer registers. These registers are not part of the standard EHCI controller.

Offset: 0x80 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000)

Bit	Reset	Description
23:0	0x0	GPTIMER0LD: This field has the value to be loaded into the GPTCNT countdown timer on a reset action. The value in this register represents the time in microseconds minus 1 for the timer duration .

19.13.8.7 USB2_CONTROLLER_2_USB2D_GPTIMER0CTRL_0

Offset: 0x84 | Read/Write: R/W | Reset: 0x00XXXXXX (0b00xxxxx0xxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
31	RW	0x0	GTPRUN: This bit enables the general-purpose timer to run. Setting or clearing this bit will not have an effect on the GPTCNT counter value.
30	WO	0x0	GPTRST: Writing a one to this bit reloads the GPTCNT with the value in GPTLD.
24	RW	0x0	GPTMODE: This bit selects between a single timer countdown and a looped countdown. In one-shot mode, the timer counts down to zero, generates an interrupt, and stops until the counter is reset by software. In repeat mode, the timer counts down to zero, generates an interrupt, and automatically reloads the counter to begin again.
23:0	RO	X	GPTCNT: This field has the value of the running timer.

19.13.8.8 USB2_CONTROLLER_2_USB2D_GPTIMER1LD_0

Offset: 0x88 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000)

Bit	Reset	Description
23:0	0x0	GPTIMER1LD: This field has the value to be loaded into the GPTCNT countdown timer on a reset action. The value in this register represents the time in microseconds minus 1 for the timer duration .

19.13.8.9 USB2_CONTROLLER_2_USB2D_GPTIMER1CTRL_0

Offset: 0x8c | Read/Write: R/W | Reset: 0x00XXXXXX (0b00xxxxx0xxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
31	RW	0x0	GTPRUN: This bit enables the general-purpose timer to run. Setting or clearing this bit will not have an effect on the GPTCNT counter value.
30	WO	0x0	GPTRST: Writing a one to this bit reloads the GPTCNT with the value in GPTLD.
24	RW	0x0	GPTMODE: This bit selects between a single timer countdown and a looped countdown. In one-shot mode, the timer counts down to zero, generates an interrupt, and stops until the counter is reset by software. In repeat mode, the timer counts down to zero, generates an interrupt, and automatically reloads the counter to begin again.
23:0	RO	X	GPTCNT: This field has the value of the running timer.

19.13.8.10 USB2_CONTROLLER_2_USB2D_CAPLENGTH_0

USB2D Capability Register Length Register

Offset: 0x100 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
7:0	X	CAPLENGTH: Indicates which offset to add to the register base address at the beginning of the Operational Register. Set to 0x30.

19.13.8.11 USB2_CONTROLLER_2_USB2D_HCIVERSON_0

USB2D Host Interface Version Number Register

Offset: 0x102 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	HCIVERSION: Contains a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision. This host controller supports EHCI revision 1.00.

19.13.8.12 USB2_CONTROLLER_2_USB2D_HCSPARAMS_0

USB2D Host Control Structural Parameters Register

Offset: 0x104 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
27:24	X	N_TT: Number of Transaction Translators: Indicates the number of embedded transaction translators associated with the USB2.0 host controller. This field is always set to 1 indicating only 1 embedded TT is implemented in this implementation. This is a non-EHCI field to support embedded TT.
23:20	X	N_PTT: Number of Ports per Transaction Translator: Indicates the number of ports assigned to each

Bit	Reset	Description
		transaction translator within the USB2.0 host controller. Field always equals N_PORTS. This is a non-EHCI field to support embedded TT.
15:12	X	N_CC: Number of Companion Controller: Indicates the number of companion controllers. This field is set to 0.
11:8	X	N_PCC: Number of Ports per Companion Controller: Indicates the number of ports supported per internal companion controller. This field is set to 0.
4	X	PPC: Port Power Control: Indicates whether the host controller implementation includes port power control. 1 = Ports have port power switches 0= Ports do not have port power switches. This field affects the functionality of the port Power field in each port status and control register. This field is set to 1.
3:0	X	N_PORTS: Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. This field is fixed to 1, since this host controller only supports 1 port.

19.13.8.13 USB2_CONTROLLER_2_USB2D_HCCPARAMS_0

USB2D Host Control Capability Parameters Register

Offset: 0x108 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
18	X	PPC: Per-Port Change Event Capability - RO. Default = 1b. This field indicates the support for per-port change events. This field is related to the USBCMD PPE field, USBSTS PPCI field, and USBINTR PPCE field.
17	X	LEN: Link Power Management Capability - RO. Default = 1b. This field indicates the support for LPM L1 state. This field is related to the USBCMD HIRD field, POSTSCx SSTS and DA fields, and HOSTPCx LEN, BA, and EPLPM fields.
15:8	X	EECP: EHCI Extended Capabilities Pointer: Indicates a capabilities list exists. A value of 00h indicates no extended capabilities are implemented. For this implementation this field is always "0".
7:4	X	IST: Isochronous Scheduling Threshold. This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. This field will always be "0".
2	X	ASP: Asynchronous Schedule Park Capability. 1 = (Default) the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the Asynchronous Schedule Park Mode Enable and Asynchronous Schedule Park Mode Count fields in the USBCMD register. This field is always 1.
1	X	PFL: Programmable Frame List Flag. 0 = System software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero. 1 = System software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous. This field will always be "1".

19.13.8.14 USB2_CONTROLLER_2_USB2D_DCIVERSION_0

USB2D Device Interface Version Number Register

Offset: 0x120 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	DCIVERSION: The device controller interface conforms to the two-byte BCD encoding of the interface version number contained in this register.

19.13.8.15 USB2_CONTROLLER_2_USB2D_DCCPARAMS_0

USB2D Device Control Capabilities Register

Offset: 0x124 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
8	X	HC: Host Capable: 1 = This controller is capable of operating as an EHCI compatible USB 2.0 host controller. This field is set to 1.
7	X	DC: Device Capable: 1 = Controller is capable of operating as USB 2.0 device. This field is set to 1.
5	X	LEN: Link Power Management Capability - RO. Default = 1b. This field indicates the support for LPM L1 state. This field is related to the DEVLCx ASUS, STL, BA, and NYT fields.
4:0	X	DEN: Device Endpoint Number: Number of endpoints built into the device controller. This is set to 16.

19.13.8.16 USB2_CONTROLLER_2_USB2D_EXTSTS_0

USB2D EXTSTS Register

Offset: 0x128 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000x

Bit	R/W	Reset	Description
4	RW	0x0	TI1: General Purpose Timer Interrupt 1 - RWC. Default = 0b. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero. Writing a one to this bit will clear it.
3	RW	0x0	TI0: General Purpose Timer Interrupt 0 - RWC. Default = 0b. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero. Writing a one to this bit will clear it.
2	RW	0x0	UPA: USB Host Periodic Interrupt (USBHSTPERINT) R/WC. This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set and the TD was from the periodic schedule. This bit is also set by the Host Controller when a short packet is detected AND the packet is on the periodic schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes. This bit is not used by the device controller and will always be zero. 0 = DISABLE 1 = ENABLE
1	RW	0x0	UAI: USB Host Asynchronous Interrupt (USBHSTASYNCINT) R/WC. This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set AND the TD was from the asynchronous schedule. This bit is also set by the Host when a short packet is detected AND the packet is on the asynchronous schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes. This bit is not used by the device controller and will always be zero. 0 = DISABLE 1 = ENABLE
0	RO	X	NAKI: NAK Interrupt Bit Read Only. This bit is read only. It is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and the corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when the all the enabled TX/RX Endpoint NAK bits are cleared. 0 = DISABLE 1 = ENABLE

19.13.8.17 USB2_CONTROLLER_2_USB2D_USBEXTINTR_0

USB2D EXTINTR Register

Offset: 0x12c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx00000

Bit	Reset	Description
4	0x0	TIE1: General Purpose Timer Interrupt Enable 1 - RWC. Default = 0b. When this bit is a one, and the TI1 bit in the EXTSTS register is a one, the controller will issue an interrupt. The interrupt is acknowledged by software clearing the TI1 bit.
3	0x0	TIE0: General Purpose Timer Interrupt Enable 0 - RWC. Default = 0b. When this bit is a one, and the TI1 bit in the EXTSTS register is a one, the controller will issue an interrupt. The interrupt is acknowledged by software clearing the TI1 bit.
2	0x0	UPIE: UPIE Interrupt Enable. 1 = USB controller issues an interrupt if UPA bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE
1	0x0	UAIE: UAIE Interrupt Enable. 1 = USB controller issues an interrupt if UAI bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE
0	0x0	NAKE: NAK Interrupt Enable. 1 = USB controller issues an interrupt if NAKI bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE

19.13.8.18 USB2_CONTROLLER_2_USB2D_USBCMD_0

USB2D USB Command Register

Offset: 0x130 | Read/Write: R/W | Reset: 0bxxxx000000001000000x1x11x0000000

Bit	R/W	Reset	Description
27:24	RW	0x0	HIRD: Host Initiated Resume Duration RW. Default = 0000b. This has the same behavior as bits 7:4 of the BA field of the HOSTPCx register. When writing to this field all BA[7:4] fields of all HOSTPCx registers will be set to this value. This field is used by system software to specify the minimum amount of time the host controller will drive the K-state during a host-initiated resume from an LPM state (e.g., L1), and is conveyed to each LPM-enabled device (via the HIRD bits within an LPM Tokens bmAttributes field) upon entry into a low-power state. Note the host controller is required to drive resume signaling for at least the amount of time specified in the HIRD value conveyed to the device during any proceeding host-initiated resume. Also note that the host controller is not required to observe this requirement during device-initiated resumes. Encoding for this field is identical to the definition for the similarly named HIRD field within an LPM Token, specifically: a value 0000b equals 50 µs and each additional increment adds 75 µs. For example, the value 0001b equals 125 µs, and a value 1111b equals 1,175 µs (~1.2ms).
23:16	RW	0x8	ITC: Interrupt Threshold Control .Read/Write. Default 08h. The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. Value Maximum Interrupt Interval 00h = Immediate (no threshold) 01h = 1 micro-frame 02h = 2 micro-frames 04h = 4 micro-frames 08h = 8 micro-frames 10h = 16 micro-frames 20h = 32 micro-frames 40h = 64 micro-frames 0 = IMMEDIATE 2 = ONE_MF 4 = TWO_MF 8 = EIGHT_MF 16 = SIXTEEN_MF 32 = THIRTY_TWO_MF 64 = SIXTY_FOUR_MF
15	RW	0x0	FS2: Bit 2 of Frame List Size.

Bit	R/W	Reset	Description
14	RW	0x0	ATDTW: Add DTD Tripwire. This bit is used as a semaphore when a dTD is added to an active (primed) endpoint. This bit is set and cleared by software and will be cleared by hardware when a hazard exists such that adding a dTD to a primed endpoint may go unnoticed. 0 = CLEAR 1 = SET
13	RW	0x0	SUTW: Setup Tripwire. This bit is used as a semaphore when the 8 bytes of setup data read extracted by the firmware. If the setup lockout mode is off, then there exists a hazard when new setup data arrives and firmware is copying setup data from the QH for a previous setup packet. This bit is set and cleared by software and will be cleared by hardware when a hazard exists. 0 = CLEAR 1 = SET
11	RW	0x1	ASPE: Asynchronous Schedule Park mode Enable. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled. This field is set to "1" in this implementation. 0 = DISABLE 1 = ENABLE
9:8	RW	0x3	ASP1_ASP0: Asynchronous Schedule Park Mode Count (OPTIONAL) Read/Write. If the Asynchronous Park Capability bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is RO. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1h to 3h. Software must not write a zero to this bit when Park Mode Enable is a one as this will result in undefined behavior. This field is set to 3h in this implementation.
7	RO	X	LR: Light Host/Device Controller Reset (OPTIONAL). Not Implemented. This field will always be "0".
6	RW	0x0	IAA: Interrupt on Async Advance Doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results. This bit is only used in Host mode. Writing a one to this bit when device mode is selected will have undefined results. 0 = CLEAR 1 = SET
5	RW	0x0	ASE: Asynchronous Schedule Enable. This bit controls whether the host controller skips processing the Asynchronous Schedule. 0 = Do not process the Asynchronous Schedule. 1 = Use the ASYNCLISTADDR register to access the Asynchronous Schedule. Only the host controller uses this bit. 0 = DISABLE 1 = ENABLE
4	RW	0x0	PSE: Periodic Schedule Enable. This bit controls whether the host controller skips processing the Periodic Schedule. 0 = Do not process the Periodic Schedule 1 = Use the PERIODICLISTBASE register to access the Periodic Schedule. Only the host controller uses this bit. 0 = DISABLE 1 = ENABLE
3:2	RW	0x0	FS1_FS0: Frame List Size 000 = Default. This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one. Hence this field is Read/Write for this implementation. This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index. Note that this field is made up from USBCMD bits 15, 3, and 2. 000 = 1024 elements (4096 bytes) Default value 001 = 512 elements (2048 bytes) 010 = 256 elements (1024 bytes) 011 = 128 elements (512 bytes)

Bit	R/W	Reset	Description
			100 = 64 elements (256 bytes) 101 = 32 elements (128 bytes) 110 = 16 elements (64 bytes) 111 = 8 elements (32 bytes) Only the host controller uses this field.
1	RW	0x0	RST: Controller Reset. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Host Controller: When software writes a one to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller results in undefined behavior. Device Controller: When software writes a one to this bit, the Device Controller resets its internal pipelines, timers, counters, state machines, etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. Writing a one to this bit in device mode is not recommended. 0 = CLEAR 1 = SET
0	RW	0x0	RS: Run/Stop: Host Controller: When set to a 1, the Host Controller proceeds with the execution of the schedule. The Host Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HCHalted bit in the status register indicates when the Host Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the host controller is in the Halted state (i.e., HCHalted in the USBSTS register is a one). Device Controller: Writing a one to this bit will cause the device controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the device controller has been properly initialized. Writing a 0 to this will cause a detach event. 0 = STOP 1 = RUN

19.13.8.19 USB2_CONTROLLER_2_USB2D_USBSTS_0

USB2D USB Status Register

Offset: 0x134 | Read/Write: R/W | Reset: 0b00000000000000000x100x0000x0000

Bit	R/W	Reset	Description
31:16	RW	0x0	PPCI: Port-n Change Detect - RW. Default = 0000h. The definition for each bit is identical to the Port Change Detect field (bit 2 of this register) except these bits are specific to a given port, where bit 16 = Port 1, 17 = Port 2, etc. For example, if bit 17 is set to a one then a port change event was detected on Port 2. The N_PORTS field in HCSPARAMS specifies how many ports are exposed by the host controller and thus how many bits in this field are valid.
15	RW	0x0	AS: Asynchronous Schedule Status. This bit reports the current real status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. If AS = ASE: 1= Enable Asynchronous Schedule 0= Disable Asynchronous Schedule Only used by the host controller. 0 = DISABLE 1 = ENABLE
14	RW	0x0	PS: Periodic Schedule Status. This bit reports the current real status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. If PS = PSE: 1 = Periodic Schedule is enabled

Bit	R/W	Reset	Description
			0 = Periodic Schedule is disabled Only used by the host controller. 0 = DISABLE 1 = ENABLE
13	RO	X	RCL: Reclamation. This is a read-only status bit used to detect an empty asynchronous schedule. Only used by the host controller. 0 = DISABLE 1 = ENABLE
12	RW	0x1	HCH: HCHalted. 1 = Default. This bit is a zero whenever the Run/Stop bit is a one. The Host Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Host Controller hardware (e.g., internal error). Only used by the host controller. 0 = UNHALTED 1 = HALTED
11	RW	0x0	UALT_INT: ULPI alt_int Interrupt. 0 = Default. This interrupt bit is set when an RXCMD is received through the ULPI interface with bit 7 set (alt_int). The alt_int itself is set when an unmasked event occurs on any bit in the Carkit Interrupt Latch Register, in the ULPI PHY. The software should read the Carkit Interrupt Latch Register (Read to Clear) through the ULPI Viewport to check the source of the interrupt. Only present in designs where configuration constant VUSB_HS_PHY_ULPI = 1. 0 = NOT_ULPI_ALT_INT 1 = ULPI_ALT_INT
10	RW	0x0	ULPI_INT: ULPI Interrupt. This bit is set whenever an interrupt is received from ULPI PHY. Software writes 1 to clear it. 0 = NOT_ULPI_INT 1 = ULPI_INT
8	RW	0x0	SLI: DCSuspend. When a device controller enters a suspend state from an active state, this bit will be set to a 1. The device controller clears the bit upon exiting from a suspend state. Only used by the device controller. 0 = NOTSUSPEND 1 = SUSPENDED
7	RW	0x0	SRI: SOF Received. When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When an SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125 µs in HS mode and will be synchronized to the actual SOF that is received. Since device controller is initialized to FS before connect, this bit will be set at an interval of 1ms during the prelude to the connect and chirp. In host mode, this bit will be set every 125 µs and can be used by host controller driver as a time base. Software writes a 1 to this bit to clear it. This is a non-EHCI status bit. 0 = SOF_NOT_RCVD 1 = SOF_RCVD
6	RW	0x0	URI: USB Reset Received. When the device controller detects a USB Reset and enters the default state, this bit is set to a 1. Software can write a 1 to this bit to clear the USB Reset Received status bit. Only used by the device controller. 0 = NO_USB_RESET 1 = USB_RESET
5	RW	0x0	AAI: Interrupt and Asynchronous Advance. System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the USBCMD register. This status bit indicates the assertion of that interrupt source. Only used by the host controller 0 = NOT_ADVANCED 1 = ADVANCED
4	RO	X	SEI: System Error. This bit is not used in this implementation and will always be set to "0". 0 = NO_ERROR 1 = ERROR
3	RW	0x0	FRI: Frame List Rollover. The Host Controller sets this bit to a 1 when the Frame List Index rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [1 3] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a 1 every time FHINDEX

Bit	R/W	Reset	Description
			[12] toggles. Only used by the host controller. 0 = NO_ROLLOVER 1 = ROLLOVER
2	RW	0x0	PCI: Port Change Detect. The Host Controller sets this bit to a 1 when on any port a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port. The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operational states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively. This bit is not EHCI compatible. 0 = NO_PORT_CHANGE 1 = PORT_CHANGE
1	RW	0x0	UEI: USB Error Interrupt. This bit gets set by the Host/Device controller when completion of a USB transaction results in an error condition. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also ad its interrupt on complete (IOC) bit set. 0 = NO_ERROR 1 = ERROR
0	RW	0x0	UI: USB Interrupt. This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) as an interrupt on complete (IOC) bit set. This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes. 0 = NO_INT 1 = INT

19.13.8.20 USB2_CONTROLLER_2_USB2D_USBINTR_0

USB2D USB Interrupt Enable Register

Offset: 0x138 | Read/Write: R/W | Reset: 0b0000000000000000xxxx00x000000000

Bit	Reset	Description
31:16	0x0	PPCE: Port-n Change Detect Enable - RW. Default = 0000h. The definition for each bit in this field is identical to bit 2 of this register (Port Change Interrupt Enable) except these bits are specific to a given port, where bit 16 = Port 1, 17 = Port 2, etc. For example, if bit 17 is set (1b) then a port change event was detected on Port 2. When a bit in this field is a one, and the corresponding Port-n Change Detect bit in the USBSTS register is a one, the host controller will issue an interrupt. The interrupt is acknowledged by software clearing the Port-n Change Detect bit.
11	0x0	UALTIE: ULPI alt_int Interrupt Enable. 1 = USB controller issues an interrupt if ULPI_ALT_INT bit in USBSTS register transitions. The interrupt is acknowledged by software by writing a 1 to the ULPI_ALT_INT bit. 0 = DISABLE 1 = ENABLE
10	0x0	ULPIE: ULPI Interrupt Enable. 1 = USB controller issues an interrupt if ULPI_INT bit in USBSTS register transitions. The interrupt is acknowledged by software by writing a 1 to the ULPI_INT bit. 0 = DISABLE 1 = ENABLE
8	0x0	SLE: Sleep Enable. 1 = Device controller issues an interrupt if DCSuspend bit in USBSTS register transitions. The interrupt is acknowledged by software by writing a 1 to the DCSuspend bit. Only used by the device controller. 0 = DISABLE 1 = ENABLE
7	0x0	SRE: SOF Received Enable. 1 = Device controller issues an interrupt if SOF Received bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the SOF Received bit. 0 = DISABLE 1 = ENABLE
6	0x0	URE: USB Reset Enable.1 = Device controller issues an interrupt if USB Reset Received bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the USB Reset Received bit. Only used by the device controller.

Bit	Reset	Description
		0 = DISABLE 1 = ENABLE
5	0x0	AAE: Interrupt on Asynchronous Advance Enable. 1 = the host controller issues an interrupt at the next interrupt threshold if Interrupt on Async Advance bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the Interrupt on Async Advance bit. Only used by the host controller. 0 = DISABLE 1 = ENABLE
4	0x0	SEE: System Error Enable. 1 = Host/device controller issues an interrupt if the System Error bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the System Error bit. 0 = DISABLE 1 = ENABLE
3	0x0	FRE: Frame List Rollover Enable. 1 = Host controller issues an interrupt if Frame List Rollover bit in the USBSTS register = 1. The interrupt is acknowledged by software clearing the Frame List Rollover bit. Only used by the host controller. 0 = DISABLE 1 = ENABLE
2	0x0	PCE: Port Change Detect Enable. 1 = Host/device controller issues an interrupt if Port Change Detect bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the Port Change Detect bit. 0 = DISABLE 1 = ENABLE
1	0x0	UEE: USB Error Interrupt Enable. 1 = Host controller issues an interrupt at the next interrupt threshold if the USBERRINT bit in USBSTS = 1. The interrupt is acknowledged by software clearing the USBERRINT bit in the USBSTS register. 0 = DISABLE 1 = ENABLE
0	0x0	UE: USB Interrupt Enable. 1 = Host/device issues an interrupt at the next interrupt threshold if the USBINT bit in USBSTS = 1. The interrupt is acknowledged by software clearing the USBINT bit. 0 = DISABLE 1 = ENABLE

19.13.8.21 USB2_CONTROLLER_2_USB2D_FRINDEX_0

USB2D USB Frame Index Register

Offset: 0x13c | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
13:0	X	FRINDEX: Frame Index. The value in this register increments at the end of each time frame (micro-frame). Bits [N: 3] are used for the Frame List current index. Each location of the frame list is accessed 8 times (frames or micro-frames) before moving to the next index. The following illustrates values of N based on the value of the Frame List Size field in the USBCMD register, when used in host mode. USBCMD [Frame List Size] Number Elements N 000b (1024) 12 001b (512) 11 010b (256) 10 011b (128) 9 100b (64) 8 101b (32) 7 110b (16) 6 111b (8) 5 In device mode, the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode, bits 2:0 indicate the current micro-frame.

19.13.8.22 USB2_CONTROLLER_2_USB2D_PERIODICLISTBASE_0

USB2D Host Controller Frame List Base Address Register

Offset: 0x144 | Read/Write: R/W | Reset: 0b00000000000000000000xxxxxxxxxxxx

Bit	Reset	Description
31:25	0x0	USBADR: Device mode. The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET_ADDRESS request.
24	0x0	USBADRA: Device Address Advance. Default=0. When this bit is 0, any writes to USBADR are instantaneous. When this bit is written to a 1 at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0). Note: After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD cannot write of the device address within 2 ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.
31:12	0x0	BASEADR: Host mode: This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence. Base Address (Low). These bits correspond to memory address signals [31:12], respectively. Only used by the host controller.

19.13.8.23 USB2_CONTROLLER_2_USB2D_ASYNCLISTADDR_0

USB2D Next Asynchronous List Address Register

Offset: 0x148 | Read/Write: R/W | Reset: 0b00000000000000000000000000xxxxx

Bit	Reset	Description
31:11	0x0	EPBASE: Device mode. This register contains the address of the top of the endpoint list in system memory. These bits correspond to memory address signals [31:11], respectively. This field will reference a list of up to 32 Queue Heads (QH). Only used by the device controller.
31:5	0x0	ASYBASE: Host mode. This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Link Pointer Low (LPL). These bits correspond to memory address signals [31:5], respectively. This field may only reference a Queue Head (OH). Only used by the host controller.

19.13.8.24 USB2_CONTROLLER_2_USB2D_ASYNCTTSTS_0

USB2D Asynchronous Buffer Status for Embedded TT Register

Offset: 0x14c | Read/Write: R/W | Reset: 0bx0000000xxxxxxxxxxxxxxxxxxxxxx0x

Bit	R/W	Reset	Description
30:24	RW	0x0	TTHA: Internal TT Hub Address representation. This field is used to match the Hub Address field in QH and siTD to determine if the packet is routed to the internal TT for directly attached FS/LS devices.If the Hub Address in the QH or siTD does not match this address then the packet will be broadcast on the High Speed ports destined a downstream High Speed hub with the address in QH/siTD.
1	RW	0x0	TTAC: Embedded TT Async Buffers Clear. (Read/Write to set). This field will clear all pending transactions in the embedded TT Async Buffer(s). The clear will take as much time as necessary

Bit	R/W	Reset	Description
			to clear buffer without interfering with a transaction in progress. TTAC will return to zero after being set by software only after the actual clear occurs.
0	RO	X	TTAS: Embedded TT Async Buffers Status. (Read Only). This read only bit will be 1 if one or more transactions are being held in the embedded TT Async. Buffers. When this bit is a zero, then all outstanding transactions in the embedded TT have been flushed.

19.13.8.25 USB2_CONTROLLER_2_USB2D_BURSTSIZE_0

USB2D Burst Size Register

Offset: 0x150 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx0000100000001000

Bit	Reset	Description
15:8	0x8	TXPBURST: Programmable TX Burst Length. (Read/Write). This register represents the maximum length of a burst in 32-bit words while moving data from system memory to the USB bus.
7:0	0x8	RXPBURST: Programmable RX Burst Length. (Read/Write). This register represents the maximum length of a burst in 32-bit words while moving data from the USB bus to system memory.

19.13.8.26 USB2_CONTROLLER_2_USB2D_TXFILLTUNING_0

USB2D Transmit Fill Tuning Register

Offset: 0x154 | Read/Write: R/W | Reset: 0bxxxxxxxxxx000010xxx0000000000000

Bit	Reset	Description
21:16	0x2	TXFIFOTHRES: FIFO Burst Threshold. (Read/Write). This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in USBMODE register is set.
12:8	0x0	TXSCHHEALTH: Scheduler Health Counter. (Read/Write To Clear) [Default = 0]. This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max out at 31.
7:0	0x0	TXSCHOH: Scheduler Overhead. (Read/Write) [Default = 0]. This register adds an additional fixed offset to the schedule time estimator described above as Tff. As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267 µs when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333 µs when a device is connected in Low/Full Speed Mode.

19.13.8.27 USB2_CONTROLLER_2_USB2D_ICUSB_CTRL_0

USB2D ICUSB Control Register

This register enables and controls the ICUSB FS/LS transceiver.

Offset: 0x15c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000

Bit	Reset	Description
3	0x0	IC_ENB1: ICUSB transceiver enable. This bit enables the ICUSB transceiver. To enable the interface, the bits PTS must be set to 11 in the PORTSCx. Writing a '1' to this bit selects the IC_USB interface. 0 = DISABLE 1 = ENABLE
2:0	0x0	IC_VDD1: ICUSB voltage select. It selects which voltage is being supplied to the ICUSB peripheral. 000 = No voltage 001 = 1.0V – reserved 010 = 1.2V - reserved 011 = 1.5V - reserved 100 = 1.8V 101 = 3.0V 110 = reserved 111 = reserved The Voltage negotiation should happen between enabling port power (PP) and asserting the run/stop bit in register.

19.13.8.28 USB2_CONTROLLER_2_USB2D_ULPI_VIEWPORT_0

USB2D ULPI Viewport Register

This register provides indirect access to the ULPI PHY register set. Although the USB controller performs access to the ULPI PHY register set, there may be extraordinary circumstances where software may need direct access.

Note: WRITES TO THE ULPI THROUGH THE VIEWPORT CAN SUBSTANTIALLY HARM STANDARD USB OPERATIONS. CURRENTLY NO USAGE MODEL HAS BEEN DEFINED WHERE SOFTWARE SHOULD NEED TO EXECUTE WRITES DIRECTLY TO THE ULPI PHY. SEE EXCEPTION REGARDING OPTIONAL FEATURES BELOW.

Note: EXECUTING READ OPERATIONS THROUGH THE ULPI VIEWPORT SHOULD HAVE NO HARMFUL SIDE EFFECTS TO STANDARD USB OPERATIONS.

There are two operations that can be performed with the ULPI Viewport: wakeup and read /write operations.

The wakeup operation is used to put the ULPI interface into normal operation mode and re-enable the clock, if necessary. A wakeup operation is required before accessing the registers when the ULPI interface is operating in low power mode, serial mode, or Carkit mode.

The ULPI state can be determined by reading the sync state bit (ULPI_SYNC_STATE). If this bit is a one, then ULPI interface is running in normal operation mode and can accept read/write operations. If the ULPI_SYNC_STATE indicates a 0 then then read/write operations will not be able to execute. Undefined behavior will result if ULPI_SYNC_STATE = 0 and a read or write operation is performed.

To execute a wakeup operation, write all 32 bits of the ULPI Viewport where ULPI_PORT is constructed appropriately and the ULPI_WAKEUP bit is a 1 and ULPI_RUN bit is a 0. Poll the ULPI Viewport until ULPI_WAKEUP is zero for the operation to complete.

To execute a read or write operation, write all 32 bits of the ULPI Viewport where ULPI_DATA_WR, ULPI_REG_ADDR, ULPI_PORT, ULPI_RD_WR are constructed appropriately and the ULPI_RUN bit is a 1. Poll the ULPI Viewport until ULPI_RUN is zero for the operation to complete. Once ULPI_RUN is zero, the ULPI_DATA_RD will be valid if the operation was a read.

The polling method above can be changed to interrupt driven using the ULPI interrupt defined in the USBSTS and USBINTR registers. When a wakeup or read/write operation is complete, the ULPI_INT interrupt will be set.

There are several optional features that may need to be enabled or disabled by system software as part of system configuration. These bits are contained in the Interface and OTG Control registers of the ULPI PHY register set. These registers also contain bits which are controlled by the link dynamically and therefore should be only modified by system software using the Set/Clear access method. Direct writes to these registers could have harmful side effects to the standard USB operations. The optional bits are as follows: Bits 3 through 7 in the Interface Control register and Bits 6 and 7 in the OTG Control register.

Refer to the ULPI Specification Revision 1.1 for further information on the use of the optional features.

Offset: 0x160 | Read/Write: R/W | Reset: 0b000xx00000000000xxxxxxxx00000000

Bit	R/W	Reset	Description
31	RW	0x0	ULPI_WAKEUP: ULPI Wakeup. Writing the 1 to this bit will begin the wakeup operation. The bit will automatically transition to 0 after the wakeup is complete. Once this bit is set, the driver cannot set it back to 0. Note: The driver must never execute a wakeup and a read/write operation at the same time. 0 = CLEAR 1 = SET
30	RW	0x0	ULPI_RUN: ULPI read/write Run. Writing the 1 to this bit will begin the read/write operation. The bit will automatically transition to 0 after the read/write is complete. Once this bit is set, the driver cannot set it back to 0. Note: The driver must never execute a wakeup and a read/write operation at the same time. 0 = CLEAR 1 = SET
29	RW	0x0	ULPI_RD_WR: ULPI read/write control. (0) Read; (1) Write. This bit selects between running a read or write operation. 0 = READ 1 = WRITE
27	RO	X	ULPI_SYNC_STATE: ULPI sync state. (1) Normal Sync. State. (0) In another state (i.e., Carkit, serial, low power). This bit represents the state of the ULPI interface. 0 = NOT_NORMAL 1 = NORMAL
26:24	RW	0x0	ULPI_PORT: ULPI PHY port number. This field should be always written as 0.
23:16	RW	0x0	ULPI_REG_ADDR: ULPI PHY register address. When doing a read or write operation to the ULPI PHY, the address of the ULPI PHY register being accessed is written to this field.
15:8	RO	X	ULPI_DATA_RD: ULPI PHY data read. The data from the ULPI PHY register can be read from here after the read operation completes.
7:0	RW	0x0	ULPI_DATA_WR: ULPI PHY data write. The data to write to the ULPI PHY register is written here.

19.13.8.29 USB2_CONTROLLER_2_USB2D_PORTSC1_0

USB2D Port Status/Control 1 Register

Offset: 0x174 | Read/Write: R/W | Reset: 0b0000000xx0000000xxx1xx00x0xx010x

Bit	R/W	Reset	Description
31:25	RW	0x0	DA: Device Address. Default = 0000000b. The 7-bit USB device address for the device attached to an immediately downstream of the associated root port. A value of zero indicates no device is present or software support for this feature is not present. This is used by the Controller when sending the LPM token. This field is only valid when the core is operating in host mode. If in device mode, it will be read only and always equal to 0000000b.

Bit	R/W	Reset	Description
24:23	RO	X	SSTS: Suspend Status. Default = 00b. These two bits are used by software to determine whether an L1-based suspend request was successful, specifically: 00b - L1 state entered with success. ACK received from peripheral. 01b - NYET received from peripheral. It was not able to enter L1 state this time. 10b - L1 state not supported by peripheral. STALL received. 11b - Peripheral did not respond or an error occurred. The value of this field is only valid when the port resides in the L0 state - that is, the meaning of these bits is invalid whenever bit 7 of this register (SUSP) is one. Ideally, the Controller driver should read this register if it receives an interrupt after issuing a suspend using L1 support. In case of a non-success a port change interrupt will be fired and this field should be checked for a possible L1 failure. This field is only valid when the core is operating in host mode. If in device mode it will be always equal to 00b. 0 = L1STATE_ENTERED 1 = NYET_PERIPH 2 = L1STATE_NOT_SUPPORTED 3 = PERIPH_NORESP_ERR
22	RW	0x0	WKOC: Default = 0b. Wake on Over-current Enable: Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. This field is zero if Port Power (PP) is zero. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behavior. 0 = DISABLE 1 = ENABLE
21	RW	0x0	WKDS: Wake on Disconnect Enable: Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if Port Power (PP) is zero or in device mode. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behavior. This bit should not be written to 1 if there is no device connected. After the device disconnect is detected, this bit should be cleared to 0. 0 = DISABLE 1 = ENABLE
20	RW	0x0	WKCN: Wake on Connect Enable: Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if Port Power (PP) is zero or in device mode. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behavior. This bit should not be written to 1 while the device is connected. After the device connection is detected, this bit should be cleared to 0. 0 = DISABLE 1 = ENABLE
19:16	RW	0x0	PTC: Port Test Control: Any value other than zero indicates that the port is operating in test mode. Value Specific Test. 0000b: Not enabled. 0001b: J_ STATE. 0010b: K_STATE. 0011b: SEQ_NAK. 0100b: Packet. 0101b: FORCE_ENABLE. 0110b to 1111b: Reserved. Refer to Chapter 7 of the USB Specification Revision 2.0 for details on each test mode. 0 = NORMAL_OP 1 = TEST_J 2 = TEST_K 3 = TEST_SE0_NAK 4 = TEST_PKT 5 = TEST_FORCE_ENABLE
15:14	RO	X	PIC: Port Indicator Control: This field is not supported in the current implementation. Please use a GPIO if you wish to use Port Indicators.
13	RO	X	PO: Port Owner. Port owner handoff is not implemented in this design, therefore this bit will always be 0.

Bit	R/W	Reset	Description
12	RW	0x1	PP: Port Power: The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows: PPC PP Operation 0b 0b Read Only. A device controller with no OTG capability does not have port power control switches. 1b 1b/0b RW. Host/OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (i.e., PP equals a 0), the port is non-functional and will not report attaches, detaches, etc. When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitioned by the host controller driver from a one to a zero (removing power from the port). 0 = NOT_POWERED 1 = POWERED
11:10	RO	X	LS: These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. The encoding of the bits is: 00b = SE0 01b = K-state 10b = J-state 11b = Undefined The value of this field is undefined if Port Power (PP) is zero in host mode. In host mode, the use of line-state by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS. In device mode, the use of line-state by the device controller driver is not necessary. 0 = SE0 1 = K_STATE 2 = J_STATE 3 = UNDEFINED
9	RW	0x0	SLP: Suspend using L1 - RW. Default = 0b. When this bit is set to '1' and a non-zero Device Address (DA) is specified Controller will instigate L1 entry during suspend (bit 7) and L1 exit during resume (bit 6). When set to zero the Controller will use the legacy (L2) mechanism. Software should only set this bit when the device attached immediately downstream supports L1 transitions. When acting as device, this bit is read-only and set to '1' by the hardware when the Controller enters is L1 state (LPM token received and accepted). Note: HSP is redundant with PSPD(27:26). This bit is not defined in the EHCI specification.
8	RW	0x0	PR: This field is zero if Port Power (PP) is zero. In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver. In Device Mode: This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register. 0 = NOT_USB_RESET 1 = USB_RESET

Bit	R/W	Reset	Description
7	RO	X	SUSP: Port suspend. 1=Port in suspend state. 0=Port not in suspend state. In Host Mode: Read/Write. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0x Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. The host controller will unconditionally set this bit to zero when software sets the Force Port Resume bit to zero. A write of zero to this bit is ignored by the host controller. If host software sets this bit to a one when the port is not enabled (i.e., Port enabled bit is a zero) the results are undefined. This field is zero if Port Power (PP) is zero in host mode. In Device Mode: Read Only. This bit is a read only status bit. 0 = NOT_SUSPEND 1 = SUSPEND
6	RW	0x0	FPR: Force Port Resume. 1= Resume detected/driven on port. 0=No resume (K state) detected/driven on port. In Host Mode: Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to one. This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver. Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit remains a one until the port has switched to the high-speed idle. Writing a zero has no effect because the port controller will time the resume operation to clear the bit when the port control state switches to HS or FS idle. This field is zero if Port Power (PP) is zero in host mode. This bit is not-EHCI compatible. In Device mode: After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to one. Software should ensure that the PHY clock is operational before writing a 1 to this bit to start the resume sequence. This is true for both Device and Host modes. 0 = NO_RESUME 1 = RESUME
5	RO	X	OCC: Over-current Change: Not supported 0 = NO_CHANGE 1 = CHANGE
4	RO	X	OCA: Over-current Active: Not supported 0 = NO_OVER_CURRENT 1 = OVER_CURRENT
3	RW	0x0	PEC: Port Enable/Disable Change: 1=Port enabled/disabled status has changed. 0=No change. In Host Mode: For the root hub, this bit gets set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is zero if Port Power (PP) is zero. In Device mode: The device port is always enabled. (This bit will be zero) 0 = NO_CHANGE 1 = CHANGE
2	RW	0x1	PE: Port Enabled/Disabled: 1=Enable. 0=Disable (default) In Host Mode: Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b)

Bit	R/W	Reset	Description
			downstream propagation of data is blocked except for reset. This field is zero if Port Power (PP) is zero in host mode. In Device Mode: The device port is always enabled. (This bit will be one) 0 = PORT_DISABLED 1 = PORT_ENABLED
1	RW	0x0	CSC: Connect Status Change: 1 =Change in Current Connect Status. 0=No change (default). In Host Mode: Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (i.e., the bit will remain set). Software clears this bit by writing a one to it. This field is zero if Port Power (PP) is zero in host mode. This bit is undefined in device controller mode. 0 = NO_CHANGE 1 = CHANGE
0	RO	X	CCS: Current Connect Status: In Host Mode: 1=Device is present on port. 0=No device is present (default). This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change bit (Bit 1) to be set. This field is zero if Port Power (PP) is zero in host mode. In Device Mode: 1=Attached 0=Not Attached (default) A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended. 0 = NOT_CONNECTED 1 = CONNECTED

19.13.8.30 USB2_CONTROLLER_2_USB2D_HOSTPC1_DEVLC_0

USB2D Device Mode LPM Behavior and Control Register

This register controls the LPM behavior and the behavior of each USB port in device mode only. This register shares the same address with the HOSTPC1 register (which is used only in host mode).

USB2D Host Mode LPM Behavior and Control Register

This register controls the LPM behavior and controls the behavior of each USB port in host mode only. This register shares the same address with the DEVLC register (which is used only in device mode).

Offset: 0x1b4 | Read/Write: R/W | Reset: 0b0000xxx0000000000000xxxxxxxxxxx0

Bit	R/W	Reset	Description
31:29	RW	0x0	PTS: Parallel transceiver select. This bit is not defined in the EHCI specification. 0 = UTMI 1 = RESERVED 2 = ULPI 3 = ICUSB_SER 4 = HSIC
28	RW	0x0	STS: Serial transceiver not selected. This is the only value supported. This bit is not defined in the EHCI specification. 0 = PARALLEL_IF 1 = SERIAL_IF
27	RO	X	PTW: Parallel Transceiver Width. Fixed to 0. This bit is not defined in the EHCI specification. 0 = EIGHT_BIT 1 = RESERVED

Bit	R/W	Reset	Description
26:25	RO	X	PSPD: This register field indicates the speed at which the port is operating. 00 = Full Speed 01 = Low Speed 10 = High Speed. This bit is not defined in the EHCI specification. 0 = FULL_SPEED 1 = LOW_SPEED 2 = HIGH_SPEED 3 = RESERVED
24	RW	0x0	ALPD: Auto Low Power While Disconnect - RW. Default = 0b. If set, this feature will be enabled and every time the port enters the disconnect state it will also enter in low power state, disabling the transceiver clock. The behavior will be same as if the PHCD bit was enabled(in fact this bit will be set to 1 as soon as low power mode is enabled).When this field is set the WKCN field of PORTSCx register(Wake on Connect Enable) will also be set. This way the core will wake up in case a connect is detected. There will be a delay between the detection of a disconnect and actually enter in low power mode. This delay can be controlled by writing to the ALPDD field in the USBMODE register. 0 = DONT_AUTO_LOW_POWER_WHILE_DISCONNECT 1 = AUTO_LOW_POWER_WHILE_DISCONNECT
23	RW	0x0	PFSC: Port Force Full Speed Connect - RW. Default = 0b. Writing this bit to a '1b' will force the port to only connect at Full Speed. It disables the chirp sequence that allows the port to identify itself as High Speed. This is useful for testing FS configurations with an HS host, hub or device. This bit is not defined in the EHCI specification. 0 = DONT_FORCE_FULL_SPEED 1 = FORCE_FULL_SPEED
22	RW	0x0	PHCD: PHY Low Power Suspend - Clock disable: Writing this bit to a 1 will disable the PHY clock. Write a 0 enables it. Reading this bit will indicate the status of the PHY clock. NOTE: The PHY clock cannot be disabled if it is being used as the system clock. In device mode, the PHY can be put into Low Power Clock Disable when the device is not running (USBCMD RS=0b) or the host has signaled suspend (PORTSCx SUSP=1b). Low Power Clock Disable will be cleared automatically when the host has signaled resume. Before forcing a resume from the device, the Controller driver must clear this bit. In host mode, the PHY can be put into Low Power Suspend Clock Disable when the downstream device has been put into suspend mode or when no downstream device is connected. Low Power Clock Disable is completely under the control of software. 0 = DISABLE 1 = ENABLE
21:20	RW	0x0	LPMX: Auto LPM set. Default = 00b. This bit field is valid during Host Mode Only. For Device Mode, this is reserved. Value Meaning 00b Disables auto LPM. 01b If there is no activity for a certain number of SOFs the controller will send an LPM token, enter in suspend and issue a port change interrupt. 10b Same as above but without issuing an interrupt. 11b Reserved for futures LPM enhancements. The detection of no activity is based on the absence of response from the downstream device. Because of this limitation this feature should not be used if ISO OUT endpoints are being used (as no handshake is expected).
17	RW	0x0	ASUS: Auto Low Power. Default = 0b. This bit field is valid during Device Mode Only. In Host Mode it is part of ELPM field. This bit is used to control the auto low power feature. If set, the auto low power feature will be enabled and every time the port enters the suspend state, it will also enter the low power state, disabling the transceiver clock. The behavior will be the same as if the PHCD bit was enabled (in fact this bit will be set to '1' as soon as low power mode is enabled). 0 = DISABLE 1 = ENABLE
19:16	RW	0x0	EPLPM: Endpoint for LPM token. Default = 0000b. This bit field is valid during Host Mode only. For Device Mode, bits [19:18] are reserved and bit 17 is ASUS, while bit 16 is STL. This sets the endpoint number to which the LPM token will be sent. It will be directly mapped to the ENDP field in the LPM token with the EXT PID.

Bit	R/W	Reset	Description
16	RW	0x0	STL: STALL reply to LPM token. Default = 0b. This bit field is valid during Device Mode only. In Host Mode it is a part of ELPM field. When this bit is set to '1', the Controller will reply always with STALL to all incoming LPM tokens. This bit overrides the LPM NYET bit (NYT). 0 = DISABLE 1 = ENABLE
15:12	RW	0x0	LPMFRM: Auto LPM SOF Threshold. Default = 0000b. This bit field is valid during Host Mode only. For Device Mode, this is reserved. This holds the SOF counter threshold. When the number of SOF with no activity in between reaches this threshold and the auto LPM is enabled, an LPM token will be sent and the port will enter in suspend state. The SOF counter for this threshold is incremented each 125 µs, even if the port is not in HS operation.
11:1	RO	X	BA: BmAttributes . Default = 00000000000b. This holds the bmAttributes field of the LPM sub-token received, after the EXT PID token.
0	RW	0x0	NYT_ASUS: NYET reply to LPM token. Default = 0b. This bit is NYT during Device Mode. Details follow: When this bit is to '1', the device controller will NYET all the LPM tokens. When this bit is set to '0', the Controller will ACK all the LPM tokens if the STALL bit (STL) is also set to '0'. This bit is ASUS in Host Mode. Details follow: This bit is used to control the auto low power feature. If set, the auto low power feature will be enabled and every time the port enters in suspend state it will also enter in low power state, disabling the transceiver clock. The behavior will be the same as if the PHCD bit was enabled (in fact this bit will be set to '1' as soon as low power mode is enabled). 0 = DISABLE 1 = ENABLE

19.13.8.31 USB2_CONTROLLER_2_USB2D_OTGSC_0

USB2D On-The-Go (OTG) Status and Control Register

Offset: 0x1f4 | Read/Write: R/W | Reset: 0bx0000000x0000000xxxxxxxxxx100x00

Bit	R/W	Reset	Description
30	RW	0x0	DPIE: Data Pulse Interrupt Enable. Setting this bit enables the Data pulse interrupt. 0 = DISABLE 1 = ENABLE
29	RW	0x0	ONEMSE: 1 millisecond timer Interrupt enable. Setting this bit enables the 1 millisecond timer interrupt. 0 = DISABLE 1 = ENABLE
28	RW	0x0	BSEIE: B Session End Interrupt Enable. Setting this bit enables the B session end interrupt 0 = DISABLE 1 = ENABLE
27	RW	0x0	BSVIE: B Session Valid Interrupt Enable. Setting this bit enables the B session valid interrupt 0 = DISABLE 1 = ENABLE
26	RW	0x0	ASVIE: A Session Valid Interrupt Enable. Setting this bit enables the A session valid interrupt 0 = DISABLE 1 = ENABLE
25	RW	0x0	AVVIE: A VBus Valid Interrupt Enable. Setting this bit enables the A VBus valid interrupt 0 = DISABLE 1 = ENABLE
24	RW	0x0	IDIE: USB ID Interrupt Enable. Setting this bit enables the USB ID interrupt 0 = DISABLE 1 = ENABLE
22	RW	0x0	DPIS: Data Pulse Interrupt Status. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC(0).PortPower = Off (0). Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET

Bit	R/W	Reset	Description
21	RW	0x0	ONEMSS: 1 millisecond timer Interrupt Status: This bit is set once every millisecond. Software writes a 1 to clear it. 0 = INT_CLEAR 1 = INT_SET
20	RW	0x0	BSEIS: B Session End Interrupt Status. This bit is set when VBus has fallen below the B session end threshold. Software writes a 1 to clear this bit . 0 = INT_CLEAR 1 = INT_SET
19	RW	0x0	BSVIS: B Session Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the B session valid threshold (0.8 VDC). Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
18	RW	0x0	ASVIS: A Session Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the A session valid threshold (0.8 VDC). Software writes a one to clear this bit. 0 = INT_CLEAR 1 = INT_SET
17	RW	0x0	AVVIS: A VBus Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the VBus valid threshold (4.4 VDC) on an A device. Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
16	RW	0x0	IDIS: USB ID Interrupt Status. This bit is set when a change on the ID input has been detected. Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
14	RO	X	DPS: Data Bus Pulsing Status. A 1 indicates data bus pulsing is being detected on the port. 0 = STS_CLEAR 1 = STS_SET
13	RO	X	ONEMST: 1 millisecond timer toggle. This bit toggles once per millisecond 0 = STS_CLEAR 1 = STS_SET
12	RO	X	BSE: B session End. Indicates VBus is below the B session end threshold 0 = STS_CLEAR 1 = STS_SET
11	RO	X	BSV: B Session Valid. Indicates VBus is above the B session valid threshold 0 = STS_CLEAR 1 = STS_SET
10	RO	X	ASV: A Session Valid. Indicates VBus is above the A session valid threshold 0 = STS_CLEAR 1 = STS_SET
9	RO	X	AVV: A VBus Valid. Indicates VBus is above the A VBus valid threshold 0 = STS_CLEAR 1 = STS_SET
8	RO	X	ID: USB ID: 0 = A-device 1 = B-device 0 = A_DEV 1 = B_DEV
5	RW	0x1	IDPU: USB ID Pullup 0 = CLEAR 1 = SET
4	RW	0x0	DP: Data Pulsing. Setting this bit causes the pull-up on DP to be asserted for data pulsing during SRP. 0 = NO_DATA_PULSE 1 = DATA_PULSE
3	RW	0x0	OT: OTG Termination. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM. 0 = NO_OTG_TERM 1 = OTG_TERM

Bit	R/W	Reset	Description
1	RW	0x0	VC: VBUS Charge. Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP. 0 = NO_VBUS_CHRG 1 = VBUS_CHRG
0	RW	0x0	VD: VBUS_Discharge. Read/write. Setting this bit causes Vbus to discharge through a resistor. 0 = NO_VBUS_DISCHRG 1 = VBUS_DISCHRG

19.13.8.32 USB2_CONTROLLER_2_USB2D_USBMODE_0

USB2D USB Device Mode Register

Offset: 0x1f8 | Read/Write: R/W | Reset: 0b00000000000000000xxxxxxxxx0xxxxx

Bit	R/W	Reset	Description
31:16	RW	0x0	ALPDD: Auto Low Power While Disconnect Delay, Used when the ALPD field of the HOSTPCx register is set. Defines the delay between disconnect detection and entering in low power mode. The delay is <this register value>*64*100/3 in milliseconds. The maximum value is 65535*64*100/3 = 139,808 ms. The minimum value is 0. Only used in host mode.
15	RW	0x0	SRT: Shorten USB Reset Time. Software should never set this bit to 1.
5	RW	0x0	VBPS: VBUS Power Select This can be used by logic that selects between an on-chip Vbus power source (charge pump) and an off-chip source in systems when both are available. Only to be used in Host Mode. No functionality is implemented for this, so software should not use this.
4	RO	X	SDIS: Stream disable: 1 Streaming is disabled - helpful to avoid overruns/underruns when system load is too high. 0 = STREAM_ENABLE 1 = STREAM_DISABLE
3	RO	X	SLOM: Setup Lockout Mode: In device mode, this bit controls the behavior of the setup lockout mechanism. 0 - Setup lockout is ON (default) 1 - Setup lockout is OFF. Firmware requires the use of setup tripwire semaphore in USB2D_USBCMD register. 0 = LOCKOUT_ON 1 = LOCKOUT_OFF
2	RO	X	ES: Endian Select: Note: For this implementation, this should be always set to 0 (little endian). 0 = LITTLE_ENDIAN 1 = RESERVED
1:0	RO	X	CM: Controller Mode: The controller mode will default to an idle state and will need to be initialized to the desired operating mode after reset. This register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the RESET bit in the USBCMD register before reprogramming this register. 00 = Idle [Default] 01 = Reserved 10 = Device Controller 11 = Host Controller. 0 = IDLE 1 = RESERVED 2 = DEVICE_MODE 3 = HOST_MODE

19.13.8.33 USB2_CONTROLLER_2_USB2D_ENDPTNAK_0

USB2D Endpoint NAK Register

Offset: 0x200 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	EPTN: TX Endpoint NAK R/WC. Each TX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received IN token for the corresponding endpoint. 0 = CLEAR 1 = SET
15:0	0x0	EPRN: RX Endpoint NAK R/WC. Each RX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received OUT or PING token for the corresponding endpoint. 0 = CLEAR 1 = SET

19.13.8.34 USB2_CONTROLLER_2_USB2D_ENDPTNAK_ENABLE_0

USB2D Endpoint NAK Enable Register

Offset: 0x204 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	EPTNE: TX Endpoint NAK Enable R/W. Each bit is an enable bit for the corresponding TX Endpoint NAK bit. If this bit is set and the corresponding TX Endpoint NAK bit is set, the NAK Interrupt bit is set. 0 = DISABLE 1 = ENABLE
15:0	0x0	EPRNE: RX Endpoint NAK Enable R/W. Each bit is an enable bit for the corresponding RX Endpoint NAK bit. If this bit is set and the corresponding RX Endpoint NAK bit is set, the NAK Interrupt bit is set. 0 = DISABLE 1 = ENABLE

19.13.8.35 USB2_CONTROLLER_2_USB2D_ENDPTSETUPSTAT_0

USB2D Endpoint Setup Status Register

Offset: 0x208 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx0000000000000000

Bit	Reset	Description
15	0x0	ENDPTSETUPSTAT15: Endpoint 15 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
14	0x0	ENDPTSETUPSTAT14: Endpoint 14 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
13	0x0	ENDPTSETUPSTAT13: Endpoint 13 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD

Bit	Reset	Description
12	0x0	ENDPTSETUPSTAT12: Endpoint 12 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
11	0x0	ENDPTSETUPSTAT11: Endpoint 11 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
10	0x0	ENDPTSETUPSTAT10: Endpoint 10 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. 19.13.8.38 USB2_CONTROLLER_2_USB2D_ENDPTSTATUS_0

USB2D Endpoint Status Register

Offset: 0x214 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	X	ETBR15: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
30	X	ETBR14: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
29	X	ETBR13: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
28	X	ETBR12: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
27	X	ETBR11: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
26	X	ETBR10: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY

Bit	Reset	Description
25	X	ETBR9: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. 19.13.8.39 USB2_CONTROLLER_2_USB2D_ENDPTCOMPLETE_0

USB2D Endpoint Complete Register

Offset: 0x218 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31	0x0	ETCE15: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
30	0x0	ETCE14: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE

Bit	Reset	Description
29	0x0	ETCE13: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
28	0x0	ETCE12: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
27	0x0	ETCE11: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
26	0x0	ETCE10: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
25	0x0	ETCE9: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
24	0x0	ETCE8: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
23	0x0	ETCE7: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE

19.13.8.40 USB2_CONTROLLER_2_USB2D_ENDPTCTRL0_0

USB2D Endpoint Control 0 Register

Offset: 0x21c | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23	X	TXE: TX Endpoint Enable. Endpoint 0 is always enabled. 0 = DISABLE 1 = ENABLE
19:18	X	TXT: TX Endpoint Type. Endpoint0 is fixed as a Control Endpoint. 0 = CTRL 1 = ISO 2 = BULK 3 = INTR
16	X	TXS: TX Endpoint Stall: Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue returning STALL until the bit is cleared by software or it will automatically be cleared upon receipt of a new SETUP request. 0 = EP_OK 1 = EP_STALL
7	X	RXE: RX Endpoint Enable. Endpoint 0 is always enabled. 0 = DISABLE 1 = ENABLE
3:2	X	RXT: RX Endpoint Type. Endpoint 0 is fixed as a Control Endpoint. 0 = CTRL 1 = ISO 2 = BULK 3 = INTR
0	X	RXS: RX Endpoint Stall: Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue returning STALL until the bit is cleared by software or it will automatically be cleared upon receipt of a new SETUP request. 0 = EP_OK 1 = EP_STALL

19.13.8.41 USB2_CONTROLLER_2_USB2D_ENDPTCTRLn_0

USB2D Endpoint Control n Register

USB2D Endpoint Control 1 through 15 registers have the same field definitions and reset value. In the register offset, the value n is the register number (1 through 15).

Offset: 0x220 + (n – 1) * 0x04 | Read/Write: R/W | Reset: 0bxxxxxxxx000x00x0xxxxxxxx000x00x0

Bit	R/W	Reset	Description
23	RW	0x0	TXE: TX Endpoint Enable. An Endpoint should be enabled only after it has been configured. 0 = DISABLE 1 = ENABLE
22	RW	0x0	TXR: TX Data Toggle Reset: Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PIDs between the Host and device. 0 = KEEP_GOING 1 = RESET_PID_SEQ
21	RW	0x0	TXI: TX Data Toggle Inhibit: This bit is only used for test and should always be written as zero. Writing a one to this bit will cause this endpoint to ignore the data toggle sequence and always transmit DATA0 for a data packet. 0 = DIS_PID_SEQ 1 = ENB_PID_SEQ
19:18	RW	0x0	TXT: TX Endpoint Type: 00 = Control. 01 = Isochronous. 10 = Bulk. 11 = Interrupt. 0 = CTRL

Bit	R/W	Reset	Description
			1 = ISO 2 = BULK 3 = INTR
17	RO	X	TXD: This bit is fixed to 0.
16	RW	0x0	TXS: TX Endpoint Stall: This bit will be set automatically upon receipt of a SETUP request if this Endpoint is not configured as a Control Endpoint. It will be cleared automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint. Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue to returning STALL until this bit is either cleared by software or automatically cleared as above. 0 = EP_OK 1 = EP_STALL
7	RW	0x0	RXE: RX Endpoint Enable. An Endpoint should be enabled only after it has been configured. 0 = DISABLE 1 = ENABLE
6	RW	0x0	RXR: RX Data Toggle Reset: Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PIDs between the host and device. 0 = KEEP_GOING 1 = RESET_PID_SEQ
5	RW	0x0	RXI: RX Data Toggle Inhibit: This bit is only used for test and should always be written as zero. Writing a one to this bit will cause this endpoint to ignore the data toggle sequence and always accept data packet regardless of their data PID. 0 = DIS_PID_SEQ 1 = ENB_PID_SEQ
3:2	RW	0x0	RXT: RX Endpoint Type: 00 = Control. 01 = Isochronous. 10 = Bulk. 11 = Interrupt. 0 = CTRL 1 = ISO 2 = BULK 3 = INTR
1	RO	X	RXD: This bit is fixed to 0.
0	RW	0x0	RXS: RX Endpoint Stall: This bit will be set automatically upon receipt of a SETUP request if this Endpoint is not configured as a Control Endpoint. It will be cleared automatically upon receipt a SETUP request if this Endpoint is configured as a Control Endpoint. Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue to returning STALL until this bit is either cleared by software or automatically cleared as above, 0 = EP_OK 1 = EP_STALL

19.13.9 USB3 Controller Interface Registers

These are used to generate the actual RTL registers for the USB3 controller interface.

19.13.9.1 USB3_IF_USB_SUSP_CTRL_0

USB Suspend Control Register

This register controls the suspend and resume behavior of the USB controller/PHY.

Offset: 0x400 | Read/Write: R/W | Reset: 0bxxxxx00xxxxx000001001000xx000000

Bit	R/W	Reset	Description
26	RW	0x0	FAST_WAKEUP_RESP: Enable Fast Response from UTMIP PHY for a Remote Wakeup request from device. This is used only for cases where wakeup response needs to be within 1 ms of spec. Used for Host mode ONLY. 0 = DISABLE 1 = ENABLE

Bit	R/W	Reset	Description
25	RW	0x0	UTMIP_SUSPL1_SET: Enable SuspendL1 for UTMIP PHY. Enabling this will only cut off clocks to the UTMIP logic. The USB PLLs, PllU and UTMIP PLL will still be running. 0 = DISABLE 1 = ENABLE
19	RW	0x0	UHSIC_PHY_ENB: Set this to 0. 0 = DISABLE 1 = ENABLE
18:16	RW	0x0	USB_WAKEUP_DEBOUNCE_COUNT: USB PHY wakeup debounce counter. The USB will debounce any wakeup event by the number of clocks programmed in this counter. A value of 0 results in no debounce.
15	RW	0x0	ICUSB_MOD_CLK_ENB: ICUSB module clock enable. Enables transceiver clock to USB controller when in ICUSB mode. After setting ICUSB_PHY_ENB, software needs to wait until PLLU output is stable before setting ICUSB_MOD_CLK_ENB to ENABLE. This will be reset to DISABLE whenever ICUSB is in suspend. Software needs to enable it after ICUSB comes out of suspend after waiting for PLLU output to be stable again. 0 = DISABLE 1 = ENABLE
14	RW	0x1	UHSIC_RESET: Reset going to UHSIC PHY (active high). This should be set to 1 whenever programming the UHSIC config registers. It should be cleared to 0 after the programming of UHSIC config registers is done. UHSIC config registers should be programmed only once before doing any transactions on UHSIC. The UHSIC PHY registers should be programmed while the UHSIC is in reset. 0 = DISABLE 1 = ENABLE
13	RW	0x0	ICUSB_PHY_ENB: Enable ICUSB PHY mode. Setting this will enable the PLLU output clock when ICUSB is not in suspend mode. 0 = DISABLE 1 = ENABLE
12	RW	0x0	UTMIP_PHY_ENB: Enable UTMIP PHY mode. Set this to 1 if using UTMIP PHY. Otherwise set this to 0. 0 = DISABLE 1 = ENABLE
11	RW	0x1	UTMIP_RESET: Reset going to UTMIP PHY (active high). This should be set to 1 whenever programming the UTMIP config registers. It should be cleared to 0 after the programming of UTMIP config registers is done. UTMIP config registers should be programmed only once before doing any transactions on USB. The UTMIP PHY registers should be programmed while UTMIP is in reset. 0 = DISABLE 1 = ENABLE
10	RW	0x0	USB_SUSP_POL: Polarity of the suspend signal going to the USB PHY. 0 = Active low (default), 1 = Active high. This should not be changed by software. 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
9	RW	0x0	USB_PHY_CLK_VALID_INT_ENB: USB PHY clock valid interrupt enable. If this bit is enabled, interrupt is generated whenever USB clocks are resumed from a suspend. 0 = DISABLE 1 = ENABLE
8	RO	0x0	USB_PHY_CLK_VALID_INT_STS: USB PHY clock valid interrupt status. This bit is set whenever the USB PHY clock is woken up from suspend. Software must write a 1 to clear this bit. 0 = UNSET 1 = SET
7	RO	X	USB_PHY_CLK_VALID: USB PHY clock valid status. This bit indicates whether the USB PHY is generating a valid clock to the USB controller. If USB PHY clock is running, this bit is set to 1, else it is set to 0. 0 = UNSET 1 = SET
6	RO	X	USB_CLKEN: USB AHB clock enable status. Indicates whether the AHB clock to the USB controller is enabled or not. If AHB clock to USB controller is enabled, this bit is set to 1, else it is

Bit	R/W	Reset	Description
			set to 0. NOTE: Even when this is set to 0, all essential blocks that are required to resume USB clocks from suspend will be active and their AHB clock will not be suspended. 0 = UNSET 1 = SET
5	RW	0x0	USB_SUSP_CLR: Suspend Clear. Software must write a 1 to this bit to bring the PHY out of suspend mode. This is used when the software stops the PHY clock during suspend and then wants to initiate a resume. Software should also write 0 to clear it. NOTE: It is required that software generate a positive pulse on this bit to guarantee proper operation. 0 = UNSET 1 = SET
4	RW	0x0	USB_WAKE_ON_DISCON_EN_DEV: Wake on Disconnect Enable (device mode). When enabled (1), USB device will wake up from suspend on a disconnect event. This is only valid when USB controller is in device mode, it is not applicable when USB controller is in host mode. 0 = DISABLE 1 = ENABLE
3	RW	0x0	USB_WAKE_ON_CNNT_EN_DEV: Wake on Connect Enable (device mode). When enabled (1), USB device will wake up from suspend on a connect event. This is only valid when USB controller is in device mode, it is not applicable when USB controller is in host mode. 0 = DISABLE 1 = ENABLE
2	RW	0x0	USB_WAKE_ON_RESUME_EN: Wake on resume enable. If this bit is enabled, USB will wake up from suspend whenever a resume event is detected on USB. This is valid for both USB device and USB host modes. 0 = DISABLE 1 = ENABLE
1	RW	0x0	USB_WAKEUP_INT_ENB: USB wakeup interrupt enable. If this bit is enabled, interrupt is generated whenever USB wakeup event is generated. 0 = DISABLE 1 = ENABLE
0	RO	0x0	USB_WAKEUP_INT_STS: USB wakeup interrupt status. This bit is set whenever USB wakes up from suspend (a wakeup event is generated). Software must write a 1 to clear this bit. Note that during the wakeup sequence, PHY clocks will be resumed from suspend. Software can check when the PHY clocks are resumed by reading the bit USB_PHY_CLK_VALID. There is also a separate interrupt generated when PHY clock is resumed if USB_PHY_CLK_VALID_INT_EN is set. During the wakeup sequence, first USB_WAKEUP_INT_STS will be set, and it will take some time for the PHY clock to resume, which can be detected by checking USB_PHY_CLK_VALID. 0 = UNSET 1 = SET

19.13.9.2 USB3_IF_USB_PHY_VBUS_SENSORS_0

USB PHY VBUS SENSORS Control Register

This register controls the OTG VBUS sensors in the USB PHY. There are 4 VBUS sensors:

- A_VBUS_VLD
- A_SESS_VLD
- B_SESS_VLD
- B_SESS_END

The debounced status of each sensor can be read from the corresponding _STS bit field of the sensor in this register. The _CHG_DET field is set to 1 whenever a change is detected in the value of the _STS bit field of the corresponding sensor. If _INT_EN is set, then an interrupt is generated to the processor. This interrupt can be routed to CPU/AVP by appropriately writing the USBD bits in the interrupt controller registers.

In case software wants to override the value for a sensor, it can set the corresponding _SW_EN to 1, and set the corresponding sensor _SW_VALUE to 1 or 0 as per the requirement.

There are two debouncers for each sensor - DEBOUNCE_A and DEBOUNCE_B. The debounce values for them are controlled by the register UTMIP_DEBOUNCE_CFG0, fields UTMIP_BIAS_DEBOUNCE_A and UTMIP_BIAS_DEBOUNCE_B. For each sensor, we can select whether to use DEBOUNCE_A or DEBOUNCE_B by setting the field _DEB_SEL_B to the appropriate value (SEL_A or SEL_B).

Note: Do not set either UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

Offset: 0x404 | Read/Write: R/W | Reset: 0bx0000x00x0000x00x0000x00x0000x00

Bit	R/W	Reset	Description
30	RW	0x0	A_VBUS_VLD_WAKEUP_EN: A_VBUS_VLD wakeup enable. If this bit is enabled, USB will wake up from suspend whenever a change is detected on A_VBUS_VLD. 0 = DISABLE 1 = ENABLE
29	RW	0x0	A_VBUS_VLD_DEB_SEL_B: A_VBUS_VLD debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
28	RW	0x0	A_VBUS_VLD_SW_VALUE: A_VBUS_VLD software value. Software should write the appropriate value (1/0) to set/unset the A_VBUS_VLD status. This is only valid when A_VBUS_VLD_SW_EN is set. 0 = UNSET 1 = SET
27	RW	0x0	A_VBUS_VLD_SW_EN: A_VBUS_VLD software enable. Enable Software Controlled A_VBUS_VLD. Software sets this bit to drive the value in A_VBUS_VLD_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE
26	RO	X	A_VBUS_VLD_STS: A_VBUS_VLD status. This is set to 1 whenever A_VBUS_VLD sensor output is 1. 0 = UNSET 1 = SET
25	RO	0x0	A_VBUS_VLD_CHG_DET: A_VBUS_VLD change detect. This field is set by hardware whenever a change is detected in the value of A_VBUS_VLD. software writes a 1 to clear it 0 = UNSET 1 = SET
24	RW	0x0	A_VBUS_VLD_INT_EN: A_VBUS_VLD interrupt enable. If this field is set to 1, an interrupt is generated whenever A_VBUS_VLD_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
22	RW	0x0	A_SESS_VLD_WAKEUP_EN: A_SESS_VLD wakeup enable. If this bit is enabled, USB will wake up from suspend whenever a change is detected on A_SESS_VLD. 0 = DISABLE 1 = ENABLE
21	RW	0x0	A_SESS_VLD_DEB_SEL_B: A_SESS_VLD debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
20	RW	0x0	A_SESS_VLD_SW_VALUE: A_SESS_VLD software value. Software should write the appropriate value (1/0) to set/unset the A_SESS_VLD status. This is only valid when A_SESS_VLD_SW_EN is set. 0 = UNSET 1 = SET
19	RW	0x0	A_SESS_VLD_SW_EN: A_SESS_VLD software enable. Enable Software Controlled A_SESS_VLD. Software sets this bit to drive the value in A_SESS_VLD_SW_VALUE to the USB controller. 0 = DISABLE

Bit	R/W	Reset	Description
			1 = ENABLE
18	RO	X	A_SESS_VLD_STS: A_SESS_VLD status. This is set to 1 whenever A_SESS_VLD sensor output is 1. 0 = UNSET 1 = SET
17	RO	0x0	A_SESS_VLD_CHG_DET: A_SESS_VLD change detect. This field is set by hardware whenever a change is detected in the value of A_SESS_VLD. Software writes a 1 to clear it. 0 = UNSET 1 = SET
16	RW	0x0	A_SESS_VLD_INT_EN: A_SESS_VLD interrupt enable. If this field is set to 1, an interrupt is generated whenever A_SESS_VLD_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
14	RW	0x0	B_SESS_VLD_WAKEUP_EN: B_SESS_VLD wakeup enable. If this bit is enabled, USB will wake up from suspend whenever a change is detected on B_SESS_VLD. 0 = DISABLE 1 = ENABLE
13	RW	0x0	B_SESS_VLD_DEB_SEL_B: B_SESS_VLD debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
12	RW	0x0	B_SESS_VLD_SW_VALUE: B_SESS_VLD software value. Software should write the appropriate value (1/0) to set/unset the B_SESS_VLD status. This is only valid when B_SESS_VLD_SW_EN is set. 0 = UNSET 1 = SET
11	RW	0x0	B_SESS_VLD_SW_EN: B_SESS_VLD software enable. Enable Software Controlled B_SESS_VLD. Software sets this bit to drive the value in B_SESS_VLD_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE
10	RO	X	B_SESS_VLD_STS: B_SESS_VLD status. This is set to 1 whenever B_SESS_VLD sensor output is 1. 0 = UNSET 1 = SET
9	RO	0x0	B_SESS_VLD_CHG_DET: B_SESS_VLD change detect. This field is set by hardware whenever a change is detected in the value of B_SESS_VLD. software writes a 1 to clear it 0 = UNSET 1 = SET
8	RW	0x0	B_SESS_VLD_INT_EN: B_SESS_VLD interrupt enable. If this field is set to 1, an interrupt is generated whenever B_SESS_VLD_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
6	RW	0x0	B_SESS_END_WAKEUP_EN: B_SESS_END wakeup enable. If this bit is enabled, USB will wake up from suspend whenever a change is detected on B_SESS_END. 0 = DISABLE 1 = ENABLE
5	RW	0x0	B_SESS_END_DEB_SEL_B: B_SESS_END debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
4	RW	0x0	B_SESS_END_SW_VALUE: B_SESS_END software value. Software should write the appropriate value (1/0) to set/unset the B_SESS_END status. This is only valid when B_SESS_END_SW_EN is set. 0 = UNSET 1 = SET

Bit	R/W	Reset	Description
3	RW	0x0	B_SESS_END_SW_EN: Enable Software Controlled B_SESS_END. Software sets this bit to drive the value in B_SESS_END_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE
2	RO	X	B_SESS_END_STS: B_SESS_END status. This is set to 1 whenever the B_SESS_END sensor output is 1. 0 = UNSET 1 = SET
1	RO	0x0	B_SESS_END_CHG_DET: B_SESS_END change detect. This field is set by hardware whenever a change is detected in the value of B_SESS_END. software writes a 1 to clear it 0 = UNSET 1 = SET
0	RW	0x0	B_SESS_END_INT_EN: B_SESS_END interrupt enable. If this field is set to 1, an interrupt is generated whenever B_SESS_END_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE

19.13.9.3 USB3_IF_USB_PHY_VBUS_WAKEUP_ID_0

USB PHY VBUS Wakeup and ID Control Register

This register controls the battery charger (VDCD_DET, VDAT_DET), VBUS_WAKEUP, and ID sensors. The following sensors are in this register:

- VBUS_WAKEUP
- ID
- VDAT_DET
- VDCD_DET

The debounced status of each sensor can be read from the corresponding _STS bit field of the sensor in this register. The _CHG_DET field is set to 1 whenever a change is detected in the value of the _STS bit field of the corresponding sensor. If _INT_EN is set, then an interrupt is generated to the processor. This interrupt can be routed to CPU/AVP by appropriately writing the USBD bits in the interrupt controller registers.

In case software wants to override the value for a sensor, it can set the corresponding _SW_EN to 1, and set the corresponding sensor _SW_VALUE to 1 or 0 as per the requirement.

There are two debouncers for each sensor - DEBOUNCE_A and DEBOUNCE_B. The debounce values for them are controlled by the register UTMIP_DEBOUNCE_CFG0, fields UTMIP_BIAS_DEBOUNCE_A and UTMIP_BIAS_DEBOUNCE_B. For each sensor, we can select whether to use DEBOUNCE_A or DEBOUNCE_B by setting the field _DEB_SEL_B to the appropriate value (SEL_A or SEL_B).

Note: Do not set either UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

There are debouncers for VDAT_DET and VDCD_DET. These use separate debouncers - CHRG_DEBOUNCE_PERIOD_A and CHRG_DEBOUNCE_PERIOD_B. The debounce values for them are controlled by the register UTMIP_CHRG_DEB_CFG0, fields UTMIP_CHRG_DEBOUNCE_PERIOD_A and UTMIP_CHRG_DEBOUNCE_PERIOD_B. For each sensor, we can select whether to use HRG_DEBOUNCE_PERIOD_A or CHRG_DEBOUNCE_PERIOD_B by setting the field _DEB_SEL_B to the appropriate value (SEL_A or SEL_B).

Note: Do not set either UTMIP_CHRG_DEBOUNCE_PERIOD_A or UTMIP_CHRG_DEBOUNCE_PERIOD_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

Offset: 0x408 | Read/Write: R/W | Reset: 0b00000x00xx000x00xx000x00x1000x00

Bit	R/W	Reset	Description
31	RW	0x0	DIV_DET_EN: Battery charger divider detection enable. This goes to the USB2OTG pad. 0 = DISABLE 1 = ENABLE
30	RW	0x0	VBUS_WAKEUP_WAKEUP_EN: VBUS_WAKEUP wakeup enable. If this bit is enabled, USB will wake up from suspend whenever a change is detected on VBUS_WAKEUP. 0 = DISABLE 1 = ENABLE
29	RW	0x0	VDCD_DET_DEB_SEL_B: VCDT_DET debounce A/B select. Selects the debounce value from UTMIP_CHRG_DEBOUNCE_PERIOD_A or UTMIP_CHRG_DEBOUNCE_PERIOD_B from the register UTMIP_CHRG_DEB_CFG0. 0 = SEL_A 1 = SEL_B
28	RW	0x0	VDCD_DET_SW_VALUE: VDCD_DET software value. Software should write the appropriate value (1/0) to set/unset the VDCD_DET status. This is only valid when VDCD_DET_SW_EN is set. 0 = UNSET 1 = SET
27	RW	0x0	VDCD_DET_SW_EN: VDCD_DET software enable. Enable Software Controlled VDCD_DET. Software sets this bit to drive the value in VDCD_DET_SW_VALUE to the USB controller 0 = DISABLE 1 = ENABLE
26	RO	X	VDCD_DET_STS: VDCD_DET status. This is set to 1 whenever VDCD_DET sensor output is 1. 0 = UNSET 1 = SET
25	RO	0x0	VDCD_DET_CHG_DET: VDCD_DET change detect. This field is set by hardware whenever a change is detected in the value of VDCD_DET. Software writes a 1 to clear it. 0 = UNSET 1 = SET
24	RW	0x0	VDCD_DET_INT_EN: VDCD_DET interrupt enable. If this field is set to 1, an interrupt is generated whenever VDCD_DET_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
23	RO	X	VOP_DIV2P7_DET:This read-only status bit is from the battery charging divider circuit of USB2OTG pad 0 = UNSET 1 = SET

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTOR7: Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

19.13.10.32 XUSB_HOST_CONFIGURATION_0

Configuration

Offset: 0x180 | Read/Write: R/W | Reset: 0x800X8X40 (0b1xxxxxxxxxxx1xxx10xxxxxx01000000)

Bit	R/W	Reset	Description
31	RW	0x1	CLKEN_OVERRIDE: This can override the clock enable in case of a malfunction.
19	RW	0x1	PW_NO_DEVSEL_ERR_CYA: Setting this bit disables detection of DECERR due to no DEVSEL for DS PWs only. What are DS and PW? PW= pass write?
18	RO	X	INITIATOR_READ_IDLE: This read-only bit provides status reads on AFI upstream A value of 1b indicates there are no outstanding reads to the initiator.
17	RO	X	INITIATOR_WRITE_IDLE: This read-only bit provides status writes on AFI upstream A value of 1b indicates there are no outstanding writes to the initiator.
15	RW	0x1	WDATA_LEAD_CYA: Used to en(dis)able the handling of write data ahead of requests on IPFS AXI target.
14	RW	0x0	WR_INTRLV_CYA: Used to en(dis)able the handling of interleaved write requests on IPFS AXI target.
11	RO	X	TARGET_READ_IDLE: This read-only bit provides status reads to IPFS target. A value of 1b indicates there are no outstanding reads to the downstream FPCI.
10	RO	X	TARGET_WRITE_IDLE: This read-only bit provides status writes to IPFS target. A value of 1b indicates there are no outstanding writes to the downstream FPCI.
9	RO	X	MSI_VEC_EMPTY: This read-only bit provides status on whether MSI Vector registers have any active bits valid or not.
7	RW	0x0	UFPCI_MSIAW: MSI After Write ordering rule. 1 = Whenever MSI is ready assert the interrupt 0 = Default behavior, apply MSIAW ordering rule
6	RW	0x1	UFPCI_PWPASSPW: Input to the upstream FPCI 1 = Whenever write is ready, send it. 0 = Write goes only when outstanding PWs outside of new write's region are retired (default).
5	RW	0x0	UFPCI_PASSPW: Input to the upstream FPCI. Allows the upstream FPCI reads to pass writes.
4	RW	0x0	UFPCI_PWPASSNPW: Used for the upstream FPCI. Allows the upstream FPCI PWs to pass NPWs.
3	RW	0x0	DFPCI_PWPASSNPW: Used for the downstream FPCI. Allows the downstream FPCI PWs to pass NPWs.

Bit	R/W	Reset	Description
2	RW	0x0	DFPCI_RSPPASSPW: Input to the downstream FPCI. Allows the downstream FPCI responses to pass writes
1	RW	0x0	DFPCI_PASSPW: Input to the downstream FPCI. Allow the downstream FPCI reads to pass writes.
0	RW	0x0	EN_FPCI: When the IPFS device block is disabled, it is completely invisible on the IPFS bus; i.e., it does not even process IPFS configuration accesses.

19.13.10.33 XUSB_HOST_FPCI_ERROR_MASKS_0

FPCI Error Masks

Offset: 0x184 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000)

Bit	Reset	Description
2	0x0	MASK_FPCI_MASTER_ABORT: This bit allows an FPCI error to be forwarded to an AXI response when the FPCI error response indicates a Master Abort. 1 = Forward error 0 = Return AXI OKAY response (2'b0)
1	0x0	MASK_FPCI_DATA_ERROR: This bit allows an FPCI error to be forwarded to an AXI response when the FPCI error response indicates a Data Error. 1 = Forward error 0 = Return AXI OKAY response (2'b0)
0	0x0	MASK_FPCI_TARGET_ABORT: This bit allows an FPCI error to be forwarded to an AXI response when FPCI error response indicates a Target Abort. This bit also covers a decode error generated when there is no DEVSEL received. 1 = Forward error 0 = Return AXI OKAY response (2'b0)

19.13.10.34 XUSB_HOST_INTR_MASK_0

Interrupt Masks

Offset: 0x188 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0xxxxxxx0xxxxxxx0)

Bit	Reset	Description
16	0x0	IP_INT_MASK: IP (SATA/AZA) interrupt to the CPU complex gated by the mask.
8	0x0	MSI_MASK: MSI to the CPU complex gated by the mask.
0	0x0	INT_MASK: Interrupt to the CPU complex gated by the mask.

19.13.10.35 XUSB_HOST_INTR_CODE_0

Interrupt Control

Offset: 0x18c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx00000)

Bit	Reset	Description
4:0	0x0	INT_CODE: Eight interrupt codes. If the code is 0, logging of the next interrupt is enabled 0 = INT_CODE_CLEAR : Clear interrupt code 1 = INT_CODE_INI_SLVERR: Interrupt code for CPU AXI SLVERR response to IPFS 2 = INT_CODE_INI_DECERR: Interrupt code for CPU AXI DECERR response to IPFS 3 = INT_CODE_TGT_SLVERR: Interrupt code for PCIe endpoint FPCI target abort or data error response to IPFS 4 = INT_CODE_TGT_DECERR: Interrupt code for PCIe2 FPCI master abort response to IPFS 5 = INT_CODE_TGT_WRERR: Interrupt code for bufferable write to non-posted write address region 6 = RSVD1: Reserved

Bit	Reset	Description
		7 = INT_CODE_DFPCI_DECERR: Interrupt code for PCIe2 response to downstream request when downstream FPCI address does not fall in a claimable downstream region 8 = INT_CODE_AXI_DECERR: Interrupt code for IPFS response to downstream request when AXI target AXI address does not fall in any IPFS downstream BARs 9 = INT_CODE_FPCI_TIMEOUT: Interrupt code for FPCI Timeout 10 = RSVD2: Reserved for future expansion 11 = RSVD3 12 = RSVD4 13 = RSVD5 14 = RSVD6 15 = INT_CODE_SM_FATAL_ERROR: Interrupt code for SM fatal error 16 = INT_CODE_SM_NON_FATAL_ERROR: Interrupt code for SM non-fatal error

19.13.10.36 XUSB_HOST_INTR_SIGNATURE_0

Interrupt Signature

Offset: 0x190 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000x0)

Bit	Reset	Description
31:2	0x0	INT_INFO: For interrupt codes 1-5/7-8, this field contains address bits [31:2], either in FPCI memory space or AXI space. For FPCI generated errors, the field contains the FPCI address. For AXI/IPFS generated errors, the field contains the AXI address.
0	0x0	DIR: Indicates the direction of the AXI/FPCI transaction. 1=RD/0=WRIF signature type is 6 (sideband message), this field is 1. 0 = WRITE: Interrupt due to a write transaction 1 = READ: Interrupt due to a read transaction

19.13.10.37 XUSB_HOST_UPPER_FPCI_ADDR_0

Upper FPCI Address

Offset: 0x194 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	INT_INFO_UPPER: These 8 bits are the upper byte of the captured FPCI address (bits [39:32]) when the interrupt code is 3, 4, or 7. These bits determine the region in the Hypertransport Address Map that was accessed.

19.13.10.38 XUSB_HOST_IPFS_INTR_ENABLE_0

IPFS Interrupt Enable

Offset: 0x198 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxx00xxxx00000000)

Bit	Reset	Description
13	0x0	EN_SM_NON_FATAL_ERROR: Enable bit for interrupt code 15
12	0x0	EN_SM_FATAL_ERROR: Enable bit for interrupt code 14
7	0x0	EN_FPCI_TIMEOUT: Enable bit for interrupt code 9
6	0x0	EN_AXI_DECERR: Enable bit for interrupt code 8
5	0x0	EN_DFPCI_DECERR: Enable bit for interrupt code 7
4	0x0	EN_TGT_WRERR: Enable bit for interrupt code 5
3	0x0	EN_TGT_DECERR: Enable bit for interrupt code 4
2	0x0	EN_TGT_SLVERR: Enable bit for interrupt code 3

Bit	Reset	Description
1	0x0	EN_INI_DECERR: Enable bit for interrupt code 2
0	0x0	EN_INI_SLVERR: Enable bit for interrupt code 1

19.13.10.39 XUSB_HOST_UFPCI_CONFIG_0

Upstream FPCI Configuration

Offset: 0x19c | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00010)

Bit	Reset	Description
4:0	0x2	UNITID_T0C0: Upstream FPCI Unit ID for controller 0. HyperTransport, upstream FPCI request

19.13.10.40 XUSB_HOST_CFG_REVID_0

CFG_REVID Register

Offset: 0x1a0 | Read/Write: R/W | Reset: 0x000X10XX (0bxxxxxxxxxxxxxxxxxx0100xxxxxxx1xx)

Bit	R/W	Reset	Description
19	RO	X	DEV2SM_NONISO_REQUEST_PEND: This bit indicates if there is a non-ISO request pending. 0 = NO 1 = YES
18	RO	X	DEV2SM_ISO_REQUEST_PEND: This bit indicates if there is an ISO request pending. 0 = NO 1 = YES
13:12	RW	0x1	STRAP_CPU_MODE: MCP: Mode to send MSI. It can be programmable. 0 = NB_INTEL 1 = NB_AMD 2 = AMD 3 = TMTA
11	RW	0x0	CFG_REVID_WRITE_ENABLE: MCP: The enable to override the rev ID. It can be programmable. 0 = CLEAR 1 = SET
10	RW	0x0	CFG_REVID_OVERRIDE: MCP: Provides a way to override the current revision ID. It can be programmable. 0 = DISABLE 1 = ENABLE
4	RO	X	DEV2LEG_NONCOH_REQUEST_PEND: MCP: Tells the leg block that a non-coherent request is pending. 0 = NO 1 = YES
3	RO	X	DEV2LEG_COH_REQUEST_PEND: MCP comment: Tells the leg block that a coherent request is pending. 0 = NO 1 = YES
2	RW	0x1	SM2DEV_FPCI_TIMEOUT_EN: FPCI timeout enable bit for Controller 0 = DISABLE 1 = ENABLE

19.13.10.41 XUSB_HOST_FPCI_TIMEOUT_0

FPCI_TIMEOUT Register

Offset: 0x1a4 | Read/Write: R/W | Reset: 0x000f0000 (0bxxxxxxxxxxxxx11110000000000000000)

Bit	Reset	Description
19:0	0xf0000	SM2ALL_FPCI_TIMEOUT_THRESH: This field sets the timeout threshold value for the FPCI bus. It starts counting for each queue (ISO/NISO- RD/WR) with a pending request in the FPCI wrapper, the count resets when the requests are popped.

19.13.10.42 XUSB_HOST_TOM_0

Top of Memory Limit

Offset: 0x1a8 | Read/Write: R/W | Reset: 0x3fff0fff (0bxx11111111111111xxxx111111111111)

Bit	Reset	Description
29:16	0x3fff	LEG2ALL_TOM2: Top of Memory Limit 2.
11:0	0xfff	LEG2ALL_TOM1: Top of Memory Limit 1.

19.13.10.43 XUSB_HOST_INITIATOR_ISO_PW_RESP_PENDING_0

Initiator ISO PW Response Pending

Offset: 0x1ac | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	NUM_INITIATOR_ISO_PW_RESP_PEND: Number of pending initiator ISO PW responses

19.13.10.44 XUSB_HOST_INITIATOR_NISO_PW_RESP_PENDING_0

Initiator Non-ISO PW Response Pending

Offset: 0x1b0 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	NUM_INITIATOR_NISO_PW_RESP_PEND: Number of pending initiator NISO PW responses

19.13.10.45 XUSB_HOST_INTR_STATUS_0

IPFS Interrupt Status

Offset: 0x1b4 | Read/Write: RO | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
2	X	IP_INTR_STATUS: Status of IP (SATA/AZA) interrupt
1	X	MSI_INTR_STATUS: Status of MSI interrupt
0	X	IPFS_INTR_STATUS: Status of IPFS interrupt

19.13.10.46 XUSB_HOST_DFPCI_BEN_0

Downstream FPCI Byte Enables

Offset: 0x1b8 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
31	0x0	EN_DFPCI_BEN: Enable bit for BEN. When set, the programmed BE is sent on the DFPCI bus

Bit	Reset	Description
3:0	0x0	DFPCI_BYTE_ENABLE_N: Active low byte enables

19.13.10.47 XUSB_HOST_CLKGATE_HYSTERESIS_0

Offset: 0x1bc | Read/Write: R/W | Reset: 0x00000014 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00010100)

Bit	Reset	Description
7:0	0x14	CLK_DISABLE_CNT: Number of IPFS clock cycles to wait after clock gating criteria are met to disable IPFS/FPCI clocks

19.13.10.48 XUSB_HOST_XUSB_HOST_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control Register

> **Note:** The FIFO timing aspects of this register are no longer supported, but are retained for software compatibility.

The clock override/ovr_mode fields of this register control the second-level clock gating for the client and MC side of the MCCIF. All clock gating is enabled by default.

A '1' written to the rclk/wclk field results in one of the following:

- With wclk/rclk override mode = LEGACY, the clock reverts to the legacy mode of operation (where the clock is on whenever the client clock is enabled).
- With wclk/rclk override mode = ON, the clock is always on inside the MCCIF and PC.

A '1' written to the cclk override field keeps the client's clock always on inside the MCCIF.Offset: 0x1dc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxx00000xxxxxxxxxxx0000)

Bit	Reset	Description
20	LEGACY	XUSB_HOST_RCLK_OVR_MODE: 0 = LEGACY 1 = ON

19.13.13.3 T_XUSB_CFG_2

PCI Revision ID and Class Code Register

Offset: 0x08 | Read/Write: R

Bits	Reset	R/W	Description
31:24	Ch	R	T_XUSB_CFG_2_BASE_CLASS: The CLASS_CODE bits identify the generic function of the device and (in some cases) a specific register-level programming interface. The register is broken into three byte-size fields. The upper byte (at offset 0BH) is a base class code which broadly classifies the type of function the device

Bits	Reset	R/W	Description
			performs. The middle-byte (at offset 0BH) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09H) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. The Class Code and Revision ID are defined by parameters per block. Ch: BASE_CLASS_SBC (default)
23:16	3h	R	T_XUSB_CFG_2_SUB_CLASS: 3h: SUB_CLASS_XUSB (default)
15:8	30h	R	T_XUSB_CFG_2_PROG_IF: 30h: PROG_IF_XHCI (default)
7:0	A1h	R	T_XUSB_CFG_2_REVISION_ID: The REVISION_ID bits specify a device specific revision identifier. The value is chosen by the vendor. Zero is an acceptable value. This field should be viewed as a vendor defined extension to the DEVICE_ID. A1h: REVISION_ID_VAL (default) A1h: REVISION_ID_A01

19.13.13.4 T_XUSB_CFG_3

PCI Configuration Register

Offset: 0x0C | Read/Write: R

Bits	Reset	R/W	Description
31:24	0	R	Reserved
23	0	R	T_XUSB_CFG_3_HEADER_TYPE_FUNC: 0h: HEADER_TYPE_FUNC_SINGLE (default) 1h: HEADER_TYPE_FUNC_MULTI
22:16	0	R	T_XUSB_CFG_3_HEADER_TYPE_DEVICE: The HEADER_TYPE bits identify the layout of the bytes 10h through 3Fh in configuration space and also whether or not the device contains multiple functions. Bit 7 in this register is used to identify a multi-function device. If the bit is 0, then the device is single function. If the bit is 1, then the device has multiple functions. Bits 6 through 0 specify the layout of bytes 10h through 3Fh. The LATENCY_TIMER and HEADER_TYPE are defined by parameters per block. 0h: HEADER_TYPE_DEVICE_NON_BRIDGE (default) 1h: HEADER_TYPE_DEVICE_P2P_BRIDGE
15:11	0	R	T_XUSB_CFG_3_LATENCY_TIMER: The LATENCY_TIMER bits contain, in units of PCI bus clocks, the value of the Latency Timer for this PCI bus master. This register must be implemented as writable by any master that can burst more than two data phases. This register may be implemented as read-only for devices that burst two or fewer data phases, but the hardwired value must be limited to 16 or less. A typical implementation would be to build the five high-order bits (leaving the bottom three as read-only), resulting in a timer granularity of eight clocks. At reset, the register should be set to 0 (if programmable). LATENCY_TIMER bits are writable. 0h: LATENCY_TIMER_0_CLOCKS (default) 1h: LATENCY_TIMER_8_CLOCKS 1Eh: LATENCY_TIMER_240_CLOCKS 1Fh: LATENCY_TIMER_248_CLOCKS
10:8	0	R	Reserved
7:0	0	R	T_XUSB_CFG_3_CACHE_LINE_SIZE: 0h: CACHE_LINE_SIZE_0 (default) 20h: CACHE_LINE_SIZE_32 40h: CACHE_LINE_SIZE_64

19.13.13.5 T_XUSB_CFG_4

PCI Configuration Register

Offset: 0x10 | Read/Write: R/W

Bits	Reset	R/W	Description
31:15	0	R/W	T_XUSB_CFG_4_BASE_ADDRESS: The BASE_ADDRESS bits contain the base address of the device. The number of upper bits that a device actually implements depends on how much of the address space the device will respond to. A device that wants a 1 MB memory address space (using a 32-bit base address register) would build the top 12 bits of the address register, hardwiring the other bits to 0. Power-up software can determine how much address space the device required by writing a value of all 1's to the register and then reading the value back. The device will return 0's in all don't-care address bits, effectively specifying the address space required. 0h: BASE_ADDRESS_DEFAULT (default)
14:4	0	R	T_XUSB_CFG_4_BAR_SIZE_32KB: 0h: BAR_SIZE_32KB_RSVD (default)
3	1h	R	T_XUSB_CFG_4_PREFETCHABLE: 0h: PREFETCHABLE_NOT 1h: PREFETCHABLE_MERGABLE (default)
2:1	2h	R	T_XUSB_CFG_4_ADDRESS_TYPE: The ADDRESS_TYPE bits contain the type of the Base Address. It can be 32 bits, 20 bits, or 64 bits wide. 0h: ADDRESS_TYPE_32_BIT 2h: ADDRESS_TYPE_64_BIT (default)
0	0	R	T_XUSB_CFG_4_SPACE_TYPE: The SPACE_TYPE bit indicates whether the register maps into Memory or I/O space. 0h: SPACE_TYPE_MEMORY (default) 1h: SPACE_TYPE_IO

31:0	0	R	T_XUSB_CFG_6_RSVD: 0h: RSVD_00 (default)

19.13.13.8 T_XUSB_CFG_11

PCI Configuration Register

The SUBSYSTEM_VENDOR_ID bits and SUBSYSTEM_ID bits are used to uniquely identify the add-in board or subsystem where the device resides. When the device is on the motherboard, there is no serial ROM and the registers both initialize to NONE. The motherboard BIOS must set the values of the Subsystem ID and Subsystem Vendor ID by writing the proper values to the SUBSYSTEM_VENDOR_ID and SUBSYSTEM_ID bits in the PCI_T_16 register (NOT PCI_T_11).

Offset: 0x2c | Read/Write: R

Bits	Reset	R/W	Description
31:16	0	R	T_XUSB_CFG_11_SUBSYSTEM_ID: 0h: SUBSYSTEM_ID_NONE (default)

Bits	Reset	R/W	Description
31:0	0	R	T_XUSB_CFG_14_RESERVED: 0h: RESERVED_0 (default)

19.13.13.12 T_XUSB_CFG_15

PCI Configuration Register

Offset: 0x3c | Read/Write: R/W

Bits	Reset	R/W	Description
31:24	0	R	T_XUSB_CFG_15_MAX_LAT: The MAX_LAT bits contain the maximum time the device requires to gain access to the CPI bus. This read-only register is used to specify the device's desired settings for Latency Timer values. The value specifies a period of time in units of 1/4 microseconds. Values of 0 indicate that the device has no major requirements for the settings of Latency Timers. MAX_LAT is nonzero. The INTR_PIN, MIN_GNT, and MAX_LAT are configurable per block. For a 64-byte buffer with two 32-byte sections, the maximum tolerable latency for the XHCI once a large XUSB ISO transaction has begun is about 23 µs. The latency timer is hardwired to 20 µs. This value only applies in External PCI operation. 0h: MAX_LAT_NO_REQUIREMENTS (default) 14h: MAX_LAT_5US 50h: MAX_LAT_20US

Bits	Reset	R/W	Description
23:16	0	R	T_XUSB_CFG_15_MIN_GNT: The MIN_GNT bits contain the length of the burst period a device needs assuming a clock rate of 33 MHz. This read-only register is used to specify the device's desired settings for Latency Timer values. The value specifies a period of time in units of 1/4 microsecond. Values of 0 indicate that the device has no major requirements for the settings of Latency Timers. MIN_GNT is nonzero. 0h: MIN_GNT_NO_REQUIREMENTS (default) 1h: MIN_GNT_240NS
15:8	1h	R	T_XUSB_CFG_15_INTR_PIN: The INTR_PIN bits contain the interrupt pin the device (or device function) uses. A value of 1 corresponds to INTA#. A value of 2 corresponds to INTB#. A value of 3 corresponds to INTC#. A value of 4 corresponds to INTD#. Devices (or device functions) that do not use an interrupt pin must put a 0 in this register. 0h: INTR_PIN_NONE 1h: INTR_PIN_INTA (default) 2h: INTR_PIN_INTB 3h: INTR_PIN_INTC 4h: INTR_PIN_INTD
7:0	0	R/W	T_XUSB_CFG_15_INTR_LINE: The INTR_LINE bits contain the interrupt routing information. The register is read/write and must be implemented by any device (or device function) that uses an interrupt pin. POST software will write the routing information into this register as it initializes and configures the system. The value in this register tells which input of the system interrupt controller(s) the device's interrupt pin is connected to. Device drivers and operating systems can use this information to determine priority and vector information. INTR_LINE is initialized to 0xff (no connection) at reset. Some PCI BIOS' cannot handle aliased INTR_LINEs. Some PCI BIOS' cannot handle INTR_LINE initialized to 0xff. 0h: INTR_LINE_IRQ0 (default) 1h: INTR_LINE_IRQ1 Fh: INTR_LINE_IRQ15 FFh: INTR_LINE_UNKNOWN

19.13.13.16 T_XUSB_CFG_24

XUSB XHCI Configuration Control

Offset: 0x60 | Read/Write: R/W

Bits	Reset	R/W	Description
31:16	0	R	Reserved
15:14	0	R	T_XUSB_CFG_24_RSVDP: 0h: RSVDP_VALUE
13:8	20h	R/W	T_XUSB_CFG_24_FLADJ: Frame Length Adjustment Register. This register is in the auxiliary power well. This feature is used to adjust any offset from the clock source that generates the clock that drives the SOF counter. When a new value is written into these six bits, the length of the frame is adjusted. Its initial programmed value is system dependent based on the accuracy of hardware USB clock and is initialized by system BIOS. This register should only be modified when the HChalted bit in the USBSTS register is a one. Changing value of this register while the host controller is operating yields undefined results. It should not be reprogrammed by USB system software unless the default or BIOS programmed values are incorrect, or the system is restoring the register while returning from a suspended state. 20h: FLADJ_VALUE (default)
7:0	30h	R	T_XUSB_CFG_24_SBRN: Serial Bus Release Number Register. This register contains the release of the Universal Serial Bus Specification with which this Universal Serial Bus Host Controller module is compliant. 30h: SBRN_VALUE

19.13.13.17 T_XUSB_CFG_EMU_RSVD

MSIX is not part of Tegra K1 processors.

The PCIe and HT capabilities are not required. PCIe capability will be trapped by the emulation only IP - the emulation only IP put the PCIe capability at 80h ~ BBh, and uses BCh ~ BFh, so these regions are reserved for the emulation only IP. (The emulation only IP will mask the pointers to insert the PCIe capability to the config space of the unit.)

Offset: 0x80-0xBB | Read/Write: R/W

Bits	Reset	R/W	Description
31:0	Unknown	R/W	T_XUSB_CFG_EMU_RSVD_FIELD

19.13.13.18 T_XUSB_MSI_CTRL

MSI Message Control and Capability Register B0h

MSI_CTRL is the main control register for MSI support.

Offset: 0xc0 | Read/Write: R/W

Bits	Reset	R/W	Description
31:25	0	R	Reserved
24	0	R	T_XUSB_MSI_CTRL_VECTOR_MASK_CAP: The VECTOR_MASK_CAP field indicates whether or not the controller supports MSI-per-vector masking. 0h: VECTOR_MASK_CAP_DIS 1h: VECTOR_MASK_CAP_EN 0h: VECTOR_MASK_CAP_DEFAULT (default)
23	1h	R	T_XUSB_MSI_CTRL_64_ADDR_CAP: The 64_ADDR_CAP field indicates whether or not the controller is capable of generating a 64-bit message address. A value of 1 means the controller is capable of generating a 64-bit message address. 0h: 64_ADDR_CAP_DIS 1h: 64_ADDR_CAP_EN 1h: 64_ADDR_CAP_DEFAULT (default)
22:20	0	R/W	T_XUSB_MSI_CTRL_MULT_MSG_ENABLE: System software writes to this field to indicate the number of allocated vectors (less than or equal to the number of vectors requested). The number of vectors is aligned as a power of two. When MSI is enabled, the controller will be allocated at least one vector. 0h: MULT_MSG_ENABLE_1 1h: MULT_MSG_ENABLE_2 2h: MULT_MSG_ENABLE_4 3h: MULT_MSG_ENABLE_8 4h: MULT_MSG_ENABLE_16 5h: MULT_MSG_ENABLE_32 0h: MULT_MSG_ENABLE_DEFAULT (default)
19:17	0	R	T_XUSB_MSI_CTRL_MULT_MSG_CAP: System software reads this field to determine the number of requested vectors. The number of requested vectors must be aligned to a power of two. Values of 6 and 7 in this field are reserved. 0h: MULT_MSG_CAP_1 1h: MULT_MSG_CAP_2 2h: MULT_MSG_CAP_4 3h: MULT_MSG_CAP_8 4h: MULT_MSG_CAP_16 5h: MULT_MSG_CAP_32 0h: MULT_MSG_CAP_DEFAULT (default)
16	0	R/W	T_XUSB_MSI_CTRL_MSI_ENABLE: The MSI_ENABLE field enables the MSI capability. If MSI_ENABLE is written to a 1, the controller is permitted to use MSI to request service and is prohibited from using the legacy interrupt. System configuration software sets this bit to enable MSI. A device driver is prohibited from writing this bit to mask the controller's service request. If this bit is written to a 0, the controller is prohibited from using MSI to request service. 0h: MSI_ENABLE_OFF 1h: MSI_ENABLE_ON 0h: MSI_ENABLE_DEFAULT (default)
15:8	E0h	R	T_XUSB_MSI_CTRL_NEXT_PTR: The NEXT_PTR field identifies the next item in the capabilities list. It is a read-only field. 70h: NEXT_PTR_MSIX DCh: NEXT_PTR_MMAP 44h: NEXT_PTR_PMCAP

Bits	Reset	R/W	Description
			0h: NEXT_PTR_NULL E0h: NEXT_PTR_MAILBOX E0h: NEXT_PTR_DEFAULT (default)
7:0	5h	R	T_XUSB_MSI_CTRL_CAP_ID: The CAP_ID field identifies this capability block as the MSI capability block. This is read-only as 0x5. 5h: CAP_ID_MSI (default)

19.13.13.19 T_XUSB_MSI_ADDR1

MSI Message Address Register 84h

MSI_ADDR1 specifies the lower 32 bits to which an MSI memory write transaction should occur.

Offset: 0xc4 | Read/Write: R/W

Bits	Reset	R/W	Description
31:2	0	R/W	T_XUSB_MSI_ADDR1_MSG_ADDR: System-specified message address. When MSI is enabled, this field specifies the Dword-aligned address for the MSI memory write transaction. 0h: MSG_ADDR_DEFAULT (default)
1:0	0	R	Reserved

19.13.13.20 T_XUSB_MSI_ADDR2

MSI Message Upper Address Register 88h

MSI_ADDR2 specifies the upper 32 bits to which an MSI memory write transaction should occur.

Offset: 0xc8 | Read/Write: R/W

Bits	Reset	R/W	Description
31:0	0	R/W	T_XUSB_MSI_ADDR2_MSG_ADDR: System-specified message address. When MSI is enabled, this field specifies the upper 32 bits of the address for the MSI memory write transaction. The contents of this register only apply when T_XUSB_CFG_MSI_CTRL_64_ADDR_CAP bit is set. 0h: MSG_ADDR_DEFAULT (default)

19.13.13.21 T_XUSB_MSI_DATA

MSI Message Data Register 8Ch

The MSI_DATA register contains the system-specified message.

Offset: 0xcc | Read/Write: R/W

Bits	Reset	R/W	Description
31:16	0	R	Reserved
15:0	0	R/W	T_XUSB_MSI_DATA_MSG_DATA: System-specified message When MSI is enabled, the message data is driven onto the lower 16 bits of the MSI memory write. The MULT_MSG_ENABLE field in configuration register 80h specifies the number of low-order message data bits that the XHCI is permitted to modify to generate its system software allocated vectors. 0h: MSG_DATA_DEFAULT (default)

19.13.14 XUSB PCIe PADCTL REFCLK Configuration Registers

19.13.17 XUSB Falcon Registers

19.13.17.1 FALCON_CPUCTL_0

Offset: 0x100 | Read/Write: R/W | Reset: 0b00000000000000000000000000xxxxx

Bit	Reset	R/W	Description
5	X	RO	STOPPED: This bit indicates whether the CPU is currently in the stopped state. The Falcon processor will exit this state if a 1 is written to the STARTCPU bit, or if an interrupt arrives on one of its two inputs and the corresponding IE bit in CSW is set 0: STOPPED_FALSE 1: STOPPED_TRUE
4	X	RO	HALTED: This bit indicates whether the CPU is currently in the halted state. The Falcon processor can only exit this state when a 1 is written to the STARTCPU bit. 0: HALTED_FALSE 1: HALTED_TRUE
3	X	WO	HRESET: Setting HRESET to true will apply a hard reset. This bit will auto-clear and setting to false has no effect. 0: HRESET_FALSE 1: HRESET_TRUE
2	X	WO	SRESET: Setting SRESET to true will apply a soft reset. This bit will auto-clear and setting to false has no effect. 0: SRESET_FALSE 1: SRESET_TRUE
1	X	WO	STARTCPU: Setting STARTCPU to true will start CPU execution while in a HALTED state. If a start request is still pending, setting to false cancel the start request. Writing any value has no effect while the CPU is running. 0: STARTCPU_FALSE 1: STARTCPU_TRUE
0	X	WO	IINVAL: Setting IINVAL to true causes all blocks in IMEM except block 0 to be marked as INVALID. This bit will auto-clear and setting to false has no effect. 0: IINVAL_FALSE 1: IINVAL_TRUE

19.13.17.2 FALCON_BOOTVEC_0

The BOOTVEC register stores the initial execution start address of the CPU when it is first started after a reset.

Offset: 0x104 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	VEC 0: VEC_INIT

19.13.17.3 FALCON_DMACTL_0

Offset: 0x10c | Read/Write: R/W | Reset: 0b00000000000000000000000xxxxxxx1

Bit	Reset	R/W	Description
7	X	RO	SECURE_STAT
6:3	X	RO	DMAQ_NUM: Indicates the valid request number at the DMA request queue
2	X	RO	IMEM_SCRUBBING:

Bit	Reset	R/W	Description
			0: Indicates scrubbing is done. For a non-secure Falcon, this value is always 0. 1: Indicates secure scrubber is pending and scrubbing IMEM, any access to IMEM will be blocked until scrubbing is done 0: IMEM_SCRUBBING_DONE 1: IMEM_SCRUBBING_PENDING
1	X	RO	DMEM_SCRUBBING: 0: Indicates scrubbing is done. For a non-secure Falcon, this value is always 0. 1: Indicates secure scrubber is pending and scrubbing DMEM, any access to DMEM will be blocked until scrubbing is done 0: DMEM_SCRUBBING_DONE 1: DMEM_SCRUBBING_PENDING
0	0x1	RW	REQUIRE_CTX: When REQUIRE_CTX is set to true, a valid context must be loaded before any DMA request can be serviced. Pending requests without a valid current context remain pending, and do not prevent the engine from reporting idle. When this bit is set to false, DMA requests are serviced regardless of the current context. Note that once a request is issued, it must complete before the engine will be able to report idle, as needed for example to process WFI context switch requests. 0:REQUIRE_CTX_FALSE 1: REQUIRE_CTX_TRUE 1: REQUIRE_CTX_INIT

19.13.17.4 FALCON_IMFILLRNG1_0

IMFILLRNG1 indicates tag values for the low and high end of the PC range to be auto-filled. The PC range is [tag_lo<<8 .. tag_hi<<8+255].

If the user enables the auto-fill feature and leaves IMFILLRNG1 as zero, instruction 0x0~0x0ff always works as auto-fill range.

19.13.19 USB3 UTMIP Configuration Registers

Note: Current UTMIP configuration registers use settings that support NV software drivers and should NOT be modified. If designing custom drivers, consult your NV representative prior to modifying these registers

19.13.19.1 USB3_UTMIP_PLL_CFG0_0

USB_PHY PLL Configuration Register 0

Note: This register has been moved to the Clock and Reset section of this document. PROGRAMMING THIS REGISTER HERE WILL HAVE NO EFFECT!

This register was used to configure the PLL inside UTMIP block prior to Tegra K1 processors. This has been defeatured from UTMIP space and moved to Clock and Reset (CAR) space. Refer to the UTMIP_PLL register descriptions in the Clock and Reset Controller section.

19.13.19.2 USB3_UTMIP_PLL_CFG1_0

UTMIP PLL and PLLU Configuration Register 1

Note: This register has been moved to the Clock and Reset section of this document. PROGRAMMING THIS REGISTER HERE WILL HAVE NO EFFECT!

This register was used to configure the PLL inside the UTMIP block prior to Tegra K1 processors. This has been defeatured from UTMIP space and moved to CAR space. Refer to the UTMIP_PLL register descriptions in the Clock and Reset Controller section.

19.13.19.3 USB3_UTMIP_XCVR_CFG0_0

UTMIP Transceiver Cell Configuration Register 0

Offset: 0x808 | Read/Write: R/W | Reset: 0b00100000001001010110010100000000

Bit	Reset	Description
31:25	0x10	UTMIP_XCVR_HSSLEW_MSB: Most significant bits of HS_SLEW.
24:22	0x0	UTMIP_XCVR_SETUP_MSB: Most significant bits of SETUP.
21	0x1	UTMIP_XCVR_LSBIAS_SEL: Low speed bias selection method for usb transceiver pad
20	0x0	UTMIP_XCVR_DISCON_METHOD: Disconnect method on the usb transceiver pad
19	0x0	UTMIP_FORCE_PDZI_POWERUP: Force PDZI input into power up.
18	0x1	UTMIP_FORCE_PDZI_POWERDOWN: Force PDZI input into power down. (Overrides FORCE_PDZI_POWERUP.)
17	0x0	UTMIP_FORCE_PD2_POWERUP: Force PD2 input into power up.
16	0x1	UTMIP_FORCE_PD2_POWERDOWN: Force PD2 input into power down. (Overrides FORCE_PD2_POWERUP.)
15	0x0	UTMIP_FORCE_PD_POWERUP: Force PD input into power up.
14	0x1	UTMIP_FORCE_PD_POWERDOWN: Force PD input into power down. (Overrides FORCE_PD_POWERUP.)
13	0x1	UTMIP_XCVR_TERMEN: Enable HS termination.
12	0x0	UTMIP_XCVR_HSLOOPBACK: Internal loopback inside XCVR cell. Used for IOBIST.
11:10	0x1	UTMIP_XCVR_LSFSLEW: LS falling slew rate control.
9:8	0x1	UTMIP_XCVR_LSRSLEW: LS rising slew rate control.
7:6	0x0	UTMIP_XCVR_FSSLEW: FS slew rate control.
5:4	0x0	UTMIP_XCVR_HSSLEW: HS slew rate control. The two LSBs.
3:0	0x0	UTMIP_XCVR_SETUP: SETUP[3:0] input of XCVR cell. HS driver output control. 4 LSBs.

19.13.19.4 USB3_UTMIP_BIAS_CFG0_0

UTMIP Bias Cell Configuration Register 0

Offset: 0x80c | Read/Write: R/W | Reset: 0bx00000001100000000000110000000000

Bit	Reset	Description
30	0x0	UTMIP_IDDIG_C_VAL: See IDDIG_C_SEL.
29	0x0	UTMIP_IDDIG_C_SEL: 0: IdDig_c = IdDig_c. 1: IdDig_c = IDDIG_C_VAL.
28	0x0	UTMIP_IDDIG_B_VAL: See IDDIG_B_SEL.
27	0x0	UTMIP_IDDIG_B_SEL: 0: IdDig_b = IdDig_b. 1: IdDig_b = IDDIG_B_VAL.
26	0x0	UTMIP_IDDIG_A_VAL: See IDDIG_A_SEL.
25	0x0	UTMIP_IDDIG_A_SEL: 0: IdDig_a = IdDig_a. 1: IdDig_a = IDDIG_A_VAL.
24	0x0	UTMIP_HSDISCON_LEVEL_MSB: Most significant bit of UTMIP_HSDISCON_LEVEL, bit 2
23	0x1	UTMIP_IDPD_VAL: See IDPD_SEL.
22	0x1	UTMIP_IDPD_SEL: 0: Reserved. Refer to the PMC registers for this feature.
21	0x0	UTMIP_IDDIG_VAL: See IDDIG_SEL.
20	0x0	UTMIP_IDDIG_SEL: 0: IdDig = IdDig. 1: IdDig = IDDIG_VAL.
19	0x0	UTMIP_GPI_VAL: See GPI_SEL.
18	0x0	UTMIP_GPI_SEL: 0: StaticGpi = IdDig. 1: StaticGpi = GPI_VAL.
17:15	0x0	UTMIP_ACTIVE_TERM_OFFSET: Active termination control offset.
14:12	0x0	UTMIP_ACTIVE_PULLUP_OFFSET: Active 1.5K pull-up control offset.
11	0x1	UTMIP_OTGPD: Power down OTG circuit.
10	0x1	UTMIP_BIASPD: Power down bias circuit.
9:8	0x0	UTMIP_VBUS_LEVEL_LEVEL: Vbus detector level.
7:6	0x0	UTMIP_SESS_LEVEL_LEVEL: SessionEnd detector level.
5:4	0x0	UTMIP_HSCHIRP_LEVEL: HS chirp detector level.
3:2	0x0	UTMIP_HSDISCON_LEVEL: HS disconnect detector level.
1:0	0x0	UTMIP_HSSQUELCH_LEVEL: HS squelch detector level.

19.13.19.5 USB3_UTMIP_HSRX_CFG0_0

UTMIP High Speed Receive Config 0

Offset: 0x810 | Read/Write: R/W | Reset: 0b10010001011001010011010000000000

Bit	Reset	Description
31:30	0x2	UTMIP_KEEP_PATT_ON_ACTIVE: Keep the stay alive pattern on active
29	0x0	UTMIP_ALLOW_CONSEC_UPDN: Allow consecutive ups and downs on the bits, debug only, set to 0.
28	0x1	UTMIP_REALIGN_ON_NEW_PKT: Realign the inertia counters on a new packet
27:24	0x1	UTMIP_PCOUNT_UPDN_DIV: The number of (edges-1) needed to move the sampling point
23:21	0x3	UTMIP_SQUELCH_EOP_DLY: Limit the delay of the squelch at EOP time
20	0x0	UTMIP_NO_STRIPPING: Do not strip incoming data
19:15	0xa	UTMIP_IDLE_WAIT: Number of idle cycles to declare IDLE.

Bit	Reset	Description
14:10	0xd	UTMIP_ELASTIC_LIMIT: Depth of elastic input store
9	0x0	UTMIP_ELASTIC_OVERRUN_DISABLE: Do not declare overrun errors until overflow of FIFO
8	0x0	UTMIP_ELASTIC_UNDERRUN_DISABLE: Do not declare underrun errors
7	0x0	UTMIP_PASS_CHIRP: When in Chirp Mode, allow chirp rx data through
6	0x0	UTMIP_PASS_FEEDBACK: Pass through the feedback, do not block it.
5:4	0x0	UTMIP_PCOUNT_INERTIA: Retime the path.
3:2	0x0	UTMIP_PHASE_ADJUST: Based on incoming edges and current sampling position, adjust phase
1	0x0	UTMIP_THREE_SYNCBITS: Sync pattern detection needs 3 consecutive samples instead of 4
0	0x0	UTMIP_USE4SYNC_TRAN: Require 4 sync pattern transitions (01) instead of 3

19.13.19.6 USB3_UTMIP_HSRX_CFG1_0

UTMIP High Speed Receive Config 1

Offset: 0x814 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxx010011

19.13.19.22 USB3_UHSIC_PLL_CFG1_0

UHSIC PLL and PLLU Configuration Register 1

This register is used to configure the PHY PLL contained in the UHSIC module as well as the PLLU power up and down.

PLL CONFIGURATION and PARAMETERS

In normal operation, the following clock generators are in play for USB:

Crystal clock -> enters PLLU to generate 12 MHz clock -> enters USB_PHY PLL to generate 480/60 MHz clock

The following parameters control the bring-up of the PLLs:

Coming out of reset or suspend

PllUOnState: start pllu_enable_count and pll_lock_count

Wait ~1 µs to enable the PLL_U (pllu_enable_count == ClkXtal * PLLU_ENABLE_DLY_COUNT * 8)

Wait ~1 ms until PLLU is stable (pll_lock_count == ClkXtal * PLLU_STABLE_COUNT * 256) => USB_PHY PLL_ENABLE

Numbers for a 19.2 MHz crystal clock

- PLLU_ENABLE_DLY_COUNT[4:0] = 1 * 19.2 / 8 = 2.4 = 3 = 0x03
- PLLU_STABLE_COUNT[11:0] = 1000 * 19.2 / 256 = 75 = 0x4b (Note: currently defaults to 0x600)
- XTAL_FREQ_COUNT[11:0] = 2500 * 19.2 / 256 = 187 = 0xbb

Bit	Reset	Description
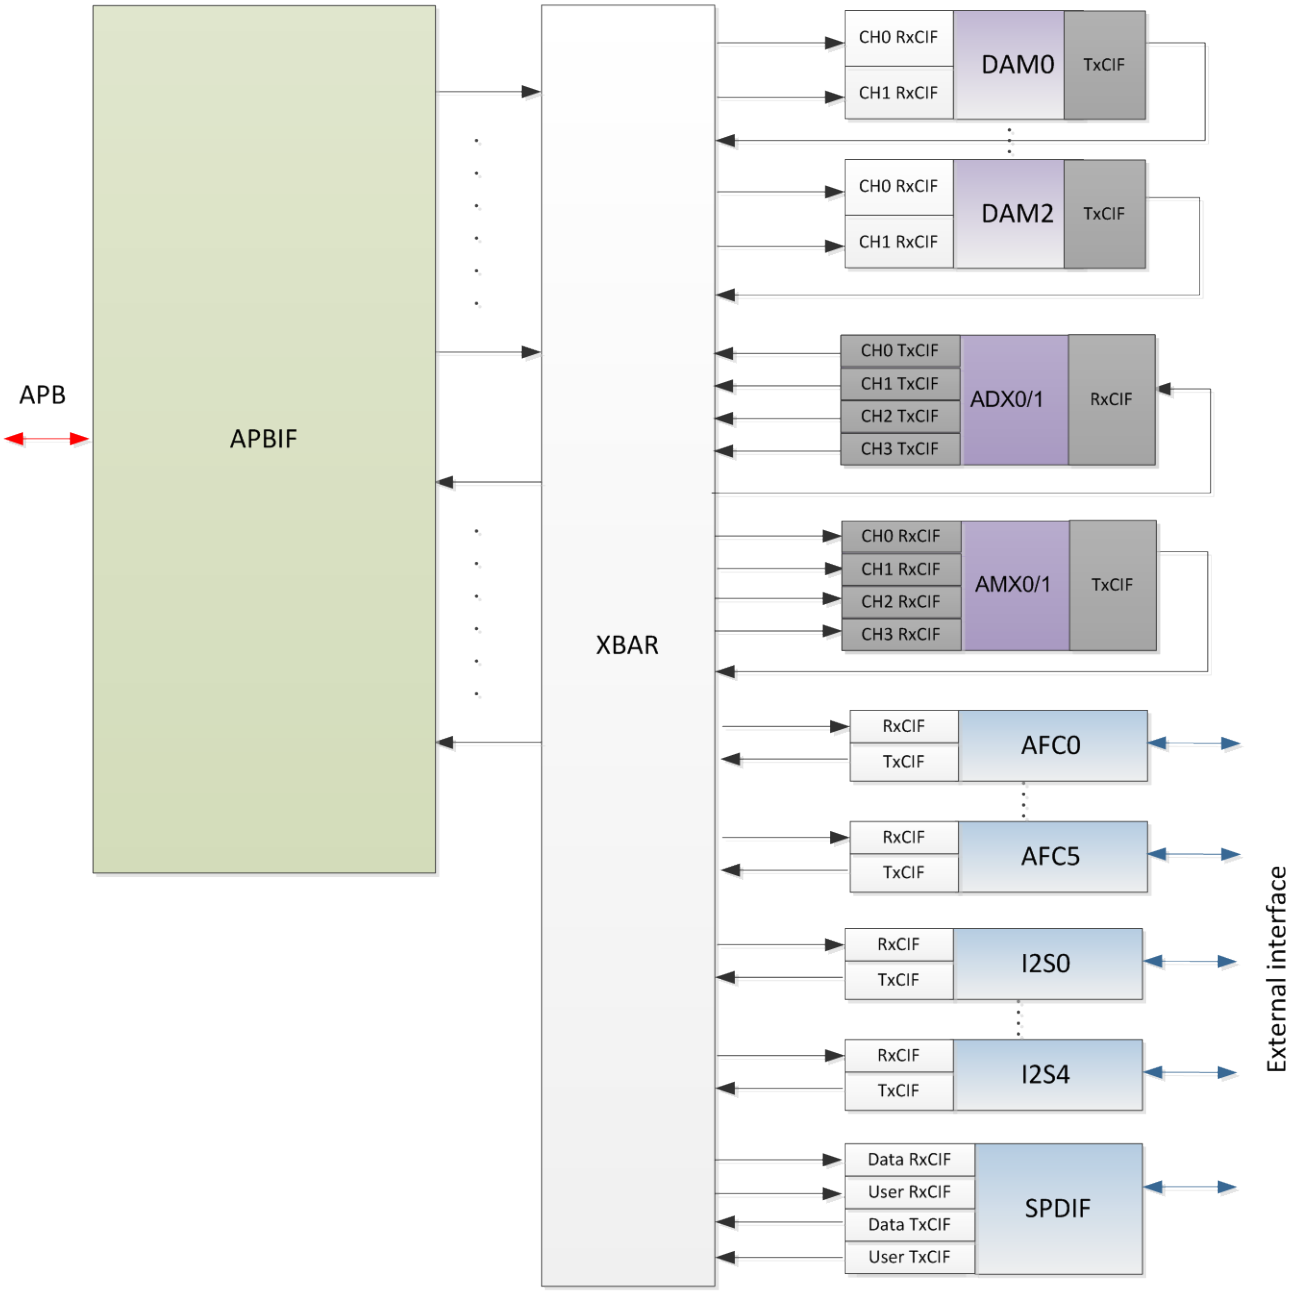
31:0	0x0	USB2D_QH: Queue Head for IN endpoint n. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint n.

20.0 AUDIO HUB (AHUB)

The audio hub (AHUB) in Tegra® K1 mobile processors has external I2S and S/PDIF interfaces. It can process audio for Digital Audio Mixers (DAMs), Audio Multiplexers (AMXs), Audio Demultiplexers (ADXs), Audio Flow Controllers (AFCs), and DMA (APBIF-DMA) channels to communicate with the memory. The AHUB supports multiple interfaces to the audio devices in the system cellular baseband; different audio codecs; Bluetooth modules; A/V receivers; etc. The AHUB can support the different interface, protocol, and signal quality requirements of these audio devices.

Figure 43: Audio Hub Functional Block Diagram



The Audio Hub (AHUB) consists of

- 10 APBIF DMA channels
- 5 I^2S controllers
- 1 S/PDIF controller
- 3 Digital Audio sample-rate conversion and Mixing blocks (DAMs)
- 2 Audio Multiplexers (AMX) and 2 Audio Demultiplexers (ADXs) for audio processing.
- 6 Audio Flow Controllers (AFCs)

20.1 Crossbar

The crossbar (XBAR) is a 36x39 full crossbar switch with unidirectional data flow, with 36 TX and 39 RX clients. The XBAR has multicasting capability: A TX client can send audio data to multiple RX clients, while a RX client can receive data from only one TX at a time. It also has the ability to connect TX clients with Rx clients in many sessions that function independently of each other.

20.1.1 XBAR Programming Guidelines

To connect two modules in AHUB, for example, DAM0's output to I2S1's input:

1. Go to the register corresponding to the receiver, in this case, the I2S1 AUDIO_I2S1_RX0_0 register.
2. Enable the bit that corresponds to the transmitter, in this case, the field DAM1_TX0.
3. Ensure that all other fields in the AUDIO_I2S1_RX0_0 register are disabled. At power on, all the fields are disabled. So this step is required only while setting up the audio routing after removing the previous use case's audio routing.

20.2 Audio Client Interface (ACIF)

Audio streams are routed through the AHUB by interconnecting various modules using the Audio Client Interface (ACIF).

All the AHUB modules have one or more Transmit Audio Client Interfaces (TxCIFs) and one or more Receive Audio Client Interfaces (RxCIFs). Hence all modules in the AHUB have registers named <module>_AUDIOCIF_<tag>_CTRL that are used to configure the interfaces. The audio CIF interface includes common functionalities that are used in all the AHUB modules such as:

- Converting the number of channels in the input stream(s) before the stream is fed into the module. This feature is limited to converting a mono stream to a stereo stream and vice-versa.
- Converting the number of bits/sample for the input stream(s) before the stream is fed into the module.

20.2.1 General ACIF Register Specification

The ACIF registers are present in the AHUB modules. For convenience of reference for the programming guidelines below, here is a sample ACIF register.

Bit	R/W	Reset	Description
29:24	RW	0x0	FIFO_THRESHOLD
23:20	RW	0x0	AUDIO_CHANNELS: 0 = CH1 1 = CH2 2 = CH3 3 = CH4 4 = CH5 5 = CH6 6 = CH7 7 = CH8 8 = CH9 9 = CH10

0	RW	0x0	MONO_CONV:

Bit	R/W	Reset	Description
			0 = ZERO 1 = COPY

20.2.2 ACIF Programming Guidelines

The following programming guidelines are common for the ACIF registers in all AHUB modules. The programming guidelines of the respective modules will refer to this subsection when it comes to programming the ACIF registers.

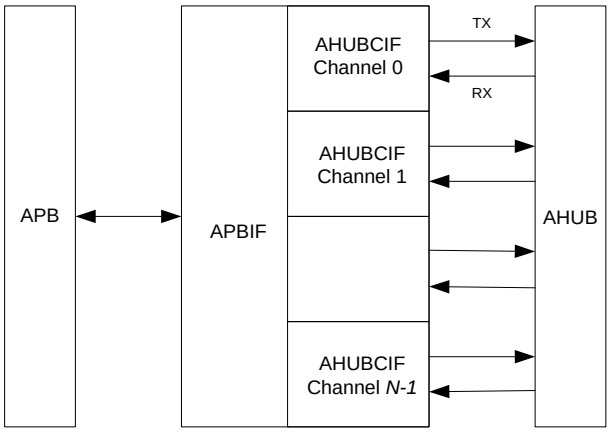
1. Set the AUDIO_CHANNELS field to the number of channels in the input or output stream of a module, depending on whether the ACIF in question is an RxCIF or TxCIF respectively
2. Set the CLIENT_CHANNELS field to the number of channels of the stream as dealt with inside the module. This setting is different from AUDIO_CHANNELS only when a conversion of the number of channels of an audio stream is desired.
3. Similarly, set the AUDIO_BITS and CLIENT_BITS fields.
4. If AUDIO_BITS and CLIENT_BITS do not match, the EXPAND and TRUNCATE fields are used to determine how to transition from AUDIO_BITS to CLIENT_BITS (in the case of a RxCIF) or from CLIENT_BITS to AUDIO_BITS (in the case of an TxCIF). Expanding always results in the actual data being shifted to the MSB bits and the rest filled with zeros, ones, or some random bits from an LFSR. TRUNCATE can be set to chopping or rounding.
5. If AUDIO_CHANNELS and the CLIENT_CHANNELS are different, the STEREO_CONV field is used to determine how a stereo stream is converted to a mono stream, and the MONO_CONV field is used to determine how a mono stream is converted to a stereo stream.

20.3 APBIF

Note: Tegra K1 devices contain identical APBIF and APBIF2 functional blocks. Unless specified otherwise, references to APBIF in this document also apply to APBIF2. Each block has its own register set.

The AMBA Peripheral Bus Interface (APBIF) is the agent for the APB control flow and DMA operation, which sends or receives data from/to Memory. The APBIF is composed of *N* instances of AHUBIF and APB interfaces as shown in the figure below.

Figure 44: APBIF Block Diagram



20.3.1 APBIF Features

- Separate APB DMA operations for all AHUB clients
- Each channel is bidirectional and needs one TX and one RX AHUBCIF.
- Scalable *N* channel design
- Maintain interrupt registers for AHUB clients

20.3.2 APBIF Programming Guidelines

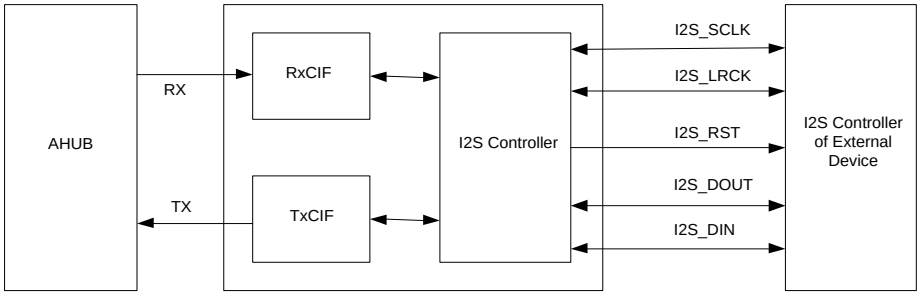
Note: APBIF is comprised of APBIF1 (channels 0 to 3) and APBIF2 (channels 4 through 9). Refer to the APBIF and APBIF2 register descriptions for more information.

1. Program the CLK_RST_CONTROLLER_CLK_OUT_ENB_V register to enable Audio XBAR and APBIF
2. Program the CLK_RST_CONTROLLER_CLK_SOURCE_AUDIO_0 register. Set the AUDIO_CLK_SRC field to CLK_SRC_ALT if an alternate clock source needs to be chosen followed by setting of AUDIO_CLK_SRC_RATE to choose the alternate clock source for DAM.
3. Deassert APBIF and AUDIO reset by programming the CLK_RST_CONTROLLER_RST_DEVICES_V register.
4. Wait for resets by polling until the reset bit clears.
5. Configure the ACIF interfaces of the APBIF according to the programming guidelines available in the ACIF Programming Guidelines section.
6. Configure the control register for the APBIF Tx and Rx channels. APBIF_CHANNEL0_CTRL_0 is the control register for both Tx and Rx channel 0 (similar control registers are present for all 10 APBIF channels). Configuration options for the Tx channels are :
   - TX_ENABLE: enables the Tx channel
   - TX_THRESHOLD: sets the FIFO threshold for sending the tx_req signal to APBDMA
   - TX_PACK_EN: enables Tx packed mode
   - TX_PACK: pack options of four 8-bit words or two 16-bit words. The options are similar for Rx channels as well
   - LOOPBACK: enables APBIF internal loopback (debugging feature).

20.4 I²S Controller

The Inter-IC Sound (I^2S) controller implements full-duplex and bidirectional and single direction point-to-point serial interfaces. It can interface with I^2S-compatible products, such as compact disc players, digital audio tape devices, digital sound processors, modems, Bluetooth chips, etc.

Figure 45: I2S Interaction with External Device



The I^2S controller can operate both as master and slave. It supports the following data transfer modes:

- I^2S mode
- Left Justified Mode (LJM)
- Right Justified Mode (RJM)

- DSP mode, as defined in the Philips inter-IC-sound (I^2S) bus specification
- PCM mode with short (one-bit-clock wide) and long-fsync (two bit-clocks wide
- Network (Telephony) mode with independent slot selection for both Tx and Rx
- TDM mode with flexibility in number of slots with up to 16 slots.
- Capability to drive-out a High-Z outside the prescribed slot for transmission

The I^2S controller can transmit and receive word lengths of 8, 16, 24, and 32.

It supports u-Law and A-Law compression/decompression.

The I^2S controller can control the flow of traffic from another I^2S controller operating on an independent bit clock (with a ppm difference compared to its own bit clock).

20.4.1 Transmission/Reception Data Formats

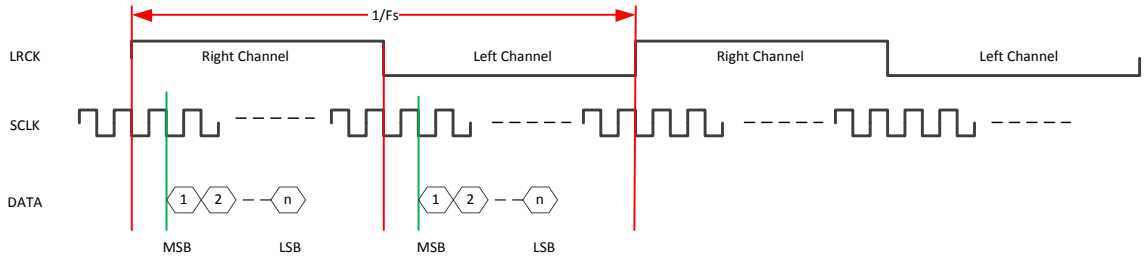
20.4.1.1 LRCK Modes

This subsection illustrates three LRCK modes: Basic I2S mode, Right Justified mode, and Left Justified mode.

Basic I2S Mode

In Basic I2S mode, data starts one sclk after the LRCK edge (offset = 1).

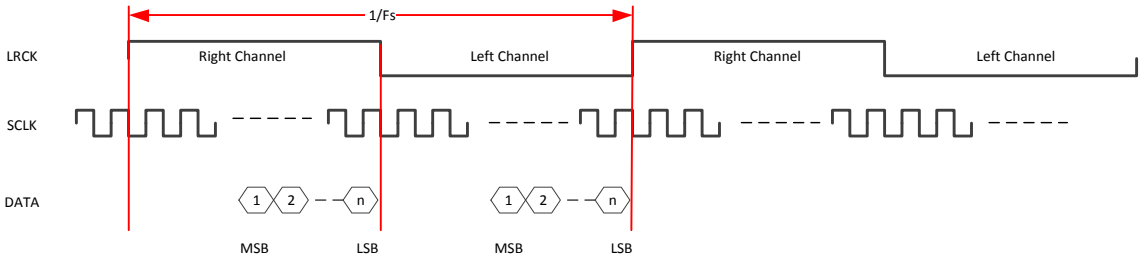
Figure 46: Basic I2S Mode



Right Justified (RJ) Mode

In RJ mode, data starts (r/2 – n) SCLKs after the LRCK edge (offset = r/2 – n, where r = number of SCLKs per LRCK, n = number of bits/sample).

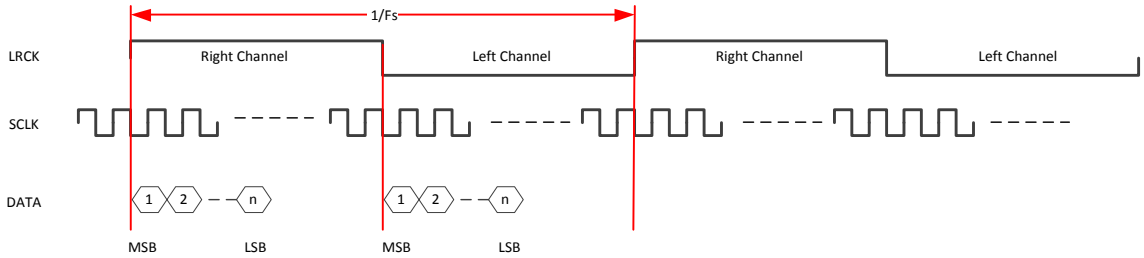
Figure 47: RJ Mode



Left Justified (LJ) Mode

In LJ mode, data starts 0 SCLKs after the LRCK edge (offset = 0).

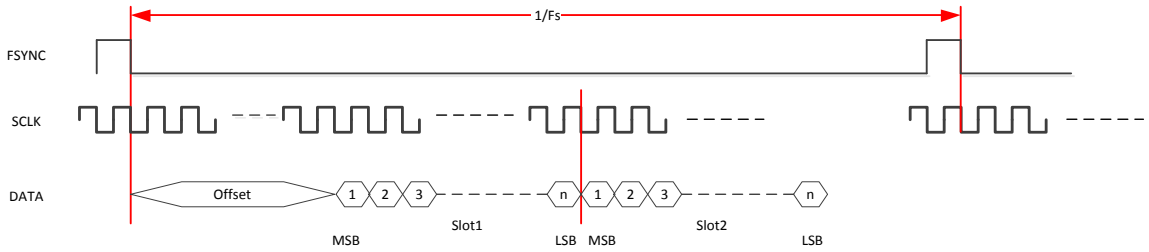
Figure 48: LJ Mode



FSYNC Modes

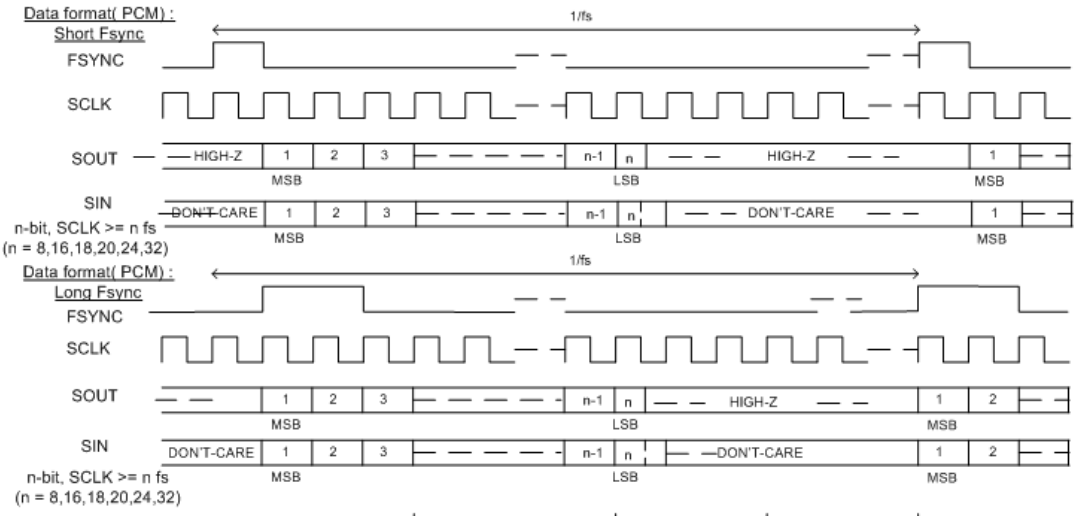
The width of the FSYNC, the offset value, number of slots and number of SCLKs per 1/Fs are all configurable. The slots are always contiguous.

Figure 49: FSync Mode

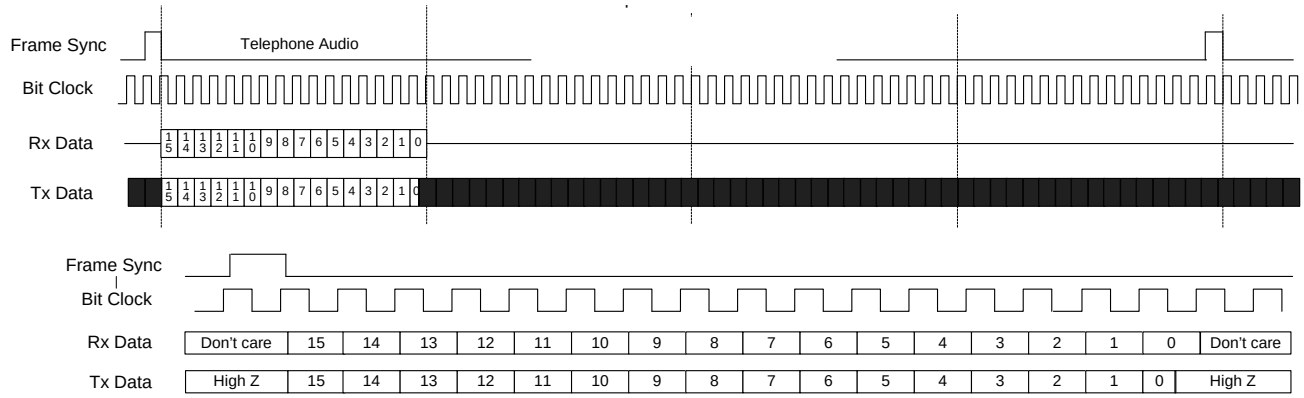


PCM Mode

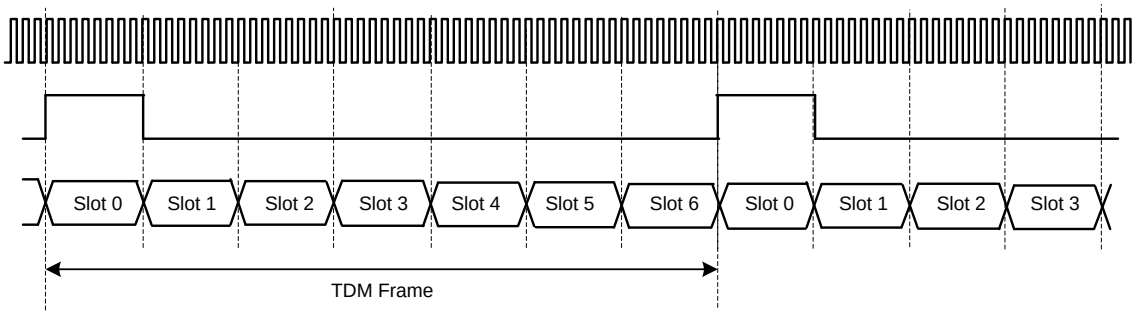
Figure 50: PCM Mode



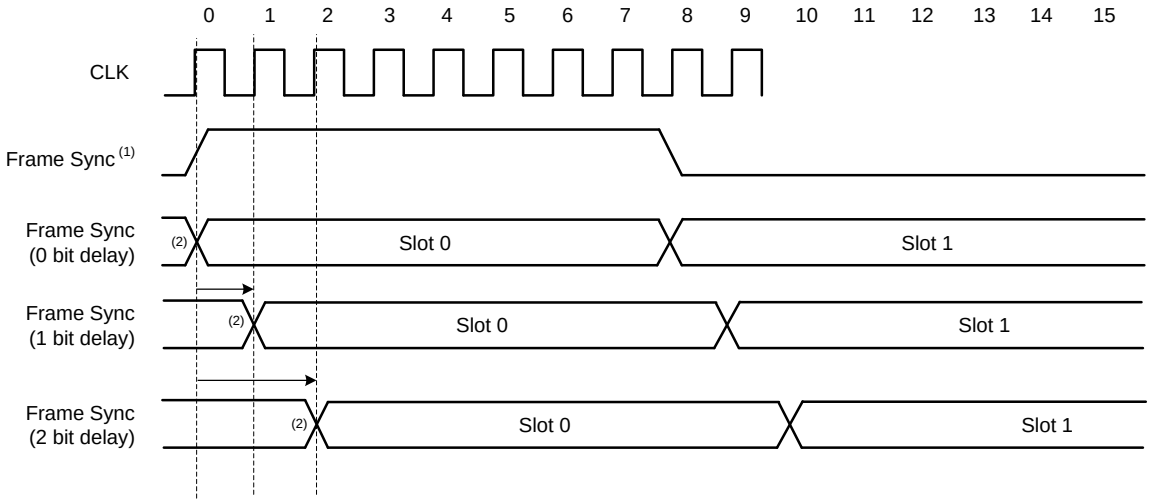
Data Formats in NW Mode



Data Format in TDM Mode



1. FS duration of a slot is shown. FS duration of a single bit is also supported.



1. FS duration of a slot is shown. FS duration of a single bit is also supported.
2. Last bit of the last slot of the previous frame. No gap is allowed between this bit and the first bit of slot 0.

20.4.2 I2S Controller Programming Guidelines

20.4.2.1 Module Initialization

1. Program the CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0 register to enable the I2S clock.
2. Program the CLK_RST_CONTROLLER_CLK_SOURCE_I2S0_0 register (for I2S0) and similar registers for other instances to program the I2S clock source. Set I2S0_CLK_SRC to select the clock source.
3. Choose SYNC_CLK as the clock source in the I2S0_CLK_SRC field of the CLK_RST_CONTROLLER_CLK_SOURCE_I2S0_0 register to select alt clock sources.
4. This should be followed by setting the CLK_RST_CONTROLLER_AUDIO_SYNC_CLK_I2S0_0 register to choose the alternate clock source for I^2S.
5. Deassert I2S0 and AUDIO resets by programming the CLK_RST_CONTROLLER_RST_DEVICES_L register.
6. Wait for resets to happen before proceeding further.
7. Configure the ACIF registers I2S_AUDIOCIF_I2SRX_CTRL_0 and I2S_AUDIOCIF_I2STX_CTRL_0 by following the guidelines in the ACIF Programming Guidelines subsection.
8. Enable Rx transmit or Tx transmit by configuring I2S_CTRL_0.

20.4.2.2 I2S Sampling Rate Selection

The channel_bit_cnt can be calculated using the equation:

channel_bit_cnt = (frequency of bit_clk) / (2 * required sampling rate) -1

If this calculation returns a fractional value, use the non-symmetry feature of the controller to attain the required sampling rate. In that case, the channel_bit_cnt value should be programmed with an integer that is closest to the fraction, but less than the fraction.

The table below contains some examples for common sampling rates with CLK_SOURCE_I2S = 24 MHz:

Sampling Rate	**I2S_NEW_TIMING[12:00] (mark-space ratio:: Left_channel : Right_channel)**				
	CLK_DIVISOR=0 BIT_CLK=24 MHz	CLK_DIVISOR=1 BIT_CLK=12 MHz	CLK_DIVISOR=3 BIT_CLK=6 MHz	CLK_DIVISOR=5 BIT_CLK=4 MHz	CLK_DIVISOR=7 BIT_CLK=3 MHz
8 KHz	0x05DB	0x02ED	0x0176	0x00F9	0x10BB
	(1500:1500)	(750:750)	(375:375)	(250:250)	(187:188)
32 KHz	0x0176	0x10BB	Not supported	0x103E	Not supported
	(375:375)	(187:188)		(62:63)	
44.1 KHz	0x010F	0x0087	0x0043	0x002C	0x0021
	(272:272)	(136:136)	(68:68)	(45:45)	(34:34)
48 KHz	0x00F9	0x007C	0x103E	Not supported	Not supported
	(250:250)	(125:125)	(62:63)		
96 KHz	0x007C	0x103E	0x101F	Not supported	Not supported
	(125:125)	(62:63)	(31:32)		

Notes:

- Ideally, any sampling rate can be generated, either accurately or approximately with any clk_src selected for I2S, if the clk_divisor and the channel_bit_cnt are programmed accordingly.
- The NON_SYM.EN feature is meant to create the sampling rates approximately by realizing an odd bit rate with a non-50:50 mark/space ratio. However, if the bit rate (2*channel_bit_cnt) itself is a fraction, the resultant sampling rate will not be accurate. The entries shown as not supported in the above table are attributed to such a deviation.
- When the channel_bit_cnt is less than 32, the bit_size should be programmed to be less than channel_bit_cnt.

20.4.2.3 Programming I2S to Operate in Various Modes

After the module initialization (reset and clock programming), program the corresponding bits of the following registers.

Table 71: I2S Programming for Various Modes

Register	Basic	LJM	RJM	DSP	PCM	NW	TDM
FRAME_FORMAT	0	0	0	1	1	1	1
LRCK_POLARITY	0	1	1	1	1	1	1
CHANNEL_BIT_CNT	Number of bit clocks in left channel	Number of bit clocks in left channel	Number of bit clocks in left channel	Number of bits in left channel + right channel	Number of bit clocks per frame	Number of bit clocks per frame	Number of bit clocks per frame
TX_DATA_OFFSET	1	0	CHANNEL_BIT_CNT -BITS_PER_SAMPLE	1	1: Short Fsync 0: Long Fsync	1	0/1/2
RX_DATA_OFFSET	1	0	CHANNEL_BIT_CNT – BITS_PER_SAMPLE	1	1:short Fsync 0:Long Fsync	1	0/1/2
FSYNC_WIDTH	Number of bit clocks in left channel	Number of bit clocks in left channel	Number of bit clocks in left channel	1	0: Short Fsync 1: Long Fsync	0	Bits per sample (slot size)
HIGHZ_CTRL	0	0	0	0	2	2	0/1/2
EDGE_CTRL	0	0	0	0	1	1	1
TOTAL_SLOTS	0	0	0	1	0	3	0,1..7
SLOT_ENABLES	0x01	0x01	0x01	0x03	0x01	*	**

* In NW mode, there can only be one active slot. So 0x01, 0x02, 0x04, 0x08 are allowed values.

** In TDM mode, there is no restriction on what/how many slots are enabled.

The only restriction on the programming sequence is that all other registers must be programmed first before the Tx/Rx channels are enabled (which is done by setting XFER_EN_TX/XFER_EN_RX).

20.4.2.4 Enabling I2S Interrupts

1. Enable the MONITOR_INT_EN bit in the I2S_FLOW_STATUS_0 register.
2. Enable the I2SX_TXCIF_OVERRUN and I2SX_RXCIF_UNDERRUN bits in the APBIF_I2S_INT_MASK_0 register.

20.4.2.5 General Guidelines

- Always enable I2S interrupts and monitor overruns in TxCIF and underruns in RxCIF. When any one of them occurs, apply soft reset to I2S before using it again.
- Enable flow control only when the signals originate (at least partly) from one I2S and go through another I2S. Use the AFC controller to do this.

20.5 Serial Peripheral Device Interface (S/PDIF)

This interface is primarily intended to carry audio data coded other than as linear PCM coded audio samples. Provisions are also made to allow the interface to carry data related to computer software or signals coded using non-linear PCM. The format specification for these applications is not part of this standard.

20.5.1 S/PDIF Features

- Fully implements the IEC-958 standard interface
- Provides mono and stereo support for sampling frequencies 32 kHz, 44.1 kHz, and 48 kHz
- Supports the following data formats.
  - 16-bit
  - 20-bit
  - 24-bit
  - Raw
- Supports “autolock” mode to automatically detect the “spdifin” sample rate and lock onto the data stream.
- Supports “override” mode to provide a manual control to sample the “spdifin” data stream.
- Provides a loopback mode to route the “spdifout” back to “spdifin” for self-testing.

20.5.2 S/PDIF Programming Guidelines

20.5.2.1 16-, 20-, 24-bit Modes

During transmission, the audio data is taken from the TX data FIFO, the channel status bit is taken from the TX channel status page buffer, and the user status bit is from the TX user FIFO. The preamble bits are generated by the hardware. The Valid bit is always zero.

During reception, the audio data is stored in the RX data FIFO, the channel status bit is stored in the RX channel status page buffer and the user status bit is stored in the RX user FIFO.

In addition to storing the audio data, the RX data FIFO also stores the preamble bits, channel status bit, user status bit and the valid bit. The reception of the channel bits start after the B-preamble is detected.

The audio-data sample has 16, 20, or 24 bits of data. Firmware has to transmit 16-, 20-, or 24-bit data and read 16-, 20-, or 24-bit data.

20.5.2.2 Raw Mode

During transmission, the audio data, the preamble bits, channel status bits, the user bits, and the valid bits are transmitted from the RX data FIFO. The firmware has to provide the correct preamble bits for the receiving device to synchronize with the transmitter. The firmware has to provide preambles according to the following table:

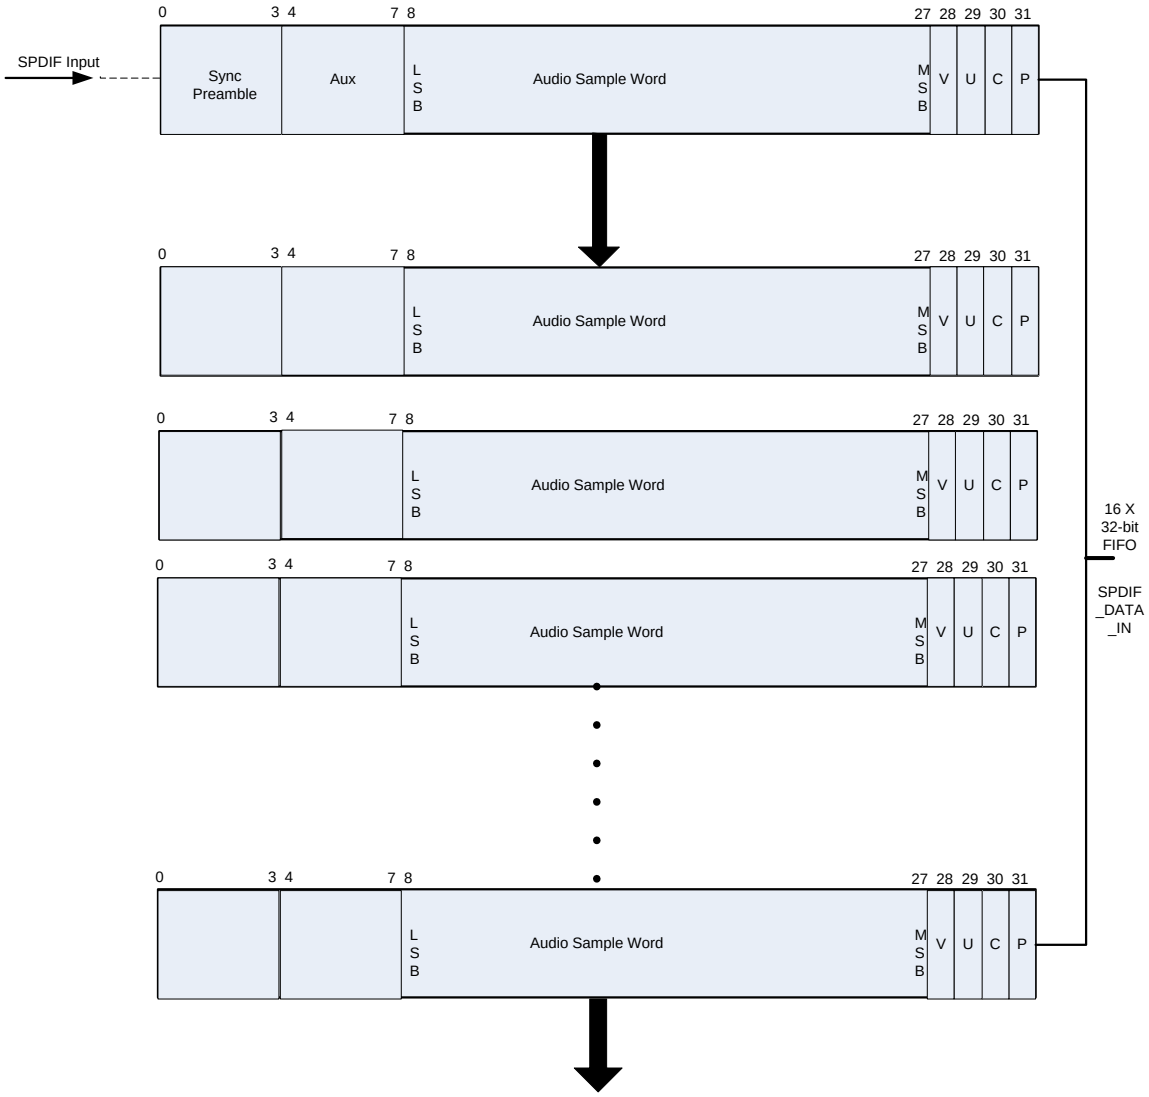
Preceding State in the Parity Bit: 0/1

Table 72: Preamble Bits

Symbol	Preamble Code	Channel Coding	Description
“B” (or “Z”)	0001/0001	11101000/00010111	Start of a block.
“M” (or “X”)	0010/0010	11100010/00011101	Start of sub-frame 1.
“W” (or “Y”)	0011/0011	11100100/00011011	Start of sub-frame 2.

During reception, the audio-data, the preamble bits, channel status bits, the user bits and the valid bits are stored in the RX data FIFO. The user bit is also stored in the RX user FIFO. The channel bit is also stored in the RX channel status page buffer. But the channel status bits are stored in the RX channel status page buffer only after the B-preamble is detected.

Figure 51: S/PDIF Data Format for Raw Mode



20.5.2.3 Module Reset

The application may initialize or reset the S/PDIF module via the clock and reset (CAR) control's RST_DEVICES_L_0 register.

20.5.2.4 Clock Source/Divider Control

The SPDIFOUT clock source/divider can be selected by programming CAR's CLK_SOURCE_SPDIF register. Refer to the S/PDIF registers below for the needed input frequency for the desire output audio sample rate.

The SPDIFIN clock source/divider can be selected by programming CAR's CLK_SOURCE_SPDIF register. Refer to the SPDIF registers below for the needed oversample frequency.

20.5.2.5 Clock Enable Control

The application may enable the S/PDIF clocks by programming the CAR's CLK_OUT_ENB_L_0 register.

20.5.2.6 Detecting Incoming Sampling Rate

The SPDIFIN is capable of detecting and locking onto the ‘spdifin’ data stream regardless of the sample rate. It achieves this by using an oversampling technique.

In addition to reading the sampling rate from the channel status information, one can also read the PERIOD field in the STROBE_CTRL_0 register to estimate the incoming sample rate. The last two digits of PERIOD indicate the fractional clock period.

Sample rate ≈ (‘spdifin’ clock frequency * 1000) / (PERIOD * 128)

If using the PERIOD method, it is better to read this field toward the end of the song or just before turning off the SPDIFIN. Although the hardware can lock onto the SPDIFIN data stream in as little as 2 subframes of time, the hardware is actually constantly re-adjusting itself (due to jitter, synchronization loss, etc. in the data stream) to provide the strobe point to the center of the biphase data stream. Over time, the strobe point will vary less and less because the hardware has already adjusted to all the variations seen in the data stream.

20.5.2.7 S/PDIF Transmit Data Flow

Make sure that the TX_FIFO is filled before enabling the transmission by setting the TX_EN field of CTRL_0 register. Never allow the TX_FIFO to go empty at any time during transmission. The interrupt is generated when the Tx Data FIFO empty count is greater than the Tx DATA attention value (TX_ATN_LVL field of DATA_FIFO_CSR_0 register) if the Tx interrupt enable is set.

20.5.2.8 S/PDIF Receive Data Flow

To enable the reception of RX_FIFO, set the RX_EN field of the CTRL_0 register. Never allow the RX_FIFO to become full at any time during reception. The interrupt is generated when the Rx Data FIFO data count is greater than the Rx DATA attention value (RX_ATN_LVL field of the DATA_FIFO_CSR register), if the Rx interrupt enable bit is set.

20.5.2.9 Method of Filling/Retrieve Data from TX/RX User/Data FIFO

Use the DMA method by programming the APB DMA and APBIF registers. With this method, the FIFO attention levels need to be set in the APBIF just like in method 2. But instead of enabling interrupts when the FIFO attention level is reached, one should program the APB DMA registers. Now, every time the attention level is reached, a DMA request will be generated by the APBIF to the APB DMA and the APB DMA will perform the data moving task from/to APBIF FIFOs to the AHB bus.

20.6 Digital Audio Mixers

The digital audio mixers (DAMs) can mix up to two input stereo streams of different frame rates and sample sizes and produce one output audio stream.

The Sample Rate Converter converts the frame rate of one of the input channels using a collection of Low-Latency Filters (LLFs):

- Input/output frequencies supported: 8, 11.025, 16, 22.05, 44.1, 48, 88.2, 96, 176.4, and192kHz
- Mono/Stereo audio for both input channels is supported. Stereo SRC is supported for channel 0. Channel 1, which is the bypass channel, does not support SRC.
- Up-conversion and down-conversion from any supported frequency to any supported frequency
- 8-, 16-, 24-, 32-bit audio data
- Fixed latency on round trip between baseband and codec of ~7 ms.

The bit-width converter at the CIF should convert the input stream to 32 bits because SRC operates only on 32-bit data

A programmable gain controller is available in both input channels. It can be programmed to give a linear gain between -8 and 7.9998.

The DAM Mixer mixes the output from channel 0 (stereo SRC channel) with channel 1 (bypass channel). The Mixer handles saturation and has the following mixing options:

- Both channels wait on each other
- Channels wait on none
- Channel 0 waits on channel 1
- Channel 1 waits on channel 0

20.6.1 DAM Programming Guidelines

1. Program the CLK_RST_CONTROLLER_CLK_OUT_ENB_V register to enable the DAM clock.
2. Program CLK_RST_CONTROLLER_CLK_SOURCE_DAM0_0 (for DAM0) and similar registers for other instances to program the DAM clock source. Set the DAM0_CLK_SRC field to CLK_SRC_ALT, if an alternate clock source is needed followed by setting DAM0_CLK_SRC_RATE to choose the DAM alternate clock source.
3. Deassert DAM0 and AUDIO reset by programming the CLK_RST_CONTROLLER_RST_DEVICES_V register.
4. Poll for this bit to clear.
5. Configure the CIF registers (DAM_AUDIOCIF_CH0_CTRL_0, DAM_AUDIOCIF_CH1_CTRL_0, and DAM_AUDIOCIF_OUT_CTRL_0) according to the guideline given in the ACIF Programming Guidelines subsection.
6. Set the input FSIN by programming DAM_CH0_CTRL for channel 0 and DAM_CH1_CTRL for channel1.
7. Set the Gain for both the channels by setting DAM_CH0_CONV and DAM_CH1_CONV for both channel 0 and channel 1, respectively.
8. Enable the DAM output by setting FSOUT into the DAM_CTRL register.
9. If the use case needs a farrow filter in its pipeline, enable the farrow filter by configuring the DAM_FARROW_PARAM register.
10. Software can manually program the coefficient RAM by setting the COEF_RAM_EN bit to 0 in the DAM_CH0_CTRL register. The values for each of the 8 use cases are stored statically in hardware and can be accessed without any software programming by setting COEF_RAM_EN bit to 1 in DAM_CH0_CTRL register.
    - For programming the coefficient RAM with the HW_ADR_EN bit unset in the DAM_AUDIORAMCTL_DAM_CTRL register, set the coefficient RAM offset in the RAM_ADR field of the DAM_AUDIORAMCTL_DAM_CTRL register and set data in the DATA field in DAM_AUDIORAMCTL_DAM_DATA.
    - For programming the coefficient RAM with the HW_ADR_EN bit set in the DAM_AUDIORAMCTL_DAM_CTRL register, set the coefficient RAM offset in the RAM_ADR field of the DAM_AUDIORAMCTL_DAM_CTRL register to 0 and set data in DATA field in DAM_AUDIORAMCTL_DAM_DATA. Hardware auto-increments RAM_ADR after each write.
11. For channel mixing, the DATA_SYNC field in both DAM_CH0_CTRL and DAM_CH1_CTRL have to be configured correctly to have mixing in 4 available modes:
    - Ch0 wait on Ch1
    - Ch1 wait on Ch0
    - Both channels wait on each other (preferred option)
    - Channels do not wait
12. Set STEREO_SRC_EN in the DAM_CTRL register to enable stereo SRC.
13. Enable the DAM by setting the ENABLE bit in DAM_CTRL.

For details on the fields within each DAM register, refer to the “DAM Registers” subsection.

20.7 Audio Multiplexer Block (AMX)

The Audio Multiplexer Block (AMX) can multiplex up to 4 input streams of up to 16 channels each and generate an output stream of up to 16 channels

A “byte RAM” helps to form an output frame by any combination of bytes from the 4 input frames

Two modes for data synchronization between input frames are available:

- Wait For All mode: At the beginning, wait for all enabled input streams to have data before forming the very first frame.
- Wait for Any mode: Start whenever data is available in any one of the enabled input streams.

In either mode, once the first output frame is sent out, AMX always waits for all active streams to have data available before forming and sending subsequent frames.

20.7.1 AMX Programming Guidelines

1. Configure Audio CIF control registers AMX_AUDIOCIF_CH0_CTRL, AMX_AUDIOCIF_CH1_CTRL, AMX_AUDIOCIF_CH2_CTRL, AMX_AUDIOCIF_CH3_CTRL, and AMX_AUDIOCIF_OUT_CTRL according to the guidelines given in the ACIF Programming Guidelines subsection.
2. Configure the CH_DEP parameter field in the AMX_CTRL_0 register to determine whether to wait for all enabled channels to have data before transfer or start sending the data when any one of the input channels has data (WT_ON_ALL & WT_ON_ANY).
3. Configure the MSTR_CH_NUM register for designated master channel, so that if the data is available on a particular channel, the output can be sent.
4. Enable the AMX output by setting BYTE_EN in AMX_OUT_BYTE_EN0 and AMX_OUT_BYTE_EN1.
5. For Byte RAMCTL programming:
   - For programming RAM with the HW_ADR_EN bit cleared in the AMX_AUDIORAMCTL_AMX_CTRL register, set the RAM offset in the RAM_ADR field of the AMX_AUDIORAMCTL_AMX_CTRL register and set data in the DATA field in the AMX_AUDIORAMCTL_AMX_DATA register.
   - For programming RAM with the HW_ADR_EN bit set in the AMX_AUDIORAMCTL_AMX_CTRL register, set the RAM offset in the RAM_ADR field of the AMX_AUDIORAMCTL_AMX_CTRL register to 0 and set data in the DATA field in the AMX_AUDIORAMCTL_AMX_DATA register. Hardware auto-increments the RAM_ADR after each write.

20.8 Demultiplexer Block (ADX)

The demultiplexer block (ADX) takes an input stream with up to 16 channels and demultiplexes it into four output streams of up to 16 channels each.

A “byte RAM” helps to form output frames by any combination of bytes from the input frame. Its design is identical to that of the byte RAM in the AMX except that the data flow direction is reversed.

20.8.1 ADX Programming Guidelines

1. Configure the Audio CIF control registers ADX_AUDIOCIF_IN_CTRL, ADX_AUDIOCIF_CH0_CTRL, ADX_AUDIOCIF_CH1_CTRL, ADX_AUDIOCIF_CH2_CTRL, and ADX_AUDIOCIF_CH3_CTRL according to the guidelines given in the ACIF Programming Guidelines subsection.
2. Configure ADX_OUT_CH_CTRL_0 for enabling or disabling four output channels.
3. Enable the ADX input by setting BYTE_EN in ADX_IN_BYTE_EN0 and ADX_IN_BYTE_EN1, respectively.
4. Byte RAMCTL:

   For programming RAM with the HW_ADR_EN bit cleared in the ADX_AUDIORAMCTL_ADX_CTRL register, set the RAM offset in the RAM_ADR field of the ADX_AUDIORAMCTL_ADX_CTRL register, and set data in the DATA field in the ADX_AUDIORAMCTL_ADX_DATA register.

   For programming RAM with the HW_ADR_EN bit set in the ADX_AUDIORAMCTL_ADX_CTRL register, set the RAM offset in the RAM_ADR field of the ADX_AUDIORAMCTL_ADX_CTRL register to 0, and set data in DATA field in the ADX_AUDIORAMCTL_ADX_DATA register. Hardware auto-increments RAM_ADR after each write.

20.9 Audio Flow Controller (AFC)

The audio flow controller (AFC) can control the flow of traffic between two I2S interfaces running at different clocks that are up to 100ppm apart.

The AFC implements high fidelity interpolation and decimation algorithms that compensate for clock differences.

It can control traffic flow anywhere in the audio route, even to the inputs of AMX blocks.

The AFC can handle burst traffic from DAMs.

20.9.1 AFC Programming Guidelines

1. Program the AFC_AUDIOCIF_AFCTX_CTRL_0 and AFC_AUDIOCIF_AFCRX_CTRL_0 registers according to the programming guidelines given in the ACIF Programming Guidelines subsection.
2. Program the START_THRESHOLD, HIGH_THRESHOLD, and LOW_THRESHOLD registers depending on the use case as shown in the following table.

Note: In the table, the numbers in parentheses are example values.

Use Case	**AFC_THRESHOLDS_I2S_0**			**AFC_THRESHOLDS_AFC_0**			**Destination I2S FIFO Threshold (To be Programmed in I2S_AUDIOCIF_I2SRX_CTRL_0. FIFO_THRESHOLD)**
Actual Value (Typical Value)	HIGH_ THRESHOLD	START_ THRESHOLD	LOW_ THRESHOLD	HIGH_ THRESHOLD	START_ THRESHOLD	LOW_ THRESHOLD	
I2S → AFC → I2S	START_ THRESHOLD+ 1 (8)	START_ THRESHOLD (7)	START_ THRESHOLD - 1 (6)	START_ THRESHOLD + 1 (8)	START_ THRESHOLD (7)	START_ THRESHOLD- 1 (6)	START_THRESHOLD + 1 (AFC_THRESHOLDS_ I2S_0) (8)
I2S → DAM → AFC → I2S	2*SRC-BURST + 1	1*SRC-BURST + 2	1*SRC-BURST	1*SRC-BURST + 1	1*SRC-BURST + 1	1*SRC-BURST + 1	START_THRESHOLD + 1 (AFC_THRESHOLDS_ I2S_0)
I2S → AFC → AMX → I2S	START_ THRESHOLD+ 1 (8)	START_ THRESHOLD (7)	START_ THRESHOLD - 1 (6)	START_ THRESHOLD + 1 (8)	START_ THRESHOLD (7)	START_ THRESHOLD- 1 (6)	Start Threshold + 1 (AFC_THRESHOLDS_ I2S_0) (8)
I2S → DAM → AFC → AMX → I2S	2*SRC-BURST +1	1*SRC-BURST +2	1*SRC-BURST	2*SRC-BURST + 4	1*SRC-BURST + 4	(4)	START_THRESHOLD + 1 (AFC_THRESHOLDS_ I2S_0)

20.10 Audio Hub Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

20.10.1 Audio Crossbar Registers

The following macro defines a register for each RX port. No more than one field can be 1 in a register because an RX port can receive from only one TX port.

Example:

```
reg DAM0_RX0 incr4
0:0         DAM0_TX0          rw        i=0
1:1         I2S0_TX0          rw        i=0
2:2         I2S1_TX0          rw        i=0
;
```

20.10.1.1 AUDIO_APBIF_RXn_0

There are 10 Audio APBIF RX Registers, one per RX port (n = 0 through 9).

For n = 0 through 3: Offset: 0x0 + (n * 0x4) | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxx00000000000000000000000)

For n = 4 through 9: Offset: 0x44 + (n * 0x4) | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxx00000000000000000000000)

Bit	Reset	Description
24	0x0	ADX0_TX3: 0 = DISABLE 1 = ENABLE
23	0x0	ADX0_TX2: 0 = DISABLE 1 = ENABLE
22	0x0	ADX0_TX1: 0 = DISABLE 1 = ENABLE
21	0x0	ADX0_TX0: 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
31:0	X	DATA

20.10.2.6 APBIF_AUDIOCIF_TXn_CTRL_0

Control Register for AUDIOCIF for both TX and RX

MONO_CONV : Convert mono to stereo

ZERO -> zero out the second channel

COPY -> copy the first channel to the second channel

valid only in 1 channel to 2 channels conversion

TRUNCATE : rounding method on LSB when deleting lower bits

CHOP -> chop off the lower bits; if 1, just chop off lower bits (truncate)

ROUND -> if immediate lower bit is 1, add 1 to the significant bits

ROUND should be chosen for signed numbers because rounding is toward positive infinite. Also, in case of the max positive number, the lower bits are just chopped off.

For example with 8 -> 4 bit rounding for signed numbers

0x7F -> 0x7

0x0F -> 0x1

0xFF -> 0x0

0x8F -> 0x9

DIRECTION : Direction of CIF

TXCIF -> TX port to AUDIO

RXCIF -> RX port from AUDIO

REPLICATE : When FIFO underflows, if the replicate bit is set then previous frame is repeated.

In Tegra K1 devices, only replicating for mono and stereo frames is supported due to the FIFO size limitation. If there are more than 2 channels, the samples in the FIFO are used to fill other multi-channels.

DISABLE -> Disable replication. All zeros will be used.

ENABLE -> Previous frame is repeated.

STEREO_CONV : Convert stereo to mono

CH0 -> pick the first channel

CH1 -> pick the second channel

AVG -> (ch0 + ch1) / 2

valid only in 2 channel to 1 channel conversion

EXPAND : Expand the additional bits with the following method

ZERO -> zero out the expanded field

ONE -> fill the expanded field with 1's

LSFR -> fill the expanded field with a random number

CLIENT_BITS : The number of bits in a sample in the client side

AUDIO_BITS : The number of bits in a sample in the AUDIO side

CLIENT_CHANNELS : The number of channels in the client side

the actual channels = CLIENT_CHANNELS + 1, i.e., 0 -> 1 channel

AUDIO_CHANNELS : The number of channels in the AUDIO side

the actual channels = AUDIO_CHANNELS + 1, i.e., 0 -> 1 channel

FIFO_THRESHOLD : This specifies the number of words that need to be present in the FIFO before a CIF starts transfers.

0 : start transfer when 1 word is received.

1 : start transfer when 2 words are received.

i : start transfer when i words are received.

For example, if FIFO_THRESHOLD is set to 3, then RxCIF gives rd_req to the I2S/ DAM core only after 4 words have been written into the FIFO. It is recommended that a non-zero value be set only for rx_cifs of I2S. For all other cases, the default value of zero is the appropriate setting.There are 4 APBIF Audio CIF TX FIFO Registers, one per channel (n = 0 through 3).

20.10.2.16 APBIF_I2S_INT_MASK_0

Because the config registers of the AUDIO clients are daisy-chained, their read latency can be high. To avoid unnecessary latency, the clients provide signals to APBI, mostly interrupt signals so that the CPU/AVP can access them promptly.

These registers should be detailed further with AUDIO clients.

Interrupt Mask and Status for AUDIO Clients

20.10.3 APBIF2 Registers

Audio channels 4 through 9 have their own set of 7 APBIF2 registers. Each channel has 32 bytes of address space. This subsection defines one complete set of APBIF2 registers. The register spaces per APBIF2 channel are listed in the table below.

Table 73: APBIF2 Channel Register Mapping

Register Space	Channel Registers
0x0 – 0x1f	Channel 4 APBIF2 Channel Registers
0x20 – 0x3f	Channel 5 APBIF2 Channel Registers
0x40 – 0x5f	Channel 6 APBIF2 Channel Registers
0x60 – 0x7f	Channel 7 APBIF2 Channel Registers
0x80 – 0x9f	Channel 8 APBIF2 Channel Registers
0xa0 – 0x17f	Channel 9 APBIF2 Channel Registers

20.10.3.1 APBIF2_CHANNELn_CTRL_0

There are 6 APBIF2 Channel Control Registers, one per channel (n = 4 through 9).

Offset: 0x0 + (n * 0x20) | Read/Write: R/W | Reset: 0x00000000 (0b000xxxxx00000000000000000x000x000)

Bit	Reset	Description
31	0x0	TX_ENABLE: Enable TX channel to AUDIO. 0 = DISABLE 1 = ENABLE
30	0x0	RX_ENABLE: Enable RX channel to AUDIO. 0 = DISABLE 1 = ENABLE
29	0x0	LOOPBACK: Debug mode. The RX CIF is directly hooked up to the TX CIF. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
23:16	0x0	TX_THRESHOLD. Trigger threshold level, number of free slots - 1. DMA request is triggered when the number of free slots is > TX_THRESHOLD. For example, If a DMA request needs to be generated when 4 free slots are available, this field needs to be set to 3.
15:8	0x0	RX_THRESHOLD: Trigger threshold level, # of data DWords - 1. DMA request is triggered when the number of DWords in the FIFO is > RX_THRESHOLD. For example, if a DMA request needs to be generated when 4 DWords are available, this field needs to be set to 3.
6	0x0	TX_PACK_EN: Enable packed data. 0 = DISABLE 1 = ENABLE
5:4	0x0	TX_PACK: 0 = NOP 1 = RSVD 2 = PACK8_4 3 = PACK16
2	0x0	RX_PACK_EN: Enable packed data. 0 = DISABLE 1 = ENABLE
1:0	0x0	RX_PACK: 0 = NOP 1 = RSVD 2 = PACK8_4 3 = PACK16

20.10.3.2 APBIF2_CHANNELn_CLEAR_0

There are 6 APBIF2 Channel Clear Registers, one per channel (n = 4 through 9).

Offset: 0x4 + (n * 0x20) | Read/Write: R/W | Reset: 0x00000000 (0b00xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	0x0	TX_SOFT_RESET: 0 = DISABLE 1 = ENABLE
30	0x0	RX_SOFT_RESET: 0 = DISABLE 1 = ENABLE

20.10.3.3 APBIF2_CHANNELn_STATUS_0

There are 6 APBIF2 Channel Status Registers, one per channel (n = 4 through 9).

Offset: 0x8 + (n * 0x20) | Read/Write: RO | Reset: 0xXXXX000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	TX_FREE_COUNT: Number of free slots in the TX FIFO.
23:16	X	RX_FREE_COUNT: Number of free slots in the RX FIFO.
1	X	TX_TRIG: TX FIFO threshold. 0 = DISABLE 1 = ENABLE
0	X	RX_TRIG: RX FIFO threshold. 0 = DISABLE 1 = ENABLE

20.10.3.4 APBIF2_CHANNELn_TXFIFO_0

There are 6 APBIF2 Channel TX FIFO Registers, one per channel (n = 4 through 9).

Offset: 0xc + (n * 0x20) | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DATA

20.10.3.5 APBIF2_CHANNELn_RXFIFO_0

There are 6 APBIF2 Channel RX FIFO Registers, one per channel (n = 4 through 9).

Offset: 0x10 + (n * 0x20) | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DATA

20.10.3.6 APBIF2_AUDIOCIF_TXn_CTRL_0

There are 6 APBIF2 Audio CIF TX Control Registers, one per channel (n = 4 through 9).

When packed mode is enabled for a transmit channel, data is unpacked based on the APBIF2 TX channel CLIENT_BITS field.

- CLIENT_BITS = 0: Reserved. Do not use because 4 bit mode is not supported by the audio cluster.
- CLIENT_BITS = 1: (8 bit mode) : Four 8-bit samples are packed into one 32 bit word.
- CLIENT_BITS = 2: (12 bit mode): Two 12-bit samples are packed into one 32 bit word.
- CLIENT_BITS = 3: (16 bit mode): Two 16-bit samples are packed into one 32 bit word.
- CLIENT_BITS > 3: Packing is not possible.

20.10.5 I2S Registers

The I^2S Controller is designed to transport streaming audio-data between the system memory and an audio-codec. The controller supports I^2S format, Left Justified Mode format, Right Justified Mode format, and DSP mode format, as defined in the Philips inter-IC-sound (I^2S) bus specification.

The controller also supports the PCM and telephony (network) mode of data-transfer. Pulse-Code-Modulation (PCM) is a standard method used to digitize audio (particularly voice) patterns for transmission over digital communication channels.

The Telephony (network) mode is used to transmit and receive data to/from an external mono codec in a slot-based scheme of time-division multiplexing.

The controller has one transmit and one receive interface. The controller can be configured to operate either as a master or a slave.

20.10.5.1 I2S_CTRL_0

The I2S control register is used to configure bit formats (I2S, LJM, RJM, DSP, PCM, NW, TDM), bit sizes (8, 16, 20, 24 and 32), FIFO formats, Master/slave selection, LR polarity, and error interrupt enables.

I2S Control Register

Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0b00000xxxxxxx0xxxx000x000xx00x000)

20.10.5.2 I2S_TIMING_0

The CHANNEL_BIT_CNT field of this register is used to program the number of bit-clocks per channel of LRCK (sampling rate) that the I^2S controller needs to send out in Master mode. This value is interpreted as follows:

- DSP mode: - Number of bit clocks (sclk) within (LEFT +RIGHT) channel width.
- Basic/LJM/RJM modes:- Number of bit clocks (sclk) within each individual channel width (LEFT or RIGHT).
- PCM/NW/TDM modes:- Number of bit clocks (sclk) per frame

The NON_SYM.EN can be used to program the I2S Controller to output a non-50:50 mark-space ratio on to the I2S bus. When the NON_SYM.EN Bit[12] is enabled, the Controller sends out exactly the programmed number of clock cycles on the left channel and one bit clock greater on the right channel. . This is used in Basic/LJM/RJM modes.

When NON_SYM.EN is enabled, the channel-bit-count should be programmed with the number of bit-clocks required in left-channel. This will ensure that the non-50:50 mark-space ratio is achieved with R_BCLK = L_BCLK + 1

The PCM/NW/TDM modes channel_bit_cnt can be calculated using the equation:

```
Channel_bit_cnt  = (frequency of bit_clk) / (2 * required sampling rate) -1;
```

If this calculation returns a fractional value, the non-symmetry feature of the controller should be used to attain the required sampling rate.

I2S Timing Register

20.10.5.8 I2S_FLOWCTL_0

This register controls the flow control mechanism and is valid only with the TX mode. The flow control is only useful when the input stream to I^2S/SPDIF is already real-time spaced such as a live stream from Baseband through another I2S_RX. If the input stream is from DMA directly, the flow control should be disabled.

FLOWCTRL

Offset: 0x1c │ Read/Write: R/W │ Reset: 0x800XXXXX (0b10xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	QUAD	FILTER: Use linear or quadratic filter. Tegra K1 devices support quadratic filter only. 0 = LINEAR 1 = QUAD
30	DISABLE	DUMMY_WR_EN: Insert a dummy frame when enabled 0 = DISABLE 1 = ENABLE

7:4	X	HIGH_THRESHOLD: High-threshold for HIGH state N-1, 0 means actual threshold = 1
3:0	X	LOW_THRESHOLD: Low-threshold for LOW state N-1, 0 means actual threshold = 1

20.10.5.9 I2S_TX_STEP_0

Offset: 0x20 | Read/Write: R/W | Reset: 0x00008000 (0bxxxxxxxxxxxxxxxx1000000000000000)

Bit	Reset	Description
15:0	0x8000	STEP_SIZE: This is a compensation value for the clock difference between input and output. To catch up the clock difference quickly, this value is supposed to be bigger than clock difference in terms of STEP_SIZE; however, to avoid sound quality degradation, it should not be much greater than the clock difference. For example, the input frame sampling rate is 44.095 kHz and the output frame sampling rate is 44.100 kHz, the clock error rate is (44100 - 44095) / 44100 = 0.000113. The step size used in the linear interpolation is 0x8000 (32768) step_size = 0.000113 * 32768 = 3.7. A threshold of 4 is recommended. If the value is less than 3 in the above example, the adjusted step size will not be able to catch up. The flow control FIFO will eventually become empty, leading to either NULL or replication of the last sample.

20.10.5.10 I2S_FLOW_STATUS_0

When the flow controller is used, the step size should be properly chosen depending on the clock frequency difference. The step size should be small enough not to degrade sound quality, but big enough to converge the FIFO depth.

If the step size is not big enough, the FIFO depth will either increase or decrease, which will cause FIFO overflow/underflow eventually. The flow controller monitor and counter can be used to fine-tune the step size. When the flow controller is enabled and a proper step size is chosen, the FIFO depth should be in [threshold -1 : threshold + 1].

When the flow controller monitor is enabled and the FIFO depth is deviated from the range, either FLOW_OVERFLOW or FLOW_UNDERFLOW will be set. Also, the interrupt signal will be asserted, if MONITOR_INT_EN is enabled. MONITOR_CLR clears the FLOW_OVERFLOW/UNDERFLOW as well as the interrupt signal to APBIF.

When the flow controller counter is enabled, it records how many samples are processed and how many times the step size is applied to either lower or raise the time step. In case of stereo samples, it counts as 1.

- FLOW_NORMAL - the total number of samples (only count left channel samples).
- FLOW_OVER - the number of samples with adding STEP_SIZE to the time step.
- FLOW_UNDER - the number of samples with subtracting STEP_SIZE from the time step.

Flow Controller Monitor/Counter

20.10.6.19 SPDIF_FLOWCTL_CTRL_0

This register controls the flow control mechanism and is valid only with the TX mode. The flow control is only useful when the input stream to I2S/SPDIF is already real-time spaced such as a live stream from Baseband through another I2S_RX. If the input stream is from DMA directly, the flow control should be disabled.

Offset: 0x70 | Read/Write: R/W | Reset: 0x80000XXX (0b10xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	QUAD	FILTER: to use linear or quadratic filter. Tegra K1 devices support quadratic filter only. 0 = LINEAR 1 = QUAD
30	DISABLE	DUMMY_WR_EN: Insert a dummy frame when enabled 0 = DISABLE 1 = ENABLE
11:8	X	START_THRESHOLD: Flow control should wait for FIFO filled N-1, 0 means actual threshold 1
7:4	X	HIGH_THRESHOLD: High-threshold for HIGH state N-1, 0 means actual threshold 1
3:0	X	LOW_THRESHOLD: Low-threshold for LOW state N-1, 0 means actual threshold 1

20.10.6.20 SPDIF_TX_STEP_0

Offset: 0x74 │ Read/Write: R/W │ Reset: 0x00008000 (0bxxxxxxxxxxxxxxxx1000000000000000)

Bit	Reset	Description
15:0	0x8000	STEP_SIZE: This is a compensation value for the clock difference between input and output. To catch up the clock difference quickly, this value is supposed to be bigger than clock difference in terms of STEP_SIZE, but to avoid the sound quality degradation it should not be much greater than the clock difference. For example, the input frame sampling rate is 44.095 kHz, the output frame sampling rate is 44.100 kHz, and the clock error rate is (44100 - 44095) / 44100 = 0.00011.3 The step size used in the linear interpolation is 0x8000 (32768) step_size = 0.000113 * 32768 = 3.7. A threshold of 4 is recommended. If the value is less than 3 in the above example, the adjusted step size will not be able to catch up. The flow control FIFO will eventually become empty, leading to either NULL or replication of the last sample.

20.10.6.21 SPDIF_FLOW_STATUS_0

When the flow controller is used, the step size should be properly chosen depending on the clock frequency difference. The step size should be small enough not to degrade sound quality, but big enough to converge the FIFO depth. If the step size is not big enough, the FIFO depth will either increase or decrease, which will cause FIFO overflow/underflow eventually.

The flow controller monitor and counter can be used to fine-tune the step size. When the flow controller is enabled and a proper step size is chosen, the FIFO depth should be in [threshold -1 : threshold + 1].

When the flow controller monitor is enabled and the FIFO depth is deviated from the range, either FLOW_OVERFLOW or FLOW_UNDERFLOW will be set. Also, the interrupt signal will be asserted, if MONITOR_INT_EN is enabled. MONITOR_CLR clears the FLOW_OVERFLOW/UNDERFLOW as well as the interrupt signal to APBIF.

When the flow controller counter is enabled, it records how many samples are processed and how many times the step size is applied to either lower or raise the time step. In case of stereo samples, it counts as 1.

- FLOW_NORMAL - the total number of samples (only count left channel samples).
- FLOW_OVER - the number of samples with adding STEP_SIZE to the time step.
- FLOW_UNDER - the number of samples with subtracting STEP_SIZE from the time step.

20.10.8 ADX Registers

20.10.8.1 ADX_CTRL_0

ADX Control Register

This register specifies the input stream parameters (the number of audio channels in the input stream and number of bits per sample).

Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0b00xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	0x0	SOFT_RESET: This bit is auto cleared. Resets ADX logic 0 = DISABLE 1 = ENABLE
30	0x0	CG_EN: Second-level clock gating enable. 0 = DISABLE 1 = ENABLE

20.10.8.2 ADX_OUT_CH_CTRL_0

Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxx0000xxxx0000)

Bit	Reset	Description
11	0x0	CH3_FORCE_DISABLE: Ch 3 enable 0 = DISABLE 1 = ENABLE
10	0x0	CH2_FORCE_DISABLE: Ch 2 enable 0 = DISABLE 1 = ENABLE
9	0x0	CH1_FORCE_DISABLE: Ch 1 enable 0 = DISABLE 1 = ENABLE
8	0x0	CH0_FORCE_DISABLE: Ch 0 enable 0 = DISABLE 1 = ENABLE
3	0x0	CH3_EN: Ch3 enable 0 = DISABLE 1 = ENABLE

21.0 DISPLAY CONTROLLER

The Tegra® K1 architecture has two entirely independent display controllers. They can support two independent display devices, typically a local display panel and an external HDMI TV. Other configurations are possible such as two local panels. Each display controller can run at a different clock rate and drive a different resolution panel.

The Tegra K1 display controllers are significantly more efficient in the way they fetch from memory compared with prior Tegra devices. They use line buffers to store scan lines required for re-use, to avoid redundant fetches when scaling or using a tiled surface format.

21.1 Features

Key features include:

- Additional serial output resource (SOR) to support LVDS, eDP concurrent with HDMI or MIPI-DSI
- Three full function display windows, A, B and C, supporting scaling and blending
- Two additional windows (collectively known as “Simple Windows”):
  - Window D: Fourth general-purpose window
  - Window T: TrustZone Secure display
- Wider horizontal filter coefficients
- Maximum panel resolution:
  - Internal panel
    - LVDS – 1920 x 1200 @ 60 Hz (2D – portrait/landscape)
    - DSI

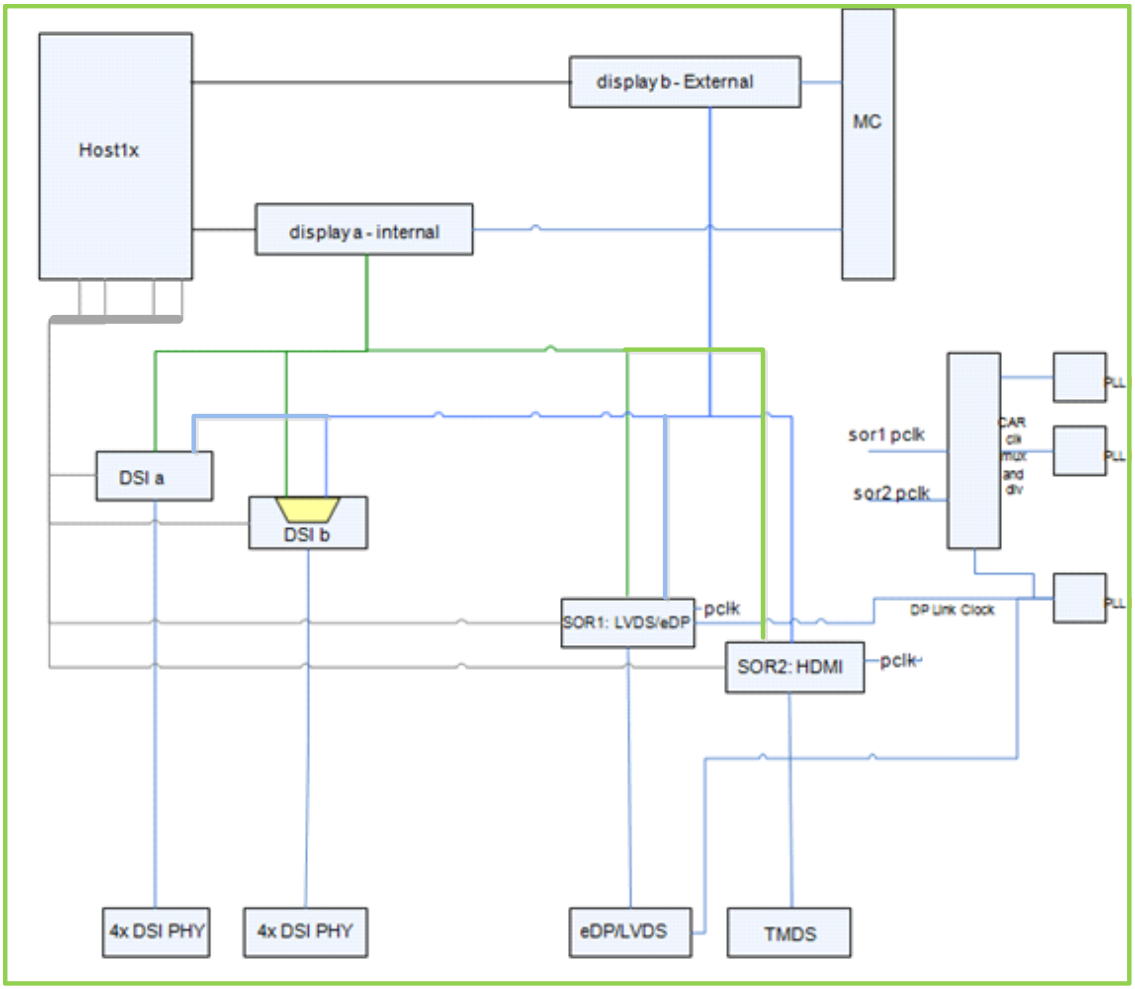
      Dual link 3200 x 2000 @ 60Hz (2D – portrait/landscape)

      Single link 2560 x 1440 @ 60Hz (2D – portrait/landscape)
    - eDP

      3840 x 2160 @ 60 Hz (2D – portrait/landscape)
  - External panel
    - HDMI 4096 x 2160 @ 30 Hz (2D – landscape)
    - HDMI 1920 x 1080 @ 60 Hz (3D – frame packed mode)
- Use of line buffering to avoid refetching data from memory on subsequent lines
- Line buffer free dithering: temporal dithering
- HDMI 1080i and HDMI YUV output support
- Efficient fetch for scaling (select windows)
- Improved handling of display buffer underflow (select windows)
- Supports high-quality scaling/filtering (select windows)
- Supports up to QHD resolution
- Support for Image Rotation in hardware
- Supports semi-planar YUV
- Extending the cursor size to 256x256 with full color and alpha-blending
- Display Color Management unit (based on a LUT and CSC in the output path)
- Improved layered blending among all windows

- Independent cursor update/activate control

Figure 52: Display Controller Top-Level Block Diagram



21.1.1 Output Capabilities

- 1 or 2 internal panels
  - MIPI-DSI on two 4-lane DSI channels, operating either independently for one or two panels, or ganged together as 2x4 for a single panel
    - Maximum panel size of 3200 x 2000 @ 60 Hz using 2x4-lane ganged DSI channels
    - Independent resolution and pixel clock when not ganged
  - LVDS supports 18/24 bpp, 3/4 data lanes, 1 clock lane, 1920 x 1200 @ 60 Hz
  - eDP supports 18/24 bpp, 1/2/4 data lanes, RBR/HBR/HBR2 up to 3840x2160 @ 60Hz
- 1 external display
  - On HDMI. Maximum 1920x1080p @ 60 Hz (3D) or 4096x2160 @ 30 Hz (2D)
  - With HDCP and multi-channel audio

21.1.2 Color Management Unit (CMU)

- Gamma (tone curve) conversion

- Color gamut conversion
- Allow conversion of sRGB content for a non-sRGB panel, for predictable colors (color matching)
- Enhanced PRISM 3 display for these panels, as the PRISM 3 algorithm assumes sRGB gamma
- Enable TCON and panels with non sRGB response
- Allows color calibrated displays, and enables end-to-end Camera / ISP -> Display color quality

21.1.3 Windows A/B/C

- Data Formats include (see the “Surface/Color Formats” subsection for a complete list):
  - B4G4R4A4
  - B5G5R5A, AB5G5R5, B5G6R5
  - B8G8R8A8, R8G8B8A8
  - YCbCr420P , YCbCr422P, YCbCr422RP (planar format)
  - YCbCr422 (packed format)
  - Palletized format limited to 8-bit mode.
- Three 256x8-bit RAMs (color palette) used for gamma correction.
- Horizontal and Vertical Flip
- Horizontal and Vertical Scaling
  - Horizontal scale-down by up to 4x, subject to clock speed limitations
  - Vertical scale-down by up to 4x for 2 bytes per pixel or 2x for 4 bytes per pixel, again subject to clock speed limitations
  - Scale-up by up to 4000x (from 1 pixel to 4000 pixels)
- Filtering (Windows A/B/C)
  - 6-tap, 16-phase programmable H filter
  - 2-tap, 16-phase programmable V filter
- YCbCr to RGB color space converter (Windows A/B/C)
- Digital Vibrance (8-level)

The table below describes a breakdown of features for a Tegra K1 Display on a window basis. Note that rotation is supported up to 2560x1600. Also note that system bandwidth, power, and other constraints might limit what combinations of resolution and features are achievable.

Table 74: Window Feature Summary

Head	Maximum Resolution	Window	Scaling	Planar Rotation	Packed Rotation
A	3840x2160 @ 60 Hz	A	Y	Y	Y
		B	Y	N	Y
		C	Y	N	Y
		D	N	N	N
		T	N	N	N
B	4096x2160 @ 30 Hz	A	Y	N	N
		B	Y	N	N
		C	Y	N	N

21.1.4 Windows D/T (Simple Windows)

Windows D and T are similar, generic windows with limited features for supporting status bars, soft buttons, and similar use cases. Window T has additional TrustZone semantics and limitations.

Windows D/T, collectively known as “simple windows”, support a subset of the registers used by the full-featured windows A/B/C.

The following table summarizes the differences among the two windows.

Table 75: Windows D/T Summary

Feature	Window D	Window T
32/16 bpp RGBA	Y	Y
Syncpt	Y	N
STATE_CONTROL shadow	Y	N
TrustZone Secure mode	N	Y
Indirect access (DISPLAY_WINDOW_HEADER)	Y	N
Class (Host1x command) access	Y	N [secure mode]

21.1.4.1 Feature Limitations

Windows D/T have similar window datapath features. Unlike window T, window D has syncpt increment and state control similar to windows A/B/C. Limitations of windows D/T relative to A/B/C include:

- Color depth is limited to a subset of RGB/RGBA single-plane formats. YCbCr/YUV/palette formats are not supported. The following formats are supported:
  - T_R8G8B8A8 – Tegra 4-style RGBA cursor uses
  - T_A8R8G8B8 – Tegra 3/Tegra 4 window A/B/C format
  - T_A8B8G8R8 – Tegra 3/Tegra 4 window A/B/C format
  - T_R5G6B5 – Best quality 16bpp format
  - T_A4R4G4B4 – 16bpp format with 4-bit alpha
  - T_A1R5G5B5 – 16bpp with 1-bit alpha format, better quality
- No scaling or filtering (DDA_INCREMENT, H/V_FILTER_ENABLE)
- Blending is limited to per-pixel alpha (ALPHA_WEIGHT and PREMULT_WEIGHT) and fixed alpha (FIX_WEIGHT). No color key or dependent weight (i.e., no dependence on non-secure pixels)
- The following features are not supported:
  - Block linear
  - H_DIRECTION, V_DIRECTION
  - Rotation (SCAN_COLUMN)
  - DV (digital vibrance)
  - BYTE_SWAP
  - H/V_INITIAL_DDA
  - DDA_INCREMENT (no scaling)

Window T has some additional feature limitations:

- No syncpt increment
- No indirect access using DISPLAY_WINDOW_HEADER – only window direct space is supported
- No class writes in secure mode. Class writes are always non-secure and therefore cannot be used in secure mode.
- Register activation and shadow control do not use STATE_CONTROL/STATE_ACCESS/REG_ACT_CONTROL. Separate registers are used.

21.1.4.2 Blending

Window D/T supports a subset of window blending registers. Because color key is not supported, only MATCH case exists.

21.1.4.3 Window T TrustZone Support

The display controller supports the ability to display TrustZone secured content in window T. Registers and memory interface in window T are separate from the other windows.

The display controller can switch dynamically between Secure and non-Secure modes. In Secure mode, window T is composited on top of 4 non-secure windows, and the cursor is disabled. The Non-secure OS can continue to run as normal, but its windows maybe obscured. All other semantics for the non-Secure OS are unchanged, including register reads, sync points, and interrupts.

TZ_SECURE is not intended for digital media DRM; the Video Protection Region is intended for that. The TZ_SECURE window T also does not have sufficient features for video use cases. TZ and VPR are orthogonal. TZ_SECURE does not require a VPR region, and VPR region access does not require TZ_SECURE.

Only displayA (internal display) has window T. But, both display A and displayB (external display) have TZ Secure host interfaces and implement the SECURE_CONTROL register. This allows the Secure OS to control the displayB output to DSI.

The display controller allows window T to use an alternate MC address-space ID (ASID) so that secure and non-secure address translation and attributes can be different. Window T is hardcoded to a different SWID (via the swid signal) from all other windows. Software can either program the two SWIDs to different ASIDs or to the same ASID.

The display controller allows disabling CRC in Secure mode, so that non-secure software cannot gain information about trusted display by examining the CRC.

Secure Mode Limitations

The TrustZone Secure OS mode has these limitations:

- No hardware cursor. The cursor could be used to spoof secure window.
- No use of display syncpt increment, interrupt or raise. The single interrupt line is shared by the whole head (all windows).
- DISPLAY_WINDOW_HEADER should not be used by TZ. TZ must use “window direct” address range only.
- Only direct Host1x writes can support TZ_SECURE accesses; indirect and CDMA/class writes might not.
- The Host1x channel should not be shared with non-TZ OS. If unavoidable, only Host1x direct read/write should be done. In particular, non-atomic Host1x sequences, such as indirect register writes, should be avoided.
- STATE_CONTROL, STATE_ACCESS, and REG_ACT_CONTROL must not be used by TZ. SECURE_STATE_CONTROL and WIN_T_STATE_ACCESS should be used instead.
- Display CRC includes the Secure Window which could confuse the non-Secure OS, if the latter uses CRC. This applies to functions like NvDPS.
- Secure window affects PRISM 3 and thus backlight brightness. It might interact poorly with SD_WINDOW* region, for example.

- Bandwidth used by window T must be accounted for in DVFS, IMP, etc.

21.1.4.4 DVFS Support

Windows D/T are also responsible for generating DVFS readiness signals similar to those generated by MEMFETCH windows. The requirements for generating ready_for_latency_event for windows D/T DVFS are the same as for full featured windows.

21.2 Block Diagrams

Figure 53: Display Controller Front End Block Diagram

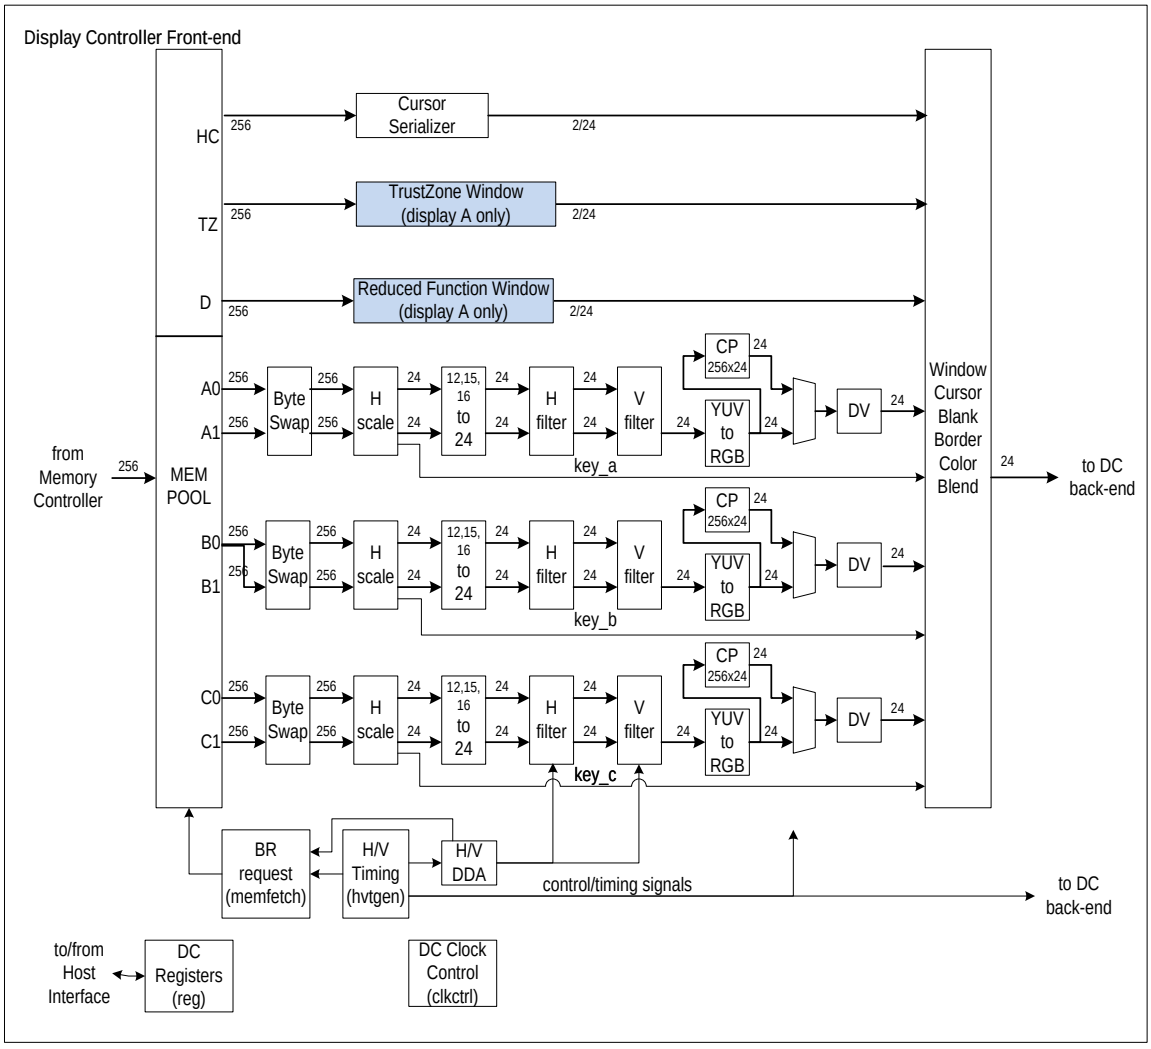


Figure 54: Display Controller Back End Block Diagram

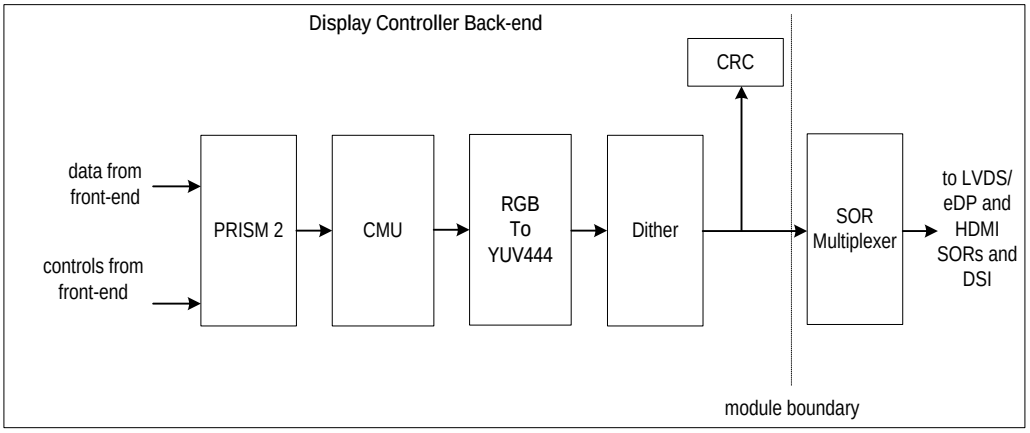


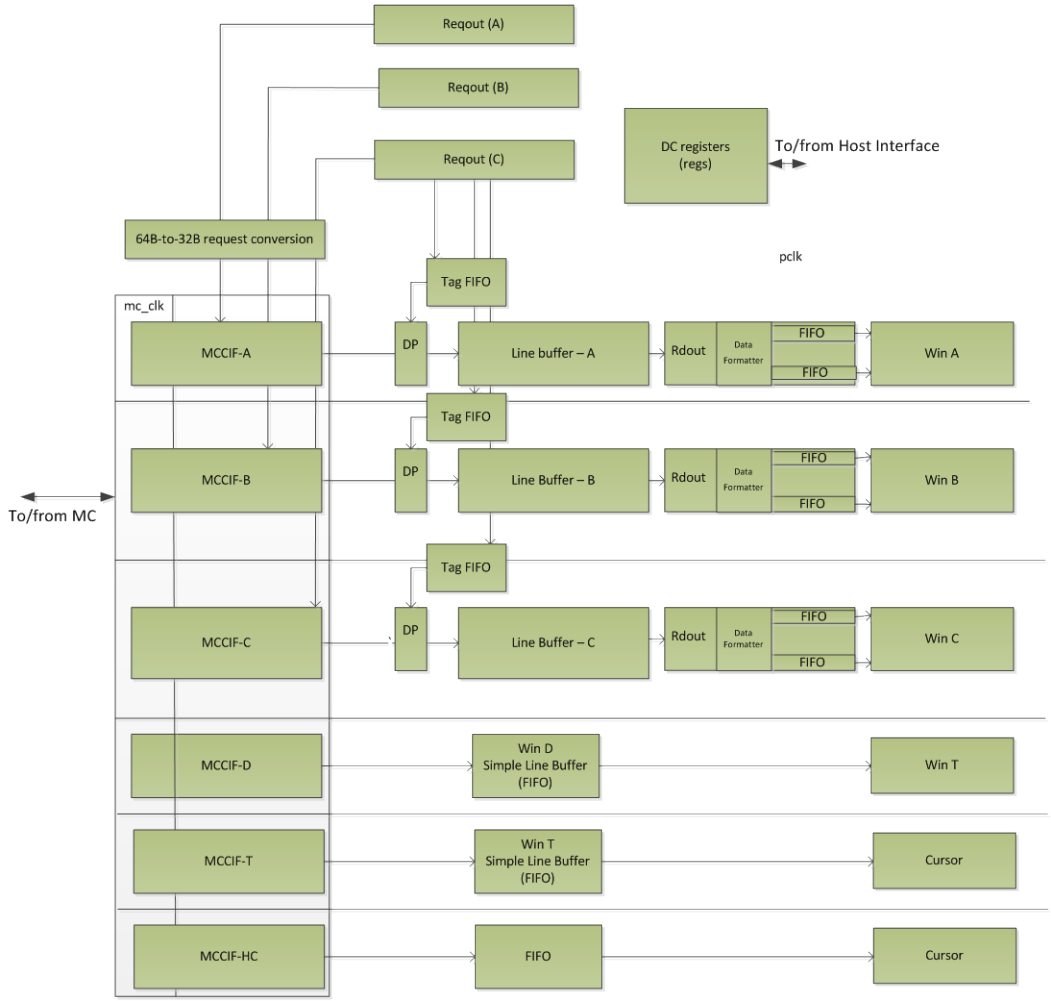
21.3 Display Controller Description

21.3.1 MEMFETCH

Figure 55 shows the top-level block diagram of the display memory interface for Tegra K1 devices. The diagram shows the memory fetch engines associated with the three full-featured windows and two simple windows in the display controller. Each window memory fetch engine has a line buffer and MCCIF. In addition to the windows, display also uses a memfetch for cursor.

Requests are issued to the memory and data is returned via MCCIF to the window line buffer. Data from the line buffer is subsequently read out, unpacked and passed to the window scaler and filter units. Windows D/T and the cursor fetch engines do not contain line buffers.

Figure 55: Memfetch Block Diagram



21.3.1.1 Request Engine

The request engine is responsible for fetching the window image from memory. Logic to translate the X, Y coordinates to a linear memory address is used to make requests to memory.

A pulse signal is sent to the request engine from the display timing generator at the beginning of the vertical blanking period to alert the request engine to start requesting the image data. Tagged requests are sent to the MCCIF. The thread ID specifying the line location of the return data is passed to the tag FIFO between the request and response engines. The thread ID is read by the data packer block when the return data is received and the data is steered to the appropriate line(s) in the line buffer.

The request engine must handle the following surface formats:

- Pitched linear surface
- Block linear surface

  16B x 2 lines – subset of 32B x 2 lines (rotation disabled)

  16B x 2 lines – subset of 32B x 4 lines (rotation enabled)

Requests are only stalled by:

- Backpressure from MCCIF
  - Occurs when MCCIF reorder buffer allocation is full

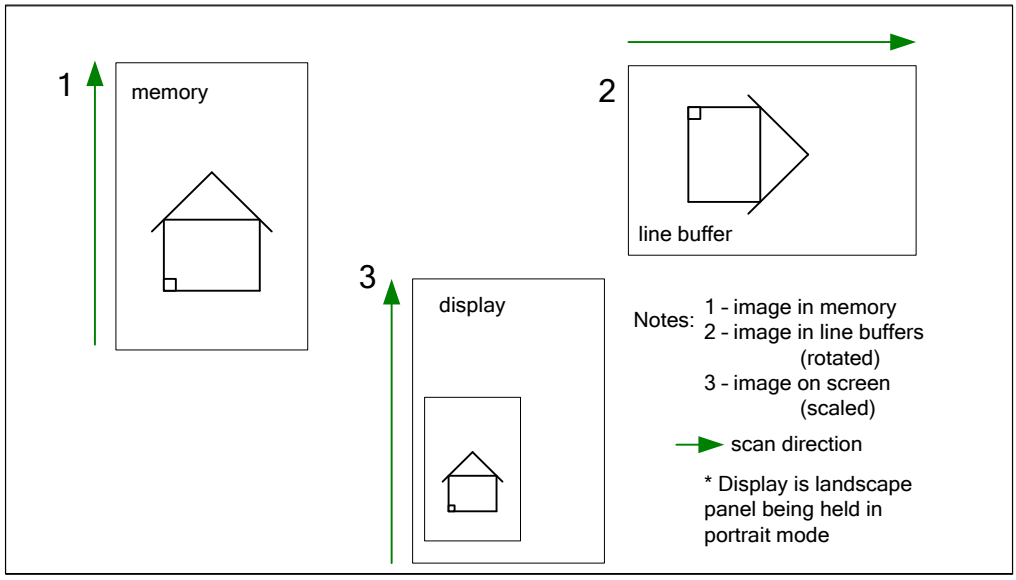
- MCCIF reorder buffer size is 6KB

- Tag FIFO full
  - Each tag represents 64 byte line buffer entry
  - Current tag FIFO depth sized at 119 entries
  - Allows for slightly over 7KB requests
  - Tag FIFO depth should be slightly greater than possible MCCIF outstanding requests

Rotation Support

The display supports 0°, 90°,180°, or 270° rotation or image flip. To support rotation, the memfetch unit rotates the data at the input to the line buffers. That is, memfetch walks the Y axis and stores these columns in memory as rows to the display. The figure below illustrates the image orientation and shape at different stages in the pipeline for rotation.

Figure 56: Example Rotation Use-Case



Memfetch only supports rotation in block linear mode. This is due to the amount of horizontal pixel data read in pitched linear versus block linear format. For pitched linear, 32B of horizontal data is fetched compared to block linear format where only 16B of horizontal data is fetched using the 16B x 4 line block linear mode. Since rotation switches rows and columns, the 4 horizontal pixels become 4 rows in the line buffer. Therefore the minimum number of lines when rotation is enabled is 4. The number of lines grows to 5 when scaling is enabled.

The request for 16Bx4 format must be communicated to the MCCIF via addressing bits 6 and 7. Memfetch will increment the Y instead of X coordinate for subsequent accesses and after reaching maximum Y will reset the coordinates to (X+16B, 0) for the next fetch of columns from memory. Selection of 32Bx2 or 16Bx4 is based on B_SCAN_COLUMN used to indicate rotation

The B_SCAN_COLUMN bit indicates if the image needs to be scanned out row by row or column by column. When this bit is enabled, the display needs to scan out lines column by column. This will provide the required 90°/270° rotated images. To achieve 90° or 270° rotation, software must use a combination of H_DIR, V_DIR, and SCAN_COLUMN as shown in the table below. It illustrates how the image is scanned in to display by the memfetch unit for each combination of (SCAN_COLUMN, H_DIR, V_DIR).

SCAN_COLUMN	H_DIR	V_DIR	Orientation
0	0	0	0 degrees
0	0	1	N/A – vertical flip

SCAN_COLUMN	H_DIR	V_DIR	Orientation
0	1	0	N/A – horizontal flip
0	1	1	180 degrees
1	0	0	N/A – vertical flip followed by rotation
1	0	1	90 degrees
1	1	0	N/A – horizontal flip followed by rotation
1	1	1	270 degrees

The window dimension registers can be confusing when rotation is introduced. Therefore it is important to note which registers apply to pre-rotation and which to post rotation.

The following registers apply to pre-rotation:

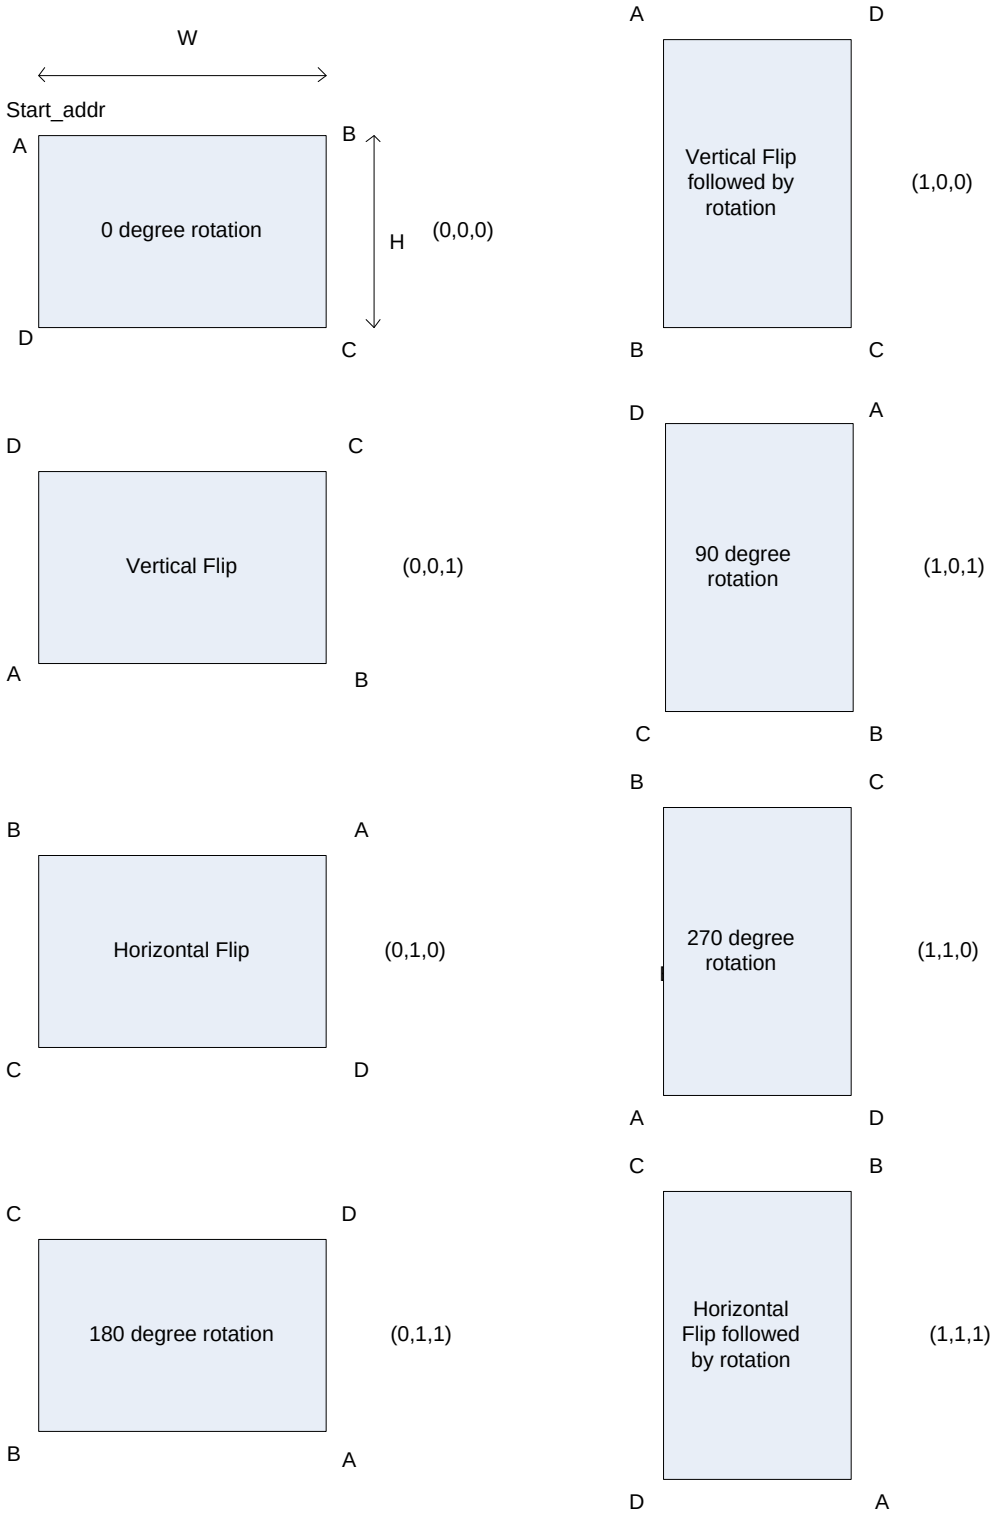
- B_WIN_OPTIONS
  - H_DIR
  - V_DIR
  - SCAN_COLUMN
- B_LINE_STRIDE
- B*_BUF_STRIDE
- B_START_ADDR_*
- B_ ADDR_H_OFFSET_*
- B_ ADDR_V_OFFSET_*

The following registers apply to post rotation:

- B_WIN_OPTIONS
  - H_FILTER*
  - V_FILTER*
  - SCAN_COLUMN
- B_PRESCALED_SIZE
- B_SIZE
- B*_INITIAL_DDA
- B_DDA_INCREMENT

Because the memfetch unit is essentially walking the Y axis in memory, the majority of the window registers and associated logic remain unchanged. Therefore except for B_ADDR_H/V_OFFSET horizontal and vertical directions are with respect to post rotation.

Figure 57: Rotation Combinations



21.3.1.2 Line Buffer

The memfetch line buffer allows the display controller to retain one or more scan lines of window data locally so that no further reading of the scan line is required from memory. The scenarios where this is required are:

- Vertical scaling and filtering
  - Requires 3 scan lines of data for non-rotated memory fetches
  - Requires 5 scan lines of data for rotated memory fetches of packed data
- Reading block linear data
  - Data is sent in 2 scan lines for non-rotated memory fetches
  - Data is sent in 4 scan lines for rotated memory fetches

Data is received from the memory interface and steered to the proper location in the line buffer based on the thread ID in the tag FIFO. Data is read out of the line buffer and unpacked based on the pixel format. These pixels are placed in an output FIFO of memfetch to be sent to the window scaler logic in the display pipe.

In the vertical scaling and filtering scenario, up to five scan lines of data are required for the vertical scaler engine for it to generate the proper scaled output. In the block linear mode scenario, only a single scan line is output but the 32B returned data contains portions of two scan lines. To ensure adequate storage of RGB packed data format and steady bandwidth consumption to the display controller, line buffers are deep enough to hold up to five lines of maximum width of packed pixel data based on the maximum use-case supported by the given window.

Support for YUV planar rotation when reading data in BL 16Bx4 format requires a larger amount of data storage. Each plane of data will return 16B per color component. Due to scaling, it is required to keep a scan line of data in the buffer when fetching the next block of 16. This will require an additional byte of data. Therefore the buffer requirements for YUV planar are:

- Number of bytes per plane = 17 bytes
  - Minimum data fetch size = 16 bytes
  - Scaling requires additional scan-line remain
  - Pixel component depth per plane = 1 byte
- Number of planes = 3
- Line buffer width = 2560 pixels –maximum width
- Line buffer size = 17 bytes/plane* 3 planes/pixel * 2560 pixels per line

  = 130560 bytes

Since the line buffer storage requirement for YUV planar is close to three times (3X) the RGB packed format, the Tegra K1 display only supports buffering support for YUV planar rotation on 1 window. This restriction applies to YUV422 packed data as well due to the implementation of expanding the data to YUV444 in the line buffer. The other two windows will contain buffering to support non YUV planar rotation (51200 bytes).

Below are the equations used to calculate buffer requirements for a given rotated video image.

- YUV444 (packed):
  - Scaling – 5 lines*4Bpp*width
  - No scaling – 4 lines*4Bpp*width
- YUV422 (packed):
  - Scaling – 9 lines*4Bpp(as data is expanded)*width
  - No scaling – 8 lines*4Bpp(as data is expanded)*width
- YUV420 (planar):
  - Scaling: 3 (number of surfaces)*17*width (17 lines @ 1B/line)
  - No scaling: 3 (number of surfaces)*16*width (16 lines @ 1B/line)

The line buffer helps to prevent refetching of data from memory. The line buffer size requirement to prevent refetch depends on the use case. Based on the use case and method of packing/unpacking pixels stored in the line buffer, there will be an

inherent pixel latency associated with the buffer. The memory controller can take advantage of this latency to temporarily stop sending pixel data to the display for cases such as changing the memory clock frequency.

Note that the line buffer can be written or read either with single or multiple lines per clock. For rotation use cases, line buffers load up to 16 lines at a time based on pixel format. Line buffers are read one or two lines at a time based on vertical scaling. The following tables and figures illustrate the line buffer size as well as inherent latency for various use cases for packed ARGB formats (4Bpp). For rotation use cases only block linear formats are supported. Remember that for rotation, block linear format is 16Bx4 lines.

Table 76: Non-Rotation Use Cases

Scenario	Vertical Scaling Enabled	Data Format	Line buffer size required to avoid refetch	Latency Tolerance Guaranteed by Line Buffer
A	NO	Pitched Linear	0	0 lines
B	NO	Block Linear	1 line	0 lines
C	YES	Pitched Linear	1 line	0 lines
D	YES	Block Linear	3 lines	0 lines

Table 77: Rotation Use Cases

Scenario	Vertical Scaling Enabled	Data Format	Line buffer size required to avoid re-fetch	Latency Tolerance Guaranteed by Line Buffer
A	NO	Block Linear	4 line	1 line
B	YES	Block Linear	5 lines	0 lines
C	NO	YUV Planer	16 line	1 line
D	YES	YUV Planer	17 lines	0 lines

The latency tolerance refers to the number of lines available in the line buffer when the line buffer is full between when a given pixel is written to and read from the line buffer. For some of these use cases, there is a relatively long period of time after a pixel is written to the buffer before it is needed in the scan line. However, note that in every case where a scan line or more of data exists, the scan lines are being written at a rate of ½ or ¼ of the pixel clock rate since either 2 or 4 scan lines are being read at once from memory at a rate of 1 pixel per clock.

The fixed size of the Tegra K1 display buffers is given below. Each buffer size has a corresponding “maximum use-case” scenario from those listed above. For those scenarios that are not “maximum use-case”, the portion of the line buffer beyond what the scenario required can be used as latency buffering. Even the “maximum use-case” scenario can use a portion of the pixel latency as latency buffering.

Table 78: Tegra K1 Display Line Buffer Sizes

Line Buffer Size (KB)	Maximum Use-Case	Maximum Resolution
128	Rotation – Scenario C	2560x1600
50	Rotation – Scenario B	2560x1600
48	Non-Rotation – Scenario D	4096x2160

To take advantage of the portion of the line buffer dedicated for handling latency MEMFETCH will send flags to the MC indicating when a programmable threshold is crossed. For each scenario, software must calculate the portion of the line buffer that can be used for latency buffering and set the threshold accordingly. Below is a list of the flags MEMFETCH will generate:

- SPOOLUP
  - Signal name: csr_display0a2mc_spool_up

- Active from when data is requested during Vblank until active space
- Active space starts with 1st pixel of window sent to display pipe

- DVFS readiness flag
  - Requires HWM threshold
  - Signal name: csr_display0a2mc_ready_for_latency_event
  - Active when:

  Buffer exceeds HWM threshold

  Window is disabled

  From the time all data is read for current frame until data is requested for subsequent frame
  - Deactivated with occurrence of underflow for the remainder of the frame
- LATENCY ALLOWANCE SCALE FACTOR buffering
  - Requires HWM/LWM thresholds
  - Signal names:

  csr_display0a2mc_la_th_above_hi = level > HWM

  deactivate with occurrence of underflow for remainder of frame

  activate when window is disabled

  csr_display0a2mc_la_th_below_lo = level < LWM

  activate with occurrence of underflow for remainder of frame

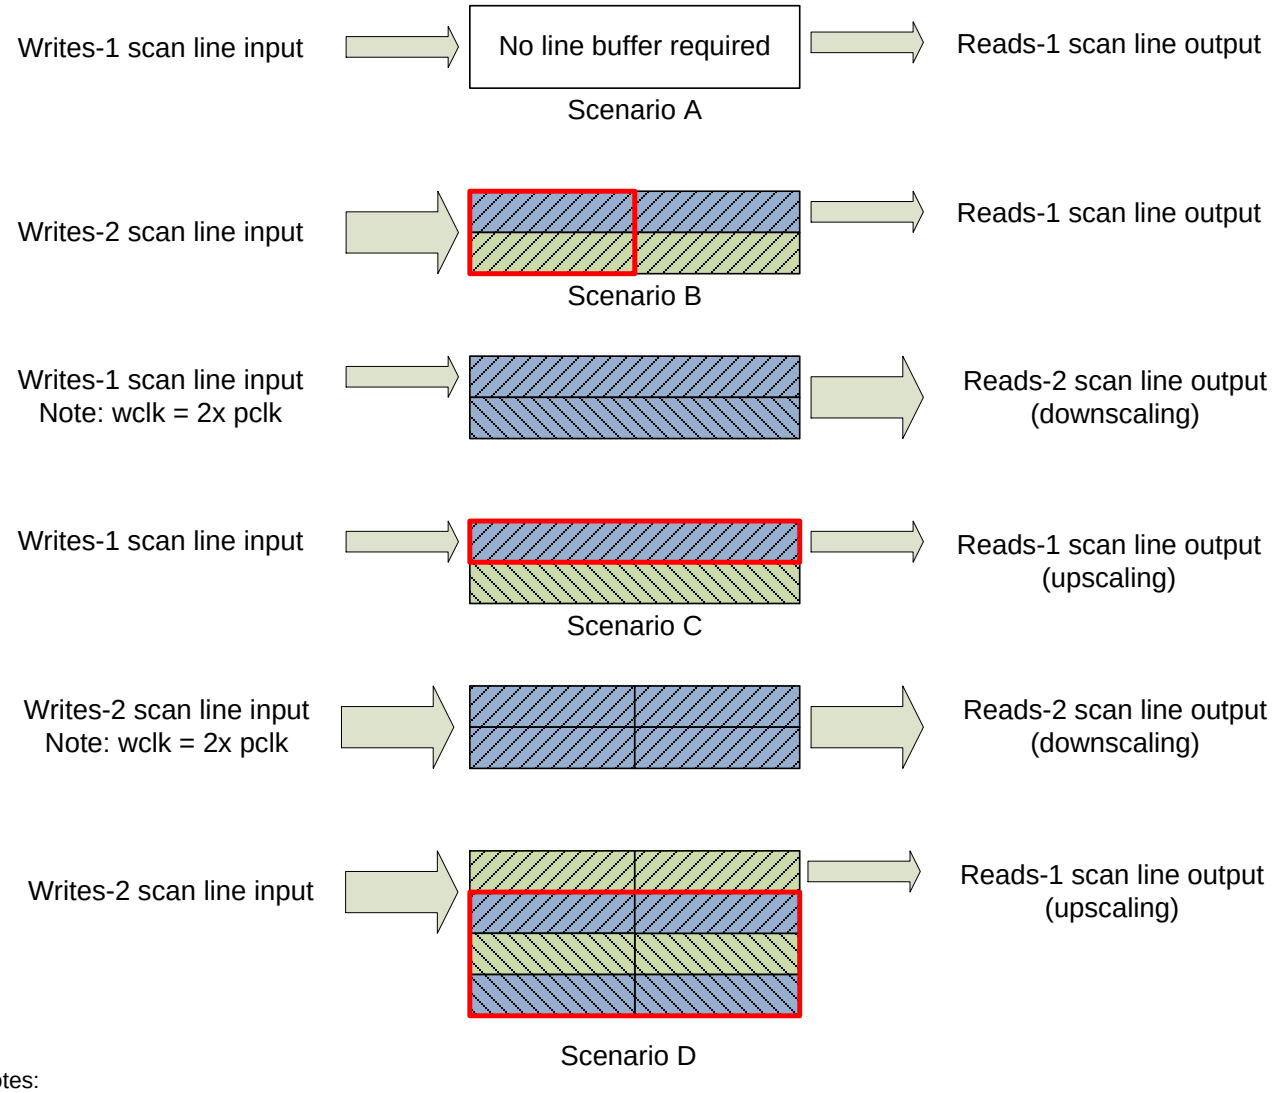
  deactivate when window is disabled

The programmable threshold will simply keep a running count of the number of bytes in the buffer and compare that value against the one in the threshold register.

Line buffering for planer YUV requires separate storage per plane. Each line is read by sending 1KB of Y requests followed by 1KB of U then 1KB of V requests. This is maintained until the entire line of YUV is read. Subsequent line requests are not issued for any component until all component requests have been issued for the current line. MEMFETCH does allow for changing the weights of the given requests per plane to help control the behavior of the requests per plane.

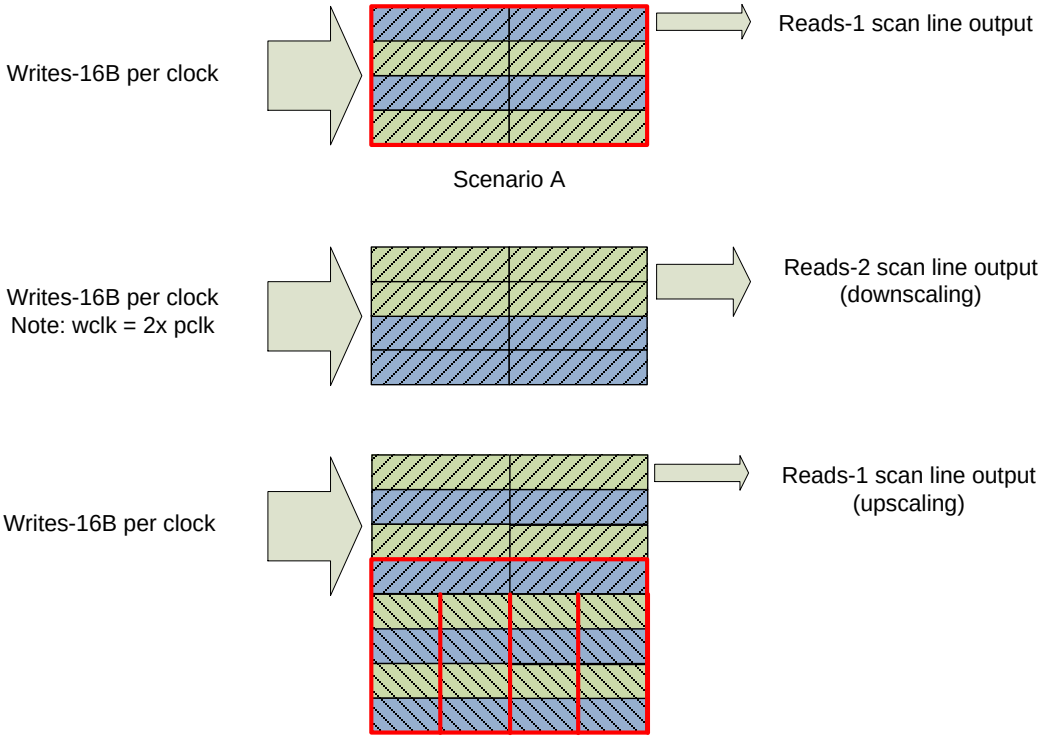
For non-rotated YUV planer use cases, the size of the line buffer is less than that of 4B ARGB since the pixel format is only 1.5B/pixel. However rotated planer YUV requires storage of 16B for each line per plane. Contact your NVIDIA AE should you need further support on this.

Figure 58: Non-Rotation Line Buffer Use Cases



Notes:
- Diagonal Lines represent the order in which data is written to the buffer (Two rows that have the same line pattern are written in parallel)
- Color represents the order in which data is read from the buffer (the same color indicates the rows are read in parallel)
- Red box indicates the line buffer size required to avoid refetch

Figure 59: Rotation Line Buffer Use Cases



Note:
- Diagonal lines Indicate the order in which data is written to the buffer.
  If the two rows have same line pattern, they are written in parallel.
- Color indicates read pattern
- Red boxes indicate line buffer size needed to avoid refetch
- Red lines indicate progress of filling line buffer as scan lines are read

21.3.1.3 Handling of Underflow

Display is an isochronous client that requires a steady bandwidth allocation. If data is not returned at a fairly constant rate and the line buffers run dry then data will not appear on the screen at the proper time. Eventually when data does start to flow to the display controller the image will appear shifted and there is no way for the image data to catch up to where it should be on the screen. This undesirable lack of guaranteed data is called underflow and it can happen in 2 forms:

- Short term underflow – pixels worth of missing data
- Long term underflow – scan-lines worth of missing data

For short term underflow it is possible for the display controller to catch up to the correct pixel by the start of the next scan-line by reading pixels during the horizontal blanking period. Short term underflow is being managed by Tegra display controller in this manner. For long term underflow it would be impossible for the display controller to throw out that much data. Short term underflow may arise when the memory controller is over-taxed based on a momentary surge in memory client requests. Long term underflow may happen when memory controller frequency changes are being made.

Tegra K1 display windows will address short term underflow similar to what is done in Tegra 3. Long term underflow is also handled in a manner similar to Tegra 3 during the active frame portion. Below is a description of Tegra K1 Underflow recovery improvements:

- Underflow recovery within a frame

- Start counter of underflow pixels when underflow occurs
- Last valid pixel is held at the beginning at the display pipeline for duration of the underflow
- Underflow pixels that eventually return to display are stored in line buffer and immediately read/discarded
- Operation continues (even during HBlank) until all underflow pixels have been discarded
- Once valid pixel is present at display pipe input memfetch operations return to normal mode
- Limit requests issued at the end of a frame if window is in underflow using the following method:

  For cases when underflow continues to the end of the frame

  Add threshold counter (B_UFLOW_THRESHOLD)

  Track prescaled scanout

  Stop issuing frame requests when

  prescaled scanout + threshold is > prescaled size

- Underflow recovery between frames
  - Add a frame bit to the tag FIFO to allow DP logic to determine which of the responses that are coming back are for the previous frame
  - Drop pixels from previous frame at 64B/pclk rate
  - Within display pipe, reset the underflowed pixel counters
  - Limit requests issued at the end of a frame if window is in underflow using method described above
  - Last pixel of previous frame is displayed

The Tegra K1 display handles cursor underflow in the following manner:

- Interface between memfetch and display pipeline senses when underflow occurs.
- For simple windows, the display pipe drives the last valid piel for the duration of the underflow.
- When underflow occurs display pipeline drives a cursor alpha value of 0 for the remainder of the underflow period. This could be until the end of 1 or more scan lines.
- Memfetch will not drive valid to the display pipeline until the start of the scan line when data is available.
- Display pipeline will not assert ready to memfetch until the beginning of the scan line when data is available and memfetch is driving valid.
- Memfetch keeps track of number of clocks of missing data and when data does appear it reads out the data until the end of the scan line is reached.

It is important to highlight underflows for debug purposes. Current display units raise an interrupt to indicate that underflow has occurred. The Tegra K1 display continues to drive an interrupt when an underflow is detected. To further assist with highlighting underflows, memfetch drives a solid color from the window that experiences an underflow if the associated enable bit is active.

21.3.2 Interlaced Fields

To support set top boxes, the Tegra K1 display supports interlaced format, which is still prevalent in many television displays and broadcast networks. Interlaced format requires half the bandwidth of progressive and alternates sending fields containing odd and even lines of the original video frame.

The CEA Standard (CEA-861-E) defines these interlaced fields as FIELD1 and FIELD2. FIELD1 contains the even lines (line 0, 2, 4, etc.). FIELD2 contains the odd lines (line 1, 3, 5, etc.). From a consumer electronic display perspective, FIELD1 contains the top lines, and FIELD2 contains the bottom lines.

Memfetch contains start (base) addresses for both fields and when interlaced mode is enabled it will toggle between these base addresses every frame. Memfetch will continue to toggle between FIELD1 and FIELD2 fields until interlace mode is disabled. When interlace mode is disabled, memfetch only uses the normal (FIELD1) registers.

IMPORTANT: The first field that is fetched when interlace mode is based on HVTGEN field1/field2 field status. It is up to software to ensure that proper field being fetched is ready when activating interlace mode in memfetch.

No parameter other than start address and offset can change between fields such as size and stride.

To support double buffering of interlaced fields, software is required to update field1/field2 base addresses on a frame (not a field) boundary. Becausse the display is treating each field as a frame, software should make sure that updates only occur after an even number of frame SYNCPTS are received. It is strongly suggested that both field1 and field2 fields are ready in memory when performing the buffer swap to avoid coordinating field updates based on current field scanout.

21.3.3 Surface/Color Formats

In general, the Tegra K1 display supports the same pixel and surface formats used in Tegra 3. These pixel formats are not supported by the Tegra K1 display controller:

- P1 – 1bpp palletized
- P2 – 2bpp palletized
- P4 – 4bpp palletized
- RGB666
- YUV422RA

Below are the surface and pixel formats supported by the Tegra K1 display controller. Formats are lsb-to-msb.

Surface formats:

- Pitched linear – scan-line data
- Block linear
  - 32B x 2 line – rotation off
  - 16B x 4 line – rotation on

Pixel formats:

- RGB packed
  - T_P8 – single 8-bit color index component. RGB value is looked up in LUT.
  - T_R5G6B5, T_B5G6R5 – 5 bits for R/B, 6 bits for G.
  - T_A4R4G4B4, T_A4B4G4R4 – 4 bits each, packed into 16-bit word. Each is expanded to 8 bits by MSB replication or 0-fill, depending on COLOR_EXPAND.
  - T_A1R5G5B5, T_R5G5B5A1, T_A1B5G5R5, T_B5G5R5A1: 5 bits each for RGB, 1 bit for alpha. Expanded to 8 bits by MSB replication or 0-fill, depending on COLOR_EXPAND.
  - T_A1R5G5B5, T_R5G5B5A1, T_A1B5G5R5, T_B5G5R5A1: 5 bits each for RGB, 1 bit for alpha. Expanded to 8 bits by MSB replication or 0-fill, depending on COLOR_EXPAND.
  - T_X1R5G5B5, T_R5G5B5X1, T_X1B5G5R5, B5G5R5X1: 5 bits for RGB Expanded to 8 bits by MSB replication or 0-fill, depending on COLOR_EXPAND.
  - T_A8R8G8B8, T_R8G8B8A8, T_A8B8G8R8, T_B8G8R8A8: 8 bits for R/G/B/A
  - T_X8R8G8B8, T_R8G8B8X8, T_X8B8G8R8, T_B8G8R8X8: 8 bits for R/G/B

- YUV packed
  - T_Y8_U8__Y8_V8, T_Y8_V8__Y8_U8, T_U8_Y8__V8_Y8, T_V8_Y8__U8_Y8: Cb and Cr are stored decimated 2:1 horizontally, yielding two bytes per pixel: Y0 Cb0 Y1 Cr0 Y2 Cb2 Y3 Cr 2 …. Cb and Cr must be replicated to generate YCbCr444 for use in display pipeline.
- YUV planar
  - T_Y8___U8___V8_N420: (YCbCr420P) Cb and Cr are stored decimated 2:1 horizontally and vertically, in separate surface planes. Cb and Cr surfaces are ¼ size of Y plane. Each Cb and Cr pixel is shared (replicated) by 4 pixels. To avoid fetching Cb and Cr lines twice for each Y line, a line buffer is needed to cache Cb and Cr.
  - T_Y8___U8___V8_N422: (YCbCr422P) Cb and Cr are stored decimated 2:1 horizontally, in separate surface planes. Cb and Cr surfaces are ½ size of Y plane. Each Cb and Cr pixel is shared (replicated) by 2 pixels.
  - T_Y8___U8___V8_N444: 4:4:4 planar.
- Semi- planar
  - T_Y8___U8V8_N420, T_Y8___V8U8_N420:(YCbCr420 semi-planar) Cb and Cr are stored decimated 4:1 horizontally, interleaved in a CbCr plane. CbCr surface is ½ size of Y plane. Each Cb and Cr pixel is shared (replicated) by 4 pixels. Y plane has: Y0 Y1 Y2 … and CbCr plane has: Cb0 Cr0 Cb4 Cr4 …
  - T_Y8___U8V8_N422, T_Y8___V8U8_N422:(YCbCr422 semi-planar) Cb and Cr are stored decimated 2:1 horizontally, interleaved in a CbCr plane. CbCr surface is same size as Y plane. Each Cb and Cr pixel is shared (replicated) by 2 pixels. Y plane has: Y0 Y1 Y2 … and CbCr plane has: Cb0 Cr0 Cb2 Cr2 …
  - T_Y8___U8V8_N444, T_Y8___V8U8_N444: 4:4:4 semiplanar.

True YUV formats are supported in display along with YCrCb. YUV differs from YCbCr in that UV is signed -127 to 128 where CbCr is offset 128 and ranges 0 to 255.

The following formats are reserved for true YUV as opposed to YCbCr:

- T_A8Y8U8V8_TRUE, T_V8U8Y8A8_TRUE
- T_U8_Y8__V8_Y8_TRUE
- T_Y8___U8___V8_N420_TRUE
- T_Y8___U8___V8_N422_TRUE
- T_Y8___U8___V8_N422R_TRUE
- T_Y8___U8___V8_N444_TRUE
- T_Y8___U8V8_N420_TRUE
- T_Y8___V8U8_N420_TRUE
- T_Y8___U8V8_N422_TRUE
- T_Y8___V8U8_N422_TRUE
- T_Y8___U8V8_N422R_TRUE
- T_Y8___V8U8_N422R_TRUE
- T_Y8___U8V8_N444_TRUE
- T_Y8___V8U8_N444_TRUE

The Tegra K1 display supports a subset of the above pixel formats natively. To support all display pixel formatsrequires use of the window B_BYTE_SWAP register. The table below gives a full list of the required display pixel formats along with the display native format and B_BYTE_SWAP settings.

Format	Color_Depth	Byte_Swap
T_B5G6R5	T_B5G6R5	NA
T_R5G6B5	T_R5G6B5	NA

Format	Color_Depth	Byte_Swap
T_A1B5G5R5	T_A1B5G5R5	NA
T_A1R5G5B5	T_A1R5G5B5	NA
T_B5G5R5A1	T_B5G5R5A1	NA
T_R5G5B5A1	T_R5G5B5A1	NA
T_X1B5G5R5	T_X1B5G5R5	NA
T_X1R5G5B5	T_X1R5G5B5	NA
T_B5G5R5X1	T_B5G5R5X1	NA
T_R5G5B5X1	T_R5G5B5X1	NA
T_A4B4G4R4	T_A4B4G4R4	NA
T_A4R4G4B4	T_A4R4G4B4	NA
T_A8B8G8R8	T_A8B8G8R8	NA
T_A8R8G8B8	T_A8R8G8B8	NA
T_B8G8R8A8	T_A8R8G8B8	SWAP4
T_R8G8B8A8	T_A8B8G8R8	SWAP4
T_X8B8G8R8	T_X8B8G8R8	NA
T_X8R8G8B8	T_X8R8G8B8	NA
T_B8G8R8X8	T_X8R8G8B8	SWAP4
T_R8G8B8X8	T_X8B8G8R8	SWAP4
T_P8	T_P8	NA
T_Y8_U8__Y8_V8 (YUV422 packed)	T_U8_Y8__V8_Y8	SWAP2
T_Y8_V8__Y8_U8 (YUV422 packed)	T_U8_Y8__V8_Y8	SWAPLEFT
T_U8_Y8__V8_Y8 (YUV422 packed)	T_U8_Y8__V8_Y8	NA
T_V8_Y8__U8_Y8 (YUV422 packed)	T_U8_Y8__V8_Y8	SWAP02
T_Y8___U8V8_N444 (YUV444 semi-planar)	T_Y8___U8V8_N444	NA
T_Y8___V8U8_N444 (YUV444 semi-planar)	T_Y8___V8U8_N444	NA
T_Y8___U8V8_N422 (YUV422 semi-planar)	T_Y8___U8V8_N422	NA
T_Y8___V8U8_N422 (YUV422 semi-planar)	T_Y8___V8U8_N422	NA

T_Y8___V8U8_N422R (YUV422R semi-planar)	T_Y8___V8U8_N422R	NA
T_Y8___U8V8_N420 (YUV420 semi-planar)	T_Y8___U8V8_N420	NA
T_Y8___V8U8_N420 (YUV420 semi-planar)	T_Y8___V8U8_N420	NA
T_Y8___U8___V8_N444 (YUV444 planar)	T_Y8___U8___V8_N444	NA
T_Y8___U8___V8_N422 (YUV422 planar)	T_Y8___U8___V8_N422	NA
T_Y8___U8___V8_N422R (YUV422R planar)	T_Y8___U8___V8_N422R	NA

Format	Color_Depth	Byte_Swap
T_Y8___U8___V8_N420 (YUV420 planar)	T_Y8___U8___V8_N420	NA

21.3.4 Horizontal Filter

Memfetch and scaler provide 6 adjacent pixels per clock, along with DDA fraction indicating filter kernel phase. Fraction selects among 16 sets of coefficients for filter kernel.

21.3.5 Vertical Filter

When enabled, memfetch provides 2 adjacent lines in parallel, which are independently horizontally filtered before being sent to vertical filter. The fractional DDA from vertical scaler (indicating filter phase) selects among 16 filter kernel coefficients. For coefficient entry N, the weights are N and 1-N.

21.3.6 Color Space Converter

Most of the display datapath is RGB. The color space conversion unit can convert YCbCr and YUV to RGB. It can also do some RGB to RGB conversions.

21.3.7 Color Palette/LUT

To support gamma and palletized formats, the LUT has three 256x8-bit tables, one each for red, green, blue. The three tables are independent and can represent arbitrary functions. For 4-bit palette modes, only the bottom 16 entries are used.

21.3.8 Digital Vibrance

Using the same algorithm as NVIDIA GeForce GPUs, digital vibrance can increase the saturation of colors.

21.3.9 Cursor

The cursor supports two pixel formats:

- Legacy 2-bit-per-pixel, where the four values are background color, foreground color, transparent, and invert. Foreground and background color are programmable via registers with 24-bit RGB values. Transparent means cursor is invisible and desktop shows through. Invert means desktop RGB is inverted (red' = 255 – red, etc.). Pixels are packed 4 per byte, and each line has 16 bytes pitch, regardless of whether it is 32 or 64 pixels wide.
  - Cursor sizes of 32x32 or 64x64
- 32-bpp RGBA pitch linear
  - Full color with alpha
  - Cursor sizes of:
    - 32x32
    - 64x64
    - 128x128
    - 256x256

The blending required for the alpha cursor will occur after the blending stage. It uses the following blend equation:

Final_image = cursor_alpha * cursor_color + (1-cursor_alpha) * blending_stage_output_color

Note: Legacy cursor does not support per-pixel or global alpha.

Cursor can be clipped to either the display, or window A, B, or C. Thus the cursor active region for blending must be computed according to that mode. In regions where cursor is clipped, or outside the cursor entirely, blending behaves as if cursor is disabled (i.e., previous blend stage passes through.)

> **Note:** The Tegra K1 display cursor supports partial clipping but does not support trivial reject of cursor when the cursor is completely outside of the window region. It is the responsibility of software to ensure that the cursor is at least partially visible.

21.3.9.1 Legacy Support for Blending

The Tegra K1 display supports cursor modes used in previous generations of the Tegra display. Legacy cursor blending uses 2 bits per pixel and programming for this mode will remain unchanged.

21.3.9.2 32-bpp RGBA Cursor Mode

In 32-bpp RGBA cursor mode, legacy adaption is disabled. Cursor RGBA is blended with the last stage of the window blending unit. Cursor alpha value controls this blending.

21.3.9.3 Interlaced Cursor Support

To support interlaced output, the cursor performs a progressive-to-interlaced format conversion of the cursor image in memory. Since the cursor is static, no low pass filtering is necessary. The display cursor reads every other line from the square cursor thus reading only half of the lines. Based on the cursor destination Y position and the field, the Tegra K1 display starts reading line 0 or 1 from memory. The decision on whether to start on cursor line 0 or 1 for the first or second field is left to software, giving more flexibility to manipulate the cursor image and set the offset for a given field. An interlace sequence example for cursor is shown below:

1. Program CURSOR_INTERLACE_ENABLE=1
2. Program CURSOR_INTERLACE_START =1
3. The cursor reads every other line from memory starting at line 1 and stores it to sequential panel lines
4. On the next “frame”, the cursor toggles the line start to 0

   CURSOR_INTERLACE_STATUS = 0
5. The cursor reads every other line from memory starting at line 0 and stores it to sequential panel lines

Repeat steps 2 through 5 in the above sequence when the cursor position is updated and set the cursor start line appropriately.

The cursor interlace control register is shown below. When the CURSOR _INTERLACE_START bit is written, hardware should update the corresponding CURSOR_INTERLACE_STATUS bit to this value. This allows the start line to track updates to the cursor position. The CURSOR_INTERLACE_FIELD1/2_VOFF_INCR bits determine if V_CURSOR_POSITION is incremented by one for that field. The field status is tracked by the hardware cursor logic using HVTGEN interlace field status information.

Table 79: Cursor Interlace Control Register

Field Name	Setting
CURSOR_INTERLACE_ENABLE	Interlace Enable 0=disable 1=enable
CURSOR_INTERLACE_FIELD1_VOFF_INCR	Field1 v position Incr Enable 0=disable 1=enable

Field Name	Setting
CURSOR_INTERLACE_FIELD2_VOFF_INCR	Field2 v position Incr Enable 0=disable 1=enable
CURSOR _INTERLACE_START	Starting line. 0=line 0, 1=line 1
CURSOR_INTERLACE_STATUS	Current line start. Read only. 0=line 0, 1=line 1

There are two possibilities for cursor vertical position in a progressive frame – odd or even line. When breaking a progressive frame into interlaced fields, it is important to know what cursor line number to start on per field when the cursor vertical position starts on an odd progressive line and when it is on an even progressive line. Consider the following examples:

Example 1 cursor starts on line 10:

- V_CURSOR_POSITION = 5
- First line of cursor is at progressive line offset 10

  Corresponds to FIELD1 line 5
- Second line of cursor is at progressive line offset 11

  Corresponds to FIELD2 line 5

Example 2 cursor starts on line 1:

- V_CURSOR_POSITION = 0
- First line of cursor is at progressive line offset 1

  Corresponds to FIELD2 line 0
- Second line of cursor is at progressive line offset 2

  Corresponds to FIELD1 line 1

  Requires setting CURSOR_INTERLACE_FIELD1_VOFF_INCR=1

The following table describes programming mechanism for line start based on progressive frame vertical cursor offset for interlaced fields FIELD1 and FIELD2.

Interlace field	Progressive frame cursor Y offset	
	Odd	Even
First field (FIELD1)	CURSOR_INTERLACE_START = Line 1 V_CURSOR_POSITION = INT(Progressive_cursor_y/2) + 1	CURSOR_INTERLACE_START = Line 0 V_CURSOR_POSITION = INT(Progressive_cursor_y/2)
Second field (FIELD2)	CURSOR_INTERLACE_START = Line 0 V_CURSOR_POSITION = INT(Progressive_cursor_y/2)	CURSOR_INTERLACE_START = Line 1 V_CURSOR_POSITION = INT(Progressive_cursor_y/2)

Note: Programming of CURSOR_INTERLACE registers listed above must line up with the interlaced field in the table. Therefore the register should be written (armed) on the previous field for it to activate on the appropriate field.

21.3.10 Blending

The Tegra K1 display uses weighted blending between windows. Legacy cursor blending must be disabled when full-color alpha-blended cursor is in use.

In Tegra K1 devices, the display blender has six sequential blending stages. Each window is assigned a depth value. The windows are sorted by depth and assigned to a blend stage. The cursor is the last (top) stage. Each stage combines its pixels with the previous stage according to programmed equations.

Figure 60: Tegra K1 Blending

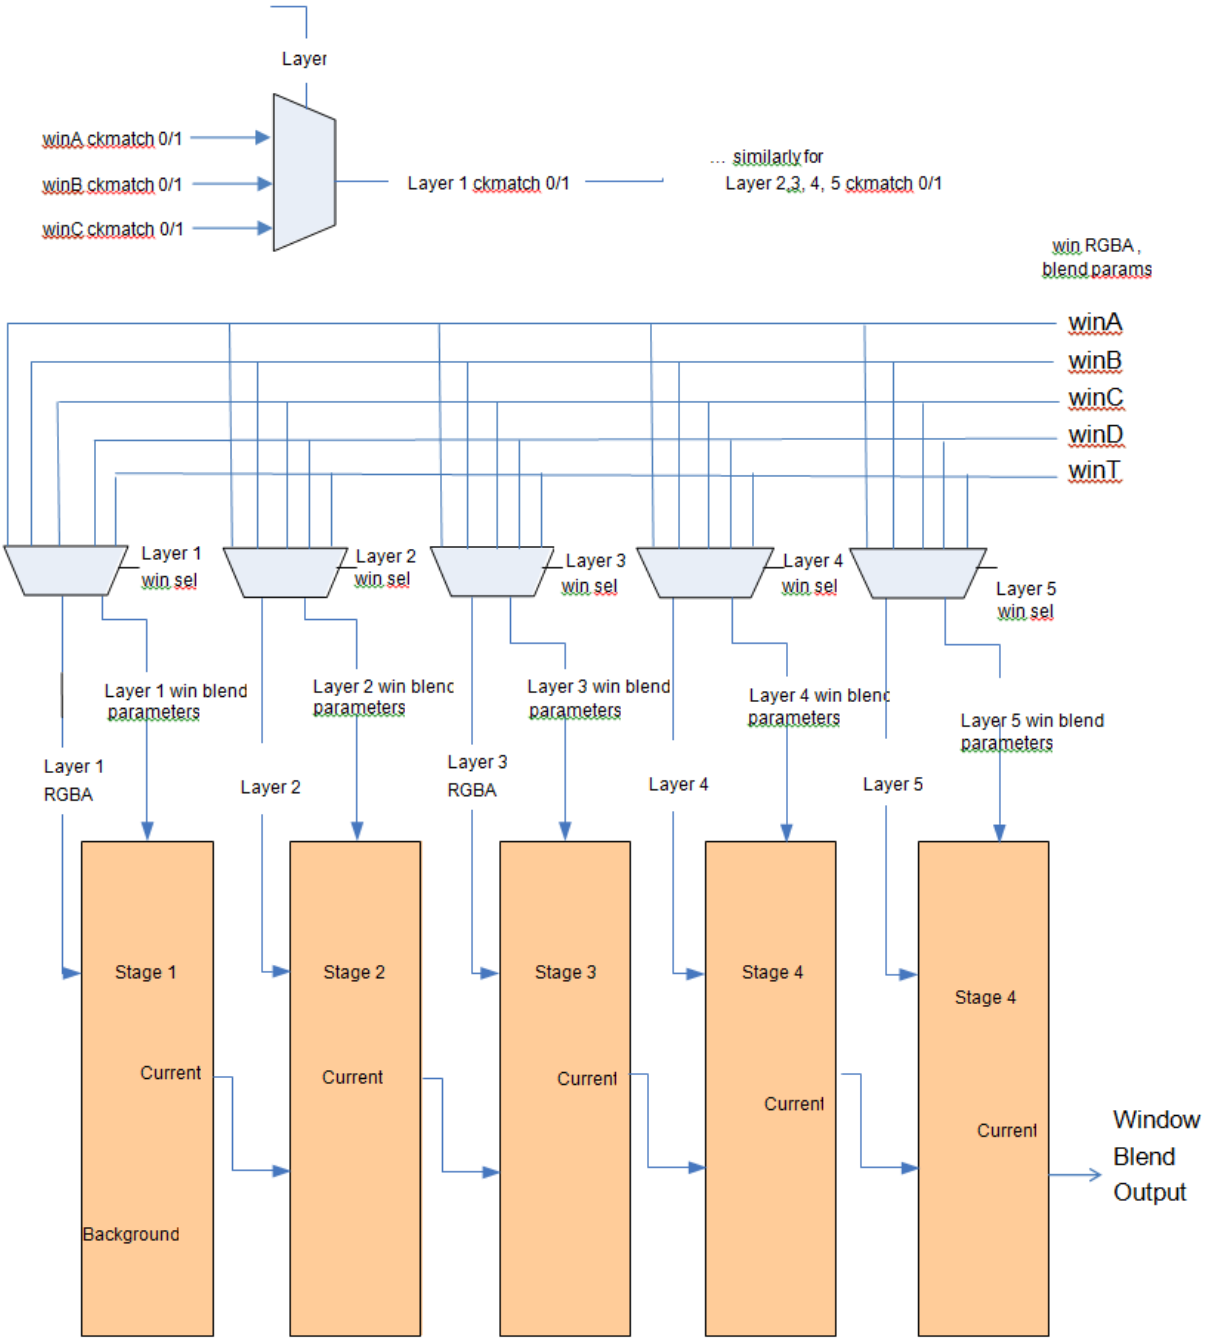

Figure 61: Tegra K1 Blender Cursor Stages

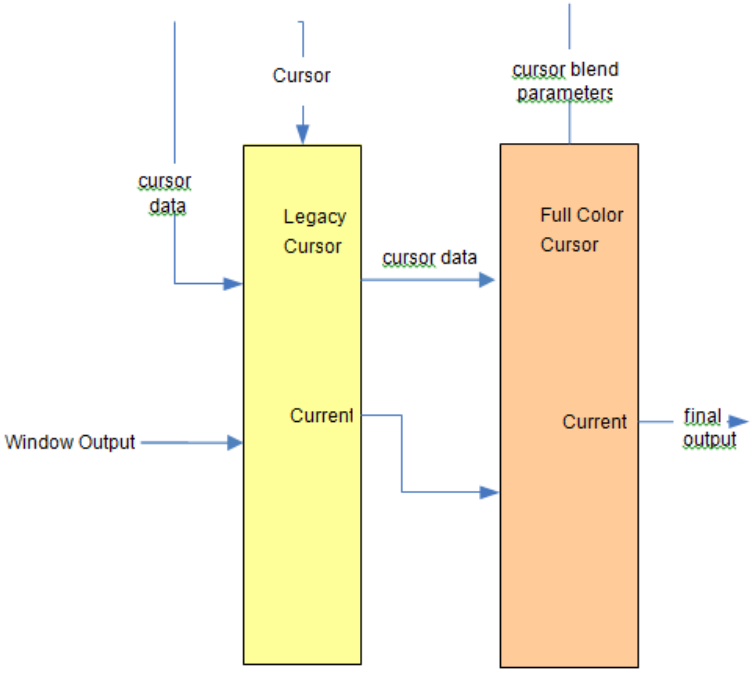


21.3.10.1 Blend Algorithm

Each blending stage requires:

- The current color from the previous stage (often called “Destination”)
- The surface color from the assigned window (often called “Source”)
- Window enable (that is, whether windows cover the current pixel)
- Blend parameters from the per-window registers

Each window has the following registers (where x is A, B, C, D, or T). The cursor settings are also described below.

```
windowx.Z  - an 8 bit z value
windowx.K1 - an 8 bit constant alpha value
windowx.K2 - an 8 bit constant alpha value
windowx.blend_bypass - a boolean

windowx.srcFactC_Match_Select - an enum with the following options:
            K1                      windowx.K1
            K1_TIMES_DST            windowx.K1*currentA
            NEG_K1_TIMES_DST        1 - (windowx.K1*currentA)
            K1_TIMES_SRC            windowx.K1*layerxA
            ZERO                    0

windowx.dstFactC_Match_Select - an enum with the following options:
            K1                      windowx.K1
            K2                      windowx.K2
            K1_TIMES_DST            windowx.K1*currentA
```

```
                NEG_K1_TIMES_DST        1 - (windowx.K1*currentA)
                NEG_K1_TIMES_SRC        1 - (windowx.K1*layerxA)
                ZERO                    0
                ONE                     1.0 (0xff)

    windowx.srcFactA_Match_Select - an enum with the following options:
                K1                      windowx.K2
                K2                      windowx.K2
                ZERO                    0

    windowx.dstFactA_Match_Select - an enum with the following options:
                K2                      windowx.K2
                ZERO                    0
                NEG_K1_TIMES_SRC        1 - (windowx.K1*layerxA)
                ONE                     1.0 (0xff)
```

Tegra K1 devices support color key; however, color key is not described in this document. The “Match” blend registers above apply to cases where color key is disabled as well as to cases where color key is enabled but the key color does not match. There is an additional set of “NoMatch” registers for the color key enabled but not matching cases.

The windows are sorted according to Z (Depth) value and assigned to blending stages 1 to 5. Cursor is layer 6. Each layerx (where x is 1 .. 6) operates as follows:

Inputs

```
    layerxRGBA - the RGBA color from the corresponding window pipeline
    windowx.* - window registers from window associated with this layer
    currentxRGBA - output from the preceding layer_blendx unit
```

Layer0 only needs the BackgroundColorRGBA (also known as Border Color) as input

Layer 6 (cursor) gets layerxRGBA from the cursor surface and gets windowx.* from special cursor.* registers as follows:

```
                windowx.key_Select = NONE
                windowx.K1 = cursor.K1
                windowx.K2 = cursor.K2
                windowx.dstFactC_Match_Select = cursor.dstFactC_Select
                windowx.srcFactC_Match_Select = cursor.srcFactC_Select
```

The following are “don’t cares” but can be set as shown:

```
                windowx.dstFactA_Match_Select   = K2
                windowx.srcFactA_Match_Select   = K2
```

Outputs

```
    outputRGBA – 32-bit blended RGBA color
```

Local State

```
    match - boolean
    dstFactC_Select - enum
    srcFactC_Select - enum
    dstFactA_Select - enum
    srcFactA_Select - enum
    dstFactC - 8 bit alpha value
    srcFactC - 8 bit alpha value
    dstFactA - 8 bit alpha value
    srcFactA - 8 bit alpha value
```

Operation

At each pixel of the output raster, the blending is performed. Only a subset of windows touch (cover) each pixel, because windows have an arbitrary size and position on the “desktop” raster.

layer_blend0 is trivial:

```
        outputRGBA = BackgroundColorRGBA
```

layer_blendx (where x is 1 through 5) does the following:

```
    - calculate fact??_Select:
        if [match] then
            srcFactC_Select = windowx.srcFactC_Match_Select
            dstFactC_Select = windowx.dstFactC_Match_Select
            srcFactA_Select = windowx.srcFactA_Match_Select
            dstFactA_Select = windowx.dstFactA_Match_Select
        else
            srcFactC_Select = windowx.srcFactC_NoMatch_Select
            dstFactC_Select = windowx.dstFactC_NoMatch_Select
            srcFactA_Select = windowx.srcFactA_NoMatch_Select
            dstFactA_Select = windowx.dstFactA_NoMatch_Select

    - calculate srcFactC:
        switch (srcFactC_Select) {
            case K1:                    srcFactC = windowx.K1
            case K1_TIMES_SRC:          srcFactC = windowx.K1*layerxA
            case K1_TIMES_DST:          srcFactC = windowx.K1*currentA
            case NEG_K1_TIMES_DST:      srcFactC = 1 - (windowx.K1*currentA)
            case ZERO:                  srcFactC = 0
            case ONE:                   srcFactC = 0
        }

    - calculate dstFactC:
        switch (dstFactC_Select) {
            case K1:                    dstFactC = windowx.K1
            case K2:                    dstFactC = windowx.K2
            case ZERO:                  dstFactC = 0
            case ONE:                   srcFactC = 0xff
            case K1_TIMES_DST:          dstFactC = windowx.K1*currentA
            case NEG_K1_TIMES_SRC:      dstFactC = 1 - (windowx.K1*layerxA)
            case NEG_K1_TIMES_DST:      dstFactC = 1 - (windowx.K1*currentA)
            case NEG_K1:                dstFactC = 1 - windowx.K1
        }

    - calculate srcFactA:
        switch (srcFactA_Select) {
            case K1:                    srcFactA = windowx.K1
            case K2:                    srcFactA = windowx.K2
            case ZERO:                  srcFactA = 0
        }

    - calculate dstFactA:
        switch (dstFactA_Select) {
            case K2:                    dstFactA = windowx.K2
            case ZERO:                  dstFactA = 0
            case ONE:                   dstFactA = 1
```

```
            case NEG_K1_TIMES_SRC:      dstFactA = 1 - (windowx.K1*layerxA)
        }
```

If the window or cursor for this layer does NOT touch this pixel, then:

```
            outputRGBA = currentRGBA
        else if windowx.blend_bypass is TRUE then
            outputRGBA = layerxRGBA
        else
            outputR = (srcFactC * layerxR) + (dstFactC * currentR)
            outputG = (srcFactC * layerxG) + (dstFactC * currentG)
            outputB = (srcFactC * layerxB) + (dstFactC * currentB)
            outputA = (srcFactA * layerxA) + (dstFactA * currentA)
```

Note: windowx.blend_bypass allows bypassing the entire blend operation and is intended to save power.

For the cursor layer, there is no need to calculate the following:

```
        outputA - not needed
        dstFactA - not needed
        srcFactA - not needed
```

Final Result

The outputRGB from layer_blend6 is the pixel value sent to the display.

21.3.10.2 Example Use Cases

The examples below assume 3 windows, not 5, for simplicity.

```
                Eye is looking down from here
                            i
                            ^
    layer 4                -----              cursor
    layer 3             -------               windowC
    layer 2                  ----------       windowB
    layer 1          ----------------------    windowA
    layer 0          ----------------------    background
```

Common Settings

If not mentioned in a use case, assume registers have the following values:

```
    BackgroundColorRGBA = background color

    key0.MinRGBA = (don't care)
    key0.MaxRGBA = (don't care)

    key1.MinRGBA = (don't care)
    key1.MaxRGBA = (don't care)

    windowA.Z  = 3
    windowB.Z  = 2
    windowC.Z  = 1

    window*.K1 = 0
    window*.K2 = 0
    window*.key_Select = NONE
    window*.dstFactC_Match_Select = K1
    window*.srcFactC_Match_Select = K1
```

```
    window*.dstFactC_NoMatch_Select = K1
    window*.srcFactC_NoMatch_Select = K1
    window*.dstFactA_Match_Select = K2
    window*.srcFactA_Match_Select = K2
    window*.dstFactA_NoMatch_Select = K2
    window*.srcFactA_NoMatch_Select = K2
```

If the cursor uses non-premultiplied alpha with fade factor F:

```
        cursor.K1 = F
        cursor.dstFactC_Select = NEG_K1_TIMES_SRC
        cursor.srcFactC_Select = K1_TIMES_SRC

        result = ((1.0-(F*cursorA)) * layer3RGB) + (F*cursorA * cursorRGB)
```

If the cursor uses premultiplied alpha with fade factor F:

```
        cursor.K1 = F
        cursor.dstFactC_Select = NEG_K1_TIMES_SRC
        cursor.srcFactC_Select = K1

        result = ((1.0-(F*cursorA)) * layer3RGB) + (F         * cursorRGB)
```

Below "use for fade" indicates that the value of windowx.K1 can be used to fade the window from invisible (transparent) at windowx.K1=0x00 to fully visible at windowx.K1=0xff.

Alpha Blend

```
   layer 4               -----              cursor
   layer 3           ccccccc                windowC non-premul
   layer 2                bbbbbbbbbb        windowB premul
   layer 1         aaaaaaaaaaaaaaaaaaaaa    windowA no alpha
   layer 0        gggggggggggggggggggggggg  background

   result         gaaaccccccbbbbbbbbaaaag
                        ^   ^ ^
                        |   | |
                        |   | +---- b blended with a
                        |   +------ c blended with (b blended with a)
                        +---------- c blended with a
```

Window A has RGB (alpha not used)

Window B has premultiplied alpha RGBA for blending with A

Window C has non-premultiplied alpha RGBA for blending with A and B

Blend Equations

```
layer0RGBA = BackgroundColorRGBA
layer1RGB  = windowA color
layer1A    = don't care
layer2RGB  =             windowB.RGB  +  (1.0 - windowB.A) * layer1RGB
layer2A    = don't care
layer3RGB  = windowC.A * windowC.RGB  +  (1.0 - windowC.A) * layer2RGB
layer3A    = don't care
layer4RGB  = blend with cursor
```

Register Settings

```
windowA.K1 = 0xff  (use for fade)
windowA.key_Select = NONE
windowA.srcFactC_Match_Select = K1
windowA.dstFactC_Match_Select = ZERO

windowB.K1 = 0xff  (use for fade)
windowB.key_Select = NONE
windowB.srcFactC_Match_Select = K1  (K1_TIMES_SRC for non-premul)
windowB.dstFactC_Match_Select = NEG_K1_TIMES_SRC

windowC.K1 = 0xff  (use for fade)
windowC.key_Select = NONE
windowC.srcFactC_Match_Select = K1_TIMES_SRC    (K1 for premul)
windowC.dstFactC_Match_Select = NEG_K1_TIMES_SRC
```

Note: Window B and window C can each be either premul or non-premul

Use windowx.K1 to fade the window (0=transparent, 0xff=opaque)

Opaque Layer with Fade

```
layer 4               -----             cursor
layer 3           ccccccc               windowC non-premul
layer 2                bbbbbbbbbb       windowB no alpha
layer 1        aaaaaaaaaaaaaaaaaaaaa    windowA no alpha
layer 0       gggggggggggggggggggggggg  background

result        gaaacccccccbbbbbbbbaaaag
                    ^   ^ ^
                    |   | |
                    |   | +---- b blended with a using L
                    |   +------ c blended with (b blended with a using L)
                    +---------- c blended with a
```

Same as case 1, but window B (or A or C or any combination) contains no alpha values (or garbage alpha values). There is a constant L which is used to fade the window.

Blend Equations

Note: "..." means "same as the last use case"

```
...
layer2RGB  = L * windowB.RGB  +  (1.0 - L) * layer1RGB
layer2A    = don't care
...
```

Register Settings

```
...
windowB.K1 = L
windowB.K2 = 1.0 - L
windowB.srcFactC_Match_Select = K1
windowB.dstFactC_Match_Select = K2
...
```

Window B's Alpha is in Window A

```
layer 4               -----             cursor
layer 3           ccccccc               windowC premul
layer 2                bbbbbbbbbb       windowB no alpha
layer 1        aaaaaaaaaaaaaaaaaaaaa    windowA alpha for blend w/ b
layer 0       gggggggggggggggggggggg    background

result        gaaacccccccbbbbbbbbaaaag
                    ^   ^ ^
                    |   | |
                    |   | +---- b blended with a using alpha from a
                    |   +------ c blended with (")
                    +---------- c blended with a
```

Same as case 1, but window B contains no alpha values (or garbage alpha values), and the alpha is needed for use from window A to blend window B with window A.

Blend Equations

```
layer0RGBA = BackgroundColorRGBA
layer1RGB  = windowA color
layer1A    = windowA alpha
layer2RGB  = windowA.A * windowB.RGB + (1.0 - windowA.A) * layer1RGB
layer2A    = don't care
layer3RGB  = windowC.RGB + (1.0 - windowC.A) * layer2RGB
layer3A    = don't care
layer4RGB  = blend with cursor
```

Register Settings

```
   windowA.K1 = 0xff  (use for fade)
   windowA.K2 = 0xff
   windowA.key_Select = NONE
   windowA.srcFactC_Match_Select = K1
   windowA.dstFactC_Match_Select = ZERO
   windowA.srcFactA_Match_Select = K2
   windowA.dstFactA_Match_Select = ZERO

   windowB.K1 = 0xff  (use for fade)
   windowB.key_Select = NONE
   windowB.srcFactC_Match_Select = NEG_K1_TIMES_DST
   windowB.dstFactC_Match_Select = K1_TIMES_DST

   windowC.K1 = 0xff  (use for fade)
   windowC.key_Select = NONE
   windowC.srcFactC_Match_Select = K1  (K1_TIMES_SRC for non-premul)
   windowC.dstFactC_Match_Select = NEG_K1_TIMES_SRC
```

There is no way to do this for B and C at the same time (unless they are known to not overlap).

If windowA.A is the opacity of window C, then use the following blend equation and register settings:

Blend Equation (windowA.A is the opacity of window C)

```
       layer2RGB  = (1.0 - windowA.A) * windowB.RGB  +  windowA.A * layer1RGB
```

Register Settings (windowA.A is the opacity of window C)

```
        windowB.srcFactC_Match_Select = NEG_K1_TIMES_DST
        windowB.dstFactC_Match_Select = K1_TIMES_DST
```

If windowA.A is the transparency of window C, then use the following blend equation and register settings:

Blend Equation (windowA.A is the transparency of window C)

```
        layer2RGB  = windowA.A * windowB.RGB  +  (1.0 - windowA.A) * layer1RGB
```

Register Settings (windowA.A is the transparency of window C)

```
        windowB.srcFactC_Match_Select = K1_TIMES_DST
        windowB.dstFactC_Match_Select = NEG_K1_TIMES_DST
```

The above assumes non-premul alpha. Premul alpha would not make sense in this case.

Window C's Alpha is in Window A

```
   layer 4               -----              cursor
   layer 3            ccccccc               windowC no alpha
   layer 2                 bbbbbbbbbb       windowB premul alpha
   layer 1         aaaaaaaaaaaaaaaaaaaaa    windowA alpha for blend w/ c
   layer 0        gggggggggggggggggggggggg  background

   result         gaaaccccccbbbbbbbbaaaag
                        ^   ^ ^
                        |   | |
                        |   | +---- b blended with a
                        |   +------ c blended with (") using alpha from a
                        +---------- c blended with a using alpha from a
```

Same as case 1, but window C contains no alpha values (or garbage alpha values), and the alpha is needed for use from window A to blend window C with window A and window B.

Blend Equations

```
layer0RGBA = BackgroundColorRGBA
layer1RGB  = windowA color
layer1A    = windowA alpha
layer2RGB  = windowB.RGB              +  (1.0 - windowB.A) * layer1RGB
layer2A    = don't care
layer3RGB  = windowA.A * windowC.RGB  +  (1.0 - windowA.A) * layer2RGB
layer3A    = don't care
layer4RGB  = blend with cursor
```

Register Settings

```
    windowA.K1 = 0xff  (use for fade)
    windowA.K2 = 0xff
    windowA.key_Select = NONE
    windowA.srcFactC_Match_Select = K1
    windowA.dstFactC_Match_Select = ZERO
    windowA.srcFactA_Match_Select = K2
    windowA.dstFactA_Match_Select = ZERO

    windowB.K1 = 0xff  (use for fade)
    windowA.K2 = 0xff
```

```
    windowB.key_Select = NONE
    windowB.srcFactC_Match_Select = K1   (K1_TIMES_SRC for non-premul)
    windowB.dstFactC_Match_Select = NEG_K1_TIMES_SRC
    windowB.srcFactA_Match_Select = ZERO
    windowB.dstFactA_Match_Select = K2

    windowC.K1 = 0xff  (use for fade)
    windowC.key_Select = NONE
    windowC.srcFactC_Match_Select = NEG_K1_TIMES_DST
    windowC.dstFactC_Match_Select = K1_TIMES_DST
```

21.3.11 PRISM 3

This section describes the enhancements to PRISM 3. PRISM 3 was formerly known as Smart Dimmer, and so the abbreviation SD is commonly used in register names for PRISM 3.

Features added:

- Programmable statistics window
- Separate crush/adaptation
- Programmable soft clipping
- Increase pixel count limits
- LUT/CSC after enhancement

21.3.11.1 Programmable Statistics Window

This feature allows statistics to be gathered over a subset of the active display. It is useful when part of the display is not interesting for PRISM 3 statistics purposes, such as letterbox or border around a video. Without this feature, the border would influence the histogram and therefore the brightness, giving suboptimal results for the video.

The programming interface is a control bit SD_WINDOW_ENABLE in SD_CONTROL register to enable the feature, and two registers containing position and size of the window. When SD_CONTROL == DISABLE (the default), the position/size registers are ignored, and the entire active display region is used, like in Tegra 3.

The coordinate system is relative to display active area – (0,0) is upper left corner of display active. The active region will have upper left corner (H_POSITION, V_POSITION), and lower right corner (H_POSITION + SD_WIN_H_SIZE – 1, V_POSITION + V_SIZE – 1) inclusive. Note this display coordinate system does not take into account surface rotation or device rotation. It is the same coordinate system use by window position (e.g., B_H_POSITION, B_V_POSITION).

The limitation on minimum pixel count of 2^16 must be obeyed.

The programmable window has no direct effect on enhancement – every pixel of display active area is enhanced.

21.3.11.2 Separate Crush/Adaptation

As in Tegra 3, the AGGRESSIVENESS register controlled both the maximum crushed pixel percentage, and the lowest K (maximum gain). This feature separates them and allows software to separately control lowest K (maximum gain). AGGRESSIVENESS continues to control the maximum crushed pixel percentage.

The programming interface is a control bit K_LIMIT_ENABLE, and a register SD_K_LIMIT.

As in Tegra 3, the initial K (as determined by accumulating histogram bins until maximum crush pixel percentage is reached). When K_LIMIT_ENABLE=ENABLE, the initial K is clamped to SD_K_LIMIT rather than default “lowest_K”. When K_LIMIT_ENABLE = DISABLE (the default), SD_K_LIMIT register is ignored and the default “lowest_L” are used based on AGRESSIVENESS.

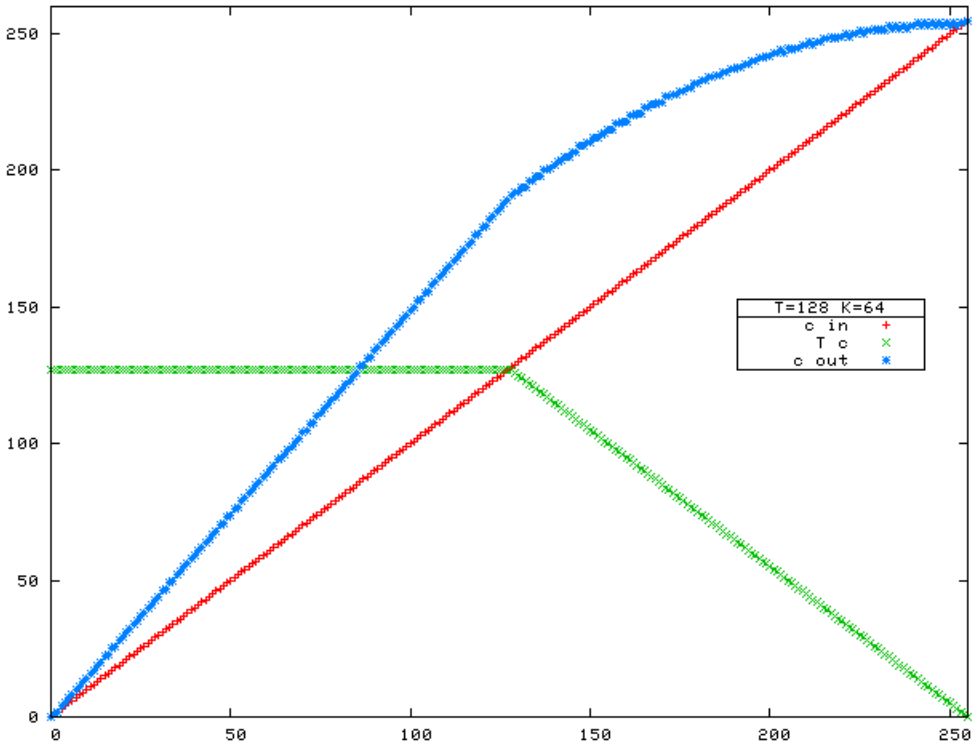
21.3.11.3 Programmable Soft Clipping

In PRISM 3 enhancement, soft clipping is employed to avoid harsh clipping of amplified high-value pixels, and resulting loss of detail in bright areas. The gain applied to high-valued pixels is reduced gradually from 1/K to 1.0, for pixels above a threshold of 128. In Tegra K1 devices, the threshold is fixed at 128, and soft clipping is always enabled. This feature gives more software control.

Since soft clipping is performed after statistics, and it affects the brightness of the image, the statistics and therefore the backlight brightness will be incorrect. This can somewhat compensated for in the backlight transfer-function and/or enhancement value lookup tables.

The Tegra K1 transfer function is shown here, for K=1.5. The T_c plot is the weight applied to fractional portion of K, and goes from 127 to 0, representing 1 to 0.

Figure 62: Default Threshold=128 at K=1.5



With programmable thresholds, other curves are possible. For example, Figure 63 and Figure 64 show more gradual curves using threshold=64 and 0 respectively.

Figure 63: Threshold=64 at K=1.5

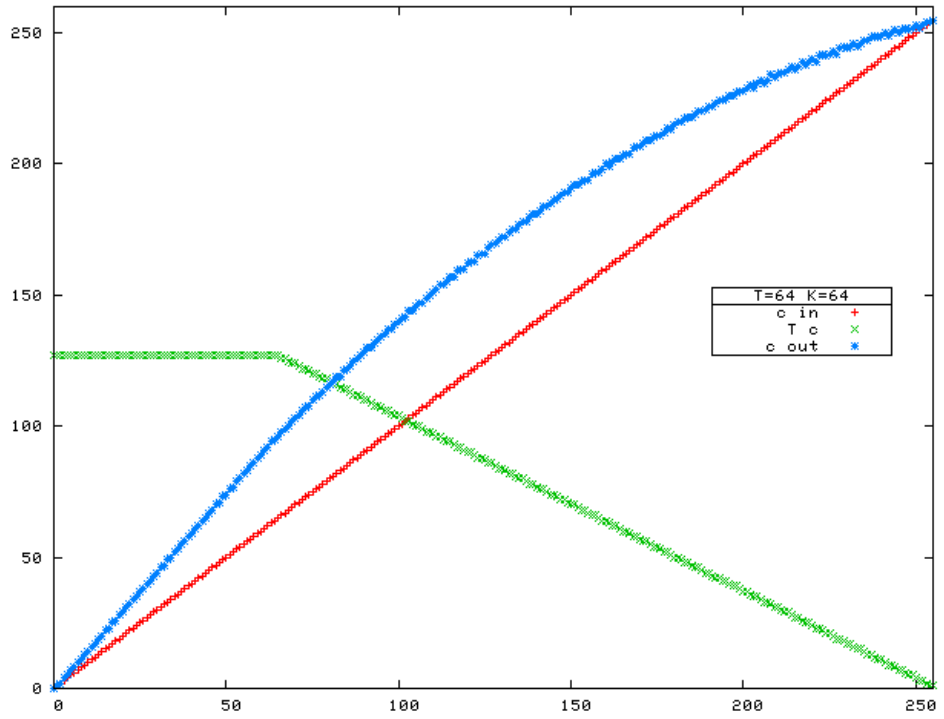


Figure 64: Threshold 0 at K=1.5

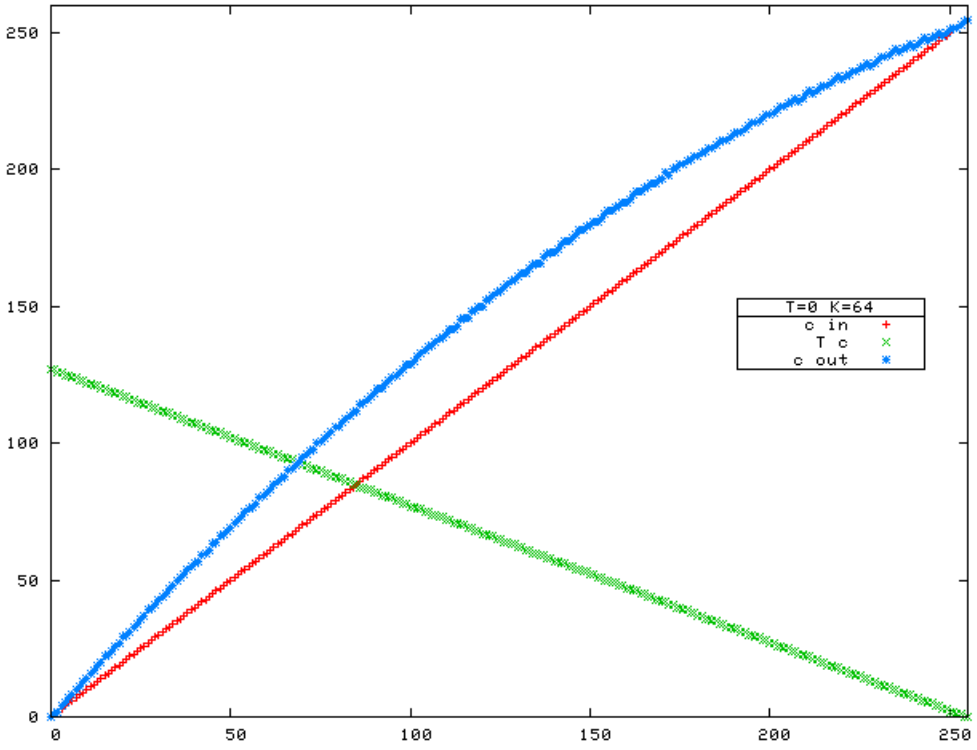

Thresholds too high are not usable, because the soft clipping does not kick in early enough to prevent clipping as K grows; note in Figure 65 (threshold 170 at K=1.5) the value of c_out rises about 255. The curve is also not monotonically increasing. Software would need to reduce maximum K to 1.25 or so for such a threshold. Figure 66 shows threshold of 170 with K = 1.25.

Figure 65: Overflowing at Threshold=170 at K=1.5

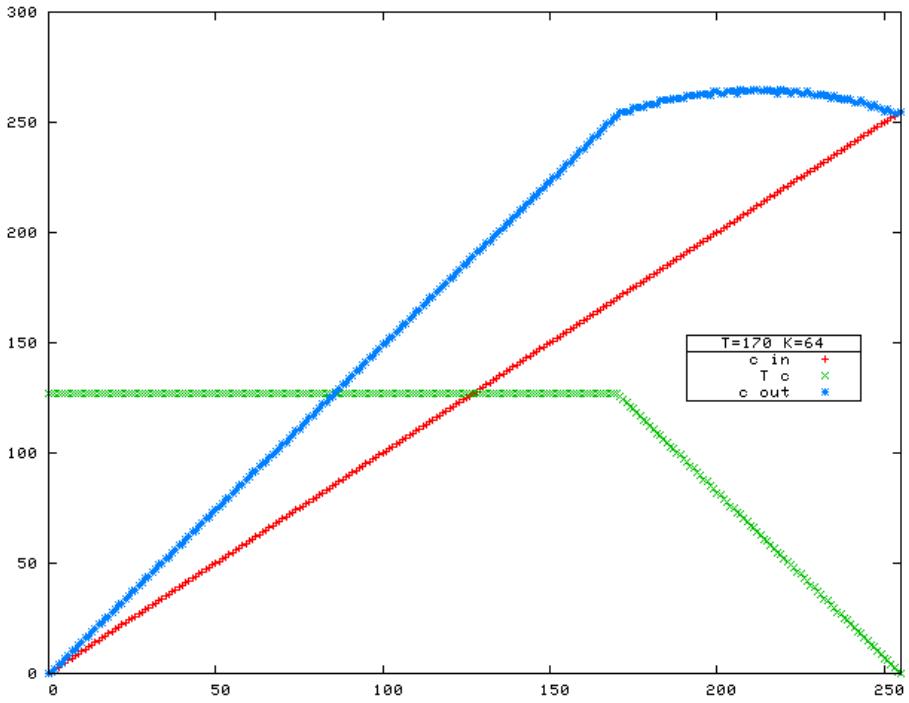

Figure 66: Threshold 170 at K=1.25

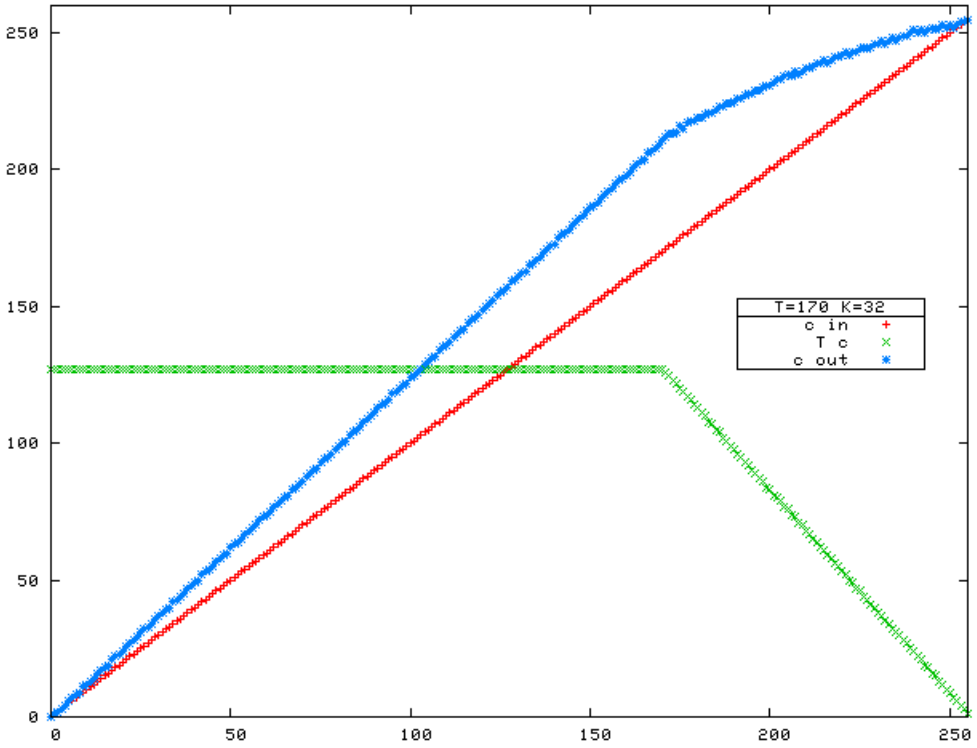


The programming interface consists of a control bit SOFT_CLIPPING_ENABLE and one register SD_SOFT_CLIPPING. The latter contains both the threshold and a software-computed reciprocal of inverse threshold. The software-computed reciprocal avoids the need to perform division in hardware. RECIP is computed as 64*1024 * 1.0 / (256 – threshold), truncated to 16-bit unsigned integer. Internally, the hardware may use fewer than 16 bits as described below.

When SOFT_CLIPPING_ENABLE=DISABLE, then SD_SOFT_CLIPPING is ignored and no clipping is done.

When SOFT_CLIPPING_ENABLE=ENABLE, SD_SOFT_CLIPPING is used. At the default values of SD_SOFT_CLIPPING, it behaves like Tegra 3.

The soft clipping equation performed in hardware, per component, is

```
If SD_CONTROL.SOFT_CLIPPING_ENABLE==ENABLE and c_in >= threshold:
        T_c = 0x7f - (((c_in - threshold) * (recip >> 2)) >> 7);
Else
        T_c = 0x7f
```

Where recip is the programmed SOFT_CLIPPING_RECIP; it is shifted right 2 bits to yield a 14-bit value. T_c is a 7-bit weight. The shift by 7 represents discarding 6 bits from recip plus one to give a 7-bit rather than 8-bit result. As before, T_c is used to scale the fractional portion of K:

```
c_k_limited = (K_c * T_c) >> 7;
```

and then apply the fractional gain to the component:

```
c_mul = (c_in * c_k_limited) >> 7;
```

and finally add the integer portion of gain (which is always 1, i.e., 1 * c_in = c_in):

```
c_out = c_in + c_mul
```

21.3.11.4 Increase Pixel Count Limits

Displays are trending to 2560x1600 and larger panels. PRISM 3 needs to support at least 2^{23} pixels. For simplification, the minimum screen size of 2^{16} is retained. Therefore the pixel count dynamic range increases from 32:1 to 128:1. The total_pixels and histogram accumulator counters must support that range. Also, the histogram normalization must support an expanded range of exponents and shifting (0-7 rather than 0-5).

The SD_HISTOGRAM bins need not expand because they contain normalized pixel percentages, not raw counts.

The programming model does not change. SD_PIXEL_COUNT already accommodates this range.

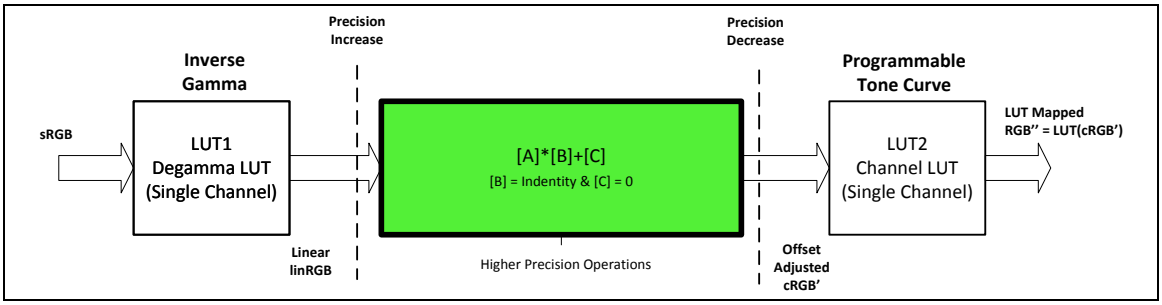
21.3.12 Display Color Management Unit (LUT/CSC)

This unit adds an additional LUT -> CSC -> LUT after the PRISM unit to enable gamma and color gamut change. While this feature is independent from PRISM, and more generally useful, it helps PRISM 3 accommodate non-standard (non-sRGB) panels. It also helps convert from the display's native gamma and gamut (de facto of sRGB) into panels.

- First stage – LUT1 – is an 8-bit to 12-bit RAM-based look-up table (LUT) to convert gamma from sRGB 2.2 to linear (1.0). The output is 8.4 unsigned fixed-point format. A single LUT may be used for all 3 channels.
- Second stage – CSC – is 3x3 matrix multiply, to convert color gamut / whitepoint. 12 bits unsigned in, and 12 bits unsigned out. Its nine coefficients are 10-bit (S1.8 signed).
- Third stage – LUT2 – is a 12-bit to 8-bit LUT to convert from linear gamma to sRGB or similar gamma (for example, 1 / 2.2). A single LUT may be used for all 3 channels.

> **Note:** The window datapaths have subunits called LUT (CP) and CSC already, but they are for different purposes. The CP is for converting linear framebuffer data into sRGB, or for color index modes, or for applying aesthetic changes like contrast. CSC is for converting YCbCr into RGB. They are for normalizing all surfaces into a common format, nominally sRGB, for blending.

Figure 67: Color Management Unit



21.3.12.1 CMU LUT1

LUT1 maps 8-bit gamma-corrected input to 12-bit linear output. A single LUT may be used for all 3 RGB channels – per-channel control is not required.

```
R′ = LUT1[R]
G′ = LUT1[G]
B′ = LUT1[B]
```

21.3.12.2 CSC Matrix

The CSC equation is:

$$\begin{bmatrix} KRR & KGR & KBR \\ KRG & KGG & KBG \\ KRB & KGB & KBB \end{bmatrix} * \begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} R' \\ G' \\ B' \end{bmatrix}$$

21.3.12.3 CMU LUT2

LUT2 maps 12-bit linear input to 8-bit gamma corrected output. A single LUT may be used for all 3 RGB channels – per-channel control is not required. LUT2 is only 960 rows deep, and divided unevenly so that precision is variable; greater precision (more entries) are allocated to darker values. The first 512 entries 0..511, representing range [0.0, 32.0), are darker values, and are mapped with full 9-bit precision (5.4). The top 448 entries are for lower-precision brighter range [32, 256); they are reduced from 8.4 to 8.1 and offset so that values [32,256) map to 512..959 rather than 576..1023.

```
R’ = LUT2[zone_select(R)]
G’ = LUT2[zone_select(G)]
B’ = LUT2[zone_select(B)]
```

The zone_select function maps a 12-bit component value to 10-bit RAM index, with variable precision:

If C >= THRESHOLD:

C’ = (C >> PRECISION_DIFF) + THRESHOLD – OVERLAP

Else:

C’ = C[9:0]

Where THRESHOLD=2^9 = 512, PRECISION_DIFF = 12 – 9 = 3, and OVERLAP = THRESHOLD >> PRECISION_DIFF = 512 >> 3 = 64.

Software would use an inverse_zone_select to initialize the LUT2.

21.3.12.4 Programming Interface

The CMU LUTs and CSC registers are single-buffered; shadow update and activation have no effect. However, the CMU_ENABLE bit is double-buffered, so it can be enabled/disabled at frame boundaries.

Host interface writes and reads take precedence over the datapath and may result in visible glitches. Software is responsible for ensuring the datapath is idle before writing or reading. An interrupt will be raised upon a conflict. The LUTs are guaranteed to be idle during blanking and when CMU_ENABLE=DISABLE. Software must explicitly enable reading, and reading is only performed for debugging reasons.

Note:	**When reading LUTs:** due to internal RAM latency, after changing read-enable or read address, data is not available until two clocks later. Best way to ensure this is to issue two back-to-back writes of same read address, as shown in read sequence.

Software initialization sequence:

```
Insure CMU_ENABLE=DISABLE or display idle
For C = 0 .. 255:
       C’ = ungamma_function(C/255) * 4095
       CMU_LUT1.LUT1_ADDR = C
       CMU_LUT1.LUT1_DATA = C’
       Write CMU_LUT1
For C = 0 .. 1023: # assume 10-bit
       C’ = gamma_function(inverse_zone_select(C)/4095) * 255
       CMU_LUT2.LUT1_ADDR = C
       CMU_LUT2.LUT1_DATA = C’
       Write CMU_LUT2
Write DISP_COLOR_CONTROL.CMU_ENABLE = ENABLE
Use GENERAL_ACT_REQ
```

Where typically functions are: ungamma_function(x) = $x^{2.2}$, and gamma_function(x) = $x^{1/2.2}$.

LUT read sequence:

```
Insure CMU_ENABLE=DISABLE or display idle
For C = 0 .. 255:
       CMU_LUT1_READ.LUT1_READ_EN = 1
       CMU_LUT1_READ.LUT1_READ_ADDR = C
       Write CMU_LUT1_READ
       Write CMU_LUT1_READ # ensure one cycle delay
       Read CMU_LUT1.LUT1_DATA
Write CMU_LUT1_READ.LUT1_READ_EN = 0
```

21.3.12.5 LUT Conflict Interrupt

To help debug conflicts caused by accessing LUTs while datapath is using them, CMU_LUT_CONFLICT interrupt is raised if:

- host write during scanout (pixel read when cmu_enable=1)
- host read during scanout
- host write during host read (i.e; LUT1_READ_EN=1)

21.3.13 Dither

Temporal dither replaces error diffusion and does not use line buffers.

21.3.14 Output RGB-to-YUV444 CSC

The Tegra K1 display outputs one of three color spaces:

- Red, Green, Blue color primaries.
- YCbCr 4:4:4 Luminance and color difference signals as defined by ITU-R BT.601
- YCbCr 4:4:4 Luminance and color difference signals as defined by ITU-R BT.709

YCbCr color space operates only on limited RGB color space of RGB[16, 235]. HDMI requires YCbCr support of limited color space and optionally extended color space. HDMI also allows for direct RGB limited color space input (that is, RGB[16, 235]). The Tegra K1 Display allows limitation of RGB color space automatically by placing hardcoded full to limited color space scaler unit prior to CSC. This allows for support of the following output formats to HDMI:

- RGB[0, 255]
- RGB[16, 235]
- BT.601 YCbCr 4:4:4 (converted from RGB[16, 235])
- BT.709 YCbCr 4:4:4 (converted from RGB[16, 235])

21.4 Programming Model

21.4.1 Software Alignment Requirements

For Tegra K1 devices, the pixel data alignment restriction is 64B boundaries. The table below describes what registers are affected.

Parameter	Register name	Pitch(packed) 1/2/4 Bpp	Pitch(Planar) 1 Bpp per surface	Block Linear (packed) 1/2/4 Bpp	Block Linear (planar) 1 Bpp per surface
line_stride	B_LINE_STRIDE	64	64	64	64
h_prescale_size	B_H_PRESCALED_SIZE	Bpp	Even	Bpp	Even
v_prescale_size	B_V_PRESCALED_SIZE	NA	Even for 420	NA	Even for 420
h_offset	B_ADDR_H_OFFSET	Bpp	Even	Bpp	Even

Parameter	Register name	Pitch(packed) 1/2/4 Bpp	Pitch(Planar) 1 Bpp per surface	Block Linear (packed) 1/2/4 Bpp	Block Linear (planar) 1 Bpp per surface
v_offset	B_ADDR_V_OFFSET	NA	Even for 420	NA	Even for 420
Startaddr	B_START_ADDR	64	64	512	512

Due to fetch size expanding to 64B, Y lines in planar/semi-planar must be fetched in multiples of 8 for 420, 422, 422R formats.

21.5 Display Controller Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

The display memory map is shown below.

21.5.1 Address Map

Space Name	Offset	Notes
DC_CMD	0x0	Non-shadowed command/sync registers
DC_D_WIN	0x80	Window D instance of DC_WIN
DC_D_WINBUF	0xc0	Window D instance of DC_WINBUF
DC_T_WIN	0x100	Window T instance of DC_WIN
DC_T_WINBUF	0x140	Window T instance of DC_WINBUF
DC_COM	0x300	Non-shadowed non-window registers
DC_DISP	0x400	Shadowed non-window registers
DC_WINC	0x500	Non-shadowed indirect window registers: indirect alias; windows A/B/C; use DISPLAY_WINDOW_HEADER
DC_WIN	0x700	Shadowed indirect window register: indirect alias; windows A/B/C/D; use DISPLAY_WINDOW_HEADER
DC_WINBUF	0x800	Triple-buffered indirect window registers: indirect alias; windows A/B/C/D; use DISPLAY_WINDOW_HEADER
DC_A_WINC	0xa00	Window A instance for DC_WINC
DC_A_WIN	0xb80	Window A instance for DC_WIN
DC_A_WINBUF	0xbc0	Window A instance for DC_WINBUF
DC_B_WINC	0xc00	Window B instance for DC_WINC
DC_B_WIN	0xd80	Window B instance for DC_WIN
DC_B_WINBUF	0xdc0	Window B instance for DC_WINBUF
DC_C_WINC	0xe00	Window C instance for DC_WINC
DC_C_WIN	0xf80	Window C instance for DC_WIN
DC_C_WINBUF	0xfc0	Window C instance for DC_WINBUF
DC_D_WINC	0x1000	Window D instance of DC_WINC (RESERVED)
DC_T_WINC	0x1200	Window T instance of DC_WINC (RESERVED)

21.5.2 New Registers for Tegra K1 Devices

The following registers are new or changed for Tegra K1 devices.

Register	Field	Description
Memfetch registers – Note: Memfetch registers are PER WINDOW		
B_ADDR_H_OFFSET	B_ADDR_H_OFFSET	Horizontal address offset. This is a byte address. It needs to be aligned to Bpp (bytes per pixel). For planar/semi-planar formats, it is the offset of Y surface.
B_ADDR_V_OFFSET	B_ADDR_V_OFFSET	Vertical address offset. For planar/semi-planar surfaces, it is the offset of Y surface. It needs to be even for 420 formats.
B_COLOR_DEPTH	B_COLOR_DEPTH	Supported color formats are described in “Surface/Color Formats”.
B_WIN_OPTIONS	B_H_DIRECTION	Horizontal drawing direction.
	B_V_DIRECTION	Vertical drawing direction.
	B_H_FILTER_ENABLE	Enable for horizontal filter.
	B_V_FILTER_ENABLE	Enable for vertical filter.
	B_V_FILTER_OPTIMIZE	Optimize vertical filter to reduce bandwidth.
	B_V_FILTER_UV_ALIGN	Align UV for vertical filter. When UV alignment is enabled, the chroma components are aligned to the even number of luma component lines. When disabled the chroma components are aligned to half a pixel below the corresponding even number of luma component lines. It is usually disabled unless the incoming video stream specifically indicates otherwise.
	B_CP_ENABLE	Enable for color palette.
	B_CSC_ENABLE	Enable for color space converter.
	B_DV_ENABLE	Enable for digital vibrance.
	B_YUV_RANGE_EXPAND	Enable range expansion for YUV.
	B_WIN_ENABLE	Window enable.
	B_H_FILTER_MODE	Horizontal filter mode.
	B_SCAN_COLUMN	Load memory columns into display line buffer.
	B_INTERLACE_ENABLE	Interlace Enable

Register	Field	Description
B_H_INITIAL_DDA	B_H_INITIAL_DDA	H initial DDA
B_V_INITIAL_DDA	B_V_INITIAL_DDA	V initial DDA
B_PRESCALED_SIZE	B_H_PRESCALED_SIZE	The H pre-scaled size is needed to determine how many bytes to fetch from memory per line. It is in terms of bytes. It needs to be aligned to bytes per pixel. For planar/semi-planar surfaces, this parameter refers to pre-scale size of Y plane.
	B_V_PRESCALED_SIZE	The V pre-scaled size is needed to determine how many lines to fetch from memory.For planar/semi-planar surfaces, this parameter refers to pre-scale size of Y plane. It needs to be even for 420 formats.
B_LINE_STRIDE	B_LINE_STRIDE	Line stride. It needs to be aligned to 64B
	B_UV_LINE_STRIDE	Line stride for u/v surface
B_START_ADDR	B_START_ADDR	Lower 32 bits of the starting address of the surface. It is aligned to 256B. For planar/semi-planar surfaces, it points to Y surface.
B_START_ADDR_NS	B_START_ADDR_NS	Lower 32 bits of the starting address of the surface. It is aligned to 256B. For planar/semi-planar surfaces, it points to Y surface.
B_START_ADDR_U	B_START_ADDR_U	Lower 32 bits of the starting address of the U surface. It is aligned to 256B. For semi-planar surfaces, it points to UV surface
B_START_ADDR_U_NS	B_START_ADDR_U_NS	Lower 32 bits of the starting address of the U surface. It is aligned to 256B. For semi-planar surfaces, it points to UV surface
B_START_ADDR_V	B_START_ADDR_V	Lower 32 bits of the starting address of the V surface. It is aligned to 256B.
B_START_ADDR_V_NS	B_START_ADDR_V_NS	Lower 32 bits of the starting address of the V surface. It is aligned to 256B.
B_START_ADDR_HI	B_START_ADDR_HI	Higher 32 bits of the starting address of the surface. It is aligned to 256B. For planar/semi-planar surfaces, it points to Y surface.
B_START_ADDR_HI_NS	B_START_ADDR_HI_NS	Higher 32 bits of the starting address of the surface. It is aligned to 256B. For planar/semi-planar surfaces, it points to Y surface.
B_START_ADDR_U_HI	B_START_ADDR_U_HI	Higher 32 bits of the starting address of the U surface. It is aligned to 256B. For semi-planar surfaces, it points to UV surface
B_START_ADDR_U_HI_NS	B_START_ADDR_U_HI_NS	Higher 32 bits of the starting address of the U surface. It is aligned to 256B. For semi-planar surfaces, it points to UV surface

Register	Field	Description
B_START_ADDR_V_HI	B_START_ADDR_V_HI	Higher 32 bits of the starting address of the V surface. It is aligned to 256B.
B_START_ADDR_V_HI_NS	B_START_ADDR_V_HI_NS	Higher 32 bits of the starting address of the V surface. It is aligned to 256B.
B_START_ADDR_FIELD2	B_START_ADDR_FIELD2	Lower 32 bits of the starting address of the surface. It is aligned to 256B. For planar/semi-planar surfaces, it points to Y surface.
B_START_ADDR_FIELD2_NS	B_START_ADDR_FIELD2_NS	Lower 32 bits of the starting address of the surface. It is aligned to 256B. For planar/semi-planar surfaces, it points to Y surface.
B_START_ADDR_U_FIELD2	B_START_ADDR_U_FIELD2	Lower 32 bits of the starting address of the U surface. It is aligned to 256B. For semi-planar surfaces, it points to UV surface
B_START_ADDR_U_FIELD2_NS	B_START_ADDR_U_FIELD2_NS	Lower 32 bits of the starting address of the U surface. It is aligned to 256B. For semi-planar surfaces, it points to UV surface
B_START_ADDR_V_FIELD2	B_START_ADDR_V_FIELD2	Lower 32 bits of the starting address of the V surface. It is aligned to 256B.
B_START_ADDR_V_FIELD2_NS	B_START_ADDR_V_FIELD2_NS	Lower 32 bits of the starting address of the V surface. It is aligned to 256B.
B_START_ADDR_HI_FIELD2	B_START_ADDR_HI_FIELD2	Higher 32 bits of the starting address of the surface. It is aligned to 256B. For planar/semi-planar surfaces, it points to Y surface.
B_START_ADDR_HI_FIELD2_NS	B_START_ADDR_HI_FIELD2_NS	Higher 32 bits of the starting address of the surface. It is aligned to 256B. For planar/semi-planar surfaces, it points to Y surface.
B_START_ADDR_U_HI_FIELD2	B_START_ADDR_U_HI_FIELD2	Higher 32 bits of the starting address of the U surface. It is aligned to 256B. For semi-planar surfaces, it points to UV surface
B_START_ADDR_U_HI_FIELD2_NS	B_START_ADDR_U_HI_FIELD2_NS	Higher 32 bits of the starting address of the U surface. It is aligned to 256B. For semi-planar surfaces, it points to UV surface
B_START_ADDR_V_HI_FIELD2	B_START_ADDR_V_HI_FIELD2	Higher 32 bits of the starting address of the V surface. It is aligned to 256B.
B_START_ADDR_V_HI_FIELD2_NS	B_START_ADDR_V_HI_FIELD2_NS	Higher 32 bits of the starting address of the V surface. It is aligned to 256B.
B_DDA_INCREMENT	B_V_DDA_INCREMENT	DDA increment is typically calculated by dividing (Pre-scaled size in pixels - 1) by (Post-scaled size in pixels - 1). The result should be rounded up and expressed as 4.12 format (4-bit integer and 12-bit fraction).
B_SIZE	B_V_SIZE	V size after scaling

Register	Field	Description
B_SURFACE_KIND	B_SURFACE_KIND	Surface kinds supported by Tegra K1 device. enum (PITCH, BL_16B2)
	B_BLOCK_HEIGHT	Height of block in GOBs. enum (HEIGHT_1, HEIGHT_2, HEIGHT_4, HEIGHT_8, HEIGHT_16, HEIGHT_32)
B_SURFACE_WEIGHT	B_SURFACE_WEIGHT_OVERRIDE	Override the default weights of the arbiter in display. 0 – disable, 1 - enable
	B_SURFACE_WEIGHT_Y	Surface weight of Y surface
	B_SURFACE_WEIGHT_U	Surface weight of U surface
	B_SURFACE_WEIGHT_V	Surface weight of V surface
B_UFLOW_STATUS	UFLOW_COUNT	Underflow count. This field indicates the number of contiguous groups of output pixels for which there was no data in the FIFO. For example, if the valid from the FIFO is low for 10 consecutive cycles and then goes high, the counter will increment by one. Reset to zero on write.
	COUNT_OFLOW	Flag bit that indicates that the underflow event counter has overflowed. There were too many events. If COUNT_OFLOW is set, UFLOW_COUNT is meaningless. Cleared on write.
B_LINE_FLIP_DELAY	B_LINE_FLIP_DELAY	Delay (in scan-line-times) between when a hsync happens and when the SYNCPT is incremented for the new LINE_FLIPPED condition.
B_UFLOW_CTRL	B_UFLOW_CTRL_DBG_MODE	When the underflow debug mode is enabled. Instead of sending out the last valid pixel, DBG_PIXEL is sent out.
B_UFLOW_DBG_PIXEL	B_UFLOW_DBG_PIXEL	32-bit debug pixel color.
B_UFLOW_THRESHOLD	B_UFLOW_THRESHOLD	Number of lines to skip when underflow continues to the point where display (XY) is greater than display memfetch request (XY)
B_H_FILTER_HI_P00-F	B_H_FILTER_HI_P0FC0-5	Horizontal Filter phase extended bits.
Color Key registers PER DISPLAY CONTROLLER		
COLOR_KEY0/1_LOWER. R/G/B/A	Key0/1.MinRGBA	RGBA or UYVA lower (32-bpp)
COLOR_KEY0/1_UPPER. R/G/B/A	Key0/1.MaxRGBA	RGBA or UYVA upper (32-bpp)
BACKGROUND_COLOR.R/G/B/A	Background Color.RGBA	RGBA or UYVA (32-bpp)

Register	Field	Description
Cursor registers – Note: Cursor registers are PER DISPLAY CONTROLLER		
CURSOR_START_ADDR	CURSOR_SIZE	Extend enums to: 32x32 64x64 128x128 256x256
Blend registers – Note: Blending registers are PER WINDOW		
Z	BLEND_DEPTH	8-bit depth
K1	BLEND_ALPHA1	8-bit alpha
K2	BLEND_ALPHA2	8-bit alpha
BYPASS	BLEND_BYPASS	boolean
KEY_SELECT	COLOR_KEY_SELECT	3-bit enum: NONE WINDOWA_KEY0 WINDOWA_KEY1 WINDOWB_KEY0 WINDOWB_KEY1 WINDOWC_KEY0 WINDOWC_KEY1
SRCFACTC_MATCH_SELECT	BLEND_MATCH. SRC_FACT_C_SEL	3-bit enum: K1 K1_TIMES_DST NEG_K1_TIMES_DST K1_TIMES_SRC ZERO ONE
DSTFACTC_MATCH_SELECT	BLEND_MATCH. DST_FACT_C_SEL	3-bit enum: K1 K2 K1_TIMES_DST NEG_K1_TIMES_DST NEG_K1_TIMES_SRC NEG_K1 ZERO ONE
SRCFACTA_MATCH_SELECT	BLEND_MATCH. SRC_FACT_A_SEL	3-bit enum: K1 K2 ZERO
DSTFACTA_MATCH_SELECT	BLEND_MATCH. DST_FACT_A_SEL	3-bit enum: K2 ZERO NEG_K1_TIMES_SRC ONE
SRCFACTC_NOMATCH_SELECT	BLEND_NOMATCH. SRC_FACT_C_SEL	3-bit enum: same enums as SRCFACTC_MATCH_SELECT

Register	Field	Description
DSTFACTC_NOMATCH_SELECT	BLEND_NOMATCH. DST_FACT_C_SEL	3-bit enum: same enums as DSTFACTC_MATCH_SELECT
SRCFACTA_NOMATCH_SELECT	BLEND_NOMATCH. SRC_FACT_A_SEL	3-bit enum: same enums as SRCFACTA_MATCH_SELECT
DSTFACTA_NOMATCH_SELECT	BLEND_NOMATCH. DST_FACT_A_SEL	3-bit: same enums as DSTFACTA_MATCH_SELECT
Cursor blend registers – Note: Cursor blend registers are PER DISPLAY CONTROLLER		
K1	BLEND_CURSOR.ALPHA1	8-bit alpha
SRCFACTC_SELECT	BLEND_CURSOR. SRC_FACT_C_SEL	2-bit enum: K1, K1_TIMES_SRC
DSTFACTC_SELECT	BLEND_CURSOR. DST_FACT_C_SEL	2-bit enum: K1, NEG_K1_TIMES_SRC
Dither registers – Note: Dither registers are PER DISPLAY CONTROLLER		
TD_DITHER_PHASE	Temporal Dither phase	2 bits: 0: no frame reset 1,2,3: frame reset to constants 1/2/3
DITHER_CONTROL	Dither enable and method selection	2 bits: 0: DISABLE 2: ORDERED 3: TEMPORAL * (replaces ERRDIFF)
ORD_DITHER_ROTATION	Static/dynamic control	2 bits: 0: STATIC 1/2/3: rotate matrix every N frames

21.5.3 Display Controller Register Definition

Each display supports three windows: Window A, Window B, Window C

The windows may have different features, as described above; however, the register interfaces are the same.

Color Palette

These appear as three instances of 256 32-bit registers with each register consisting of one RGB pixel so not all 32 bits in the registers are used. One instance is used for window A, another instance is used for window B, and the third instance is used for window C. In reality, each instance is implemented as triple 256-word dual-port register files (2P RF) with one read port and one write port (1R1W) and with each word consisting of 1 red/green/blue component. Read port of the color palettes are used for the corresponding window A, window B, or window C and write port of the color palettes are used for host write.

Note that the host cannot read these color palettes, so it must cache this color palette somewhere else to be able to read them. This is done to reduce area.

21.5.4 Display Shadow Registers

Display registers have three shadow types:

1. Not Shadowed

   Writes to these registers take effect immediately.

2. Double Buffered

   Each register has two copies: ASSEMBLY and ACTIVE. ACTIVE is the working copy.

These two copies share the same address/offset.

WRITE_MUX can be programmed to choose which copy the subsequent register writes goes to:

When set to ACTIVE, both ACTIVE and ASSEMBLY copies will be written

When set to ASSEMBLY, only ASSEMBLY copy will be written

READ_MUX can be programmed to choose which copy the subsequent register reads comes from.

If display is in STOP mode, ASSEMBLY copy is latched into ACTIVE copy immediately after

(GENERAL/WIN_A/WIN_B/WIN_C)_ACT_REQ is programmed. In other modes the latching happens on the next frame boundary after (GENERAL/WIN_A/WIN_B/WIN_C)_ACT_REQ is programmed.

3. Triple Buffered

Each register has three copies: ASSEMBLY, ARM, and ACTIVE. ACTIVE is the working copy.

ASSEMBLY and ACTIVE copies share the same address/offset, the ARM copy is located at the address/offset one bigger than the ASSEMBLY/ACTIVE copy.

WRITE_MUX can be programmed to choose which copy the subsequent register writes goes to:

When set to ACTIVE, all three copies will be written

When set to ASSEMBLY, only ASSEMBLY copy will be written

READ_MUX can be programmed to choose which copy the subsequent register reads comes from.

To read back ASSEMBLY or ACTIVE copy, set READ_MUX correctly before register reads.

These two copies share the same address.

To read back ARM copy, do not set READ_MUX, but read back the register/register-field with "_NS" in their names, the offset of which is 1 bigger than its ASSEMBLY/ACTIVE counterpart.

ASSEMBLY copy is latched into ARM copy immediately after GENERAL/WIN_A/WIN_B/WIN_C)_UPDATE is programmed.

If display is in STOP mode, ARM copy is latched into ACTIVE copy immediately after (GENERAL/WIN_A/WIN_B/WIN_C)_ACT_REQ is programmed. In other modes the latching happens on the next frame boundary after (GENERAL/WIN_A/WIN_B/WIN_C)_ACT_REQ is programmed.

21.5.5 Display Control Modes

The DISPLAY_COMMAND is used to set display control mode (**CONTINUOUS**, **ONE-SHOT**, or **STOP**).

Display switches mode when CONTROL_MODE is programmed to shadow register and then activated.

Display enters a mode when the register activation happens, either on frame boundary when entering **STOP** mode, or immediately when exiting **STOP** mode.

In **STOP** mode, display is in idle. Pixel clock is not running.

In **CONTINUOUS** mode, display keeps refreshing the output frame by frame. This mode is mostly used for the panels without internal frame buffer.

In **ONE-SHOT** mode, also known as non-continuous mode, display waits for a trigger before refreshing each frame. Between those frames, display is in idle. This mode is usually for the panels with internal frame buffer.

In ONE-SHOT mode, there are different types of triggers as follows:

- Input triggers

  Input trigger is to notify DISPLAY that a new memory surface is ready to be displayed.

  Host Trigger

  Host trigger is requested when NC_HOST_TRIG_ENABLE is programmed. This register field is in the same register as shadow registers UPDATE/ACT_REQ so that the trigger can happen atomically with register updates

for the new frame. When host trigger is requested within a frame, the requested frame will start immediately after the end of the current frame.

- Output Triggers

  Output trigger is to notify DISPLAY that a panel is ready to receive data from DISPLAY.

  Tear Effect Signal Triggers

  When MSF/SSF register field is set to ENABLE, DISPLAY holds off a frame requested by input triggers until DISPLAY receives a "ready" from the pins that connect to the tearing effect signals from the panel, then sends a new frame to panel. However, if no input trigger has been requested, DISPLAY does not send a new frame.

In CONTINUOUS mode, the meaning of the triggers is different.

- Input Triggers

  Since in CONTINUOUS mode trigger happen automatically and repeatedly, trigger here only affects the buffer address change on a window.

  - Host Trigger

    Host can change the buffer address and then write WIN_A/B/C_ACT_REQ to request the buffer address change. Note that for syncpt logic, it cannot tell if a WIN_A/B/C register activation indicates the change of address, so it always behaves like a change of address happens on any register activation requested by WIN_A/B/C_ACT_REQ. As the result, RD_DONE/OP_DONE is returned.

- Output triggers

  These triggers are not applicable in CONTINUOUS mode. MSF/SSF_ENABLE should never be set in CONTINUOUS mode.

21.5.6 Sync Points

DISPLAY has 4 syncpt clients:

- GENERAL

  Conditions

  - 0: IMMEDIATE return INDX immediately
  - 1: OP_DONE not meaningful, same as IMMEDIATE
  - 2: RD_DONE not meaningful, same as IMMEDIATE
  - 3: REG_WR_SAFE returns INDX whenever it is safe to program GENERAL shadow registers (when all previous GENERAL activation has happened)
  - 4: HSPI returns INDX whenever it is safe to send HSPI data (when all HSPI_*** registers are safe to be programmed)
  - 5: FRAME_DONE returns INDX on the next frame end
  - 6: VPULSE3 returns INDX on the next vpulse3 leading edge (for timing sensitive operations if needed)
  - 7: FRAME_START returns INDX on the next frame start (currently for hardware testing, but can be used if needed)

- WIN_A

  Conditions

  - 0: IMMEDIATE return INDX immediately
  - 1: OP_DONE same as RD_DONE
  - 2: RD_DONE returns INDX when all WIN_A reads for frames activated before the INCR_SYNCPT are complete. In ONE-SHOT mode with TVO disabled, this happens after the last row of window A display. In CONTINUOUS

mode, or in ONE-SHOT mode with TVO enabled, this happens on the last row of window A or on frame end (depending if the INCR_SYNCPT is issued before or after the window A last row).

- 3: REG_WR_SAFE returns INDX whenever it is safe to program WIN_A shadow registers (when all previous WIN_A activation has happened)
- 4: LINE_FLIPPED returns INDX whenver the activation has happened and the previous surface has been completely read out. This is particularly useful for line flip case, when s/w could use the syncpt to free up the previously read surface. As hardware moves on to the new surface.

- WIN_B

  Similar to WIN_A
- WIN_C

  Similar to WIN_A
- DISPLAY Continuous syncpt

  VSYNC: When enabled, return syncpt whenever a vblank start happens.

21.5.7 Raise Actions (Legacy)

The Raise action is used to check the state of the display's command execution. The Raise action can be enabled by itself or with other actions.

The raise value is returned to the host controller if the current and all previous commands have completed execution. If the command is executed with the delayed mode, the raise is not returned till that command is executed at the end of the frame.

If there is no pending command when the Raise is issued, the raise value is returned immediately. The raise value is a 4-bit number included in the command.

Context switch acknowledge, register reads, and raises are returned to the host through a read FIFO. However, because there may be more than one raise, read, or acknowledge available for writing to the FIFO in a certain cycle, there must be a priority encoder. Here is the priority:

1. Context switch
2. Register read
3. SIGNAL_RAISE
4. SIGNAL_RAISE1
5. SIGNAL_RAISE2
6. SIGNAL_RAISE3
7. DISP_COMMAND_RAISE
8. HSPI_RAISE
9. Refcount

These packets are for verification; they have no relevance to software. The RAISE packet should include the intended return channel. This channel should be passed back to the host so the RAISE will be reflected in the correct channel.

21.6 Display CMD Registers

21.6.1 DC_CMD_GENERAL_INCR_SYNCPT_0

Offset: 0x0 | Byte Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	GENERAL_COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = HSPI 5 = FRAME_DONE 6 = VPULSE3 7 = FRAME_START 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15 16 = COND_16 17 = COND_17 18 = COND_18 19 = COND_19 20 = COND_20 21 = COND_21 22 = COND_22 23 = COND_23 24 = COND_24 25 = COND_25 26 = COND_26 27 = COND_27 28 = COND_28 29 = COND_29 30 = COND_30 31 = COND_31
7:0	0x0	GENERAL_INDX: syncpt index value

21.6.2 DC_CMD_GENERAL_INCR_SYNCPT_CNTRL_0

Offset: 0x1 | Byte Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxx0)

Bit	Reset	Description
8	0x0	GENERAL_INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	GENERAL_INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do a soft reset, first set SOFT_RESET of all Host1x clients affected, then clear all SOFT_RESETs.

21.6.3 DC_CMD_GENERAL_INCR_SYNCPT_ERROR_0

Offset: 0x2 | Byte Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	GENERAL_COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

21.6.4 DC_CMD_WIN_A_INCR_SYNCPT_0

Offset: 0x8 | Byte Offset: 0x20 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	WIN_A_COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = COND_4 5 = COND_5 6 = COND_6 7 = COND_7 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15 16 = COND_16 17 = COND_17 18 = COND_18 19 = COND_19 20 = COND_20 21 = COND_21 22 = COND_22 23 = COND_23 24 = COND_24 25 = COND_25 26 = COND_26 27 = COND_27 28 = COND_28 29 = COND_29 30 = COND_30 31 = COND_31
7:0	0x0	WIN_A_INDX: syncpt index value

21.6.5 DC_CMD_WIN_A_INCR_SYNCPT_CNTRL_0

Offset: 0x9 | Byte Offset: 0x24 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxx0)

Bit	Reset	Description
8	0x0	WIN_A_INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.

Bit	Reset	Description
0	0x0	WIN_A_INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal states of the client syncpt block will be reset. To do a soft reset, first set SOFT_RESET of all Host1x clients affected, then clear all SOFT_RESETs.

21.6.6 DC_CMD_WIN_A_INCR_SYNCPT_ERROR_0

Offset: 0xa | Byte Offset: 0x28 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	WIN_A_COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

21.6.7 DC_CMD_WIN_B_INCR_SYNCPT_0

Offset: 0x10 | Byte Offset: 0x40 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	WIN_B_COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = COND_4 5 = COND_5 6 = COND_6 7 = COND_7 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15 16 = COND_16 17 = COND_17 18 = COND_18 19 = COND_19 20 = COND_20 21 = COND_21 22 = COND_22 23 = COND_23 24 = COND_24 25 = COND_25 26 = COND_26 27 = COND_27 28 = COND_28 29 = COND_29 30 = COND_30 31 = COND_31
7:0	0x0	WIN_B_INDX: syncpt index value

21.6.8 DC_CMD_WIN_B_INCR_SYNCPT_CNTRL_0

Offset: 0x11 | Byte Offset: 0x44 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxxx0)

Bit	Reset	Description
8	0x0	WIN_B_INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	WIN_B_INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal states of the client syncpt block will be reset. To do a soft reset, first set SOFT_RESET of all Host1x clients affected, then clear all SOFT_RESETs.

21.6.9 DC_CMD_WIN_B_INCR_SYNCPT_ERROR_0

Offset: 0x12 | Byte Offset: 0x48 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	WIN_B_COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

21.6.10 DC_CMD_WIN_C_INCR_SYNCPT_0

Offset: 0x18 | Byte Offset: 0x60 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	WIN_C_COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = COND_4 5 = COND_5 6 = COND_6 7 = COND_7 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15 16 = COND_16 17 = COND_17 18 = COND_18 19 = COND_19 20 = COND_20 21 = COND_21 22 = COND_22 23 = COND_23 24 = COND_24 25 = COND_25 26 = COND_26 27 = COND_27 28 = COND_28 29 = COND_29 30 = COND_30 31 = COND_31
7:0	0x0	WIN_C_INDX: syncpt index value

21.6.11 DC_CMD_WIN_C_INCR_SYNCPT_CNTRL_0

Offset: 0x19 | Byte Offset: 0x64 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxxx0)

Bit	Reset	Description
8	0x0	WIN_C_INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	WIN_C_INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal states of the client syncpt block will be reset. To do a soft reset, first set SOFT_RESET of all Host1x clients affected, then clear all SOFT_RESETs.

21.6.12 DC_CMD_WIN_C_INCR_SYNCPT_ERROR_0

Offset: 0x1a | Byte Offset: 0x68 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	WIN_C_COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

21.6.13 DC_CMD_CONT_SYNCPT_VSYNC_0

Offset: 0x28 | Byte Offset: 0xa0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxxx)

Bit	Reset	Description
8	0x0	VSYNC_EN: On host read bus every time VSYNC (V-blank leading edge) happens and VSYNC_EN is set 0 = DISABLE 1 = ENABLE
7:0	X	VSYNC_INDX: Return INDX (set HOST_CLRD packet TYPE field to SYNCPT)

21.6.14 DC_CMD_CTXSW_0

Context switch registers for class and channel

Should be common to all modules. Includes the current channel/class (writable by software) and the next channel/class (which the hardware sets when it receives a context switch).

Context switch works like this:

Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS (see vmod/chexample). Software sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be pre-loaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts.

Another way to avoid context switch interrupts is to set the AUTO_ACK bit.

This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 0x30 | Byte Offset: 0xc0 | Read/Write: R/W | Reset: 0xf000f800 (0bxxxxxxxxxxxxxxxx11111x0000000000)

Bit	R/W	Reset	Description
31:28	RO	X	NEXT_CHANNEL: Next requested channel
25:16	RO	X	NEXT_CLASS: Next requested class
15:12	RW	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	RW	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests 0 = MANUAL 1 = AUTOACK
9:0	RW	0x0	CURR_CLASS: Current working class

21.6.15 DC_CMD_DISPLAY_COMMAND_OPTION0_0

Display Controller Option 0. This register is not effective until DISPLAY_COMMAND is written.

Class: Display Command

Offset: 0x31 | Byte Offset: 0xc4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxx000xxxxxxx00000000)

Bit	Reset	Description
18	0x0	WINDOW_C_NC_DISPLAY: Window C Non-Continuous Display. This is effective only in Non-Continuous Display mode when window B buffer switching is not controlled by host. If this bit is enabled, a frame is sent whenever Window B buffer is switched. 0 = DISABLE 1 = ENABLE
17	0x0	WINDOW_B_NC_DISPLAY: Window B Non-Continuous Display. This is effective only in Non-Continuous Display mode when window B buffer switching is not controlled by host. If this bit is enabled, a frame is sent whenever Window B buffer is switched. 0 = DISABLE 1 = ENABLE
16	0x0	WINDOW_A_NC_DISPLAY: Window A Non-Continuous Display. This is effective only in Non-Continuous Display mode when window A buffer switching is not controlled by host. If this bit is enabled, a frame is sent whenever Window A buffer is switched. 0 = DISABLE 1 = ENABLE
7:6	0x0	SSF_SOURCE: Source pin for the SSF input. Controls which pin will be used as the source for the trigger input when MSF mode is enabled. Note that although the same pins are available for both MSF and SSF, the order in the enum and hence the values differ between the pins. This is to maintain backwards compatibility with previous chips, which had a fixed mapping. The init value and the first value in the enum reflect this historical mapping. 0= LCD_DC pin (legacy default) 1= LCD_SPI pin 2= LCD_SDI pin 3= RESERVED for future use. 0 = SSF_LDC 1 = SSF_LSPI 2 = SSF_LSDI
5	0x0	SSF_ENABLE: Sub-Display Stop Frame (SSF) input. This is effective only in Non-Continuous Display mode. When enabled, SSF signal can be input through LDC pin. When SSF is enabled a trigger to send a frame in Non-Continuous Display mode will be delayed until SSF is active. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
4	0x0	SSF_POLARITY: Sub-Display Stop Frame (SSF) Polarity 0= Active high 1= Active low
3:2	0x0	MSF_SOURCE: Source pin for the MSF input. Controls which pin will be used as the source for the trigger input when MSF mode is enabled. Note that although the same pins are available for both MSF and SSF, the order in the enum and hence the values differ between the pins. This is to maintain backwards compatibility with previous chips, which had a fixed mapping. The init value and the first value in the enum reflects this historical mapping. 0= LCD_SPI pin (legacy default) 1= LCD_DC pin 2= LCD_SDI pin 3= RESERVED for future use. 0 = MSF_LSPI 1 = MSF_LDC 2 = MSF_LSDI
1	0x0	MSF_ENABLE: Main-Display Stop Frame (MSF) input This is effective only in Non-Continuous Display mode. When enabled, the MSF signal can be input through the LSPI pin. When MSF is enabled, a trigger to send a frame in Non-Continuous Display mode will be delayed until MSF is active. 0 = DISABLE 1 = ENABLE
0	0x0	MSF_POLARITY: Main-Display Stop Frame (MSF) Polarity 0= Active high 1= Active low

21.6.16 DC_CMD_DISPLAY_COMMAND_0

Display Command

Offset: 0x32 | Byte Offset: 0xc8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx00xxxx0)

Bit	Reset	Description
30:27	X	DISP_COMMAND_RAISE_CHANNEL_ID: Display Command Channel ID
26:22	X	DISP_COMMAND_RAISE_VECTOR: Display Command Raise Vector. This raise vector is at the next line or frame boundary, depending on GENERAL_ACT_CNTR_SEL
6:5	0x0	DISPLAY_CTRL_MODE: Display Controller Mode 0= Stop Display, this can be used to stop sending frame at the next frame boundary. This is automatically generated in Non-Continuous Display after sending one frame. If this is issued when display controller is already stopped then there is no frame sent. Raise vector (if raise is enabled) is also returned immediately. This command can also be used in non-continuous display mode to stop accepting non-host trigger conditions from other clients. 1= Continuous Display, the display controller will continuously send frame. Continuous display mode can be stopped by switching to Non-Continuous Display or by issuing Stop Display. 2= Non-Continuous Display, the display controller is forced to send one frame of each active display and then wait for the next time this command is issued or for other (non-host) trigger conditions to send frame. The sending of frames may be delayed by MSF or SSF input signals from the display device. If a Stop Display is issued while in non-continuous display mode then non-host trigger conditions will no longer be accepted until the next time Non-Continuous Display is issued 0 = STOP 1 = C_DISPLAY 2 = NC_DISPLAY
0	0x0	DISP_COMMAND_RAISE: Display Command Raise. Raise vector will be returned at the end of command completion 0 = DISABLE 1 = ENABLE

21.6.17 DC_CMD_SIGNAL_RAISE_0

When written, the next occurrence of the selected SIGNAL will cause a RAISE to be sent to the host. Software must not write this register if a previous request (from previous write) is still outstanding. Added SIGNAL_RAISE_TYPE option so that multiple raises can be returned without software intervention. SIGNAL_RAISE1, SIGNAL_RAISE2, or SIGNAL_RAISE3 can be used if more than one source signal is needed.

Offset: 0x33 | Byte Offset: 0xcc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxx0xxxxxxxxxxx)

Bit	Reset	Description
19:16	X	SIGNAL_RAISE_CHANNEL_ID: Signal Raise Channel ID
12	0x0	SIGNAL_RAISE_TYPE: 0= One-shot, single raise returned. 1= Continuous, raise is returned persistently whenever raise event is true until this register is reprogrammed such that SIGNAL_RAISE_SELECT=NONE or SIGNAL_RAISE_TYPE=ONESHOT 0 = ONESHOT 1 = CONT
10:8	X	SIGNAL_RAISE_SELECT: which signal to raise on 0= none, no raise sent back 1= Frame End signal 2= V Blank signal 3= V Pulse 3 signal 4= Rising edge of V Blank signal 5= Falling edge of V Blank signal 6= Rising edge of V Pulse 3 signal 7= Falling edge of V Pulse 3 signal 0 = NONE 1 = FRAME_END 2 = VBLANK 3 = VPULSE3 4 = VBLANK_START 5 = VBLANK_END 6 = VPULSE3_START 7 = VPULSE3_END
4:0	X	SIGNAL_RAISE_VECTOR: bit number to raise

21.6.18 DC_CMD_DISPLAY_POWER_CONTROL_0

PW0, PW1, PW2, and PW3 are tied internally to the same value corresponding to PW3.

Software is required to program all these register fields to ENABLE - PW0 to PW3 simultaneously, in the same register write access.

The power sequencing provided by PW0 - PW3 was LCD output specific, which is not applicable to Tegra K1 devices.

Display Power Control

Offset: 0x36 | Byte Offset: 0xd8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxx00xxxxx0x0xxxxxxx0x0x0x0x0)

Bit	Reset	Description
25	0x0	HSPI_ENABLE: Host SPI write cycle enable. SPI_ENABLE must be enabled also for this bit to be effective. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
24	0x0	SPI_ENABLE: SPI interface enable. This enables clock to SPI interface logic for Host SPI, IS SPI, and LCD SPI. 0 = DISABLE 1 = ENABLE
18	0x0	PM1_ENABLE: PM1 signal enable 0 = DISABLE 1 = ENABLE
16	0x0	PM0_ENABLE: PM0 signal enable 0 = DISABLE 1 = ENABLE
8	0x0	PW4_ENABLE: PW4 signal enable. This signal can be output at the pad for display power sequencing. 0 = DISABLE 1 = ENABLE
6	0x0	PW3_ENABLE: PW3 signal enable. This signal can be output at the pad for display power sequencing. 0 = DISABLE 1 = ENABLE
4	0x0	PW2_ENABLE: PW2 signal enable. This signal controls pixel data processing. It should be enabled during V blank time. This signal also controls the time when pin polarity takes effect at the pad. This signal can be output at the pad for display power sequencing. 0 = DISABLE 1 = ENABLE
2	0x0	PW1_ENABLE: PW1 signal enable. This signal can be output at the pad for display power sequencing. 0 = DISABLE 1 = ENABLE
0	0x0	PW0_ENABLE: PW0 signal enable. This signal controls the display H and V counters. It must be enabled first and disabled last during display power sequencing. This signal can be output at the pad for display power sequencing. 0 = DISABLE 1 = ENABLE

21.6.19 DC_CMD_INT_STATUS_0

This reflects status of all pending interrupts which is valid as long as the interrupt is not cleared even if the interrupt is masked. A pending interrupt can be cleared by writing a '1' to this the corresponding interrupt status bit in this register.

Display Interrupt and Status

Offset: 0x37 | Byte Offset: 0xdc | Read/Write: R/W | Reset: 0x0XXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
25	X	WIN_T_UF_INT: Window T Underflow Interrupt Status 0= interrupt not pending 1= interrupt pending
24	X	WIN_D_UF_INT: Window D Underflow Interrupt Status 0= interrupt not pending 1= interrupt pending
23	X	HC_UF_INT: Cursor Underflow Interrupt Status 0= interrupt not pending 1= interrupt pending

Bit	Reset	Description
22	X	CMU_LUT_CONFLICT_INT: CMU LUT read/write conflict; write 1 to clear
16	X	WIN_C_OF_INT: Window C Overflow Interrupt Status 0= interrupt not pending 1= interrupt pending
15	X	WIN_B_OF_INT: Window B Overflow Interrupt Status 0= interrupt not pending 1= interrupt pending

4	X	V_PULSE3_INT: Vertical Pulse 3 Interrupt 0= interrupt not pending 1= interrupt pending
3	X	H_BLANK_INT: Horizontal Blank Interrupt 0= interrupt not pending 1= interrupt pending
2	X	V_BLANK_INT: Vertical Blank Interrupt 0= interrupt not pending 1= interrupt pending
1	X	FRAME_END_INT: Frame End Interrupt 0= interrupt not pending 1= interrupt pending

Bit	Reset	Description
0	X	CTXSW_INT: Context Switch Interrupt Status (this is cleared on write) 0= interrupt not pending 1= interrupt pending

21.6.20 DC_CMD_INT_MASK_0

Setting bits in this register masks the corresponding interrupt but neither clears a pending interrupt nor prevents a pending interrupt from being generated. Masking an interrupt also does not clear a pending interrupt status and does not prevent a pending interrupt status from being generated.

Interrupt Mask

Offset: 0x38 | Byte Offset: 0xe0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxx0000xxxxx00000x0000x000000)

Bit	Reset	Description
25	0x0	WIN_T_UF_INT_MASK: Window T Underflow Interrupt Mask. 0 = MASKED 1 = NOTMASKED
24	0x0	WIN_D_UF_INT_MASK: Window D Underflow Interrupt Mask. 0 = MASKED 1 = NOTMASKED
23	0x0	HC_UF_INT_MASK: Cursor Underflow Interrupt Mask. 0 = MASKED 1 = NOTMASKED
22	0x0	CMU_LUT_CONFLICT_INT_MASK: CMU LUT read/write conflict. 0 = MASKED 1 = NOTMASKED
16	0x0	WIN_C_OF_INT_MASK: Window C Overflow Interrupt Mask 0 = MASKED 1 = NOTMASKED
15	0x0	WIN_B_OF_INT_MASK: Window B Overflow Interrupt Mask 0 = MASKED 1 = NOTMASKED
14	0x0	WIN_A_OF_INT_MASK: Window A Overflow Interrupt Mask 0 = MASKED 1 = NOTMASKED
13	0x0	SSF_INT_MASK: Sub-Display Stop Frame Interrupt Mask 0 = MASKED 1 = NOTMASKED
12	0x0	MSF_INT_MASK: Main-Display Stop Frame Interrupt Mask 0 = MASKED 1 = NOTMASKED
10	0x0	WIN_C_UF_INT_MASK: Window C Underflow Interrupt Mask 0 = MASKED 1 = NOTMASKED
9	0x0	WIN_B_UF_INT_MASK: Window B Underflow Interrupt Mask 0 = MASKED 1 = NOTMASKED

Bit	Reset	Description
8	0x0	WIN_A_UF_INT_MASK: Window A Underflow Interrupt Mask 0 = MASKED 1 = NOTMASKED
7	0x0	SPI_BUSY_INT_MASK: SPI Busy Interrupt Mask 0 = MASKED 1 = NOTMASKED
5	0x0	V_PULSE2_INT_MASK: Vertical Pulse 2 Interrupt Mask 0 = MASKED 1 = NOTMASKED
4	0x0	V_PULSE3_INT_MASK: Vertical Pulse 3 Interrupt Mask 0 = MASKED 1 = NOTMASKED
3	0x0	H_BLANK_INT_MASK: Horizontal Blank Interrupt Mask 0 = MASKED 1 = NOTMASKED
2	0x0	V_BLANK_INT_MASK: Vertical Blank Interrupt Mask 0 = MASKED 1 = NOTMASKED
1	0x0	FRAME_END_INT_MASK: Frame End Interrupt Mask 0 = MASKED 1 = NOTMASKED
0	0x0	CTXSW_INT_MASK: Context Switch Interrupt Mask 0 = MASKED 1 = NOTMASKED

21.6.21 DC_CMD_INT_ENABLE_0

Setting bits in this register enable the corresponding interrupt event to generate a pending interrupt. Interrupt output signal will be activated only if the corresponding interrupt is not masked.

Disabling an interrupt will not clear a corresponding pending interrupt - it only prevents a new interrupt event to generate a pending interrupt.

Interrupt Enable

Offset: 0x39 | Byte Offset: 0xe4 | Read/Write: R/W | Reset: 0x00000001 (0bxxxxxx0000xxxxx00000x0000x000001)

Bit	Reset	Description
25	0x0	WIN_T_UF_INT_ENABLE: Window T Underflow Interrupt Enable 0 = DISABLE 1 = ENABLE
24	0x0	WIN_D_UF_INT_ENABLE: Window D Underflow Interrupt Enable 0 = DISABLE 1 = ENABLE
23	0x0	HC_UF_INT_ENABLE: Cursor Underflow Interrupt Enable 0 = DISABLE 1 = ENABLE

21.6.27 DC_CMD_STATE_ACCESS_0

Double/triple buffers read and write access control

Offset: 0x40 | Byte Offset: 0x100 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0x0)

Bit	Reset	Description
2	0x0	WRITE_MUX: Write access control 0= write assembly state 1= write active state When set to ACTIVE, register writes also propagate to assembly set for double buffered registers, to both assembly and arm set for triple buffered registers. 0 = ASSEMBLY 1 = ACTIVE

Bit	Reset	Description
0	0x0	READ_MUX: Read access control 0= read assembly state 1= read active state ARM state register read is not controlled by this mux, but by reading the registers with "_NS" suffix 0 = ASSEMBLY 1 = ACTIVE

21.6.28 DC_CMD_STATE_CONTROL_0

State Control for Activating/Arming New Register State

Restrictions: ACT_REQ cannot be programmed at the same time the corresponding "UPDATE" is programmed.

If so desired, it should be split into two consecutive writes to this register.

Offset: 0x41 | Byte Offset: 0x104 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxx0xxxxxxx0xx000000xx00000)

Bit	Reset	Description
24	0x0	NC_HOST_TRIG_ENABLE: Host trigger enable. Effective only in Non-continuous mode. The exception is that when TVO is enabled, this trigger is ignored so as not to corrupt TV output. Note that when this field is enabled, GENERAL_ACT_REQ must be enabled at the same time. 0= disable: no frame is triggered 0 = DISABLE 1 = ENABLE
15	0x0	CURSOR_UPDATE: Trigger for the arming state (from assembly to armed state) for a subset of the triple buffered registers. This register is also known as "Update Register" 0 = DISABLE 1 = ENABLE
12	0x0	WIN_D_UPDATE: Trigger for the arming state (from assembly to armed state) for the win D subset of the triple buffered registers. This register is also known as "Update Register" 0 = DISABLE 1 = ENABLE
11	0x0	WIN_C_UPDATE: Trigger for arming state (from assembly to armed state) for the win C subset of the triple buffered registers. This register is also known as "Update Register" 0 = DISABLE 1 = ENABLE
10	0x0	WIN_B_UPDATE: Trigger for arming state (from assembly to armed state) for the win B subset of the triple buffered registers. This register is also known as "Update Register" 0 = DISABLE 1 = ENABLE
9	0x0	WIN_A_UPDATE: Trigger for arming state (from assembly to armed state) for the win A subset of the triple buffered registers. This register is also known as "Update Register" 0 = DISABLE 1 = ENABLE
8	0x0	GENERAL_UPDATE: Trigger for arming state (from assembly to armed state) for a subset of the triple buffered registers. This register is also known as "Update Register" 0 = DISABLE 1 = ENABLE
7	0x0	CURSOR_ACT_REQ: Non-window specific 0= no request pending/request completed 1= activation requested/pending 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
4	0x0	WIN_D_ACT_REQ: Window D activation request 0= no request pending/request completed 1= activation requested/pending 0 = DISABLE 1 = ENABLE
3	0x0	WIN_C_ACT_REQ: Window C activation request 0= no request pending/request completed. 1= activation requested/pending 0 = DISABLE 1 = ENABLE
2	0x0	WIN_B_ACT_REQ: Window B activation request 0= no request pending/request completed. 1= activation requested/pending 0 = DISABLE 1 = ENABLE
1	0x0	WIN_A_ACT_REQ: Window A activation request 0= no request pending/request completed. 1= activation requested/pending 0 = DISABLE 1 = ENABLE
0	0x0	GENERAL_ACT_REQ: Non-window-specific 0= no request pending/request completed. 1= activation requested/pending 0 = DISABLE 1 = ENABLE

21.6.29 DC_CMD_DISPLAY_WINDOW_HEADER_0

Display Window Header for programming display windows and their corresponding buffer start addresses.

Class: Display Window Programming Header

Offset: 0x42 | Byte Offset: 0x108 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0000xxxx)

Bit	Reset	Description
7	0x0	WINDOW_D_SELECT: Window D Select 0= disable window D programming 1= enable window D programming 0 = DISABLE 1 = ENABLE
6	0x0	WINDOW_C_SELECT: Window C Select. 0= disable window C programming. 1= enable window C programming 0 = DISABLE 1 = ENABLE
5	0x0	WINDOW_B_SELECT: Window B Select. 0= disable window B programming. 1= enable window B programming 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
4	0x0	WINDOW_A_SELECT: Window A Select. 0= disable window A programming. 1= enable window A programming 0 = DISABLE 1 = ENABLE

21.6.30 DC_CMD_REG_ACT_CONTROL_0

Register activation options

Offset: 0x43 | Byte Offset: 0x10c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxx0xx00x0x0x0)

Bit	Reset	Description
10	0x0	WIN_D_ACT_CNTR_SEL: Select which counter to use for window D activation 0= vertical counter 1= horizontal counter 0 = VCOUNTER 1 = HCOUNTER
7	0x0	CURSOR_ACT_CNTR_SEL: Select which counter to use for window C activation 0= vertical counter 1= horizontal counter 0 = VCOUNTER 1 = HCOUNTER

2	0x0	WIN_A_ACT_CNTR_SEL: Select which counter to use for window A activation 0= vertical counter 1= horizontal counter 0 = VCOUNTER 1 = HCOUNTER
0	0x0	GENERAL_ACT_CNTR_SEL: Select which counter to use for general activation 0= vertical counter 1= horizontal counter 0 = VCOUNTER 1 = HCOUNTER

21.6.31 DC_CMD_WIN_T_STATE_CONTROL_0

WIN_T State control register for activating/arming new register state

Restrictions:

- ACT_REQ cannot be programmed at the same time the corresponding "UPDATE" is programmed. If so desired, it should be split into two consecutive writes to this register.
- When SECURE_CONTROL.SECURE_ENABLE=1, this register is only accessible when HOST1X secure bit is set.
- If SECURE_CONTROL.SECURE_ENABLE is zero, this register is accessible regardless of HOST1X secure bit level.

Offset: 0x44 | Byte Offset: 0x110 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxxx0)

Bit	Reset	Description
8	0x0	WIN_T_UPDATE: Trigger for the arming state (from assembly to armed state) for the win B subset of the triple buffered registers. This register is also known as "Update Register" 0 = DISABLE 1 = ENABLE
0	0x0	WIN_T_ACT_REQ: 0= no request pending/request completed 0 = DISABLE 1 = ENABLE

21.6.32 DC_CMD_SECURE_CONTROL_0

Secure control register for enabling secure mode and controlling host1x register loads and reads

Restrictions:

- This register is only accessible when the HOST1X secure bit is set. If the HOST1X secure bit is zero writes to this register are ignored and reads return 0.

Offset: 0x45 | Byte Offset: 0x114 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxx000000xxxxx000)

Bit	Reset	Description
13	DISABLE	SECURE_SOR_PROTECT: if ENABLE, blanks the display output to SOR when SECURE_ENABLE is true. 0 = DISABLE 1 = ENABLE
12	DISABLE	SECURE_DSIB_PROTECT: if ENABLE, blanks the display output to DSIB when SECURE_ENABLE is true. 0 = DISABLE 1 = ENABLE
11	DISABLE	SECURE_DSIA_PROTECT: If ENABLE, blanks the display output to DSIA when SECURE_ENABLE is true. 0 = DISABLE 1 = ENABLE
10	DISABLE	SECURE_HDMI_PROTECT: If ENABLE, blanks the display output to HDMI when SECURE_ENABLE is true. 0 = DISABLE 1 = ENABLE
9	ASSEMBLY	SECURE_READ_MUX: Controls which of the double-buffered window registers are read in TZ Secure mode (host1x secure bit set). Similar to STATE_ACCESS.READ_MUX 0 = ASSEMBLY 1 = ACTIVE
8	ASSEMBLY	SECURE_WRITE_MUX: Controls which of the double-buffered window registers are written in TZ Secure mode (host1x secure bit set). Similar to STATE_ACCESS.WRITE_MUX 0 = ASSEMBLY 1 = ACTIVE
2	DISABLE	SECURE_CRC_PROTECT: If ENABLE, and SECURE_ENABLE=ENABLE, CRC computation is disabled. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
1	DISABLE	SECURE_CMU_PROTECT: If ENABLE, and SECURE_ENABLE=ENABLE, CMU registers are only accessible in TZ Secure mode . 0 = DISABLE 1 = ENABLE
0	DISABLE	SECURE_ENABLE: Double-buffered: Active state changed at next frame boundary, or immediately in STOP mode. Read returns active state. Changes window T to and from Secure mode 0 = DISABLE 1 = ENABLE

21.6.33 DC_CMD_WIN_D_INCR_SYNCPT_0

Offset: 0x4c | Byte Offset: 0x130 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	WIN_D_COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = COND_4 5 = COND_5 6 = COND_6 7 = COND_7 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15 16 = COND_16 17 = COND_17 18 = COND_18 19 = COND_19 20 = COND_20 21 = COND_21 22 = COND_22 23 = COND_23 24 = COND_24 25 = COND_25 26 = COND_26 27 = COND_27 28 = COND_28 29 = COND_29 30 = COND_30 31 = COND_31
7:0	0x0	WIN_D_INDX: syncpt index value

21.6.34 DC_CMD_WIN_D_INCR_SYNCPT_CNTRL_0

Offset: 0x4d | Byte Offset: 0x134 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxxx0)

Bit	Reset	Description
8	0x0	WIN_D_INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.

Bit	Reset	Description
0	0x0	WIN_D_INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal states of the client syncpt block will be reset. To do a soft reset, first set SOFT_RESET of all Host1x clients affected, then clear all SOFT_RESETs.

21.6.35 DC_CMD_WIN_D_INCR_SYNCPT_ERROR_0

Offset: 0x4e | Byte Offset: 0x138 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	WIN_D_COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

21.7 Display COM Registers

21.7.1 DC_COM_CRC_CONTROL_0

CRC Control

CRC is provided for at speed testing and diagnostic. When CRC is enabled, the CRC logic waits for the next VSync pulse or the one after that (depending on CRC_WAIT) and then it captures one frame of data at the end of display pipeline and computes the CRC value.

After one frame of data is captured, the CRC logic will stop capturing data.

When CRC_INPUT_DATA = FULL_FRAME, DISPLAY_COMMAND.DISPLAY_CTRL_MODE should be programmed to C_DISPLAY so that CRC works properly.

When CRC_INPUT_DATA = ACTIVE_DATA, it can work on both NC_DISPLAY and C_DISPLAY modes, and can work for multiple frames if CRC is checked, disabled, and re-enabled after the end of frame v-active area and before next VSYNC.

CRC logic takes 8 bits of control signals and 24-bit RGB pixel after dither and after display color (R and B) swap option.

Input [31:0] into CRC depends on CRC_INPUT_DATA. If programmed as FULL_FRAME, input data is { LVP1, LPV0, LHP2, LHP1, LHP0, VSYNC, HSYNC, ACTIVE, R[7:0], G[7:0], B[7:0]} and CRC runs over the entire frame (including blank). If programmed as ACTIVE_DATA, input data is {R[7:0], G[7:0], B[7:0]} and CRC runs only during active display area.

Offset: 0x300 | Byte Offset: 0xc00 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
3	0x0	CRC_ALWAYS: CRC always: calculates CRC for every following frame. Must use with CRC_INPUT_DATA = ACTIVE_DATA. If enabled, CRC_WAIT field is ignored. 0 = DISABLE 1 = ENABLE
2	0x0	CRC_INPUT_DATA: CRC input data 0= Full frame (RGB data and control) 1= Active display (Only RGB data) 0 = FULL_FRAME 1 = ACTIVE_DATA
1	0x0	CRC_WAIT: CRC Wait 0= 1 Vsync 1= 2 Vsyncs

Bit	Reset	Description
0	0x0	CRC_ENABLE: CRC Enable 0 = DISABLE 1 = ENABLE

21.7.2 DC_COM_CRC_CHECKSUM_0

CRC Checksum

This register can be read by host after CRC logic stops capturing data.

Offset: 0x301 | Byte Offset: 0xc04 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	0x0	CRC_CHECKSUM: CRC Checksum

21.7.3 DC_COM_PIN_MISC_CONTROL_0

Pin Miscellaneous Control

Pin Miscellaneous Control

Offset: 0x31b | Byte Offset: 0xc6c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0xx)

Bit	Reset	Description
2	0x0	DISP_CLOCK_OUTPUT: Display Clock (DCLK) Enable. 0= disable. 1= enable display clock to be output on LCD_DE pin (LCD_DE output select must be appropriately programmed for this to be effective) 0 = DISABLE 1 = ENABLE

21.7.4 DC_COM_PM0_CONTROL_0

PM0 Signal Control

Class: Pulse Width Modulation

PM0 signal is programmable pulse width modulation signal that can be output on several pins. The control register should be initialized once before PM0 is enabled.

Note: The period is expressed as multiples of 4 times the divider value.
The actual period - in clock cycles - is given by:
period = (1 + PM0_CLOCK_DIVIDER) * ((PM0_PERIOD + 1) * 4)

Offset: 0x31c | Byte Offset: 0xc70 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:18	X	PM0_PERIOD: PM0 Period (4, 8, ... , 256 clock cycles)
17:4	X	PM0_CLOCK_DIVIDER: PM0 Clock Divider (1 to 16384)

Bit	Reset	Description
1:0	X	PM0_CLOCK_SELECT: PM0 Clock Select. 0= output of shift clock divider 1= pixel clock 2= line clock 3= frame clock Notes: 1) Pixel clock, line clock, and frame clock are running only when the PW0 signal is enabled. 2) In non-continuous mode, shift clock and pixel clock run continuously, but line clock and frame clock only run while a frame is being sent.

21.7.5 DC_COM_PM0_DUTY_CYCLE_0

PM0 Duty Cycle

A counter repeatedly counts up from 0 to ((PM0_PERIOD << 2) + 3) pre-scaled cycles.

The period always starts with the output value == 1. After DUTY_CYCLE number of pre-scaled cycles, the output value is cleared for the remainder of the period. In order to output constant 0, simply set the DUTY_CYCLE to 0. To output a constant 1, set DUTY_CYCLE to be any value greater than ((PM0_PERIOD << 2) + 3).

Offset: 0x31d | Byte Offset: 0xc74 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
8:0	X	PM0_DUTY_CYCLE: PM0 Duty Cycle (or D) From 1/P to D/P pulse high time where P is the period.

21.7.6 DC_COM_SCRATCH_REGISTER_A_0

Scratch Register A

Class: Software Scratch Registers

Offset: 0x325 | Byte Offset: 0xc94 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	SCRATCH_REGISTER_A: Scratch Register A

21.7.7 DC_COM_SCRATCH_REGISTER_B_0

Scratch Register B

Offset: 0x326 | Byte Offset: 0xc98 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	SCRATCH_REGISTER_B: Scratch Register B

21.7.8 DC_COM_CRC_CHECKSUM_LATCHED_0

CRC Checksum latched

This register is a latched version of CRC_CHECKSUM. Latching happens at frame end.

> **Note:** CRC_INPUT_DATA needs to be set to ACTIVE_DATA if this register is used. In full frame mode, CRC is frozen two cycles after frame end due to pipelining, so only in active area mode, CRC is consistent and independent of display control mode, and can be checked continuously frame by frame.

Offset: 0x329 | Byte Offset: 0xca4 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	0x0	CRC_CHECKSUM_LATCHED: CRC Checksum latched

21.7.9 DC_COM_CMU_CSC_KRR_0

CMU Color Space Conversion Matrix

- R' = sat(KRR * R + KGR * G + KBR * B)
- G' = sat(KRG * R + KGG * G + KBG * B)
- B' = sat(KRB * R + KGB * G + KBB * B)

Coefficients are signed 1.8 fixed point, for a range of approximately [-2.0, +1.996]

21.8.3 DC_DISP_DISP_TIMING_OPTIONS_0

Display Timing Options

Class: Display Standard Timings

Programming of display timing registers must meet these restrictions:

- Constraint 1: H_REF_TO_SYNC + H_SYNC_WIDTH + H_BACK_PORCH > 20.
- Constraint 2: V_REF_TO_SYNC + V_SYNC_WIDTH + V_BACK_PORCH > 1.
- Constraint 3: V_FRONT_PORCH + V_SYNC_WIDTH + V_BACK_PORCH > 1 (vertical blank).
- Constraint 4: V_SYNC_WIDTH >= 1

  H_SYNC_WIDTH >= 1
- Constraint 5: V_REF_TO_SYNC >= 1

  H_REF_TO_SYNC >= 0
- Constraint 6: V_FRONT_PORCH >= (V_REF_TO_SYNC + 1)

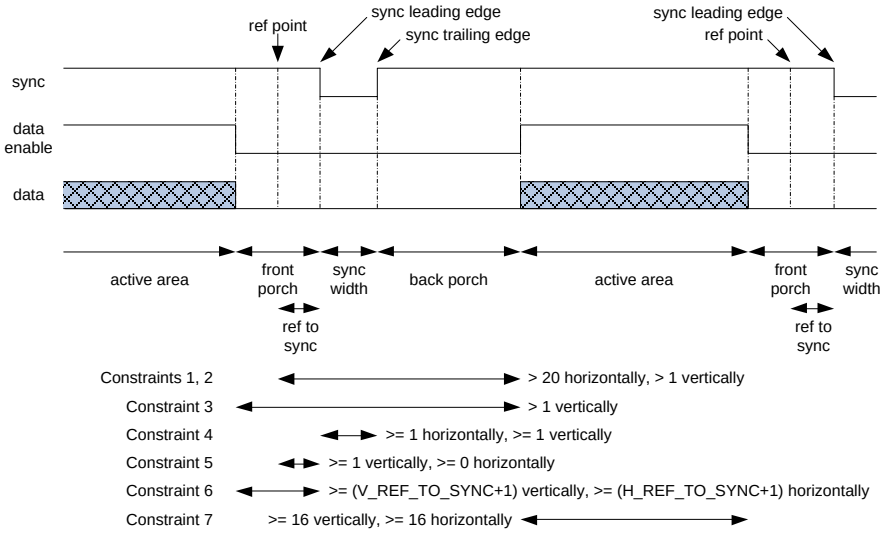
  H_FRONT_PORCH >= (H_REF_TO_SYNC + 1)
- Constraint 7: H_DISP_ACTIVE >= 16

  V_DISP_ACTIVE >= 16

Timing Diagram

- This diagram applies to both vertical and horizontal timing
- The back porch is the only parameter that can be negative

Figure 68: Display Timing Options Timing Diagram



This register specifies display timing options for HSYNC and VSYNC.

Offset: 0x405 | Byte Offset: 0x1014 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxx0000000000000)

Bit	Reset	Description
12:0	0x0	VSYNC_H_POSITION: VSYNC Horizontal Position. This parameter specifies the position where VSYNC can toggle with respect to H reference point.

21.8.4 DC_DISP_REF_TO_SYNC_0

H/V Reference to Sync

This register specifies the start position of HSYNC and VSYNC with respect to H and V reference point (line and frame start) correspondingly. The H and V reference points correspond to the time when H and V display timing counter is re-initialized to zero correspondingly.

The H reference point also determines the point where V display timing counter is incremented so this points the horizontal relationship between HSYNC and VSYNC.

Note: VSYNC's rising/falling edge is fixed at H reference point zero.

Offset: 0x406 | Byte Offset: 0x1018 | Read/Write: R/W | Reset: 0x00000000 (0bxxx0000000000000xxx0000000000000)

Bit	Reset	Description
28:16	0x0	V_REF_TO_SYNC: V reference to VSYNC (minimum 1 line clock)
12:0	0x0	H_REF_TO_SYNC: H reference to HSYNC (minimum 0 pixel clock)

21.8.5 DC_DISP_SYNC_WIDTH_0

H/V SYNC Pulse Width

This register specifies the width of HSYNC and VSYNC pulses. Check the Display Timing Options section for programming restrictions for REF_TO_SYNC.

Offset: 0x407 | Byte Offset: 0x101c | Read/Write: R/W | Reset: 0x00000000 (0bxxx0000000000000xxx0000000000000)

Bit	Reset	Description
28:16	0x0	V_SYNC_WIDTH: VSYNC pulse width (minimum 1 line clock)
12:0	0x0	H_SYNC_WIDTH: HSYNC pulse width (minimum 1 pixel clock)

21.8.6 DC_DISP_BACK_PORCH_0

H/V Back Porch

This register specifies the distance between H/V SYNC trailing edge to beginning of display active area. This is a 2's complement value, and a negative value indicates that H/V SYNC overlaps with the corresponding display active area. Check the Display Timing Options section for programming restrictions for REF_TO_SYNC.

Offset: 0x408 | Byte Offset: 0x1020 | Read/Write: R/W | Reset: 0x00000000 (0bxxx0000000000000xxx0000000000000)

Bit	Reset	Description
28:16	0x0	V_BACK_PORCH: V back porch
12:0	0x0	H_BACK_PORCH: H back porch

21.8.7 DC_DISP_DISP_ACTIVE_0

H/V Display Active Width

This register specifies the width of the H/V display active area. Check the Display Timing Options section for programming restrictions for REF_TO_SYNC.

Offset: 0x409 | Byte Offset: 0x1024 | Read/Write: R/W | Reset: 0x00030003 (0bxxx0000000000011xxx0000000000011)

Bit	Reset	Description
28:16	0x3	V_DISP_ACTIVE: V display active width (minimum 16 lines)
12:0	0x3	H_DISP_ACTIVE: H display active width (minimum 16 pixels)

21.8.8 DC_DISP_FRONT_PORCH_0

H/V Front Porch

This register specifies the distance between end of H/V display active area to the leading edge of the corresponding H/V SYNC.

Design Note: H/V active end plus the H/V front porch value minus the H/V reference to H/VSYNC determines the H/V total (final H/V count value for the H/V display counter). Check the Display Timing Options section for programming restrictions for REF_TO_SYNC.

Offset: 0x40a | Byte Offset: 0x1028 | Read/Write: R/W | Reset: 0x00000000 (0bxxx0000000000000xxx0000000000000)

Bit	Reset	Description
28:16	0x0	V_FRONT_PORCH: VSYNC front porch (minimum -=PS_=-V_REF_TO_SYNC + 1)
12:0	0x0	H_FRONT_PORCH: HSYNC front porch (minimum -=PS_=-H_REF_TO_SYNC + 1)

21.8.9 DC_DISP_H_PULSE0_CONTROL_0

H Pulse 0 Control

Class: Display Extended Timings

Horizontal pulse 0 is programmable pulse that repeats every line.

In NORMAL mode, this signal can have several pulses (A to D) per line with programmable width as defined by the pairs of start and end positions. The pulses must not overlap and must occur in sequence: pulse A, then pulse B, etc. In this case, the Enable field must be set to one of the End position. If the Enable field is set to one of the Start position then the pulse generator will stop as if the Enable field is set to the previous End position. If the Enable field is set to the Start A position, then no pulse is generated.

In ONE_CLOCK mode, this signal can have up to twice the number of pulses per line with each pulse having a width of 1 pixel clock. In this mode, the position of the one-clock pulses corresponds to the enabled Start and End positions.

Regardless of the mode, the pulse generator processes the pairs of start and end position sequentially in the order of: Start A, End A, Start B, End B, etc.

So these start/end positions should be programmed in increasing order. If any of the positions are programmed in non-increasing order (has invalid value) then the pulse generator will stop at the last valid position.

Polarity adjustment is made prior to V display qualification. This register specifies options for Horizontal pulse 0.

21.8.19 DC_DISP_H_PULSE2_CONTROL_0

H Pulse 2 Control

Horizontal pulse 2 is a programmable pulse that repeats every line.

In NORMAL mode, this signal can have several pulses (A to D) per line with programmable width as defined by the pairs of start and end positions. The pulses must not overlap and must occur in sequence: pulse A, then pulse B, etc. In this case, the Enable field must be set to one of the End position. If the Enable field is set to one of the Start position then the pulse

generator will stop as if the Enable field is set to the previous End position. If the Enable field is set to the Start A position, then no pulse is generated.

In ONE_CLOCK mode this signal can have up to twice the number of pulses per line with each pulse having a width of 1 pixel clock. In this mode, the position of the one-clock pulses corresponds to the enabled Start and End positions.

Regardless of the mode, the pulse generator processes the pairs of start and end position sequentially in the order of: Start A, End A, Start B, End B, etc. So these start/end positions should be programmed in increasing order. If any of the positions are programmed in non-increasing order (has invalid value), then the pulse generator will stop at the last valid position. Polarity adjustment is made prior to V display qualification. This register specifies options for Horizontal pulse 2.

21.8.36 DC_DISP_DISP_CLOCK_CONTROL_0

Display Clock Control

The shift clock divider is used to divide root clock for display controller module to generate internal shift clock for shifting data to the display. Output of this divider is typically used to generate the external shift clock which is sent to the display (SC0 and/or SC1) except for 1-pixel/1-clock parallel display.

The output of this divider is also used to generate Programmable Pulse (PP) signal. For 1-pixel/1-clock parallel display, SC0 and SC1 are generated using the output of pixel clock divider which can be set to 1, 2, or 4 for 1-pixel/1-clock parallel display.

The reason pixel clock divider 2 and 4 are allowed for 1-pixel/1-clock parallel display interface is so that the clock that generates PP can be generated with 2x or 4x higher frequency than pixel clock and therefore can produce higher resolution PP pulse positions. For all cases of parallel display, SC0 and SC1 can be further divided by 1, 2, or 4.

Class: Display Interface Settings

This register controls generation of shift clock to the display and internal pixel clock. Internal display pipeline runs with pixel clock and processes 1 pixel per clock.

Offset: 0x42e │ Byte Offset: 0x10b8 │ Read/Write: R/W │ Reset: 0x00000006 (0bxxxxxxxxxxxxxxxxxxxx000000000110)

7:0	0x6	NONE	SHIFT_CLK_DIVIDER: Shift Clock Divider. 0 = divide by 1 1 = divide by 1.5 2 = divide by 2 3 = divide by 2.5 4 = divide by 3 : : : : 254 = divide by 128 255 = divide by 128.5 Pixel clock divider is used to divide output of internal shift clock divider to generate internal pixel clock which is used to clock the internal horizontal and vertical counters. This divider also determines the output format for parallel interface, serial interface, and LCD SPI interface in conjunction with Display Data Format parameter. For 1-pixel/1-clock parallel display interface, valid settings are PCD1, PCD2, and PCD4. Note that the main reason to use PCD2 and PCD4 is to get higher frequency PP clock because the PP clock is always generated from the output of shift clock divider. For non 1-pixel/1-clock parallel display interface, valid settings are, PCD1H (2-pixel/3-clock), PCD2 (1-pixel/2-clock), and PCD3 (1-pixel/3-clock). For 1-channel serial display interface, valid settings are PCD3 (3-bpp 1-ch), PCD4 (3-bpp 1-ch), PCD6 (6-bpp 1-ch), PCD9 (9-bpp 1-ch), PCD12 (12-bpp 1-ch), PCD16 (16-bpp 1-ch), PCD18 (18-bpp 1-ch). For 2-channel serial display interface, valid settings are PCD2 (3-bpp 2-ch), PCD3 (6-bpp 2-ch), PCD6 (12-bpp 2-ch), PCD8 (16-bpp 2-ch), PCD9 (18-bpp 2-ch). For 3-channel serial display interface, valid settings are PCD1 (3-bpp 3-ch), PCD2 (6-bpp 3-ch), PCD3 (9-bpp 3-ch), PCD4 (12-bpp 3-ch), PCD6 (18-bpp 3-ch). For LCD SPI interface, valid settings are PCD12 (B4G4R4), PCD16 (B5G6R5), PCD18 (B6G6R6), PCD24 (B8G8R8), PCD8 (B5G6R5 with data/command bit), PCD6 (B5G6R5 with data/command start byte - depending on data/command bit), PCD4 (P8 for spi8), PCD9 (B5G6R5 with chip select deassertion at 8-bit boundary, spi16x2), PCD3 (P8 for spidc), PCD2 (B5G6R5 with data/command bit and chip select deassertion at 9-bit boundary, spi16x2dc), and PCD13 (spi12p2, no chip select deassertion between pairs of pixels).

13:12	0x0	ORD_DITHER_ROTATION: Ordered Dither Frame Rotation. This parameter specifies the rotation frequency of the dither matrix in terms of number of frames. If programmed to 0, there is no dither matrix rotation. If programmed to N, where N is larger than 0, the dither matrix is rotated clockwise every N frame.
9:8	X	DITHER_CONTROL: Dither Control 00= dither disabled 01= reserved 10= ordered dither 11= temporal dithering Design Note: initial dither matrix (where d is 2 dither bits) d=00 d=01 d=10 d=11 --------- ---------- --------- --------- 0 0 1 0 0 1 0 1 --------- --------- --------- --------- 0 0 0 0 1 0 1 1 --------- ---- Note: 0 in the matrix specifies no addition to base color 1 in the matrix specifies incrementation of base color (with saturation) 0 = DISABLE 2 = ORDERED 3 = TEMPORAL

Bit	Reset	Description
7:6	0x0	TEMPORAL_DITHER_PHASE: Temporal dither LFSR phase control 2'b01: random_data <= 34'h3fffffff 2'b10: random_data <= 34'h155555555 2'b11: random_data <= 34'h2aaaaaaaa 2'b00: retains previous value Temporal dither supports only 8 to 6 bits dithering.
3:0	0x0	BASE_COLOR_SIZE: Display Base Color Size. This parameter determines the number of bits per color after dither. 0= 6 bits 1= 1 bit 2= 2 bits 3= 3 bits 4= 4 bits 5= 5 bits 6= 5 bits for R,B and 6 bits for G 7= 3 bits for R,G and 2 bits for B 8= 8 bits, this also forces dither to be disabled. This setting can be used to output 24-bit data in 1-pixel/clock parallel display data format. 0 = BASE666 1 = BASE111 2 = BASE222 3 = BASE333 4 = BASE444 5 = BASE555 6 = BASE565 7 = BASE332 8 = BASE888

21.8.39 DC_DISP_COLOR_KEY0_LOWER_0

Color Key 0 Lower Value

Color Key 0 and Color Key 1

Two ranges of color key are defined and they are common for all windows because it is expected that typically only one window will have the color key enabled. Because there are two sets of color key, it is possible to have 2 windows each using one color key set.

Usage of this color key is described in the Display Color Key and Blending class.

21.8.43 DC_DISP_CURSOR_FOREGROUND_0

Cursor Foreground color

Class: Hardware Cursor

Hardware cursor is supported for 32x32 or for 64x64 2-bpp cursor.

Cursor start address is aligned to 1 KB boundary. All cursor registers except for cursor foreground and background colors are triple buffered.

GENERAL_UPDATE controls ASSEMBLY->ARM latching, GENERAL_ACT_REQ controls ARM->ACTIVE latching.

Cursor scaling and flipping are not implemented so this must be done by software if needed. Cursor H/V positions are signed number with respect to one of the display windows or with respect to upper left position of display active area as specified by cursor clipping parameter which also determines cursor clipping boundary. If cursor position is with respect to one of the display window and the corresponding display window is disabled then cursor will also be disabled.

In legacy cursor mode, only 32x32 and 64x64 are supported

21.8.49 DC_DISP_DC_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control Register (where applicable) and Clock Gating Control

Note: The FIFO timing aspects of this register are no longer supported, but are retained for software compatibility. The clock override/ovr_mode fields of this register control the second level clock gating for the client and MC side of the MCCIF. All clock gating is enabled by default.

A ‘1’ written to the rclk/wclk override filed will result in one of the following:

- With wclk/rclk override mode = LEGACY, the clock reverts to the legacy mode of operation (where the clock is on whenever the client clock is enabled.
- With wclk/rclk override mode = ON, the clock is always on inside the MCCIF and PC.

A '1' written to the cclk override field keeps the client's clock always on inside the MCCIF.

Offset: 0x480 │ Byte Offset: 0x1200 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxx00000xxxxxxxxxxxx0000)

21.8.54 DC_DISP_SD_CONTROL_0

The Smart Dimmer (PRISM 3) function takes advantage of the fact that a perceived pixel brightness in an LCD depends on both the pixel brightness value and the backlight intensity to reduce the backlight intensity to save power. Statistics are gathered on the current video frame and an "enhancement" is applied to subsequent frames that increases the pixel brightness value and reduces the backlight brightness to give an overall image intensity that is mostly the same as before.

PRISM 3 Control

Offset: 0x4c2 | Byte Offset: 0x1308 | Read/Write: R/W | Reset: 0x00004000 (0bx000xxxxxxxxxxx0100000000000000)

Bit	Reset	Description
30:29	BIAS0	K_INIT_BIAS: BIAS of the initial K bias MSB of count 0 = BIAS0 : bias 0 1 = BIAS1 : bias 1.0 2 = BIAS_HALF : bias 0.5 3 = BIAS_MSB
28	VSYNC	SD_FRAME_PROC_CONTROL: when to run per-frame processing. VSYNC is legacy behavior. 0 = VSYNC 1 = VPULSE2
15	DISABLE	SMOOTH_K_ENABLE: When enable, maximum raw K change per frame is limited to SMOOTH_K_INCR 0 = DISABLE 1 = ENABLE
14	ENABLE	SOFT_CLIPPING_ENABLE: When enabled, enhancement gain (K) is reduced for pixels above SOFT_CLIPPING_THRESHOLD level to avoid saturation (clipping). 0 = DISABLE 1 = ENABLE
13	DISABLE	SD_WINDOW_ENABLE: When enabled, constrain histogram (and therefore backlight) to a rectangular subset of display. The rectangle has upper/left corner described by SD_WINDOW_POSITION, and width/height by SD_WINDOW_SIZE. Useful for when display has regions that should not influence SD, such as letterbox borders, etc. Enhancement is always performed on whole display, regardless. DISABLE: SD histogram done over whole display ENABLE: SD histogram done over rectangular subset given by SD_WINDOW* registers 0 = DISABLE 1 = ENABLE
12	DISABLE	K_LIMIT_ENABLE: When enabled, Max. K is taken from K_LIMIT register rather than computed from AGGRESSIVENESS. DISABLE: K is limited by AGGRESSIVENESS ENABLE: K is limited by K_LIMIT register. 0 = DISABLE

Bit	Reset	Description
		1 = ENABLE
11	0x0	SD_CORRECTION_MODE: Determines which K values are used to modify the pixel values. MANUAL : The K values in the SD_MAN_K_VALUES register are used to modify pixel values. 0 = AUTO_CORRECT : AUTO_CORRECT : SD Hardware computed K values are used to 1 = MANUAL
10	0x0	SD_ONE_SHOT: Enables the PRISM 3 function for one frame only. on which the SD statistics are gathered. NOTE: The SD_ENABLE field (see above) must be set to ONE_SHOT in order to use this function. 0 = DISABLE : Automatically cleared to DISABLE at the end of the frame 1 = ENABLE
9:8	0x0	HW_UPDATE_DLY: Determines the delay - in video frames - of the update of the hardware enhancement value that is applied to the pixels. This is useful for allowing the software some time to update the backlight control, when the control must be sent via side-band control packets or by some other means of control that incurs a sizeable delay. Being able to delay the hardware update ensures that the modification of the pixels occurs as nearly simultaneously with the update of the backlight as possible. Value Description 0 No delay - pixels modified immediately 1 New enhancement value delayed by 1 frame. 2 New enhancement value delayed by 2 frames. 3 New enhancement value delayed by 3 frames.
7:5	0x0	AGGRESSIVENESS: The "aggressiveness" level of the PRISM 3 algorithm. Higher aggressiveness levels result in higher power savings at the potential expense of image quality. The number programmed determines how many highlight pixels will be allowed to exceed the maximum representable brightness value and be clipped to that value. It also determines the maximum allowed enhancement value (k) applied to the pixel brightness. AGGRESSIVENESS Description % pixels Max. k value crushed value 0 Essentially off 0% 1.00 1 Highest quality < 5% 1.10 2 Higher quality < 10% 1.15 3 Balanced < 15% 1.20 4 Higher battery life < 20% 1.25 5 Highest battery life < 25% 1.50
4:3	0x0	BIN_WIDTH: Width of the Histogram bins, in quantization levels. EIGHT = 8 levels per bin. Bins span range from 0 to 255 0 = ONE : ONE = 1 level per bin. Bins span range from 224 to 255 1 = TWO : TWO = 2 levels per bin. Bins span range from 192 to 255 2 = FOUR : FOUR = 4 levels per bin. Bins span range from 128 to 255 3 = EIGHT
2	0x0	USE_VID_LUMA: Use Video Luminance control of luminance: Luminance = MAX(R, G, B) ENABLE = use "video" luminance, which is determined by the coefficients in the SD_CSC_COEFFS register See the SD_CSC_COEFFS register for details. 0 = DISABLE : DISABLE = use Hue Saturation Value (HSV) version 1 = ENABLE
1:0	0x0	SD_ENABLE: Enables the PRISM 3 Function ONE_SHOT = SD function enabled, but statistics gathering limited to the next frame only. 0 = DISABLE : DISABLE = SD function disabled. 1 = ENABLE : ENABLE = SD function enabled and operational. 2 = ONE_SHOT

21.8.55 DC_DISP_SD_CSC_COEFF_0

Luminance calculation coefficients used to convert the red, green, and blue color components into a luminance value. The conversion is performed according to the following equation: Luminance = (R * R_COEFF + G * G_COEFF + B * B_COEFF) >> 4 It is suggested that the values of the coefficients be programmed as shown below, though user-defined color spaces are also accommodated. Color Space R_COEFF G_COEFF B_COEFF ITU-R Bt601 5 9 2 ITU-R Bt709 3 12 1. The coefficients

do not have to be particularly accurate, hence their low precision, and the coefficients used are open to experimentation to obtain the best results.

Offset: 0x4c3 | Byte Offset: 0x130c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx0000xxxx0000xxxx0000xxxx)

Bit	Reset	Description
23:20	0x0	B_COEFF: Blue coefficient for luminance calculation
15:12	0x0	G_COEFF: Green coefficient for luminance calculation
7:4	0x0	R_COEFF: Red coefficient for luminance calculation

21.8.56 DC_DISP_SD_LUT_0

Enhancement value (k) Look Up Table. Each LUT entry contains the value of k for each of the three color components. Since the value of k for the color components must be the reciprocal of the hardware-computed value of k, and the hardware value is guaranteed to be less than or equal to 1, the values in the LUT represent the fractional part of k, with an implied 1 to the left of the decimal place. For example, if the programmed value of R_LUT was 64 (01000000 in binary), then the actual value of k generated would be 1.01000000 in binary or 1.25 in decimal. To program a default, linear response into the LUT, use the following code as a guide: for (i = 0; i < 9; i++) { t = (4096 / (8 + i)) - 256; if (t > 255) t = 255; R_LUT[i] = t; G_LUT[i] = t; B_LUT[i] = t; } For other non-linear response curves (for example, to take display gamma into consideration), this code will have to be modified.
This is an array of 9 identical register entries; the register fields below apply to each entry.

Offset: 0x4c4..0x4cc | Byte Offset: 0x1310..0x1330 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

21.8.60 DC_DISP_SD_BL_PARAMETERS_0

Backlight response parameters. Defines the parameters for the backlight temporal response model.

Offset: 0x4d7 │ Byte Offset: 0x135c │ Read/Write: R/W │ Reset: 0x00000400 (0bxxxxxxxx00000000xxxxx10000000000) | Default: 0x00ff0000

Bit	Reset	SW Default	Description
23:16	0x0	0xff	STEP: Determines the instantaneous portion of the target value of enhancement that is applied. 0 = 0% : response is entirely exponential and determined by TIME_CONSTANT 128 = 50% : response will instantly step up by 50% and will then be exponential. 255 = 100% : response is entirely instantaneous. TIME_CONSTANT has no effect.
10:0	0x400	NONE	TIME_CONSTANT: The time constant for the response curve. This value represents the fraction by which the value of enhancement value approaches the target value each frame. Example values are shown below: 0 : The value will never reach the target (infinite TC) 512 : The next value will be halfway between the current value and the target value. 1024 : The next value will be 100% of the target value. In other words - an instantaneous response.

21.8.61 DC_DISP_SD_BL_TF_0

Backlight Transfer Function

Each register contains 4 points on the Transfer Function curve that defines how the backlight output changes with respect to the control input. Each point defines a value at the vertex of a 16 segment line. The 17th point is defined to be the maximum value (it is assumed 100% control == 100% light output).

This is an array of 4 identical register entries; the register fields below apply to each entry.

21.8.62 DC_DISP_SD_BL_CONTROL_0

Backlight Control Register

Offset: 0x4dc │ Byte Offset: 0x1370 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	R/W	Reset	Description
15:8	RO	X	BRIGHTNESS: Backlight brightness modification value. This value is determined by the hardware according to all the other control registers and the image content. The amount by which the backlight should be modified is given as a fraction with 0 representing that the backlight should be off and 255 representing no change in the backlight intensity. Other values vary linearly between these two extremes. New BL control = (Old BL control * BRIGHTNESS) / 255
1:0	RW	0x0	BL_MODE: Control Mode: and adjust the backlight brightness itself. PWM_AUTO : Hardware will adjust the backlight PWM control signal directly using the value in BRIGHTNESS. * OTHER VALUES ARE RESERVED FOR FUTURE USE * 0 = MANUAL : MANUAL : Hardware makes no BL corrections. Software must read the BRIGHTNESS field 1 = PWM_AUTO

21.8.63 DC_DISP_SD_HW_K_VALUES_0

Hardware-computed values of K for each color component. These values are used to modify the pixel values when CORRECTION_MODE in the SD_CONTROL register is set to AUTO_CORRECT. The numerical format is a fractional 10-bit number. Since we only ever want to make the pixel values bigger, there is an implied integer "1" not present in the register value. Only the fractional part is returned. Also in Tegra K1 devices, only the top 7 bits of the 10-bit K word have any meaning. The bottom 3 bits are always 0 and are reserved for future expansion. This register is read only.

Offset: 0x4dd │ Byte Offset: 0x1374 │ Read/Write: RO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
29:20	X	HW_K_BLUE: Value of K for blue pixels.
19:10	X	HW_K_GREEN: Value of K for green pixels.
9:0	X	HW_K_RED: Value of K for red pixels.

21.8.64 DC_DISP_SD_MAN_K_VALUES_0

Manual values of K for each color component. These values are used to modify the pixel values when CORRECTION_MODE in the SD_CONTROL register is set to MANUAL. The numerical format is a fractional 10-bit number. Since we only ever want to make the pixel values bigger, there is an implied integer "1" not present in the register value. Only the fractional part can be programmed. Therefore, K values can only be programmed from 1.0 to slightly less than 2.0 .Also note that only the top 7 bits of the 10-bit K word have any effect in the hardware. The bottom 3 bits are reserved for future expansion.

Offset: 0x4de | Byte Offset: 0x1378 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
29:20	X	MAN_K_BLUE: Value of K for blue pixels.
19:10	X	MAN_K_GREEN: Value of K for green pixels.
9:0	X	MAN_K_RED: Value of K for red pixels.

21.8.65 DC_DISP_SD_K_LIMIT_0

Offset: 0x4df | Byte Offset: 0x137c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
9:0	X	K_LIMIT: When K_LIMIT_ENABLE=ENABLE, limits raw K independently of AGGRESSIVENESS. Currently, only the bottom 8 bits are effective. The upper 2 are reserved for future expansion.

21.8.66 DC_DISP_SD_WINDOW_POSITION_0

SD Window Position

Offset: 0x4e0 | Byte Offset: 0x1380 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	SD_WIN_V_POSITION: SD window vertical position. This is specified with respect to the top edge of active display area.
12:0	X	SD_WIN_H_POSITION: SD window horizontal position (pixels). This is specified with respect to the left edge of active display area.

21.8.67 DC_DISP_SD_WINDOW_SIZE_0

SD Window Size

Offset: 0x4e1 | Byte Offset: 0x1384 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	SD_WIN_V_SIZE: SD window vertical height (lines).
12:0	X	SD_WIN_H_SIZE: SD window horizontal width (pixels).

21.8.68 DC_DISP_SD_SOFT_CLIPPING_0

SD soft clipping parameters. Software programs both threshold and a reciprocal thereof.

Offset: 0x4e2 | Byte Offset: 0x1388 | Read/Write: R/W | Reset: 0x02000080 (0b00000010000000000xxxxxxx10000000)

Bit	Reset	Description
31:16	0x200	SOFT_CLIPPING_RECIP: Reciprocal of inverse threshold. Compute as RECIP = int(64*1024 * 1.0 / (256 - THRESHOLD)). For example, for THRESHOLD=128, RECIP = int(64*1024 * 1.0 / (256 - 128)) = 512.
7:0	0x80	SOFT_CLIPPING_THRESHOLD: Threshold at which pixel enhancement gain is reduced.

21.8.69 DC_DISP_SD_SMOOTH_K_0

Offset: 0x4e3 | Byte Offset: 0x138c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
13:0	X	SMOOTH_K_INCR: When SMOOTH_K_ENABLE=1, the raw K is changed at most by SMOOTH_K_INCR per frame. 8.6 fixed-point fraction, with resolution 1/64. Currently, only the top 12 bits are effective. The bottom 2 are reserved for future expansion, so the effective resolution is 1/16.

21.8.70 DC_DISP_BLEND_BACKGROUND_COLOR_0

Offset: 0x4e4 | Byte Offset: 0x1390 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:24	0x0	BKGND_ALPHA
23:16	0x0	BKGND_BLUE
15:8	0x0	BKGND_GREEN
7:0	0x0	BKGND_RED

21.8.71 DC_DISP_INTERLACE_CONTROL_0

1080i Related Register

This register controls whether interlacing is enabled or disabled. When interlacing is enabled, the data is fetched from memory at 1080i (interlaced) and all fields are passed directly to the panel. A set of even (normal) and odd (new for interlacing) registers define the field base addresses and timings.

If interlacing is disabled, the following interlacing related registers will have NO effect.

Offset: 0x4e5 | Byte Offset: 0x1394 | Read/Write: R/W | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	R/W	Reset	Description
2	RO	X	INTERLACE_STATUS: 0 = field1 1 = field2 0 = FIELD1 1 = FIELD2
1	RW	0x0	INTERLACE_START: 0 = field1 1 = field2 0 = FIELD1 1 = FIELD2
0	RW	0x0	INTERLACE_ENABLE: 0 = DISABLE 1 = ENABLE

21.8.72 DC_DISP_INTERLACE_FIELD2_REF_TO_SYNC_0

1080i Related Register

This register controls the ref to sync offset for H sync and V sync for FIELD2.

Offset: 0x4e6 | Byte Offset: 0x1398 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	FIELD2_V_REF_TO_SYNC: V reference to VSYNC for FIELD2. IMP - Units are in pixel clocks. Generally, for the non-interlaced timing, the units are in line clocks; however, for interlaced V sync must be generated at a pixel granularity with respect to V ref.
12:0	X	FIELD2_H_REF_TO_SYNC: H reference to HSYNC for FIELD2. Units are in pixel clocks.

21.8.73 DC_DISP_INTERLACE_FIELD2_SYNC_WIDTH_0

1080i Related Register

This register controls the H and V sync widths for FIELD2.

Offset: 0x4e7 | Byte Offset: 0x139c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	FIELD2_V_SYNC_WIDTH: This field controls the V sync widths for FIELD2. Units are in line clocks.
12:0	X	FIELD2_H_SYNC_WIDTH: This field controls the H sync widths for FIELD2. Units are in pixel clocks.

21.8.74 DC_DISP_INTERLACE_FIELD2_BACK_PORCH_0

1080i Related Register

This register controls the H and V back porch widths for FIELD2.

Offset: 0x4e8 | Byte Offset: 0x13a0 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	FIELD2_V_BACK_PORCH: V back porch. Units are in line clocks.
12:0	X	FIELD2_H_BACK_PORCH: H back porch. Units are in pixel clocks.

21.8.75 DC_DISP_INTERLACE_FIELD2_FRONT_PORCH_0

1080i Related Register

This register controls the H and V front porch widths for FIELD2.

Offset: 0x4e9 | Byte Offset: 0x13a4 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	FIELD2_V_FRONT_PORCH: V front porch. Units are in line clocks.
12:0	X	FIELD2_H_FRONT_PORCH: H front porch. Units are in pixel clocks.

21.8.76 DC_DISP_INTERLACE_FIELD2_DISP_ACTIVE_0

1080i Related Register

This register controls the H and V active widths for FIELD2.

Offset: 0x4ea | Byte Offset: 0x13a8 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	FIELD2_V_DISP_ACTIVE: V active width. Units are in line clocks.
12:0	X	FIELD2_H_DISP_ACTIVE: H active width. Units are in pixel clocks.

21.8.77 DC_DISP_CURSOR_UNDERFLOW_CTRL_0

Offset: 0x4eb | Byte Offset: 0x13ac | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxx0)

Bit	Reset	Description
7	0x0	CURSOR_UFLOW_CYA: 0 = DISABLE 1 = ENABLE
0	0x0	CURSOR_UFLOW_CTRL_DBG_MODE: 0 = DISABLE 1 = ENABLE

21.8.78 DC_DISP_CURSOR_START_ADDR_HI_0

Cursor Start Address

Offset: 0x4ec | Byte Offset: 0x13b0 | Read/Write: R/W | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
1:0	X	CURSOR_START_ADDR_HI: Cursor Start Address bits 33:32

21.8.79 DC_DISP_CURSOR_START_ADDR_HI_NS_0

Shadow of Cursor Start Address

Offset: 0x4ed | Byte Offset: 0x13b4 | Read/Write: R/W | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
1:0	X	CURSOR_START_ADDR_HI_NS

21.8.80 DC_DISP_CURSOR_INTERLACE_CONTROL_0

This register controls whether interlacing is enabled or disabled. If interlacing is disabled, the interlacing related registers will have NO effect.

Cursor Start Address bits 33:32

Offset: 0x4ee | Byte Offset: 0x13b8 | Read/Write: R/W | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx00x00)

Bit	R/W	Reset	Description
4	RW	0x0	CURSOR_INTERLACE_FIELD2_VOFF_INCR: FIELD2 v position incr Enable 0 = DISABLE 1 = ENABLE

Bit	R/W	Reset	Description
3	RW	0x0	CURSOR_INTERLACE_FIELD1_VOFF_INCR: FIELD1 v position incr Enable 0 = DISABLE 1 = ENABLE
2	RO	X	CURSOR_INTERLACE_STATUS: Current line start. 0= line 0 1= line 1 0 = LINE0 1 = LINE1
1	RW	0x0	CURSOR_INTERLACE_START: Starting line 0= line 0 1= line 1 0 = LINE0 1 = LINE1
0	RW	0x0	CURSOR_INTERLACE_ENABLE: Interlace enable 0 = DISABLE 1 = ENABLE

21.8.81 DC_DISP_CSC2_CONTROL_0

The CSC2 can be used for RGB to YCbCr conversion used in 1080i HDMI output. This hardcoded color space converter supports YCBCR709 and YCBCR601 output as YUV444.

Offset: 0x4ef | Byte Offset: 0x13bc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000)

Bit	Reset	Description
2	0x0	LIMIT_RGB_COLOR: scale RGB [0,255] to [16,235] 0 = DISABLE 1 = ENABLE
1:0	RGB	OUTPUT_COLOR_SELECT: output color select: RGB for normal output, YCBCR709 for HDMI or YCBCR601 for older television color formats. 0 = RGB 1 = YCBCR709 2 = YCBCR601

21.8.82 DC_DISP_BLEND_CURSOR_CONTROL_0

Offset: 0x4f1 | Byte Offset: 0x13c4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxx0xxxxxx00xxxxxx0000000000)

Bit	Reset	Description
24	0x0	CURSOR_MODE_SELECT: 0 = LEGACY 1 = NORMAL
17:16	0x0	CURSOR_DST_BLEND_FACTOR_SELECT: 0 = ZERO 1 = K1 2 = NEG_K1_TIMES_SRC
9:8	0x0	CURSOR_SRC_BLEND_FACTOR_SELECT: 0 = K1 1 = K1_TIMES_SRC
7:0	0x0	CURSOR_ALPHA

21.8.83 DC_DISP_DVFS_CURSOR_CONTROL_0

Offset: 0x4f2 | Byte Offset: 0x13c8 | Read/Write: R/W | Reset: 0x00000003 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000011)

Bit	Reset	Description
8	DISABLE	CURSOR_DVFS_ENABLE: DISABLE: Forces ready_for_latency_event true (i.e., always allows DVFS event) ENABLE: Allows ready_for_latency_event to toggle, based on CURSOR_DVFS_THRESHOLD 0 = DISABLE 1 = ENABLE
7:0	0x3	CURSOR_DVFS_THRESHOLD

21.8.84 DC_DISP_CURSOR_UFLOW_DBG_PIXEL_0

Offset: 0x4f3 | Byte Offset: 0x13cc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	CURSOR_UFLOW_DBG_PIXEL

21.8.85 DC_DISP_CURSOR_SPOOLUP_CONTROL_0

Programmable spool up for cursor. If spoolup count > hc_vactive_start, it will be clamped to zero.

Offset: 0x4f4 | Byte Offset: 0x13d0 | Read/Write: R/W | Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000001)

Bit	Reset	Description
7:0	0x1	CURSOR_SPOOLUP_START

21.8.86 DC_DISP_DISPLAY_CLK_GATE_OVERRIDE_0

Offset: 0x4f5 | Byte Offset: 0x13d4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	CMU_CLK_GATE_OVERRIDE: Disable clock-gating of the CMU module. 0 = DISABLE 1 = ENABLE
0	0x0	CURSOR_CLK_GATE_OVERRIDE: Disable clock-gating of cursor memfetch/control modules 0 = DISABLE 1 = ENABLE

21.8.87 DC_DISP_DISPLAY_DBG_TIMING_0

Offset: 0x4f6 | Byte Offset: 0x13d8 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	X	H_BLANK
28:16	X	H_COUNT
15	X	V_BLANK
12:0	X	V_COUNT

21.8.88 DC_DISP_DISPLAY_SPARE0_0

Offset: 0x4f7 | Byte Offset: 0x13dc | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	SCRATCH_0

21.8.89 DC_DISP_DISPLAY_SPARE1_0

Offset: 0x4f8 | Byte Offset: 0x13e0 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	SCRATCH_1

21.9 Window A (WINC_A) Registers

These registers control window A parameters.

> **Note:** There are three copies of these registers for windows A, B, and C. Windows A, B, and C support different features. Windows D, H, and T have subsets of these registers.

Windows A/B/C: color palette, digital vibrance, color space conversion, horizontal/vertical filtering

Window T: only 2BPP and 4BPP pitched linear format. None of the features listed in Windows A/B/C. The registers under DC_WINT are only accessed directly and not triple buffered.

21.9.1 DC_WINC_A_COLOR_PALETTE_0

This is used for palletized data format (color depth of 8 bpp or less) or for gamma correction for non-palletized data formats (color depth of more than 8-bpp).

Each window has its own color palette which consists of three 256x8 register files which can be written by the host and indexed (read) by the window.

For palletized data formats less than 8 bpp, the pixel data is aligned to least significant bits of the palette index (address), and the remaining upper bits are filled with the corresponding bits of the Palette Color Extension. For example, for 4-bpp mode, the pixel data occupies bits 3:0 of the palette index, and bits 7:4 of the palette index are set to bits 7:4 of the Palette Color Extension.

Note that a host read is assumed to be not needed - software can cache the color palette in system memory.

This is an array of 256 identical register entries; the register fields below apply to each entry.

Window A Color Palette

Offset: 0x500..0x5ff | Byte Offset: 0x1400..0x17fc | Read/Write: WO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:16	X	A_COLOR_PALETTE_B: Blue Color Palette
15:8	X	A_COLOR_PALETTE_G: Green Color Palette
7:0	X	A_COLOR_PALETTE_R: Red Color Palette

21.9.2 DC_WINC_A_PALETTE_COLOR_EXT_0

Palette extension for 1-bpp, 2-bpp, and 4-bpp. These bits provide the upper most significant bits for indexing the color palette.

Window A Palette Color Extension

Offset: 0x600 │ Byte Offset: 0x1800 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:1	X	A_PALETTE_COLOR_EXT: Window A Palette Color Extension. Bits 7:1 are used for 1-bpp mode, bits 7:2 are used for 2-bpp mode, and bits 7:4 are used for 4-bpp mode

21.9.3 DC_WINC_A_H_FILTER_P00_0

Horizontal Scaling Filter Coefficients

Horizontal scaling filter is a 6-tap filter with 4-bit positional phase.

- Coefficients 0 and 5 are 3-bit signed values ranging from -4 to 3.
- Coefficients 1 and 4 are 5-bit signed values ranging from -16 to 15.
- Coefficients 2 and 3 are 8-bit unsigned values ranging from 0 to 128.
- Coefficient 0 is the multiplier for the earliest pixel (P0) in the group of 6 pixels and
- Coefficient 5 is the multiplier for the latest pixel (P5) in the group. The output pixel positional phase is defined as centered in P2 if the positional phase is 0 or proportionally in between P2 and P3 if the positional phase is larger than 0.

The sum of all coefficients for each phase should be 128 typically, and software should never program the sum of all coefficients for a phase to be more than 128.

For each horizontal positional phase, the 6 filter coefficients require 32 register bits.

Note that color value ranges from 0 to 255 for Y, R, G, B, and -128 to 127 for U and V.

Window A Horizontal Filter phase 00

Offset: 0x601 │ Byte Offset: 0x1804 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:29	X	A_H_FILTER_P00C5: Phase 00 coefficient 5 (typically 0)
28:24	X	A_H_FILTER_P00C4: Phase 00 coefficient 4 (typically 0)
23:16	X	A_H_FILTER_P00C3: Phase 00 coefficient 3 (typically 0)
15:8	X	A_H_FILTER_P00C2: Phase 00 coefficient 2 (typically 128)
7:3	X	A_H_FILTER_P00C1: Phase 00 coefficient 1 (typically 0)
2:0	X	A_H_FILTER_P00C0: Phase 00 coefficient 0 (typically 0)

21.9.4 DC_WINC_A_H_FILTER_P01_0

Window A Horizontal Filter phase 01

Offset: 0x602 | Byte Offset: 0x1808 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:29	X	A_H_FILTER_P01C5: Phase 01 coefficient 5 (typically 1)

21.9.19 DC_WINC_A_CSC_YOF_0

Color Space Conversion Coefficients

The CSC can be used for YUV to RGB conversion with brightness and hue/saturation control. The CSC can only be enabled for window A controlled by CSC_ENABLE register bits.

For Y color, the Y offset is applied first and saturation (clipping) is performed immediately after the Y offset is applied.

R = sat(KYRGB * sat(Y + YOF) + KUR * U + KVR * V)

G = sat(KYRGB * sat(Y + YOF) + KUG * U + KVG * V)

B = sat(KYRGB * sat(Y + YOF) + KUB * U + KVB * V)

Saturation and rounding is performed in the range of 0 to 255 for the above equations.

Typical values are:

YOF = -16.000, KYRGB = 1.1644

KUR = 0.0000, KVR = 1.5960

KUG = -0.3918, KVG = -0.8130

KUB = 2.0172, KVB = 0.0000

KUR and KVB are typically 0.0000 but they may be programmed non-zero for hue rotation.

The CSC can also take RGB input, in which case YOF, KVB, KUG, and KUR should be programmed to 0, and KYRGB will be forced to 0 by the hardware for generating R and B. KYRGB will not be forced to 0 for generating G. KVR, KYRGB, and KUB can be programmed to 1.0 or used as gain control for R, G, B, correspondingly.

Note that color value ranges from 0 to 255 for Y, R, G, B, and -128 to 127 for U and V.

21.9.27 DC_WINC_A_V_FILTER_P00_0

Vertical Scaling Filter Coefficients

The vertical scaling filter is a 2-tap filter with 4-bit positional phase. Coefficients 0 and 1 are 8-bit unsigned values ranging from 0 to 128.

Coefficient 0 is the multiplier for the earlier pixel (P0) in the group of 2 pixels, and coefficient 1 is the multiplier for the later pixel (P1) in the group. The output pixel positional phase is defined as centered in P0 if the positional phase is 0 or proportionally in between P0 and P1 if the positional phase is larger than 0.

The sum of all coefficients for each phase should be 128 typically. Therefore coefficient 1 can be calculated from (1 - coefficient 0) and only coefficient 0 is programmed. For each vertical positional phase, the filter coefficient requires 8 register bits. Note that color value ranges from 0 to 255 for Y, R, G, B, and -128 to 127 for U and V.

21.9.59 DC_WIN_A_WIN_OPTIONS_0

Window A Options

Class: Display Window Settings

Display Window A parameters

Offset: 0x700 │ Byte Offset: 0x1c00 │ Read/Write: R/W │ Reset: 0x00XXXXXX (0b00xxxxxx0xxxxxx0x0xxxxxxxxx0xxxx)

Bit	Reset	Description
31	0x0	A_H_FILTER_MODE: Horizontal filter mode. 0 = With previous Tegra horizontal coeffients widths. 0,5 - signed 5 bits 1,4 - signed 9 bits 2,3 - unsigned 9 bits 1 = New mode. With the expanded horizontal filter coefficients widths. 0,5- signed 5 bits 1,4- signed 7 bits 2,3- unsigned 9 bits 0 = OLD 1 = NEW
30	0x0	A_WIN_ENABLE: Window A Window enable 0 = DISABLE 1 = ENABLE
23	0x0	A_INTERLACE_ENABLE: Window A Interlace enable. This controls the fetch unit toggle between odd and even (normal) base addresses at the start of each field. Base address select between odd/even field is determined by HVTGEN field status. 0 = DISABLE 1 = ENABLE
22	X	A_YUV_RANGE_EXPAND: Window A Enable range expansion in the cases where RANGEREDFRM is 1 from mpd. Formula: Y = clip((Y-128)*2 + 128); Cb = clip((Cb-128)*2 + 128); Cr = clip((Cr-128)*2 + 128); where clip() function clips between 0 and 255. 0 = DISABLE 1 = ENABLE
20	X	A_DV_ENABLE: Window A Digital Vibrance Enable 0 = DISABLE 1 = ENABLE
18	X	A_CSC_ENABLE: Window A Color Space Conversion Enable. This controls the color space conversion and should be enabled for YCbCr/YUV color modes for conversion to B8G8R8 and for hue and saturation control. This can also be used for gain control for RGB color modes. 0 = DISABLE 1 = ENABLE
16	0x0	A_CP_ENABLE: Window A Color Palette Enable. This controls the color palette and should be enabled for palletized color modes. For non-palletized color modes, the color palette can be enabled for gamma correction. 0 = DISABLE 1 = ENABLE
14	0x0	A_V_FILTER_UV_ALIGN: Window A V Filter UV Alignment. This is effective only when vertical scaling filter is enabled and only on these formats YCbCr420P, YUV420P, YCbCr422R, YUV422R, YCbCr422RA YUV422RA. When UV alignment is enabled, the chroma components are aligned to the even number of luma component lines. When disabled the chroma components are aligned to half a pixel below the corresponding even number of luma component lines. It is usually disabled unless the incoming video stream specifically indicates otherwise. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
12	X	A_V_FILTER_OPTIMIZE: Window A V Filter Optimization. This is effective only when vertical scaling filter is enabled. This can be used (enabled) to temporarily disable the vertical scaling filter when the vertical scaling DDA fraction is zero. In this case the next line is not fetched from memory to save bandwidth and power. This feature cannot be used in 420P/422R/422RA formats. 0 = DISABLE 1 = ENABLE
10	X	A_V_FILTER_ENABLE: Window A V Filter Enable. This controls V scaling filter and is effective only for non-palletized color modes. If V filter is disabled, only one line is read from memory for each output line. NOTE: This feature is not supported,. This bit is ignored and is a don't care. 0 = DISABLE 1 = ENABLE
8	X	A_H_FILTER_ENABLE: Window A H Filter Enable. This controls H scaling filter and is effective only for non-palletized color modes. 0 = DISABLE 1 = ENABLE
6	X	A_COLOR_EXPAND: Window A 12/15/16/18-to-24 bpp color expansion. This bit should be enabled only for 12-bpp B4G4R4A4, 15-bpp B5G5R5A, 16-bpp B5G6R5, 18-bpp B6G6R6 color modes. If enabled the color conversion is performed prior to horizontal scaling. 0 = DISABLE 1 = ENABLE
4	0x0	A_SCAN_COLUMN: Window A Scanning direction 0= Scan in horizontal direction (for 0 or 180 degrees) 1= Scan in vertical direction (for 90 or 270 degrees) 0 = DISABLE 1 = ENABLE
2	X	A_V_DIRECTION: Window A Vertical (Y) drawing Direction 0 = INCREMENT 1 = DECREMENT
0	X	A_H_DIRECTION: Window A Horizontal (X) drawing Direction 0 = INCREMENT 1 = DECREMENT

21.9.60 DC_WIN_A_BYTE_SWAP_0

21.9.61 DC_WIN_A_COLOR_DEPTH_0

Window A Color Depth For YCbCr data format, Cb and Cr are 8-bit unsigned values. For YUV data format, U and V are 8-bit signed values.

YCbCr422R is similar to YCbCr422P but the Cb and Cr are shared vertically.

YUV422R is similar to YUV422P but the U and V are shared vertically.

YCbCr422RA is the same as YCbCr422R in memory, and YUV422RA is the same as YUV422R in memory. However, while reading from memory, for YCbCr422RA and YUV422RA, chroma averaging is applied for each pixel pair so that they can be processed as YUV422 by the display pipeline.

For YCbCr422R and YUV422R, every other chroma pixels are not used (discarded) by the display pipeline. B6x2G6x2R6x2A8 is similar to B8G8R6A8 but with the 2 LSBs zeroed out.

R6x2G6x2B6x2A8 is similar to R8G8B6A8 but with the 2 LSBs zeroed out. Some formats have NVCF_ or T_ prefix aliases for NVidia surface format naming convention, wherein left-to-right component names correspond to MSB to LSB bits within a word. In old names without NVCF_ or T_, left-to-right component names generally map LSB to MSB within a word.

21.9.62 DC_WIN_A_POSITION_0

Window A Position

This register defines the H position and size of Window A after scaling (if there is any)

Offset: 0x704 │ Byte Offset: 0x1c10 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	A_V_POSITION: Window A V Position. This is specified with respect to the top edge of active display area.
12:0	X	A_H_POSITION: Window A H Position. This is specified with respect to the left edge of active display area.

21.9.63 DC_WIN_A_SIZE_0

Window A Size

This register defines the V position and size of Window A after scaling (if there is any)

Note: programming on window size should guarantee the whole window is inside the active area, otherwise extra rows/columns will be fetched and discarded which affects performance.

Offset: 0x705 │ Byte Offset: 0x1c14 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	A_V_SIZE: Window A V Size (lines). This is the vertical size after scaling.
12:0	X	A_H_SIZE: Window A H Size (pixels). This is the horizontal size after scaling.

21.9.64 DC_WIN_A_PRESCALED_SIZE_0

Window A Pre-scaled Size

This register defines Window A pre-scaled size.

The H pre-scaled size is needed to determine how many bytes to fetch from memory per line and this parameter must be programmed exactly as needed taking into account the scaling factor. For planar YUV or YCbCr data formats, this parameter refer to the H pre-scaled of the Y plane.

The total number of lines to be fetched from memory is determined by post-scale V size but V pre-scaled size is needed to 'clamp' the last valid line if the vertical DDA is exactly or slightly beyond the specified V pre-scaled size.

H pre-scaled size ideally should be in terms of pixel but then hardware needs to convert this precisely to bytes to determine the amount of data to request from memory.

Offset: 0x706 │ Byte Offset: 0x1c18 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	A_V_PRESCALED_SIZE: Window A V Pre-scaled Size (lines). In 420P/422R/422RA formats, it must be even.
14:0	X	A_H_PRESCALED_SIZE: Window A H Pre-scaled Size (bytes). In 420P and 422P formats, it must be even.

21.9.65 DC_WIN_A_H_INITIAL_DDA_0

Window A H Initial DDA

The first pixel of pre-scaled image is always used to output the first pixel so essentially this is the same as forcing the H Initial DDA integer portion to 1 initially even though the user typically programs this to 0. If it makes the implementation easier, it is possible to force software to program the Initial DDA integer portion to 1. Similarly, with the V Initial DDA.

Offset: 0x707 | Byte Offset: 0x1c1c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	A_H_INITIAL_DDA: Window A H Initial DDA (4.12). This is typically programmed to 0.0

21.9.66 DC_WIN_A_V_INITIAL_DDA_0

Window A V Initial DDA

Offset: 0x708 | Byte Offset: 0x1c20 | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	A_V_INITIAL_DDA: Window A V Initial DDA (4.12). This is typically programmed to 0.0 for both non-interlaced and interlaced sources.

21.9.67 DC_WIN_A_DDA_INCREMENT_0

Window A DDA Increment

DDA increment is typically calculated by dividing (Pre-scaled size in pixels - 1) by (Post-scaled size in pixels - 1). The result should be rounded up and expressed as 4.12 format (4-bit integer and 12-bit fraction). For non-filtered image this value can be slightly larger so that it is not missing the last row/column. Reference programming values (H and V should be calculated separately depending on filter on/off and sizes):

- Filter on: min(round((prescaled_size_in_pixels - 1) * 0x1000 / (post_scaled_size_in_pixels - 1)) + initial_dda_bias, MAX)
- Filter off: min(round(prescaled_size_in_pixels * 0x1000 / (post_scaled_size_in_pixels - 1) - 0.5) + initial_dda_bias, MAX)

Where the value of MAX is as follows:

For V_DDA_INCREMENT: 15.0 (0xF000)

For H_DDA_INCREMENT: 4.0 (0x4000) for 4 Bytes/pixel formats.

8.0 (0x8000) for 2 Bytes/pixel formats.

Where the value of initial_dda_bias is as follows:

For V_DDA_INCREMENT: initial_dda_bias = (v_intial_dda == negative) ? mod(v_initial_dda)/(post_scaled_size_in_pixels - 1) : 0 ;

For H_DDA_INCREMENT: initial_dda_bias = 0;

They are theoretically the biggest values that guarantee not displaying beyond an image boundary. If the DDA increment is less than 1.0, then the image is upscaled. If the DDA increment is more than 1.0, then the image is downscaled.

Offset: 0x709 | Byte Offset: 0x1c24 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	A_V_DDA_INCREMENT: Window A Vertical DDA Increment (4.12). This should be set to 1.0 if there is no scaling. Maximum value is 15.0 regardless of the number of bytes per pixel.

Bit	Reset	Description
15:0	X	A_H_DDA_INCREMENT: Window A Horizontal DDA Increment (4.12). This should be set to 1.0 if there is no scaling. The maximum value for downscaling depends on the number of bytes per pixel. For 4-byte/pixel modes (32-bpp) the maximum value is 4.0 and for all other modes the maximum value is 8.0.

21.9.68 DC_WIN_A_LINE_STRIDE_0

Window A Line Stride

Offset: 0x70a │ Byte Offset: 0x1c28 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	A_UV_LINE_STRIDE: Window A Line Stride for Chroma. This is stride (in bytes) for planar YUV or YCbCr data formats for the chroma plane, with the restriction that it must be programmed to be multiples of 4 (16 if tiled or in horizontal flipping) This is not used (ignored) for other non-planar data formats.
15:0	X	A_LINE_STRIDE: Window A Line Stride. This is stride (in bytes) for all non-planar data formats. If the memory surface is tiled, the stride needs to be a multiple of 16. If H_DIRECTION of window A is set to DECREMENT, the stride also needs to be a multiple of 16. For planar YUV or YCbCr data formats, this is stride (in bytes) for the luma plane with the restriction that it must be multiples of 8 (16 if tiled or in horizontal flipping) For tiled surface this value may affect starting address of a window. Refer to the comment of START_ADDR for detail.

21.9.69 DC_WIN_A_DV_CONTROL_0

Window A Digital Vibrance Control

If enabled, Digital Vibrance is applied after H and V scaling and after color palette or color space conversion logic but before color keying multiplexer and before cursor multiplexer.

- After DV, new R = R + (2R - G - B) * FR, where FR is fraction from 0 to 7/8
- After DV, new G = G + (2G - R - B) * FG, where FG is fraction from 0 to 7/8
- After DV, new B = B + (2B - R - G) * FB, where FB is fraction from 0 to 7/8

Offset: 0x70e │ Byte Offset: 0x1c38 │ Read/Write: R/W │ Reset: 0x000X0X0X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18:16	X	A_DV_CONTROL_B: Digital Vibrance control for B
10:8	X	A_DV_CONTROL_G: Digital Vibrance control for G
2:0	X	A_DV_CONTROL_R: Digital Vibrance control for R

Class: Display Color Keying and Blending

Color keying and blending of the display windows are done prior to cursor blending.

Cursor always goes on top of the blended windows. Blending is controlled independently on each possible overlap area of the display windows. If 3 windows are enabled there are 7 possible overlap area combinations. For every window in each overlap area combination, color key can be disabled or enabled. Also, for every window in each overlap area combination, there is a corresponding window blend control parameter and a window blend weight parameter. The window blend control parameter is

always effective but the window blend weight is not always used. The window blend weight can also be derived from pixel alpha value or from the reverse of other overlapping windows weight.

Color keying has the highest priority for display window blending. Color key consists of a range of color which is searched independently for each window. If more than 1 windows color key is enabled, then Window A color key has the highest priority, followed by Window B color key, and then followed by Window C color key. Two sets of color key ranges (Color Key 0 and Color Key 1) can be defined; they are shared for all windows. It is possible to use both color key sets for the same window or for two separate windows.

The two sets of color key ranges should not overlap. If they do, the overlapped colors are treated as if they are part of Color Key 0 and not part of Color Key 1.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for any overlap condition and the window pixel is not within the color key range (key not match), then the window pixel will not be blended with other overlapping window pixels but it will be weighted. The weight is not dependent on the overlap condition it is controlled by the same set of parameters for all overlapping condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for a particular overlap condition and the window pixel is within the color key range (key match), then the window pixel will be weighted and blended with other overlapping pixels and this is controlled separately for each overlap condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is disabled then the window pixel will be blended with other overlapping pixels and this is controlled separately for each overlap condition.

Display Color Key parameters

For B4G4R4A4, B5G6R5A, and B5G6R5 modes, the color key should be compared prior to color conversion to 24-bpp and unused least significant bits of the pixel are filled with zeros.

For palletized mode, the color key is compared prior to the color palette, and the palletized color is compared against the green color key values/mask.

For YUV mode, U and V are offset by +128 before performing the color key comparison. In all cases, the color key is compared prior to the horizontal/vertical scaling filter and prior to digital vibrance control.

Both upper and lower values are inclusive.

21.9.70 DC_WIN_A_BLEND_LAYER_CONTROL_0

Window A

Offset: 0x716 | Byte Offset: 0x1c58 | Read/Write: R/W | Reset: 0x01000000 (0bxxxx00010000000000000000000000)

21.10 WINBUF_A Registers

The registers under DC_WINBUF are triple-buffered.

21.10.1 DC_WINBUF_A_START_ADDR_0

Window A Start Address

Overview

START_ADDR, BUF_STRIDE, LINE_STRIDE, ADDR_H_OFFSET, ADDR_V_OFFSET combined, specify the starting address of a window buffer in the memory surface. Generally, START_ADDR is programmed with the starting address of the memory surface. H/V_OFFSET specifies the address offsets of the pixel at the beginning of the window with respect to the starting address of the memory surface. (There is an exception to that when memory surface is not well aligned, see ”For linear address mode” in Programming Restrictions below.)

Note that "beginning of the window" here means the top-left corner of a window in normal mode, top-right corner in horizontal flipping, bottom-left corner in vertical flipping, and bottom-right in horizontal+vertical flipping.

Starting Address Calculation

These formulae are same for both tiled and linear modes. However, for linear mode, the addresses calculated are real physical addresses. For tiled mode, these addresses will be translated to the real physical addresses by the memory controller client before being used.

- When a window is host triggered, starting address of a window is calculated as follows by hardware:
  - non-YUV-planar modes:

    starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar modes:

    Y-starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    U-starting-address = START_ADDR_U + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    V-starting-address = START_ADDR_V + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by hardware.
- When a window is non-host triggered, starting address of a window buffer is calculated as below.

- non-YUV-planar mode:

  starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

- YUV-planar mode:

  Y-starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

  U-starting-address = START_ADDR_U + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

  V-starting-address = START_ADDR_V + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by hardware.

  buf_index is the index transmitted by the triggering module pointing to the first buffer of a frame.

Programming Restrictions

i. For tiled address mode:

Image surface can only aligned to multiples of 256, thus the following restrictions.

- START_ADDR, START_ADDR_U, START_ADDR_V need to be multiples of 256.
- BUF_STRIDE, UV_BUF_STRIDE need to be multiples of 256
- LINE_STRIDE, UV_LINE_STRIDE need to be multiples of 16
- ADDR_H_OFFSET needs to be even in YUV planar format, or a multiple of bytes per pixel in other formats. If H_DIRECTION=DECREMENT, however, it should point to last valid byte, which is an odd offset.
- ADDR_V_OFFSET needs to be a multiple of 2 in YUV planar format, unless H_DIRECTION=DECREMENT, but with no restrictions on other color formats.

ii. For linear address mode:

Image surface can be aligned 2, 4 or 8 bytes, depending on the color formats.

As an additional restriction for display, START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16.

When a surface is not aligned to 16 bytes, program START_ADDR with the memory surface address with its least 4 significant bits zeroed out and add these 4 address bits to the original H_OFFSET. (So the formulae in Starting Address Calculation above still hold)

- For all formats:
  - START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16.
- For 16-bpp formats,
  - (START_ADDR+H_OFFSET) need to be a multiple of 2.
- For 32-bpp formats,
  - (START_ADDR+H_OFFSTE) needs to be a multiple of 4.
- For YUV planar formats:
  - BUF_STRIDE, UV_BUF_STRIDE:

    BUF_STRIDE[2:1]=UV_BUF_STRIDE[1:0]

    or as a stricter constraint: BUF_STRIDE is a multiple of 8, UV_BUF_STRIDE is a multiple of 4.
  - LINE_STRIDE, UV_LINE_STRIDE:

LINE_STRIDE and UV_LINE_STRIDE need to be at least 16.

LINE_STRIDE needs to be a multiple of 8, UV_LINE_STRIDE needs to be a multiple of 4.

- ADDR_H_OFFSET: Needs to be even unless H_DIRECTION=DECREMENT, in which case should point to the last byte pixel, which is at an odd offset. .
- ADDR_V_OFFSET: Needs to be even unless V_DIRECTION=DECREMENT, in which case should point to the last valid line, which is at an odd offset. .

iii. Memory allocation for non-host triggered case:

When a window buffer is not controlled by host (software) then a frame may be stored in multiple buffers. In this case, the buffers must be contiguous in the memory because display will use the same luma or chroma line strides for all lines in the frame. Also buffer wraparound must not occur in the middle of the displayed part of the frame.

The controlling module will send frame start and frame end indicators (flags) to display module to indicate the beginning and end of frame. Buffer start address is latched when frame start flag is active but the actual buffer start address is not switched until frame end flag is active. In the case where one buffer corresponds to one frame then frame start and frame end flag are active every time a buffer index is sent.

Offset: 0x800 | Byte Offset: 0x2000 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_START_ADDR: Window A Start Address. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

21.10.2 DC_WINBUF_A_START_ADDR_NS_0

Window A Shadowed Start Address

Offset: 0x801 | Byte Offset: 0x2004 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_START_ADDR_NS: Window A Shadowed Start Address. This is ARM set shadow of Start Address.

21.10.3 DC_WINBUF_A_START_ADDR_U_0

Window A Start Address for U plane

Offset: 0x802 | Byte Offset: 0x2008 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_START_ADDR_U: Window A Start Address for U plane. This is a byte address.

21.10.4 DC_WINBUF_A_START_ADDR_U_NS_0

Window A Shadowed Start Address for U plane

Offset: 0x803 | Byte Offset: 0x200c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_START_ADDR_U_NS: Window A Shadowed Start Address for U plane. This is ARM set shadow register of U start address

21.10.5 DC_WINBUF_A_START_ADDR_V_0

Window A Start Address for V plane

Offset: 0x804 | Byte Offset: 0x2010 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_START_ADDR_V: Window A Start Address for V plane. This is a byte address.

21.10.6 DC_WINBUF_A_START_ADDR_V_NS_0

Window A Shadowed Start Address for V plane

Offset: 0x805 | Byte Offset: 0x2014 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_START_ADDR_V_NS: Window A Shadowed Start Address for V plane. This is ARM set shadow register of U start address

21.10.7 DC_WINBUF_A_ADDR_H_OFFSET_0

Window A Horizontal Address Offset

Offset: 0x806 | Byte Offset: 0x2018 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_ADDR_H_OFFSET: Window A Horizontal address offset. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies horizontal offset of Y plane. The horizontal offsets of U/V plane is derived by hardware.

21.10.8 DC_WINBUF_A_ADDR_H_OFFSET_NS_0

Window A Shadowed Horizontal Address Offset

Offset: 0x807 | Byte Offset: 0x201c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_ADDR_H_OFFSET_NS: Window A Shadowed Horizontal address offset. This is ARM set shadow of ADDR_H_OFFSET

21.10.9 DC_WINBUF_A_ADDR_V_OFFSET_0

Window A Vertical Address Offset

Offset: 0x808 | Byte Offset: 0x2020 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_ADDR_V_OFFSET: Window A Vertical address offset. This is a line number. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies vertical offset of Y plane. The vertical offsets of U/V plane is derived by hardware.

21.10.10 DC_WINBUF_A_ADDR_V_OFFSET_NS_0

Window A Shadowed Vertical Address Offset

Offset: 0x809 | Byte Offset: 0x2024 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_ADDR_V_OFFSET_NS: Window A Shadowed Vertical address offset. This is the ARM set shadow of ADDR_V_OFFSET

21.10.11 DC_WINBUF_A_UFLOW_STATUS_0

Window A FIFO Underflow Status Register

Offset: 0x80a | Byte Offset: 0x2028 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
30	X	COUNT_OFLOW: Flag bit that indicates that the underflow event counter has overflowed. There were too many events. If COUNT_OFLOW is set, UFLOW_COUNT is meaningless. Cleared on write.
23:0	X	UFLOW_COUNT: Underflow count. This field indicates the number of contiguous groups of output pixels for which there was no data in the FIFO. For example, if the valid from the FIFO is low for 10 consecutive cycles and then goes high, the counter will increment by one. Reset to zero on write.

21.10.12 DC_WINBUF_A_SURFACE_KIND_0

Window A Surface Kind

Offset: 0x80b | Byte Offset: 0x202c | Read/Write: R/W | Reset: 0x00000010 (0bxxxxxxxxxxxxxxxxxxxxxxxxx001xx00)

Bit	Reset	Description
6:4	0x1	A_BLOCK_HEIGHT: Block Height: For block linear, height of block in GOBs 0 = HEIGHT_1 1 = HEIGHT_2 2 = HEIGHT_4 3 = HEIGHT_8 4 = HEIGHT_16 5 = HEIGHT_32
1:0	0x0	A_SURFACE_KIND: Surface Kind: Pitched, Tiled, or Block Linear 0 = PITCH 1 = TILED 2 = BL_16B2

21.10.13 DC_WINBUF_A_SURFACE_WEIGHT_0

Window A Surface Weights

Offset: 0x80c | Byte Offset: 0x2030 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
6:5	X	A_SURFACE_WEIGHT_V: Window A V Surface Weights. 00 - Weight is 2 01 - Weight is 4 10 - Weight is 8 11 - Weight is 16

Bit	Reset	Description
		0 = WEIGHT_2 1 = WEIGHT_4 2 = WEIGHT_8 3 = WEIGHT_16
4:3	X	A_SURFACE_WEIGHT_U: Window A U or UV Surface Weights. 00 - Weight is 2 01 - Weight is 4 10 - Weight is 8 11 - Weight is 16 0 = WEIGHT_2 1 = WEIGHT_4 2 = WEIGHT_8 3 = WEIGHT_16
2:1	X	A_SURFACE_WEIGHT_Y: Window A Y or packed Surface Weights. 00 - Weight is 2 01 - Weight is 4 10 - Weight is 8 11 - Weight is 16 0 = WEIGHT_2 1 = WEIGHT_4 2 = WEIGHT_8 3 = WEIGHT_16
0	0x0	A_SURFACE_WEIGHT_OVERRIDE: Weight Override 0 = DISABLE 1 = ENABLE

21.10.14 DC_WINBUF_A_START_ADDR_HI_0

Window A Higher 2 bits of Start Address

Makes the start address 34 bits by adding the higher 2 bits below.

Offset: 0x80d │ Byte Offset: 0x2034 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	A_START_ADDR_HI: Window A Start Address. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

21.10.15 DC_WINBUF_A_START_ADDR_HI_NS_0

Window A Shadowed Higher 2 bits of Start Address

Makes the start address 34 bits by adding the higher 2 bits below.

Offset: 0x80e │ Byte Offset: 0x2038 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	A_START_ADDR_HI_NS: Window A Shadowed Start Address. This is ARM set shadow of Start Address.

21.10.16 DC_WINBUF_A_START_ADDR_HI_U_0

Window A Higher 2 bits of Start Address for U Plane

Makes the start address 34 bits by adding the higher 2 bits below.

Offset: 0x80f │ Byte Offset: 0x203c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	A_START_ADDR_HI_U: Window A Start Address for U plane. This is a byte address.

21.10.17 DC_WINBUF_A_START_ADDR_HI_U_NS_0

Window A Shadowed Higher 2 bits of Start Address for U Plane

Makes the start address 34 bits by adding the higher 2 bits below.

Offset: 0x810 │ Byte Offset: 0x2040 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	A_START_ADDR_HI_U_NS: Window A Shadowed Higher 2 bits of Start Address for U plane. This is ARM set shadow register of U start address

21.10.18 DC_WINBUF_A_START_ADDR_HI_V_0

Window A Higher 2 bits of Start Address for V Plane

Makes the start address 34 bits by adding the higher 2 bits below.

Offset: 0x811 │ Byte Offset: 0x2044 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	A_START_ADDR_HI_V: Window A Higher 2 bits of Start Address for V plane. This is a byte address.

21.10.19 DC_WINBUF_A_START_ADDR_HI_V_NS_0

Window A Shadowed Higher 2 bits of Start Address for V Plane

Makes the start address 34 bits by adding the higher 2 bits below.

Offset: 0x812 │ Byte Offset: 0x2048 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	A_START_ADDR_HI_V_NS: Window A Shadowed Higher 2 bits of Start Address for V plane. This is ARM set shadow register of U start address

21.10.20 DC_WINBUF_A_START_ADDR_FIELD2_0

Window A Start Address

Interlace/Stereo support. 64-bit base address for the odd field/right frame.

Offset: 0x813 | Byte Offset: 0x204c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_START_ADDR_FIELD2: Window A Start Address. This is a byte address. The LSB is not used for the 16-bpp non-planar pixel format, and the last 2 LSBs are not used for the 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

21.10.21 DC_WINBUF_A_START_ADDR_FIELD2_NS_0

Window A Shadowed Start Address

Offset: 0x814 | Byte Offset: 0x2050 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_START_ADDR_FIELD2_NS: Window A Shadowed Start Address. This is the ARM set shadow of the start address.

21.10.22 DC_WINBUF_A_START_ADDR_FIELD2_U_0

Window A Start Address for U plane

Offset: 0x815 | Byte Offset: 0x2054 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_START_ADDR_FIELD2_U: Window A Start Address for U plane. This is a byte address.

21.10.23 DC_WINBUF_A_START_ADDR_FIELD2_U_NS_0

Window A Shadowed Start Address for U plane

Offset: 0x816 | Byte Offset: 0x2058 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_START_ADDR_FIELD2_U_NS: Window A Shadowed Start Address for U plane. This is the ARM set shadow register of the U start address.

21.10.24 DC_WINBUF_A_START_ADDR_FIELD2_V_0

Window A Start Address for V plane

Offset: 0x817 | Byte Offset: 0x205c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_START_ADDR_FIELD2_V: Window A Start Address for V plane. This is a byte address.

21.10.25 DC_WINBUF_A_START_ADDR_FIELD2_V_NS_0

Window A Shadowed Start Address for V plane

Offset: 0x818 | Byte Offset: 0x2060 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_START_ADDR_FIELD2_V_NS: Window A Shadowed Start Address for V plane. This is the ARM set shadow register of the U start address.

21.10.26 DC_WINBUF_A_START_ADDR_FIELD2_HI_0

Window A Higher 2 bits of Start Address

Makes the start address 34 bits by adding the higher 2 bits below.

Offset: 0x819 | Byte Offset: 0x2064 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	A_START_ADDR_FIELD2_HI: Window A Start Address. This is a byte address. The LSB is not used for the 16-bpp non-planar pixel format, and the last 2 LSBs are not used for the 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies the start address for the Y plane.

21.10.27 DC_WINBUF_A_START_ADDR_FIELD2_HI_NS_0

Window A Shadowed Higher 2 bits of Start Address

Makes the start address 34 bits by adding the higher 2 bits below.

Offset: 0x81a | Byte Offset: 0x2068 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	A_START_ADDR_FIELD2_HI_NS: Window A Shadowed Start Address. This is the ARM set shadow of the start address.

21.10.28 DC_WINBUF_A_START_ADDR_FIELD2_HI_U_0

Window A Higher 2 bits of Start Address for U plane

Makes the start address 34 bits by adding the higher 2 bits below.

Offset: 0x81b | Byte Offset: 0x206c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	A_START_ADDR_FIELD2_HI_U: Window A Start Address for U plane. This is a byte address.

21.10.29 DC_WINBUF_A_START_ADDR_FIELD2_HI_U_NS_0

Window A Shadowed Higher 32 bits of Start Address for U plane

Makes the start address 34 bits by adding the higher 2 bits below.

Offset: 0x81c | Byte Offset: 0x2070 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	A_START_ADDR_FIELD2_HI_U_NS: Window A Shadowed Higher 2 bits of Start Address for U plane.

Bit	Reset	Description
		This is the ARM set shadow register of the U start address.

21.10.30 DC_WINBUF_A_START_ADDR_FIELD2_HI_V_0

Window A Higher 2 bits of Start Address for V plane

Makes the start address 34 bits by adding the higher 2 bits below.

Offset: 0x81d | Byte Offset: 0x2074 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	A_START_ADDR_FIELD2_HI_V: Window A Higher 2 bits of Start Address for V plane. This is a byte address.

21.10.31 DC_WINBUF_A_START_ADDR_FIELD2_HI_V_NS_0

Window A Shadowed Higher 2 bits of Start Address for V plane

Makes the start address 34 bits by adding the higher 2 bits below.

Offset: 0x81e | Byte Offset: 0x2078 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	A_START_ADDR_FIELD2_HI_V_NS: Window A Shadowed Higher 2 bits of Start Address for V plane. This is the ARM set shadow register of the U start address.

21.10.32 DC_WINBUF_A_ADDR_H_OFFSET_FIELD2_0

Window A Horizontal address offset

Offset: 0x81f | Byte Offset: 0x207c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_ADDR_H_OFFSET_FIELD2: Window A Horizontal address offset. This is a byte address. The LSB is not used for the 16-bpp non-planar pixel format, and the last 2 LSBs are not used for the 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies the horizontal offset of the Y plane. The horizontal offsets of U/V plane are derived by hardware.

21.10.33 DC_WINBUF_A_ADDR_H_OFFSET_FIELD2_NS_0

Window A Shadowed Horizontal address offset

Offset: 0x820 | Byte Offset: 0x2080 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_ADDR_H_OFFSET_FIELD2_NS: Window A Shadowed Horizontal address offset. This is the ARM set shadow of ADDR_H_OFFSET.

21.10.34 DC_WINBUF_A_ADDR_V_OFFSET_FIELD2_0

Window A Vertical address offset

Offset: 0x821 | Byte Offset: 0x2084 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_ADDR_V_OFFSET_FIELD2: Window A Vertical address offset. This is the vertical coordinate. For YUV planar pixel format, this specifies the vertical coordinate of the Y plane. The vertical coordinate of U/V plane is derived by hardware.

21.10.35 DC_WINBUF_A_ADDR_V_OFFSET_FIELD2_NS_0

Window A Shadowed Vertical address offset

Offset: 0x822 | Byte Offset: 0x2088 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_ADDR_V_OFFSET_FIELD2_NS: Window A Shadowed Vertical address offset. This is the ARM set shadow of ADDR_V_OFFSET

21.10.36 DC_WINBUF_A_UFLOW_CTRL_0

When the underflow debug mode is enabled. Instead of sending out the last valid pixel, DBG_PIXEL is sent out.

Offset: 0x824 | Byte Offset: 0x2090 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	A_UFLOW_CTRL_DBG_MODE: 0 = DISABLE 1 = ENABLE

21.10.37 DC_WINBUF_A_UFLOW_DBG_PIXEL_0

Bit	Reset	Description
31:0	X	A_UFLOW_DBG_PIXEL

21.10.38 DC_WINBUF_A_UFLOW_THRESHOLD_0

Offset: 0x826 | Byte Offset: 0x2098 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxx0000000000000)

Bit	Reset	Description
12:0	0x0	A_UFLOW_THRESHOLD

21.10.39 DC_WINBUF_A_SPOOL_UP_0

Spool up time configuration for different windows related logic.

SPOOL_UP_CTRL = MAX - This is the current Tegra K1 behavior. This allows for memfetch to start fetching for a window (irrespective of its relative position on the screen), at the very beginning of the Vblank of the next frame. Since the spool up time is maximum, this should have the least probability of underflow of the display pipe. However, on the down side, since all three windows would start fetching at the same time, and since display is a high priority client for MC, it has a high potential to starve out other clients.

SPOOL_UP_CTRL = PROGRAMMABLE, SPOOL_UP_DURATION = 1 - This corresponds to the Tegra 3 behavior. Since the fetch starts only 1 line prior to the active scan line of a window, this has high probability of causing underflow, but has a lesser impact on the other MC clients.

So, this register programmability programs a method to modulate the spool up time between the best and worst, if required, when other MC clients are present. For example when GPU/VIC is active, we may not want a very aggressive spool up and program some definite spool up duration. So, spool up time is a general knob, which would be a function of the resolution, bpp, active clients, memory speed, etc.

SPOOL_UP_EDGE :- By default the memfetch start signal generated by the hvtgen logic is one line clock wide.

For SPOOL_UP_CTRL = MAX:

- In this case if SPOOL_UP_EDGE is programmed to NEGEDGE. This ensures that if any act_req is sent during the time vcounter = 0(at the beginning of the frame). The activate value is loaded into the active state and the memfetch would see the latest updated value. The downside of programming it to NEGDGE is that we lose out on 1 line clock worth of spool up. This is required based upon Tegra compatibility and the way tests are written.
- In this case if SPOOL_UP_EDGE is programmed to POSEDGE. Then the memfetch would start fetching at the very beginning of the frame start pulse (1 line clock wide) and would give maximum spool up time. However, this may give test failure and potential Tegra compatibility issues as described above

FOR SPOOL_UP_CTRL = PROGRAMMABLE :

- Special care must be taken here. If SPOOL_UP_DURATION is set to 1. SPOOL_UP_EDGE must be set to POSEDGE to allow for at least 1 line worth of spool up.
- If SPOOL_UP_DURATION is > 1. Then SPOOL_UP_EDGE can be either POSEDGE or NEGEDGE. If it is NEGEDGE, then the effective spool up duration would be 1 line clock less than the SPOOL_UP_DURATION.

Offset: 0x827 │ Byte Offset: 0x209c │ Read/Write: R/W │Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
28:16	X	A_SPOOL_UP_DURATION
1	0x0	A_SPOOL_UP_EDGE: 0 = NEGEDGE 1 = POSEDGE
0	0x0	A_SPOOL_UP_CTRL: 0 = MAX 1 = PROGRAMMABLE

21.10.40 DC_WINBUF_A_SCALEFACTOR_THRESHOLD_0

Registers for latency allowance scaling. Threshold is in terms of 64 byte atoms. Display memfetch compares its buffer occupancy with the threshold and generates indication to MC if its buffer occupancy is above HWM or below LWM.

Offset: 0x828 │ Byte Offset: 0x20a0 │ Read/Write: R/W │ Reset: 0xffffffff (0b11111111111111111111111111111111)

Bit	Reset	Description
31:16	0xffff	A_SF_LWM_THRESHOLD
15:0	0xffff	A_SF_HWM_THRESHOLD

21.10.41 DC_WINBUF_A_LATENCY_THRESHOLD_0

The LATENCY_THRESHOLD register controls the behavior of the rdy4_latency_event from the display to the MC.

If B_RDY4LATENCY_THRESHOLD_ENABLE is set to DISABLE, the sideband rdy4_latency_event is always asserted, indicating that the display is always ready for a DVFS event.

The B_RDY4LATENCY_THRESHOLD field indicates the required occupancy of line buffers of windows below which the sideband rdy4_latency_event is deasserted. The occupancy figure is in units of 64B atoms for memfetch windows and in units of scan lines for regular windows.

The B_RDY4LATENCY_SPOOLUP_DURATION field indicates the number of scan lines during when the sideband will remain asserted (DVFS is allowed). This takes affect only when B_RDY4LATENCY_SPOOLUP_CTRL is set to ALLOW.

If the B_RDY4LATENCY_SPOOLUP_CTRL field is set to DISALLOW, the above register field is not affected and DVFS is disallowed until the threshold is reached.

Offset: 0x829 │ Byte Offset: 0x20a4 │ Read/Write: R/W │ Reset: 0x0000ffff (0b00x00000000000001111111111111111)

Bit	Reset	Description
31	DISABLE	A_RDY4LATENCY_THRESHOLD_ENABLE: 0 = DISABLE 1 = ENABLE

21.11 Window B (WINC_B) Registers

These registers control window B parameters.

21.11.1 DC_WINC_B_COLOR_PALETTE_0

Window B Color Palette

This is used for palletized data format (color depth of 8-bpp or less) or for gamma correction for non-palletized data formats (color depth of more than 8-bpp).

Each window has its own color palette which consists of three 256x8 register file which can be written by host and indexed (read) by the window.

For palletized data format less than 8-bpp, the pixel data is aligned to least significant bits of the palette index (address) and the remaining upper bits are filled with the corresponding bits of the Palette Color Extension. For example, for 4-bpp mode, the pixel data occupies bits 3-0 of the palette index, and bits 7-4 of the palette index are set to bits 7-4 of the Palette Color Extension.

Note that host read is assumed to be not needed - software can cache the color palette in system memory.

This is an array of 256 identical register entries; the register fields below apply to each entry.

21.11.3 DC_WINC_B_H_FILTER_P00_0

Window B Horizontal Filter phase 00

Horizontal Scaling Filter Coefficients

Horizontal scaling filter is a 6-tap filter with 4-bit positional phase.

- Coefficients 0 and 5 are 3-bit signed values ranging from -4 to 3.
- Coefficients 1 and 4 are 5-bit signed values ranging from -16 to 15.
- Coefficients 2 and 3 are 8-bit unsigned values ranging from 0 to 128.
- Coefficient 0 is the multiplier for the earliest pixel (P0) in the group of 6 pixels and coefficient 5 is the multiplier for the latest pixel (P5) in the group. The output pixel positional phase is defined as centered in P2 if the positional phase is 0 or proportionally in between P2 and P3 if the positional phase is larger than 0.

Sum of all coefficients for each phase should be 128 typically, and software should never program the sum of all coefficients for a phase to be more than 128. For each horizontal positional phase, the 6 filter coefficients requires 32 register bits. Note that color value ranges from 0 to 255 for Y, R, G, B, and -128 to 127 for U and V.

21.11.19 DC_WINC_B_CSC_YOF_0

Window B CSC Y Offset

Color Space Conversion coefficients.

The CSC can be used for YUV to RGB conversion with brightness and hue/saturation control.

The CSC can only be enabled for window B controlled by CSC_ENABLE register bits.

For Y color, the Y offset is applied first and saturation (clipping) is performed immediately after the Y offset is applied.

R = sat(KYRGB * sat(Y + YOF) + KUR * U + KVR * V)

G = sat(KYRGB * sat(Y + YOF) + KUG * U + KVG * V)

B = sat(KYRGB * sat(Y + YOF) + KUB * U + KVB * V)

Saturation and rounding is performed in the range of 0 to 255 for the above equations.

Typical values are:

YOF = -16.000, KYRGB = 1.1644

KUR = 0.0000, KVR = 1.5960

KUG = -0.3918, KVG = -0.8130

KUB = 2.0172, KVB = 0.0000

KUR and KVB are typically 0.0000 but they may be programmed non-zero for hue rotation.

The CSC can also take RGB input, in which case YOF, KVB, KUG, KUR should be programmed to 0, and KYRGB will be forced to 0 by the hardware for generating R and B. KYRGB will not be forced to 0 for generating G. KVR, KYRGB, and KUB can be programmed to 1.0 or used as gain control for R, G, B, correspondingly.

Note that color value ranges from 0 to 255 for Y, R, G, B and -128 to 127 for U and V.

21.11.27 DC_WINC_B_V_FILTER_P00_0

Window B Vertical Filter phase 00

Vertical scaling filter coefficients

Vertical scaling filter is a 2-tap filter with 4-bit positional phase.

Coefficients 0 and 1 are 8-bit unsigned values ranging from 0 to 128.

Coefficient 0 is the multiplier for the earlier pixel (P0) in the group of 2 pixels and coefficient 1 is the multiplier for the later pixel (P1) in the group. The output pixel positional phase is defined as centered in P0 if the positional phase is 0 or proportionally in between P0 and P1 if the positional phase is larger than 0.

Sum of all coefficients for each phase should be 128 typically therefore coefficient 1 can be calculated from (1 - coefficient 0) and therefore only coefficient 0 is programmed.

For each vertical positional phase, the filter coefficient requires 8 register bits. Note that color value ranges from 0 to 255 for Y, R, G, B, and -128 to 127 for U and V.

Display Window B parameters

Offset: 0x700 | Byte Offset: 0x1c00 | Read/Write: R/W | Reset: 0x00XXXXXX (0b00xxxxxx0xxxxxx0x0xxxxxxxxx0xxxx)

Bit	Reset	Description
31	0x0	B_H_FILTER_MODE: Horizontal filter mode. 0 = With previous Tegra horizontal coeffients widths. 0,5 - signed 5 bits 1,4 - signed 9 bits 2,3 - unsigned 9 bits 1 = New mode. With the expanded horizontal filter coefficients widths. 0,5- signed 5 bits 1,4- signed 7 bits 2,3- unsigned 9 bits 0 = OLD 1 = NEW
30	0x0	B_WIN_ENABLE: Window B Window enable 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
23	0x0	B_INTERLACE_ENABLE: Window B Interlace enable. This controls the fetch unit toggle between odd and even (normal) base addresses at the start of each field. Base address select between odd/even fields is determined by HVTGEN field status. 0 = DISABLE 1 = ENABLE
22	X	B_YUV_RANGE_EXPAND: Window B Enable range expansion in the cases where RANGEREDFRM is 1 from mpd. Formula: Y = clip((Y-128)*2 + 128); Cb = clip((Cb-128)*2 + 128); Cr = clip((Cr-128)*2 + 128); where clip() function clips between 0 and 255. 0 = DISABLE 1 = ENABLE
20	X	B_DV_ENABLE: Window B Digital Vibrance Enable 0 = DISABLE 1 = ENABLE
18	X	B_CSC_ENABLE: Window B Color Space Conversion Enable. This controls the color space conversion and should be enabled for YCbCr/YUV color modes for conversion to B8G8R8 and for hue and saturation control. This can also be used for gain control for RGB color modes 0 = DISABLE 1 = ENABLE
16	0x0	B_CP_ENABLE: Window B Color Palette Enable. This controls the color palette and should be enabled for palletized color modes. For non-palletized color modes, the color palette can be enabled for gamma correction. 0 = DISABLE 1 = ENABLE
14	0x0	B_V_FILTER_UV_ALIGN: Window B V Filter UV Alignment. This is effective only when vertical scaling filter is enabled and only on these formats YCbCr420P, YUV420P, YCbCr422R, YUV422R, YCbCr422RA YUV422RA. When UV alignment is enabled, the chroma components are aligned to the even number of luma component lines. When disabled the chroma components are aligned to half a pixel below the corresponding even number of luma component lines. It is usually disabled unless the incoming video stream specifically indicates otherwise. 0 = DISABLE 1 = ENABLE
12	X	B_V_FILTER_OPTIMIZE: Window B V Filter Optimization. This is effective only when vertical scaling filter is enabled. This can be used (enabled) to temporarily disable the vertical scaling filter when the vertical scaling DDA fraction is zero. In this case the next line is not fetched from memory to save bandwidth and power. This feature cannot be used in 420P/422R/422RA formats. 0 = DISABLE 1 = ENABLE
10	X	B_V_FILTER_ENABLE: Window B V Filter Enable. This controls V scaling filter and is effective only for non-palletized color modes. If V filter is disabled, only one line is read from memory for each output line. NOTE: This feature is not supported. This bit is ignored and is a don't care. 0 = DISABLE 1 = ENABLE
8	X	B_H_FILTER_ENABLE: Window B H Filter Enable. This controls H scaling filter and is effective only for non-palletized color modes. 0 = DISABLE 1 = ENABLE
6	X	B_COLOR_EXPAND: Window B 12/15/16/18-to-24 bpp color expansion. This bit should be enabled only for 12-bpp B4G4R4A4, 15-bpp B5G5R5A, 16-bpp B5G6R5, 18-bpp B6G6R6 color modes. If enabled the color conversion is performed prior to horizontal scaling. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
4	0x0	B_SCAN_COLUMN: Window B Scanning direction. 0= Scan in horizontal direction (for 0 or 180 degrees) 1= Scan in vertical direction (for 90 or 270 degrees) 0 = DISABLE 1 = ENABLE
2	X	B_V_DIRECTION: Window B Vertical (Y) drawing Direction 0 = INCREMENT 1 = DECREMENT
0	X	B_H_DIRECTION: Window B Horizontal (X) drawing Direction 0 = INCREMENT 1 = DECREMENT

21.11.60 DC_WIN_B_BYTE_SWAP_0

Window B Byte Swap

Offset: 0x701 │ Byte Offset: 0x1c04 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
2:0	X	B_BYTE_SWAP: Window B Byte Swap. This controls byte swap of frame data read from memory prior to any data processing in the display module. 000= no byte swap (3 2 1 0) 001= byte swap for each 2-byte word (2 3 0 1) 010= byte swap for each 4-byte word (0 1 2 3) 011= word swap for each 4-byte word (1 0 3 2) 100= byte0 swapped with byte2 (3 0 1 2) 101= left shift every byte (2 1 0 3) 0 = NOSWAP 1 = SWAP2 2 = SWAP4 3 = SWAP4HW 4 = SWAP02 5 = SWAPLEFT

DC_WIN_B_COLOR_DEPTH_0

Window B Color Depth for YCbCr data format. Cb and Cr are 8-bit unsigned values. For YUV data format, U and V are 8-bit signed values. YCbCr422R is similar to YCbCr422P, but the Cb and Cr are shared vertically.

YUV422R is similar to YUV422P, but the U and V are shared vertically. YCbCr422RA is the same as YCbCr422R in memory, and YUV422RA is the same as YUV422R in memory but while reading from memory, for YCbCr422RA and YUV422RA, chroma averaging is applied for each pixel pair so that they can be processed as YUV422 by the display pipeline.

For YCbCr422R and YUV422R, every other chroma pixel is not used (discarded) by the display pipeline. B6x2G6x2R6x2A8 is similar to B8G8R6A8 but with the 2 LSBs zeroed out. R6x2G6x2B6x2A8 is similar to R8G8B6A8 but with the 2 LSBs zeroed out.

Some formats have NVCF_ or T_ prefix aliases for NVIDIA surface format naming convention, wherein left-to-right component names correspond to MSB to LSB bits within a word. In old names without NVCF_ or T_, left-to-right component names generally map LSB to MSB within a word.

Offset: 0x703 │ Byte Offset: 0x1c0c │ Read/Write: R/W │ Reset: 0x0000000c (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx0001100)

Bit	Reset	Description
6:0	B8G8R8A8	B_COLOR_DEPTH: Window B Color Depth. Supported color depths are: P8 = 8-bpp (palletized) B4G4R4A4 = 12-bpp B4G4R4 B5G5R5A = 15-bpp B5G5R5

21.11.61 DC_WIN_B_POSITION_0

Window B Position

This register defines H position and size of Window B after scaling (if there is any)

Offset: 0x704 │ Byte Offset: 0x1c10 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	B_V_POSITION: Window B V Position. This is specified with respect to the top edge of active display area.
12:0	X	B_H_POSITION: Window B H Position. This is specified with respect to the left edge of active display area.

21.11.62 DC_WIN_B_SIZE_0

Window B Size

This register defines V position and size of Window B after scaling (if there is any)

Note: programming on window size should guarantee the whole window is inside the active area; otherwise extra rows/columns will be fetched and discarded, affecting performance.

Offset: 0x705 │ Byte Offset: 0x1c14 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	B_V_SIZE: Window B V Size (lines). This is the vertical size after scaling.
12:0	X	B_H_SIZE: Window B H Size (pixels). This is the horizontal size after scaling.

21.11.63 DC_WIN_B_PRESCALED_SIZE_0

Window B Pre-scaled Size

This register defines Window B pre-scaled size.

The H pre-scaled size is needed to determine how many bytes to fetch from memory per line and this parameter must be programmed exactly as needed taking into account the scaling factor. For planar YUV or YCbCr data formats, this parameter refer to the H pre-scaled of the Y plane.

The total number of lines to be fetched from memory is determined by post-scale V size but V pre-scaled size is needed to 'clamp' the last valid line if the vertical DDA is exactly or slightly beyond the specified V pre-scaled size.

H pre-scaled size ideally should be in terms of pixel but then hardware needs to convert this precisely to bytes to determine the amount of data to request from memory.

Offset: 0x706 │ Byte Offset: 0x1c18 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	B_V_PRESCALED_SIZE: Window B V Pre-scaled Size (lines). In 420P/422R/422RA formats, it must be even.
14:0	X	B_H_PRESCALED_SIZE: Window B H Pre-scaled Size (bytes). In 420P and 422P formats, it must be even.

21.11.64 DC_WIN_B_H_INITIAL_DDA_0

Window B H Initial DDA

The first pixel of pre-scaled image is always used to output the first pixel so essentially this is the same as forcing the H Initial DDA integer portion to 1 initially even though user typically programs this to 0. If it makes the implementation easier, it is possible to force software to program the Initial DDA integer portion to 1. Similarly with the V Initial DDA.

Offset: 0x707 │ Byte Offset: 0x1c1c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	B_H_INITIAL_DDA: Window B H Initial DDA (4.12). This is typically programmed to 0.0

21.11.65 DC_WIN_B_V_INITIAL_DDA_0

Window B V Initial DDA

Offset: 0x708 │ Byte Offset: 0x1c20 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	B_V_INITIAL_DDA: Window B V Initial DDA (4.12). This is typically programmed to 0.0 for both non-interlaced and interlaced sources.

21.11.66 DC_WIN_B_DDA_INCREMENT_0

Window B DDA Increment

The DDA increment is typically calculated by dividing (Pre-scaled size in pixels - 1) by (Post-scaled size in pixels - 1). The result should be rounded up and expressed as 4.12 format (4-bit integer and 12-bit fraction). For non-filtered images, this value can be slightly larger so that it is not missing the last row/column. Reference programming values (H and V should be calculated separately depending on filter on/off and sizes):

- Filter on: min(round((prescaled_size_in_pixels - 1) * 0x1000 / (post_scaled_size_in_pixels - 1)) + initial_dda_bias, MAX)
- Filter off: min(round(prescaled_size_in_pixels * 0x1000 / (post_scaled_size_in_pixels - 1) - 0.5) + initial_dda_bias, MAX)

Where the value of MAX is as follows:

For V_DDA_INCREMENT: 15.0 (0xF000)

For H_DDA_INCREMENT: 4.0 (0x4000) for 4 Bytes/pixel formats.

8.0 (0x8000) for 2 Bytes/pixel formats.

Where the value of initial_dda_bias is as follows:

For V_DDA_INCREMENT: initial_dda_bias = (v_intial_dda == negative) ? mod(v_initial_dda)/(post_scaled_size_in_pixels - 1) : 0 ;

For H_DDA_INCREMENT: initial_dda_bias = 0;

They are theoretically the biggest values that guarantee not displaying beyond an image boundary.

If the DDA increment is less than 1.0 then the image will be upscaled.If the DDA increment is more than 1.0 then the image will be downscaled.

Offset: 0x709 │ Byte Offset: 0x1c24 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	B_V_DDA_INCREMENT: Window B Vertical DDA Increment (4.12) This should be set to 1.0 if there is no scaling. Maximum value is 15.0 regardless of the number of bytes per pixel.
15:0	X	B_H_DDA_INCREMENT: Window B Horizontal DDA Increment (4.12) This should be set to 1.0 if there is no scaling. The maximum value for downscaling depends on the number of bytes per pixel. For 4-byte/pixel modes (32-bpp) the maximum value is 4.0 and for all other modes the maximum value is 8.0.

21.11.67 DC_WIN_B_LINE_STRIDE_0

Window B Line Stride

Offset: 0x70a │ Byte Offset: 0x1c28 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	B_UV_LINE_STRIDE: Window B Line Stride for Chroma This is stride (in bytes) for planar YUV or YCbCr data formats for the chroma plane, with the restriction that it must be programmed to be multiples of 4 (16 if tiled or in horizontal flipping) This is not used (ignored) for other non-planar data formats.
15:0	X	B_LINE_STRIDE: Window B Line Stride This is stride (in bytes) for all non-planar data formats. If the memory surface is tiled, the stride needs to be a multiple of 16. If H_DIRECTION of window B is set to DECREMENT, the stride also needs to be a multiple of 16. For planar YUV or YCbCr data formats, this is stride (in bytes) for the luma plane with the restriction that it must be multiples of 8 (16 if tiled or in horizontal flipping). For tiled surface, this value may affect starting address of a window. Refer to the comment of START_ADDR for detail.

21.11.68 DC_WIN_B_DV_CONTROL_0

Window B Digital Vibrance Control

If enabled, Digital Vibrance is applied after H and V scaling and after color palette or color space conversion logic but before color keying multiplexer and before cursor multiplexer.

- After DV, new R = R + (2R - G - B) * FR, where FR is fraction from 0 to 7/8
- After DV, new G = G + (2G - R - B) * FG, where FG is fraction from 0 to 7/8
- After DV, new B = B + (2B - R - G) * FB, where FB is fraction from 0 to 7/8

Offset: 0x70e │ Byte Offset: 0x1c38 │ Read/Write: R/W │ Reset: 0x000X0X0X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18:16	X	B_DV_CONTROL_B: Digital Vibrance control for B
10:8	X	B_DV_CONTROL_G: Digital Vibrance control for G
2:0	X	B_DV_CONTROL_R: Digital Vibrance control for R

Class: Display Color Keying and Blending

Color keying and blending of the display windows are done prior to cursor blending.

Cursor always goes on top of the blended windows. Blending is controlled independently on each possible overlap area of the display windows. If 3 windows are enabled there are 7 possible overlap area combinations. For every window in each overlap area combination, color key can be disabled or enabled. Also, for every window in each overlap area combination, there is a corresponding window blend control parameter and a window blend weight parameter. The window blend control parameter is always effective but the window blend weight is not always used. The window blend weight can also be derived from pixel alpha value or from the reverse of other overlapping windows weight.

Color keying has the highest priority for display window blending. Color key consists of a range of color which is searched independently for each windows. If more than 1 windows color key is enabled, then Window A color key has the highest priority, followed by Window B color key, and then followed by Window C color key. Two sets of color key ranges (Color Key 0 and Color Key 1) can be defined; they are shared for all windows. It is possible to use both color key sets for the same window or for two separate windows.

The two sets of color key ranges should not overlap. If they do, the overlapped colors are treated as if they are part of Color Key 0 and not part of Color Key 1.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for any overlap condition and the window pixel is not within the color key range (key not match), then the window pixel will not be blended with other overlapping window pixels but it will be weighted. The weight is not dependent on the overlap condition it is controlled by the same set of parameters for all overlapping condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for a particular overlap condition and the window pixel is within the color key range (key match), then the window pixel will be weighted and blended with other overlapping pixels and this is controlled separately for each overlap condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is disabled then the window pixel will be blended with other overlapping pixels and this is controlled separately for each overlap condition.

Display Color Key Parameters

For B4G4R4A4, B5G6R5A, B5G6R5 modes, the color key should be compared prior to color conversion to 24-bpp and unused least significant bits of the pixel are filled with zeros.

For palletized mode, the color key is compared prior to the color palette, and the palletized color is compared against the green color key values/mask.

For YUV mode, U and V are offset by +128 before performing the color key comparison.

In all cases, the color key is compared prior to the horizontal/vertical scaling filter and prior to digital vibrance control. Both upper and lower values are inclusive.

21.11.69 DC_WIN_B_BLEND_LAYER_CONTROL_0

21.12 WINBUF_B Registers

The registers under DC_WINBUF are triple-buffered.

21.12.1 DC_WINBUF_B_START_ADDR_0

Window B Start Address

Overview

START_ADDR, BUF_STRIDE, LINE_STRIDE, ADDR_H_OFFSET, ADDR_V_OFFSET combined, specify the starting address of a window buffer in the memory surface. Generally START_ADDR is programmed with the starting address of the memory surface. H/V_OFFSET specifies the address offsets of the pixel at the beginning of the window, with respect to the starting address of the memory surface. (There is an exception to that when memory surface is not well aligned, see ”For linear address mode” in Programming Restrictions below.)

Note that "beginning of the window" here means the top-left corner of a window in normal mode, top-right corner in horizontal flipping, bottom-left corner in vertical flipping, and bottom-right in horizontal+vertical flipping.

Starting Address Calculation

These formulae are the same for both tiled and linear modes. However, for linear mode, the addresses calculated are real physical addresses, but for tiled mode, these addresses will be translated to the real physical addresses by the memory controller client before used.

- When a window is host triggered, the starting address of a window is calculated as follows by hardware:
  - non-YUV-planar modes:

    starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar modes:

    Y-starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    U-starting-address = START_ADDR_U + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    V-starting-address = START_ADDR_V + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by hardware.
- When a window is non-host triggered, starting address of a window buffer is calculated as below:
  - non-YUV-planar mode:

    starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar mode:

    Y-starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    U-starting-address = START_ADDR_U + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    V-starting-address = START_ADDR_V + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by hardware.

    buf_index is the index transmitted by the triggering module pointing to the first buffer of a frame.

Programming Restrictions

- For tiled address mode:

  Image surface can only aligned to multiples of 256, thus the following restrictions.
  - START_ADDR, START_ADDR_U, START_ADDR_V need to be multiples of 256.
  - BUF_STRIDE, UV_BUF_STRIDE need to be multiples of 256
  - LINE_STRIDE, UV_LINE_STRIDE need to be multiples of 16
  - ADDR_H_OFFSET needs to be even in YUV planar format, or a multiple of bytes per pixel in other formats. If H_DIRECTION=DECREMENT, however, it should point to last valid byte, which is an odd offset.
  - ADDR_V_OFFSET needs to be multiple of 2 in YUV planar format, unless H_DIRECTION=DECREMENT, but with no restrictions on other color formats.
- For linear address mode:

  Image surface can be aligned 2, 4 or 8 bytes, depending on the color formats.

  As an additional restriction for display, START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16.

When a surface is not aligned to 16 bytes, program START_ADDR with the memory surface address with its least 4 significant bits zeroed out and add these 4 address bits to the original H_OFFSET. (So the formulae in Starting Address Calculation above still hold)

- For all formats:

  START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16.
- For 16-bpp formats,

  (START_ADDR+H_OFFSET) needs to be a multiple of 2.
- For 32-bpp formats,

  (START_ADDR+H_OFFSET) needs to be a multiple of 4.
- For YUV planar formats:

  BUF_STRIDE, UV_BUF_STRIDE:

  BUF_STRIDE[2:1]=UV_BUF_STRIDE[1:0]

  or as a stricter constraint: BUF_STRIDE be multiple of 8, UV_BUF_STRIDE be a multiple of 4.

  LINE_STRIDE, UV_LINE_STRIDE:

  LINE_STRIDE and UV_LINE_STRIDE need to be at least 16.

  LINE_STRIDE needs to be multiple of 8, UV_LINE_STRIDE needs to be a multiple of 4.

  ADDR_H_OFFSET: Needs to be even unless H_DIRECTION=DECREMENT, in which case should point to the last byte pixel, which is at an odd offset.

  ADDR_V_OFFSET: Needs to be even unless V_DIRECTION=DECREMENT, in which case should point to the last valid line, which is at an odd offset.

- Memory allocation for non-host triggered case

  When a window buffer is not controlled by host (software) then a frame may be stored in multiple buffers. In this case, the buffers must be contiguous in the memory because the display will use the same luma or chroma line strides for all lines in the frame.

  Also buffer wraparound must not occur in the middle of the displayed part of the frame. The controlling module will send frame start and frame end indicators (flags) to display module to indicate the beginning and end of frame. Buffer start address is latched when frame start flag is active but the actual buffer start address is not switched until frame end flag is active. In the case where one buffer corresponds to one frame then frame start and frame end flag are active every time a buffer index is sent.

Offset: 0x800 │ Byte Offset: 0x2000 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_START_ADDR: Window B Start Address. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

21.12.2 DC_WINBUF_B_START_ADDR_NS_0

Window B Shadowed Start Address

Offset: 0x801 │ Byte Offset: 0x2004 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_START_ADDR_NS: Window B Shadowed Start Address. This is ARM set shadow of Start Address.

21.12.3 DC_WINBUF_B_START_ADDR_U_0

Window B Start Address for U plane

Offset: 0x802 | Byte Offset: 0x2008 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_START_ADDR_U: Window B Start Address for U plane. This is a byte address.

21.12.4 DC_WINBUF_B_START_ADDR_U_NS_0

Window B Shadowed Start Address for U plane

Offset: 0x803 | Byte Offset: 0x200c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_START_ADDR_U_NS: Window B Shadowed Start Address for U plane. This is ARM set shadow register of U start address

21.12.5 DC_WINBUF_B_START_ADDR_V_0

Window B Start Address for V plane

Offset: 0x804 | Byte Offset: 0x2010 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_START_ADDR_V: Window B Start Address for V plane. This is a byte address.

21.12.6 DC_WINBUF_B_START_ADDR_V_NS_0

Window B Shadowed Start Address for V plane

Offset: 0x805 | Byte Offset: 0x2014 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_START_ADDR_V_NS: Window B Shadowed Start Address for V plane. This is ARM set shadow register of U start address

21.12.7 DC_WINBUF_B_ADDR_H_OFFSET_0

Window B Horizontal address offset

Offset: 0x806 | Byte Offset: 0x2018 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_ADDR_H_OFFSET: Window B Horizontal address offset. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies horizontal offset of Y plane. The horizontal offsets of U/V plane is derived by hardware.

21.12.8 DC_WINBUF_B_ADDR_H_OFFSET_NS_0

Window B Shadowed Horizontal address offset

Offset: 0x807 | Byte Offset: 0x201c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_ADDR_H_OFFSET_NS: Window B Shadowed Horizontal address offset. This is ARM set shadow of ADDR_H_OFFSET

21.12.9 DC_WINBUF_B_ADDR_V_OFFSET_0

Window B Vertical address offset

Offset: 0x808 | Byte Offset: 0x2020 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_ADDR_V_OFFSET: Window B Vertical address offset. This is the vertical coordinate. For YUV planar pixel format, this specifies the vertical coordinate of Y plane. The vertical coordinate of U/V plane is derived by hardware.

21.12.10 DC_WINBUF_B_ADDR_V_OFFSET_NS_0

Window B Shadowed Vertical address offset

Offset: 0x809 | Byte Offset: 0x2024 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_ADDR_V_OFFSET_NS: Window B Shadowed Vertical address offset. This is ARM set shadow of ADDR_V_OFFSET.

21.12.11 DC_WINBUF_B_UFLOW_STATUS_0

Window B FIFO Underflow Status Register

Offset: 0x80a | Byte Offset: 0x2028 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
30	X	COUNT_OFLOW: Flag bit that indicates that the underflow event counter has overflowed. There were too many events. If COUNT_OFLOW is set, UFLOW_COUNT is meaningless. Cleared on write.
23:0	X	UFLOW_COUNT: Underflow count. This field indicates the number of contiguous groups of output pixels for which there was no data in the FIFO. For example, if the valid from the FIFO is low for 10 consecutive cycles and then goes high, the counter will increment by one. Reset to zero on write.

21.12.12 DC_WINBUF_B_SURFACE_KIND_0

Window B Surface Kind

Offset: 0x80b | Byte Offset: 0x202c | Read/Write: R/W | Reset: 0x00000010 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx001xx00)

Bit	Reset	Description

21.12.19 DC_WINBUF_B_START_ADDR_HI_V_NS_0

Window B Shadowed Higher 32 bits of Start Address for V plane

Offset: 0x812 │ Byte Offset: 0x2048 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00))

Bit	Reset	Description
1:0	0x0	B_START_ADDR_HI_V_NS: Window B Shadowed Higher 32 bits of Start Address for V plane. This is ARM set shadow register of U start address

21.12.20 DC_WINBUF_B_START_ADDR_FIELD2_0

Window B Start Address

Interlace/Stereo support. 64-bit base address for the odd field/right frame.

Offset: 0x813 | Byte Offset: 0x204c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_START_ADDR_FIELD2: Window B Start Address. This is a byte address. The LSB is not used for the 16-bpp non-planar pixel format, and the last 2 LSBs are not used for the 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

21.12.21 DC_WINBUF_B_START_ADDR_FIELD2_NS_0

Window B Shadowed Start Address

Offset: 0x814 | Byte Offset: 0x2050 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_START_ADDR_FIELD2_NS: Window B Shadowed Start Address. This is the ARM set shadow of the start address.

21.12.22 DC_WINBUF_B_START_ADDR_FIELD2_U_0

Window B Start Address for U plane

Offset: 0x815 | Byte Offset: 0x2054 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_START_ADDR_FIELD2_U: Window B Start Address for U plane. This is a byte address.

21.12.23 DC_WINBUF_B_START_ADDR_FIELD2_U_NS_0

Window B Shadowed Start Address for U plane

Offset: 0x816 | Byte Offset: 0x2058 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_START_ADDR_FIELD2_U_NS: Window B Shadowed Start Address for U plane. This is the ARM set shadow register of the U start address.

21.12.24 DC_WINBUF_B_START_ADDR_FIELD2_V_0

Window B Start Address for V plane

Offset: 0x817 | Byte Offset: 0x205c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_START_ADDR_FIELD2_V: Window B Start Address for V plane. This is a byte address.

21.12.25 DC_WINBUF_B_START_ADDR_FIELD2_V_NS_0

Window B Shadowed Start Address for V plane

Offset: 0x818 | Byte Offset: 0x2060 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_START_ADDR_FIELD2_V_NS: Window B Shadowed Start Address for V plane. This is the ARM set shadow register of the U start address.

21.12.26 DC_WINBUF_B_START_ADDR_FIELD2_HI_0

Window B Higher 32 bits of Start Address

Offset: 0x819 | Byte Offset: 0x2064 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	B_START_ADDR_FIELD2_HI: Window B Start Address. This is a byte address. The LSB is not used for the 16-bpp non-planar pixel format, and the last 2 LSBs are not used for the 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies the start address for the Y plane.

21.12.27 DC_WINBUF_B_START_ADDR_FIELD2_HI_NS_0

Window B Shadowed Higher 32 bits of Start Address

Offset: 0x81a | Byte Offset: 0x2068 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

21.12.38 DC_WINBUF_B_UFLOW_THRESHOLD_0

Offset: 0x826 | Byte Offset: 0x2098 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxx0000000000000)

Bit	Reset	Description
12:0	0x0	B_UFLOW_THRESHOLD

21.12.39 DC_WINBUF_B_SPOOL_UP_0

Spool up time configuration for different windows related logic.

SPOOL_UP_CTRL = MAX - This is the current Tegra K1 behavior. This allows for memfetch to start fetching for a window (irrespective of its relative position on the screen), at the very beginning of the vblank of the next frame. Since the spool up time is maximum, this should have the least probability of underflow of the display pipe. However, on the down side, since all three windows would start fetching at the same time, and since display is a high priority client for MC, it has a high potential to starve out other clients.

SPOOL_UP_CTRL = PROGRAMMABLE, SPOOL_UP_DURATION = 1 - This corresponds to the Tegra 3 behavior. Since the fetch starts only 1 line prior to the active scan line of a window, this has high probability of causing underflow, but has a lesser impact on the other MC clients.

So, this register programmability programs us a method to modulate the spool up time between the best and worst, if required, when other MC clients are present. Let's say when GPU/VIC is active, we may not want a very aggressive spool up and program some definite spool up duration. So, spool up time is a general knob, which would be a function of the resolution, bpp, active clients, memory speed, etc.

SPOOL_UP_EDGE:- By default the memfetch start signal generated by the hvtgen logic is one line clock wide.

For SPOOL_UP_CTRL = MAX:

- In this case if SPOOL_UP_EDGE is programmed to NEGEDGE. This ensures that if any act_req is sent during the time vcounter = 0(at the beginning of the frame). The activate value is loaded into the active state and the memfetch would see the latest updated value. The downside of programming it to NEGDGE is that 1 line clock worth of spool up is lost. This is required based upon Tegra 3 compatibility and the way tests are written.
- In this case if SPOOL_UP_EDGE is programmed to POSEDGE. Then the memfetch would start fetching at the very beginning of the frame start pulse (1 line clock wide) and would give maximum spool up time. However, this may give test failure and potential Tegra 3 compatibility issues as described above

FOR SPOOL_UP_CTRL = PROGRAMMABLE:

- Special care must be taken here. If SPOOL_UP_DURATION is set to 1. SPOOL_UP_EDGE must be set to POSEDGE to allow for at least 1 line worth of spool up.
- If SPOOL_UP_DURATION is > 1. Then SPOOL_UP_EDGE can be either POSEDGE or NEGEDGE. If its NEGEDGE, then the effective spool up duration would be 1 line clock less than the SPOOL_UP_DURATION.

Offset: 0x827 │ Byte Offset: 0x209c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
28:16	X	B_SPOOL_UP_DURATION
1	0x0	B_SPOOL_UP_EDGE: 0 = NEGEDGE 1 = POSEDGE
0	0x0	B_SPOOL_UP_CTRL: 0 = MAX 1 = PROGRAMMABLE

21.12.40 DC_WINBUF_B_SCALEFACTOR_THRESHOLD_0

Registers for latency allowance scaling. Threshold is in terms of 64 byte atoms. Display memfetch compares its buffer occupancy with the threshold and generates indication to MC if its buffer occupancy is above HWM or below LWM.

Offset: 0x828 │ Byte Offset: 0x20a0 │ Read/Write: R/W │ Reset: 0xffffffff (0b11111111111111111111111111111111)

Bit	Reset	Description
31:16	0xffff	B_SF_LWM_THRESHOLD
15:0	0xffff	B_SF_HWM_THRESHOLD

21.12.41 DC_WINBUF_B_LATENCY_THRESHOLD_0

The LATENCY_THRESHOLD register controls the behavior of the rdy4_latency_event from the display to the MC.

If B_RDY4LATENCY_THRESHOLD_ENABLE is set to DISABLE, the sideband rdy4_latency_event is always asserted, indicating that the display is always ready for a DVFS event.

The B_RDY4LATENCY_THRESHOLD field indicates the required occupancy of line buffers of windows below which the sideband rdy4_latency_event is deasserted. The occupancy figure is in units of 64B atoms for memfetch windows and in units of scan lines for regular windows.

The B_RDY4LATENCY_SPOOLUP_DURATION field indicates the number of scan lines during spool-up when the sideband will remain asserted (DVFS is allowed). This takes affect only when B_RDY4LATENCY_SPOOLUP_CTRL is set to ALLOW.

If the B_RDY4LATENCY_SPOOLUP_CTRL field is set to DISALLOW, the above register field is not affected and DVFS is disallowed until the threshold is reached.

Offset: 0x829 │ Byte Offset: 0x20a4 │ Read/Write: R/W │ Reset: 0x0000ffff (0b00x00000000000001111111111111111)

Bit	Reset	Description
31	DISABLE	B_RDY4LATENCY_THRESHOLD_ENABLE: 0 = DISABLE 1 = ENABLE
30	DISALLOW	B_RDY4LATENCY_SPOOLUP_CTRL: 0 = DISALLOW 1 = ALLOW
28:16	0x0	B_RDY4LATENCY_SPOOLUP_DURATION
15:0	0xffff	B_RDY4LATENCY_THRESHOLD

21.12.42 DC_WINBUF_B_MEMFETCH_DEBUG_STATUS_0

Memfetch Debug Status

Offset: 0x82a │ Byte Offset: 0x20a8 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx00000000000000000)

Bit	Reset	Description
16	0x0	B_DEBUG_ENABLE:reg to enable FGCG for flops added to debug signals in memfetch.
15	0x0	B_ALIGN_FIFO_NON_IDLE: align FIFO idle at end of frame. 0= align FIFO is idle at end of frame. 1= align FIFO is not idle at end of frame

Bit	Reset	Description
31:0	0x0	B_SCRATCH_REGISTER_1:Scratch register 1

21.13 Window C (WIN_C) Registers

These registers control window C parameters.

21.13.1 DC_WINC_C_COLOR_PALETTE_0

Window C Color Palette

This is used for palletized data format (color depth of 8-bpp or less) or for gamma correction for non-palletized data formats (color depth of more than 8-bpp). Each window has its own color palette which consists of three 256x8 register file which can be written by host and indexed (read) by the window.

For palletized data format less than 8-bpp, the pixel data is aligned to least significant bits of the palette index (address) and the remaining upper bits are filled with the corresponding bits of the Palette Color Extension. For example, for 4-bpp mode, the pixel data occupies bits 3:0 of the palette index and bits 7:4 of the palette index are set to bits 7:4 of the Palette Color Extension. Host read is assumed to be not needed - software can cache the color palette in system memory. This is an array of 256 identical register entries; the register fields below apply to each entry.

Color Palette

Offset: 0x500..0x5ff │ Byte Offset: 0x1400..0x17fc │ Read/Write: WO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:16	X	C_COLOR_PALETTE_B: Blue Color Palette
15:8	X	C_COLOR_PALETTE_G: Green Color Palette
7:0	X	C_COLOR_PALETTE_R: Red Color Palette

21.13.2 DC_WINC_C_PALETTE_COLOR_EXT_0

Window C Palette Color Extension

Palette extension for 1-bpp, 2-bpp, and 4-bpp. These bits provide the upper most significant bits for indexing the color palette.

Offset: 0x600 │ Byte Offset: 0x1800 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:1	X	C_PALETTE_COLOR_EXT: Window C Palette Color Extension. Bits 7:1 are used for 1-bpp mode, bits 7:2 are used for 2-bpp mode, and bits 7:4 are used for 4-bpp mode

21.13.3 DC_WINC_C_H_FILTER_P00_0

Window C Horizontal Filter phase 00

Horizontal scaling filter coefficients.

Horizontal scaling filter is a 6-tap filter with 4-bit positional phase.

- Coefficients 0 and 5 are 3-bit signed values ranging from -4 to 3.
- Coefficients 1 and 4 are 5-bit signed values ranging from -16 to 15.
- Coefficients 2 and 3 are 8-bit unsigned values ranging from 0 to 128.

- Coefficient 0 is the multiplier for the earliest pixel (P0) in the group of 6 pixels and coefficient 5 is the multiplier for the latest pixel (P5) in the group. The output pixel positional phase is defined as centered in P2 if the positional phase is 0 or proportionally in between P2 and P3 if the positional phase is larger than 0.

Sum of all coefficients for each phase should be 128 typically, and software should never program the sum of all coefficients for a phase to be more than 128.

For each horizontal positional phase, the 6 filter coefficients require 32 register bits. Note that color value ranges from 0 to 255 for Y, R, G, B and -128 to 127 for U and V.

Offset: 0x601 │ Byte Offset: 0x1804 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:29	X	C_H_FILTER_P00C5: Phase 00 coefficient 5 (typically 0)

21.13.19 DC_WINC_C_CSC_YOF_0

Window C CSC Y Offset

Color Space Conversion coefficients

The CSC can be used for YUV to RGB conversion with brightness and hue/saturation control. The CSC can only be enabled for window C controlled by CSC_ENABLE register bits.

For Y color, the Y offset is applied first and saturation (clipping) is performed immediately after the Y offset is applied.

- R = sat(KYRGB * sat(Y + YOF) + KUR * U + KVR * V)
- G = sat(KYRGB * sat(Y + YOF) + KUG * U + KVG * V)
- B = sat(KYRGB * sat(Y + YOF) + KUB * U + KVB * V)

Saturation and rounding is performed in the range of 0 to 255 for the above equations.

Typical values are:

- YOF = -16.000, KYRGB = 1.1644

- KUR = 0.0000, KVR = 1.5960
- KUG = -0.3918, KVG = -0.8130
- KUB = 2.0172, KVB = 0.0000

KUR and KVB are typically 0.0000 but they may be programmed non-zero for hue rotation.

The CSC can also take RGB input, in which case YOF, KVB, KUG, and KUR should be programmed to 0, and KYRGB will be forced to 0 by the hardware for generating R and B. KYRGB will not be forced to 0 for generating G. KVR, KYRGB, and KUB can be programmed to 1.0 or used as gain control for R, G, B, correspondingly. Note that color value ranges from 0 to 255 for Y, R, G, B, and -128 to 127 for U and V.

21.13.27 DC_WINC_C_V_FILTER_P00_0

Window C Vertical Filter phase 00

Vertical scaling filter coefficients

Vertical scaling filter is a 2-tap filter with 4-bit positional phase. Coefficients 0 and 1 are 8-bit unsigned values ranging from 0 to 128.

Coefficient 0 is the multiplier for the earlier pixel (P0) in the group of 2-pixels and coefficient 1 is the multiplier for the later pixel (P1) in the group. The output pixel positional phase is defined as centered in P0 if the positional phase is 0 or proportionally in between P0 and P1 if the positional phase is larger than 0.

Sum of all coefficients for each phase should be 128 typically; therefore coefficient 1 can be calculated from (1 - coefficient 0) and only coefficient 0 is programmed.

For each vertical positional phase, the filter coefficient requires 8 register bits. Note that color value ranges from 0 to 255 for Y, R, G, B and -128 to 127 for U and V.

The registers under DC_WIN are double buffered.

21.13.59 DC_WIN_C_WIN_OPTIONS_0

Window C Options

Class: Display Window Settings

Display Window C parameters

Offset: 0x700 │ Byte Offset: 0x1c00 │ Read/Write: R/W │ Reset: 0x00XXXXXX (0b00xxxxxx0xxxxxx0x0xxxxxxxxx0xxxx)

Bit	Reset	Description
31	0x0	c_H_FILTER_MODE: Horizontal filter mode. 0 = With previous Tegra horizontal coeffients widths. 0,5 - signed 5 bits 1,4 - signed 9 bits 2,3 - unsigned 9 bits 1 = New mode. With the expanded horizontal filter coefficients widths. 0,5- signed 5 bits 1,4- signed 7 bits 2,3- unsigned 9 bits 0 = OLD 1 = NEW
30	0x0	C_WIN_ENABLE: Window C Window enable 0 = DISABLE 1 = ENABLE
23	0x0	C_INTERLACE_ENABLE: Window C Interlace enable. This controls the fetch unit toggle between odd and even (normal) base addresses at the start of each field. Base address select between odd/even fields is determined by HVTGEN field status. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
22	X	C_YUV_RANGE_EXPAND: Window C Enable range expansion in the cases where RANGEREDFRM is 1 from mpd. Formula: Y = clip((Y-128)*2 + 128); Cb = clip((Cb-128)*2 + 128); Cr = clip((Cr-128)*2 + 128); where clip() function clips between 0 and 255. 0 = DISABLE 1 = ENABLE
20	X	C_DV_ENABLE: Window C Digital Vibrance Enable 0 = DISABLE 1 = ENABLE
18	X	C_CSC_ENABLE: Window C Color Space Conversion Enable. This controls the color space conversion and should be enabled for YCbCr/YUV color modes for conversion to B8G8R8 and for hue and saturation control. This can also be used for gain control for RGB color modes. 0 = DISABLE 1 = ENABLE
16	0x0	C_CP_ENABLE: Window C Color Palette Enable. This controls the color palette and should be enabled for palletized color modes. For non-palletized color modes, the color palette can be enabled for gamma correction. 0 = DISABLE 1 = ENABLE
14	0x0	C_V_FILTER_UV_ALIGN: Window C V Filter UV Alignment. This is effective only when vertical scaling filter is enabled and only on these formats YCbCr420P, YUV420P, YCbCr422R, YUV422R, YCbCr422RA YUV422RA. When UV alignment is enabled, the chroma components are aligned to the even number of luma component lines. When disabled the chroma components are aligned to half a pixel below the corresponding even number of luma component lines. It is usually disabled unless the incoming video stream specifically indicates otherwise. 0 = DISABLE 1 = ENABLE
12	X	C_V_FILTER_OPTIMIZE: Window C V Filter Optimization. This is effective only when vertical scaling filter is enabled. This can be used (enabled) to temporarily disable the vertical scaling filter when the vertical scaling DDA fraction is zero. In this case the next line is not fetched from memory to save bandwidth and power. This feature cannot be used in 420P/422R/422RA formats. 0 = DISABLE 1 = ENABLE
10	X	C_V_FILTER_ENABLE: Window C V Filter Enable. This controls the V scaling filter and is effective only for non-palletized color modes. If V filter is disabled, only one line is read from memory for each output line. NOTE: This feature is not supported. This bit is ignored and is a don't care. 0 = DISABLE 1 = ENABLE
8	X	C_H_FILTER_ENABLE: Window C H Filter Enable. This controls H scaling filter and is effective only for non-palletized color modes. 0 = DISABLE 1 = ENABLE
6	X	C_COLOR_EXPAND: Window C 12/15/16/18-to-24 bpp color expansion. This bit should be enabled only for 12-bpp B4G4R4A4, 15-bpp B5G5R5A, 16-bpp B5G6R5, 18-bpp B6G6R6 color modes. If enabled, the color conversion is performed prior to horizontal scaling. 0 = DISABLE 1 = ENABLE
4	0x0	C_SCAN_COLUMN: Window C Scanning direction. 0= Scan in horizontal direction (for 0 or 180 degrees). 1= Scan in vertical direction (for 90 or 270 degrees) 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
2	X	C_V_DIRECTION: Window C Vertical (Y) drawing Direction 0 = INCREMENT 1 = DECREMENT
0	X	C_H_DIRECTION: Window C Horizontal (X) drawing Direction 0 = INCREMENT 1 = DECREMENT

21.13.60 DC_WIN_C_BYTE_SWAP_0

Window C Byte Swap

Offset: 0x701 │ Byte Offset: 0x1c04 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
2:0	X	C_BYTE_SWAP: Window C Byte Swap. This controls byte swap of frame data read from memory prior to any data processing in the display module. 000= no byte swap (3 2 1 0) 001= byte swap for each 2-byte word (2 3 0 1) 010= byte swap for each 4-byte word (0 1 2 3) 011= word swap for each 4-byte word (1 0 3 2) 100= byte0 swapped with byte2 (3 0 1 2) 101= left shift every byte (2 1 0 3) 0 = NOSWAP 1 = SWAP2 2 = SWAP4 3 = SWAP4HW 4 = SWAP02 5 = SWAPLEFT

21.13.61 DC_WIN_C_COLOR_DEPTH_0

Window C Color Depth. For YCbCr data format, Cb and Cr are 8-bit unsigned values. For YUV data format, U and V are 8-bit signed values. YCbCr422R is similar to YCbCr422P but the Cb and Cr are shared vertically.

YUV422R is similar to YUV422P, but the U and V are shared vertically. YCbCr422RA is the same as YCbCr422R in memory and YUV422RA is the same as YUV422R in memory but while reading from memory, for YCbCr422RA and YUV422RA, chroma averaging is applied for each pixel pair so that they can be processed as YUV422 by the display pipeline.

For YCbCr422R and YUV422R, every other chroma pixels are not used (discarded) by the display pipeline. B6x2G6x2R6x2A8 is similar to B8G8R6A8 but with the 2 LSBs zeroed out. R6x2G6x2B6x2A8 is similar to R8G8B6A8 but with the 2 LSBs zeroed out.

Some formats have NVCF_ or T_ prefix aliases for NVidia surface format naming convention, wherein left-to-right component names correspond to MSB to LSB bits within a word. In old names without NVCF_ or T_, left-to-right component names generally map LSB to MSB within a word.

21.13.62 DC_WIN_C_POSITION_0

Window C Position

This register defines H position and size of Window C after scaling (if there is any)

Offset: 0x704 │ Byte Offset: 0x1c10 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	C_V_POSITION: Window C V Position. This is specified with respect to the top edge of active display area.
12:0	X	C_H_POSITION: Window C H Position. This is specified with respect to the left edge of active display area.

21.13.63 DC_WIN_C_SIZE_0

Window C Size

This register defines V position and size of Window C after scaling (if there is any)

Note: Programming on window size should guarantee the whole window is inside the active area, otherwise extra rows/columns will be fetched and discarded which affects performance.

Offset: 0x705 │ Byte Offset: 0x1c14 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	C_V_SIZE: Window C V Size (lines). This is the vertical size after scaling.
12:0	X	C_H_SIZE: Window C H Size (pixels). This is the horizontal size after scaling.

21.13.64 DC_WIN_C_PRESCALED_SIZE_0

Window C Pre-scaled Size

This register defines Window C pre-scaled size.

The H pre-scaled size is needed to determine how many bytes to fetch from memory per line and this parameter must be programmed exactly as needed taking into account the scaling factor. For planar YUV or YCbCr data formats, this parameter refer to the H pre-scaled of the Y plane.

The total number of lines to be fetched from memory is determined by post-scale V size but V pre-scaled size is needed to 'clamp' the last valid line if the vertical DDA is exactly or slightly beyond the specified V pre-scaled size.

H pre-scaled size ideally should be in terms of pixel but then hardware needs to convert this precisely to bytes to determine the amount of data to request from memory.

Offset: 0x706 │ Byte Offset: 0x1c18 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	C_V_PRESCALED_SIZE: Window C V Pre-scaled Size (lines). In 420P/422R/422RA formats, it must be even.
14:0	X	C_H_PRESCALED_SIZE: Window C H Pre-scaled Size (bytes). In 420P and 422P formats, it must be even.

21.13.65 DC_WIN_C_H_INITIAL_DDA_0

Window C H Initial DDA

The first pixel of the pre-scaled image is always used to output the first pixel, so essentially this is the same as forcing the H Initial DDA integer portion to 1 initially even though user typically programs this to 0. If it makes the implementation easier, it is possible to force software to program the Initial DDA integer portion to 1. Similarly with the V Initial DDA.

Offset: 0x707 │ Byte Offset: 0x1c1c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	C_H_INITIAL_DDA: Window C H Initial DDA (4.12). This is typically programmed to 0.0

21.13.66 DC_WIN_C_V_INITIAL_DDA_0

Window C V Initial DDA

Offset: 0x708 │ Byte Offset: 0x1c20 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	C_V_INITIAL_DDA: Window C V Initial DDA (4.12). This is typically programmed to 0.0 for both non-interlaced and interlaced sources.

21.13.67 DC_WIN_C_DDA_INCREMENT_0

Window C DDA Increment

DDA increment is typically calculated by dividing (Pre-scaled size in pixels - 1) by (Post-scaled size in pixels - 1). The result should be rounded up and expressed as 4.12 format (4-bit integer and 12-bit fraction). For non-filtered image this value can be slightly larger so that it is not missing the last row/column. Reference programming values (H and V should be calculated separately depending on filter on/off and sizes):

- Filter on: min(round((prescaled_size_in_pixels - 1) * 0x1000 / (post_scaled_size_in_pixels - 1)) + initial_dda_bias, MAX)
- Filter off: min(round(prescaled_size_in_pixels * 0x1000 / (post_scaled_size_in_pixels - 1) - 0.5) + initial_dda_bias, MAX)

Where the value of MAX is as follows:

- For V_DDA_INCREMENT: 15.0 (0xF000)
- For H_DDA_INCREMENT: 4.0 (0x4000) for 4 Bytes/pixel formats.

  8.0 (0x8000) for 2 Bytes/pixel formats.

Where the value of initial_dda_bias is as follows:

For V_DDA_INCREMENT: initial_dda_bias = (v_intial_dda == negative) ? mod(v_initial_dda)/(post_scaled_size_in_pixels - 1) : 0 ;

For H_DDA_INCREMENT: initial_dda_bias = 0;

They are theoretically the biggest values that guarantee not displaying beyond an image boundary. If the DDA increment is less than 1.0 then image will be upscaled and if DDA increment is more than 1.0, then the image will be downscaled.

Offset: 0x709 | Byte Offset: 0x1c24 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	C_V_DDA_INCREMENT: Window C Vertical DDA Increment (4.12). This should be set to 1.0 if there is no scaling. Maximum value is 15.0 regardless of the number of bytes per pixel.
15:0	X	C_H_DDA_INCREMENT: Window C Horizontal DDA Increment (4.12). This should be set to 1.0 if there is no scaling. The maximum value for downscaling depends on the number of bytes per pixel. For 4-byte/pixel modes (32-bpp) the maximum value is 4.0 and for all other modes the maximum value is 8.0.

21.13.68 DC_WIN_C_LINE_STRIDE_0

Window C Line Stride

Offset: 0x70a | Byte Offset: 0x1c28 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	C_UV_LINE_STRIDE: Window C Line Stride for Chroma. This is stride (in bytes) for planar YUV or YCbCr data formats for the chroma plane, with the restriction that it must be programmed to be multiples of 4 (16 if tiled or in horizontal flipping) This is not used (ignored) for other non-planar data formats.
15:0	X	C_LINE_STRIDE: Window C Line Stride. This is stride (in bytes) for all non-planar data formats. If the memory surface is tiled, the stride needs to be a multiple of 16. If H_DIRECTION of window C is set to DECREMENT, the stride also needs to be a multiple of 16. For planar YUV or YCbCr data formats, this is stride (in bytes) for the luma plane with the restriction that it must be multiples of 8 (16 if tiled or in horizontal flipping) For tiled surface this value may affect starting address of a window. Refer to the comment of START_ADDR for detail.

21.13.69 DC_WIN_C_DV_CONTROL_0

Window C Digital Vibrance Control

If enabled, Digital Vibrance is applied after H and V scaling and after color palette or color space conversion logic but before color keying multiplexer and before cursor multiplexer.

- After DV, new R = R + (2R - G - B) * FR, where FR is fraction from 0 to 7/8
- After DV, new G = G + (2G - R - B) * FG, where FG is fraction from 0 to 7/8
- After DV, new B = B + (2B - R - G) * FB, where FB is fraction from 0 to 7/8

Offset: 0x70e | Byte Offset: 0x1c38 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18:16	X	C_DV_CONTROL_B: Digital Vibrance control for B
10:8	X	C_DV_CONTROL_G: Digital Vibrance control for G
2:0	X	C_DV_CONTROL_R: Digital Vibrance control for R

Class: Display Color Keying and Blending

Color keying and blending of the display windows are done prior to cursor blending. Cursor always goes on top of the blended windows. Blending is controlled independently on each possible overlap area of the display windows. If 3 windows are enabled there are 7 possible overlap area combinations. For every window in each overlap area combination, color key can be

disabled or enabled. Also, for every window in each overlap area combination, there is a corresponding window blend control parameter and a window blend weight parameter. The window blend control parameter is always effective but the window blend weight is not always used. The window blend weight can also be derived from pixel alpha value or from the reverse of other overlapping windows weight.

Color keying has the highest priority for display window blending. Color key consists of a range of color which is searched independently for each window. If more than 1 windows color key is enabled, then Window A color key has the highest priority, followed by Window B color key, and then followed by Window C color key. Two sets of color key ranges (Color Key 0 and Color Key 1) can be defined; they are shared for all windows. It is possible to use both color key sets for the same window or for two separate windows.

The two sets of color key ranges should not overlap. If they do, the overlapped colors are treated as if they are part of Color Key 0 and not part of Color Key 1.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for any overlap condition and the window pixel is not within the color key range (key not match), then the window pixel will not be blended with other overlapping window pixels but it will be weighted. The weight is not dependent on the overlap condition it is controlled by the same set of parameters for all overlapping condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for a particular overlap condition and the window pixel is within the color key range (key match), then the window pixel will be weighted and blended with other overlapping pixels and this is controlled separately for each overlap condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is disabled then the window pixel will be blended with other overlapping pixels and this is controlled separately for each overlap condition.

Display Color Key Parameters

For B4G4R4A4, B5G6R5A, B5G6R5 modes, the color key should be compared prior to the color conversion to 24-bpp and the unused least significant bits of the pixel are filled with zeros.

For palletized mode, the color key is compared prior to the color palette, and the palletized color is compared against the green color key values/mask.

For YUV mode, U and V are offset by +128 before performing the color key comparison.

In all cases, the color key is compared prior to the horizontal/vertical scaling filter and prior to digital vibrance control.

Both upper and lower values are inclusive.

21.14 WINBUF_C Registers

The registers under DC_WINBUF are triple-buffered.

21.14.1 DC_WINBUF_C_START_ADDR_0

Window C Start Address

Overview

START_ADDR, BUF_STRIDE, LINE_STRIDE, ADDR_H_OFFSET, ADDR_V_OFFSET combined, specify the starting address of a window buffer in the memory surface. Generally START_ADDR is programmed with the starting address of the memory surface. H/V_OFFSET specifies the address offsets of the pixel at the beginning of the window, with respect to the starting address of the memory surface. (There is an exception to that when memory surface is not well aligned, see “For linear address mode” under Programming Restrictions below.)

Note that "beginning of the window" here means the top-left corner of a window in normal mode, top-right corner in horizontal flipping, bottom-left corner in vertical flipping, and bottom-right in horizontal+vertical flipping.

Starting Address Calculation

These formulae are same for both tiled and linear modes. However, for linear mode, the addresses calculated are real physical addresses. For tiled mode, these addresses will be translated to the real physical addresses by the memory controller client before being used.

- When a window is host triggered, the starting address of a window is calculated as follows by hardware.
  - non-YUV-planar modes

    starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar modes

    Y-starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    U-starting-address = START_ADDR_U + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    V-starting-address = START_ADDR_V + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by hardware.

- When a window is non-host triggered, starting address of a window buffer is calculated as below.
  - non-YUV-planar mode

    starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar mode:

    Y-starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    U-starting-address = START_ADDR_U + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    V-starting-address = START_ADDR_V + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    where denom1/denom2 are equal to 1 or 2 depending on the actual planar format, derived natively by hardware.

    buf_index is the index transmitted by the triggering module pointing to the first buffer of a frame.

Programming Restrictions

- For tiled address mode

  Image surface can only aligned to multiples of 256, thus the following restrictions.
  - START_ADDR, START_ADDR_U, START_ADDR_V need to be multiples of 256.
  - BUF_STRIDE, UV_BUF_STRIDE need to be multiples of 256
  - LINE_STRIDE, UV_LINE_STRIDE need to be multiples of 16
  - ADDR_H_OFFSET needs to be even in yuv planar format, or a multiple of bytes per pixel in other formats. If H_DIRECTION=DECREMENT, however, it should point to last valid byte, which is an odd offset..
  - ADDR_V_OFFSET needs to be multiple of 2 in YUV planar format, unless H_DIRECTION=DECREMENT, but with no restrictions on other color formats
- For linear address mode

  Image surface can be aligned 2, 4, or 8 bytes, depending on the color formats.

  As an additional restriction for display, START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16. When a surface is not aligned to 16 bytes, program START_ADDR with the memory surface address with its least 4 significant bits zeroed out and add these 4 address bits to the original H_OFFSET. (So the formulae in Starting Address Calculation above still hold)
  - For all formats:

    START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16.

    For 16-bpp formats,

    (START_ADDR+H_OFFSET) need to be a multiple of 2.

    For 32-bpp formats,

    (START_ADDR+H_OFFSET) needs to be a multiple of 4.
  - For yuv planar formats:

    BUF_STRIDE, UV_BUF_STRIDE:

    BUF_STRIDE[2:1]=UV_BUF_STRIDE[1:0]

    or as a stricter constraint: BUF_STRIDE be a multiple of 8, UV_BUF_STRIDE be a multiple of 4.

    LINE_STRIDE, UV_LINE_STRIDE:

    LINE_STRIDE and UV_LINE_STRIDE need to be at least 16.

    LINE_STRIDE needs to be a multiple of 8, UV_LINE_STRIDE needs to be a multiple of 4.

ADDR_H_OFFSET: Needs to be even unless H_DIRECTION=DECREMENT, in which case should point to the last byte pixel, which is at an odd offset.

ADDR_V_OFFSET: Needs to be even unless V_DIRECTION=DECREMENT, in which case should point to the last valid line, which is at an odd offset

- Memory allocation for non-host triggered case:

  When a window buffer is not controlled by host (software) then a frame may be stored in multiple buffers. In this case, the buffers must be contiguous in the memory because display will use the same luma or chroma line strides for all lines in the frame.

  Also buffer wraparound must not occur in the middle of the displayed part of the frame. The controlling module will send frame start and frame end indicators (flags) to display module to indicate the beginning and end of frame. Buffer start address is latched when frame start flag is active but the actual buffer start address is not switched until frame end flag is active. In the case where one buffer corresponds to one frame then frame start and frame end flag are active every time a buffer index is sent.

Offset: 0x800 | Byte Offset: 0x2000 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_START_ADDR: Window C Start Address. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

21.14.2 DC_WINBUF_C_START_ADDR_NS_0

Window C Shadowed Start Address

Offset: 0x801 | Byte Offset: 0x2004 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_START_ADDR_NS: Window C Shadowed Start Address. This is ARM set shadow of Start Address.

21.14.3 DC_WINBUF_C_START_ADDR_U_0

Window C Start Address for U plane

Offset: 0x802 | Byte Offset: 0x2008 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_START_ADDR_U: Window C Start Address for U plane. This is a byte address.

21.14.4 DC_WINBUF_C_START_ADDR_U_NS_0

Window C Shadowed Start Address for U plane

Offset: 0x803 | Byte Offset: 0x200c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_START_ADDR_U_NS: Window C Shadowed Start Address for U plane. This is ARM set shadow register of U start address

21.14.5 DC_WINBUF_C_START_ADDR_V_0

Window C Start Address for V plane

Offset: 0x804 | Byte Offset: 0x2010 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_START_ADDR_V: Window C Start Address for V plane. This is a byte address.

21.14.6 DC_WINBUF_C_START_ADDR_V_NS_0

Window C Shadowed Start Address for V plane

Offset: 0x805 | Byte Offset: 0x2014 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_START_ADDR_V_NS: Window C Shadowed Start Address for V plane. This is ARM set shadow register of U start address

21.14.7 DC_WINBUF_C_ADDR_H_OFFSET_0

Window C Horizontal address offset

Offset: 0x806 | Byte Offset: 0x2018 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_ADDR_H_OFFSET: Window C Horizontal address offset. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies horizontal offset of Y plane. The horizontal offsets of U/V plane is derived by hardware.

21.14.8 DC_WINBUF_C_ADDR_H_OFFSET_NS_0

Window C Shadowed Horizontal address offset

Offset: 0x807 | Byte Offset: 0x201c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_ADDR_H_OFFSET_NS: Window C Shadowed Horizontal address offset. This is ARM set shadow of ADDR_H_OFFSET

21.14.9 DC_WINBUF_C_ADDR_V_OFFSET_0

Window C Vertical address offset

Offset: 0x808 | Byte Offset: 0x2020 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_ADDR_V_OFFSET: Window C Vertical address offset. This is the vertical coordinate. For YUV planar pixel format, this specifies the vertical coordinate of Y plane. The vertical coordinate of U/V plane is derived by hardware.

21.14.10 DC_WINBUF_C_ADDR_V_OFFSET_NS_0

Window C Shadowed Vertical address offset

Offset: 0x809 | Byte Offset: 0x2024 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_ADDR_V_OFFSET_NS: Window C Shadowed Vertical address offset. This is ARM set shadow of ADDR_V_OFFSET

21.14.11 DC_WINBUF_C_UFLOW_STATUS_0

Window C FIFO Underflow Status Register

Offset: 0x80a | Byte Offset: 0x2028 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
30	X	COUNT_OFLOW: Flag bit that indicates that the underflow event counter has overflowed. There were too many events. If COUNT_OFLOW is set, UFLOW_COUNT is meaningless. Cleared on write.
23:0	X	UFLOW_COUNT: Underflow count. This field indicates the number of contiguous groups of output pixels for which there was no data in the FIFO. For example, if the valid from the FIFO is low for 10 consecutive cycles and then goes high, the counter will increment by one. Reset to zero on write.

21.14.12 DC_WINBUF_C_SURFACE_KIND_0

Window C Surface Kind

Offset: 0x80b | Byte Offset: 0x202c | Read/Write: R/W | Reset: 0x00000010 (0bxxxxxxxxxxxxxxxxxxxxxxxxx001xx00)

Bit	Reset	Description
6:4	0x1	C_BLOCK_HEIGHT: Block Height: For block linear, height of block in GOBs 0 = HEIGHT_1 1 = HEIGHT_2 2 = HEIGHT_4 3 = HEIGHT_8 4 = HEIGHT_16 5 = HEIGHT_32
1:0	0x0	C_SURFACE_KIND: Surface Kind: Pitched, Tiled, or Block Linear 0 = PITCH 1 = TILED 2 = BL_16B2

21.14.13 DC_WINBUF_C_SURFACE_WEIGHT_0

Window C Surface Weights

Offset: 0x80c | Byte Offset: 0x2030 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
6:5	X	C_SURFACE_WEIGHT_V: Window C V Surface Weights. 00 - Weight is 2 01 - Weight is 4 10 - Weight is 8 11 - Weight is 16

Bit	Reset	Description
		0 = WEIGHT_2 1 = WEIGHT_4 2 = WEIGHT_8 3 = WEIGHT_16
4:3	X	C_SURFACE_WEIGHT_U: Window C U or UV Surface Weights. 00 - Weight is 2 01 - Weight is 4 10 - Weight is 8 11 - Weight is 16 0 = WEIGHT_2 1 = WEIGHT_4 2 = WEIGHT_8 3 = WEIGHT_16
2:1	X	C_SURFACE_WEIGHT_Y: Window C Y or packed Surface Weights. 00 - Weight is 2 01 - Weight is 4 10 - Weight is 8 11 - Weight is 16 0 = WEIGHT_2 1 = WEIGHT_4 2 = WEIGHT_8 3 = WEIGHT_16
0	0x0	C_SURFACE_WEIGHT_OVERRIDE: Weight override 0 = DISABLE 1 = ENABLE

21.14.14 DC_WINBUF_C_START_ADDR_HI_0

Window C Higher 32 bits of Start Address

Makes the start address 64 bits by adding the higher 32 bits below.

Offset: 0x80d │ Byte Offset: 0x2034 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	C_START_ADDR_HI: Window C Start Address. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

21.14.15 DC_WINBUF_C_START_ADDR_HI_NS_0

Window C Shadowed Higher 32 bits of Start Address

Offset: 0x80e │ Byte Offset: 0x2038 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	C_START_ADDR_HI_NS: Window C Shadowed Start Address. This is ARM set shadow of Start Address.

21.14.16 DC_WINBUF_C_START_ADDR_HI_U_0

Window C Higher 32 bits of Start Address for U plane

21.14.20 DC_WINBUF_C_START_ADDR_FIELD2_0

Window C Start Address

Interlace/Stereo support. 64-bit base address for the odd field/right frame.

Offset: 0x813 | Byte Offset: 0x204c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_START_ADDR_FIELD2: Window C Start Address. This is a byte address. The LSB is not used for the 16-bpp non-planar pixel format, and the last 2 LSBs are not used for the 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

21.14.21 DC_WINBUF_C_START_ADDR_FIELD2_NS_0

Window C Shadowed Start Address

Offset: 0x814 | Byte Offset: 0x2050 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_START_ADDR_FIELD2_NS: Window C Shadowed Start Address. This is the ARM set shadow of the start address.

21.14.22 DC_WINBUF_C_START_ADDR_FIELD2_U_0

Window C Start Address for U plane

Offset: 0x815 | Byte Offset: 0x2054 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_START_ADDR_FIELD2_U: Window C Start Address for U plane. This is a byte address.

21.14.23 DC_WINBUF_C_START_ADDR_FIELD2_U_NS_0

Window C Shadowed Start Address for U plane

Offset: 0x816 | Byte Offset: 0x2058 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_START_ADDR_FIELD2_U_NS: Window C Shadowed Start Address for U plane. This is the ARM set shadow register of the U start address.

21.14.24 DC_WINBUF_C_START_ADDR_FIELD2_V_0

Window C Start Address for V plane

Offset: 0x817 | Byte Offset: 0x205c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_START_ADDR_FIELD2_V: Window C Start Address for V plane. This is a byte address.

21.14.25 DC_WINBUF_C_START_ADDR_FIELD2_V_NS_0

Window C Shadowed Start Address for V plane

Offset: 0x818 | Byte Offset: 0x2060 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_START_ADDR_FIELD2_V_NS: Window C Shadowed Start Address for V plane. This is the ARM set shadow register of the U start address.

21.14.26 DC_WINBUF_C_START_ADDR_FIELD2_HI_0

Window C Higher 32 bits of Start Address

Offset: 0x819 | Byte Offset: 0x2064 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	C_START_ADDR_FIELD2_HI: Window C Start Address. This is a byte address. The LSB is not used for the 16-bpp non-planar pixel format, and the last 2 LSBs are not used for the 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies the start address for the Y plane.

21.14.27 DC_WINBUF_C_START_ADDR_FIELD2_HI_NS_0

Window C Shadowed Higher 32 bits of Start Address

Offset: 0x81a | Byte Offset: 0x2068 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	C_START_ADDR_FIELD2_HI_NS: Window C Shadowed Start Address. This is the ARM set shadow of the start address.

21.14.28 DC_WINBUF_C_START_ADDR_FIELD2_HI_U_0

Window C Higher 32 bits of Start Address for U plane

Offset: 0x81b | Byte Offset: 0x206c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	C_START_ADDR_FIELD2_HI_U: Window C Start Address for U plane. This is a byte address.

21.14.29 DC_WINBUF_C_START_ADDR_FIELD2_HI_U_NS_0

Window C Shadowed Higher 32 bits of Start Address for U plane

Offset: 0x81c | Byte Offset: 0x2070 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	C_START_ADDR_FIELD2_HI_U_NS: Window C Shadowed Higher 32 bits of Start Address for U plane. This is the ARM set shadow register of the U start address.

21.14.30 DC_WINBUF_C_START_ADDR_FIELD2_HI_V_0

Window C Higher 32 bits of Start Address for V plane

Offset: 0x81d | Byte Offset: 0x2074 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	C_START_ADDR_FIELD2_HI_V: Window C Higher 32 bits of Start Address for V plane. This is a byte address.

21.14.31 DC_WINBUF_C_START_ADDR_FIELD2_HI_V_NS_0

Window C Shadowed Higher 32 bits of Start Address for V plane

Offset: 0x81e | Byte Offset: 0x2078 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	C_START_ADDR_FIELD2_HI_V_NS: Window C Shadowed Higher 32 bits of Start Address for V plane. This is the ARM set shadow register of the U start address.

21.14.32 DC_WINBUF_C_ADDR_H_OFFSET_FIELD2_0

Window C Horizontal address offset

Offset: 0x81f | Byte Offset: 0x207c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_ADDR_H_OFFSET_FIELD2: Window C Horizontal address offset. This is a byte address. The LSB is not used for the 16-bpp non-planar pixel format, and the last 2 LSBs are not used for the 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies the horizontal offset of the Y plane. The horizontal offsets of U/V plane are derived by hardware.

21.14.33 DC_WINBUF_C_ADDR_H_OFFSET_FIELD2_NS_0

Window C Shadowed Horizontal address offset

Offset: 0x820 | Byte Offset: 0x2080 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_ADDR_H_OFFSET_FIELD2_NS: Window C Shadowed Horizontal address offset. This is the ARM set shadow of ADDR_H_OFFSET.

21.14.34 DC_WINBUF_C_ADDR_V_OFFSET_FIELD2_0

Window C Vertical address offset

Offset: 0x821 | Byte Offset: 0x2084 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_ADDR_V_OFFSET_FIELD2: Window C Vertical address offset. This is the vertical coordinate. For YUV planar pixel format, this specifies the vertical coordinate of the Y plane. The vertical coordinate of U/V plane is derived by hardware.

21.14.35 DC_WINBUF_C_ADDR_V_OFFSET_FIELD2_NS_0

Window C Shadowed Vertical address offset

Offset: 0x822 | Byte Offset: 0x2088 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_ADDR_V_OFFSET_FIELD2_NS: Window C Shadowed Vertical address offset. This is the ARM set shadow of ADDR_V_OFFSET

21.14.36 DC_WINBUF_C_UFLOW_CTRL_0

When the underflow debug mode is enabled. Instead of sending out the last valid pixel, DBG_PIXEL is sent out.

Offset: 0x824 │ Byte Offset: 0x2090 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	C_UFLOW_CTRL_DBG_MODE: 0 = DISABLE 1 = ENABLE

21.14.37 DC_WINBUF_C_UFLOW_DBG_PIXEL_0

Offset: 0x825 │ Byte Offset: 0x2094 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	C_UFLOW_DBG_PIXEL

21.14.38 DC_WINBUF_C_UFLOW_THRESHOLD_0

Offset: 0x826 │ Byte Offset: 0x2098 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxx0000000000000)

Bit	Reset	Description
12:0	0x0	C_UFLOW_THRESHOLD

21.14.39 DC_WINBUF_C_SPOOL_UP_0

Spool up time configuration for different windows related logic.

SPOOL_UP_CTRL = MAX - This is the current Tegra K1 behavior. This allows for memfetch to start fetching for a window (irrespective of its relative position on the screen), at the very beginning of the VBlank of the next frame. Since the spool up time is maximum, this should have the least probability of underflow of the display pipe. However, on the down side, since all three windows would start fetching at the same time, and since display is a high priority client for the MC, it has a high potential to starve out other clients.

SPOOL_UP_EDGE :- By default the memfetch start signal generated by the hvtgen logic is one line clock wide.

For SPOOL_UP_CTRL = MAX:

- If SPOOL_UP_EDGE is programmed to NEGEDGE, it ensures that if any act_req is sent during the time vcounter = 0 (at the beginning of the frame). The activate value is loaded into the active state and the memfetch would see the latest updated value.

  The downside of programming SPOOL_UP_EDGE to NEGDGE is 1 line clock worth of spool up is lost. This is required based upon Tegra compatibility.
- If SPOOL_UP_EDGE is programmed to POSEDGE, the memfetch starts fetching at the very beginning of the frame start pulse (1 line clock wide) and gives maximum spool up time. However, this may give test failure and potential Tegra compatibility issues as described above.

Offset: 0x827 │ Byte Offset: 0x209c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
28:16	X	C_SPOOL_UP_DURATION
1	0x0	C_SPOOL_UP_EDGE: 0 = NEGEDGE 1 = POSEDGE

Bit	Reset	Description
0	0x0	C_SPOOL_UP_CTRL. This bit should be set to MAX for Tegra K1 devices. 0 = MAX 1 = PROGRAMMABLE

21.14.40 DC_WINBUF_C_SCALEFACTOR_THRESHOLD_0

Registers for latency allowance scaling. Threshold is in terms of 64 byte atoms. Display memfetch compares its buffer occupancy with the threshold and generates indication to MC if its buffer occupancy is above HWM or below LWM.

Offset: 0x828 │ Byte Offset: 0x20a0 │ Read/Write: R/W │ Reset: 0xffffffff (0b11111111111111111111111111111111)

Bit	Reset	Description
31:16	0xffff	C_SF_LWM_THRESHOLD
15:0	0xffff	C_SF_HWM_THRESHOLD

21.14.41 DC_WINBUF_C_LATENCY_THRESHOLD_0

The LATENCY_THRESHOLD register controls the behavior of the rdy4_latency_event from the display to the MC.

If B_RDY4LATENCY_THRESHOLD_ENABLE is set to DISABLE, the sideband rdy4_latency_event is always asserted, indicating that the display is always ready for a DVFS event.

The B_RDY4LATENCY_THRESHOLD field indicates the required occupancy of line buffers of windows below which the sideband rdy4_latency_event is deasserted. The occupancy figure is in units of 64B atoms for memfetch windows and in units of scan lines for regular windows.

The B_RDY4LATENCY_SPOOLUP_DURATION field indicates the number of scan lines during spool-up when the sideband will remain asserted (DVFS is allowed). This takes affect only when B_RDY4LATENCY_SPOOLUP_CTRL is set to ALLOW.

If the B_RDY4LATENCY_SPOOLUP_CTRL field is set to DISALLOW, the above register field is not affected and DVFS is disallowed until the threshold is reached.

Offset: 0x829 │ Byte Offset: 0x20a4 │ Read/Write: R/W │ Reset: 0x0000ffff (0b00x00000000000001111111111111111)

Bit	Reset	Description
31	DISABLE	C_RDY4LATENCY_THRESHOLD_ENABLE: 0 = DISABLE 1 = ENABLE
30	DISALLOW	C_RDY4LATENCY_SPOOLUP_CTRL: 0 = DISALLOW 1 = ALLOW
28:16	0x0	C_RDY4LATENCY_SPOOLUP_DURATION
15:0	0xffff	C_RDY4LATENCY_THRESHOLD

21.14.42 DC_WINBUF_C_MEMFETCH_DEBUG_STATUS_0

Memfetch Debug Status

Offset: 0x82a │ Byte Offset: 0x20a8 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
16	0x0	C_DEBUG_ENABLE: enable FGCG for flops added to debug signals in memfetch.

Offset: 0x82e | Byte Offset: 0x20b8 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	C_SCRATCH_REGISTER_1: Scratch register 1

21.15 Window D (WIN_D) Registers

These registers control window D parameters.

The registers under DC_WIN are double buffered.

21.15.1 DC_WIN_D_WIN_OPTIONS_0

Window D Options

Class: Display Window Settings

Display Window D parameters

Offset: 0x700 | Byte Offset: 0x1c00 | Read/Write: R/W | Reset: 0x000000X0 (0bx0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
30	0x0	D_WIN_ENABLE: Window D Window enable 0 = DISABLE 1 = ENABLE
6	X	D_COLOR_EXPAND: Window D 12/15/16/18-to-24 bpp color expansion. This bit should be enabled only for 12-bpp B4G4R4A4, 15-bpp B5G5R5A, 16-bpp B5G6R5, 18-bpp B6G6R6 color modes. If enabled, the color conversion is performed prior to horizontal scaling. 0 = DISABLE 1 = ENABLE

21.15.2 DC_WIN_D_COLOR_DEPTH_0

Window D Color Depth. For YCbCr data format, Cb and Cr are 8-bit unsigned values. For YUV data format, U and V are 8-bit signed values. YCbCr422R is similar to YCbCr422P but the Cb and Cr are shared vertically.

YUV422R is similar to YUV422P, but the U and V are shared vertically. YCbCr422RA is the same as YCbCr422R in memory and YUV422RA is the same as YUV422R in memory but while reading from memory, for YCbCr422RA and YUV422RA, chroma averaging is applied for each pixel pair so that they can be processed as YUV422 by the display pipeline.

For YCbCr422R and YUV422R, every other chroma pixels are not used (discarded) by the display pipeline. B6x2G6x2R6x2A8 is similar to B8G8R6A8 but with the 2 LSBs zeroed out. R6x2G6x2B6x2A8 is similar to R8G8B6A8 but with the 2 LSBs zeroed out.

Some formats have NVCF_ or T_ prefix aliases for NVidia surface format naming convention, wherein left-to-right component names correspond to MSB to LSB bits within a word. In old names without NVCF_ or T_, left-to-right component names generally map LSB to MSB within a word.

Offset: 0x703 │ Byte Offset: 0x1c0c │ Read/Write: R/W │ Reset: 0x0000000c (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx0001100)

21.15.3 DC_WIN_D_POSITION_0

Window D Position

This register defines the H position and size of Window D after scaling (if there is any).

Offset: 0x704 │ Byte Offset: 0x1c10 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	D_V_POSITION: Window D V Position. This is specified with respect to the top edge of active display area.
12:0	X	D_H_POSITION: Window D H Position. This is specified with respect to the left edge of active display area.

21.15.4 DC_WIN_D_SIZE_0

Window D Size

This register defines the V position and size of Window D after scaling (if there is any).

Note: Programming on window size should guarantee the whole window is inside the active area, otherwise extra rows/columns will be fetched and discarded which affects performance.

Offset: 0x705 │ Byte Offset: 0x1c14 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	D_V_SIZE: Window D V Size (lines). This is the vertical size after scaling.
12:0	X	D_H_SIZE: Window D H Size (pixels). This is the horizontal size after scaling.

21.15.5 DC_WIN_D_LINE_STRIDE_0

Window D Line Stride

Offset: 0x70a | Byte Offset: 0x1c28 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	D_LINE_STRIDE: Window D Line Stride. This is stride (in bytes) for all non-planar data formats. If the memory surface is tiled, the stride needs to be a multiple of 16. If H_DIRECTION of window D is set to DECREMENT, the stride also needs to be a multiple of 16. For planar YUV or YCbCr data formats, this is stride (in bytes) for the luma plane with the restriction that it must be in multiples of 8 (16 if tiled or in horizontal flipping) For tiled surface this value may affect starting address of a window. Refer to the comment of START_ADDR for detail.

21.15.6 DC_WIN_D_BLEND_LAYER_CONTROL_0

Offset: 0x716 | Byte Offset: 0x1c58 | Read/Write: R/W | Reset: 0x01000000 (0bxxxxxxx10000000000000000000000)

21.15.8 DC_WIN_D_BLEND_ALPHA_1BIT_0

Offset: 0x719 | Byte Offset: 0x1c64 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	D_BLEND_WEIGHT1: This is used only for 1-bit alpha and alpha value of 1
7:0	0x0	D_BLEND_WEIGHT0: This is used only for 1-bit alpha and alpha value of 0.

21.16 WINBUF_D Registers

The registers under DC_WINBUF are triple-buffered.

21.16.1 DC_WINBUF_D_START_ADDR_0

Window D Start Address

Overview

START_ADDR, BUF_STRIDE, LINE_STRIDE, ADDR_H_OFFSET, ADDR_V_OFFSET combined, specify the starting address of a window buffer in the memory surface. Generally START_ADDR is programmed with the starting address of the memory surface. H/V_OFFSET specifies the address offsets of the pixel at the beginning of the window, with respect to the starting address of the memory surface. (There is an exception to that when memory surface is not well aligned, see “For linear address mode” under Programming Restrictions below.)

Note that "beginning of the window" here means the top-left corner of a window in normal mode, top-right corner in horizontal flipping, bottom-left corner in vertical flipping, and bottom-right in horizontal+vertical flipping.

Starting Address Calculation

These formulae are same for both tiled and linear modes. However, for linear mode, the addresses calculated are real physical addresses. For tiled mode, these addresses will be translated to the real physical addresses by the memory controller client before being used.

- When a window is host triggered, the starting address of a window is calculated as follows by hardware.
  - non-YUV-planar modes

    starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar modes

    Y-starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    U-starting-address = START_ADDR_U + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

V-starting-address = START_ADDR_V + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by hardware.

- When a window is non-host triggered, starting address of a window buffer is calculated as below.
  - non-YUV-planar mode

    starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar mode:

    Y-starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    U-starting-address = START_ADDR_U + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    V-starting-address = START_ADDR_V + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    where denom1/denom2 are equal to 1 or 2 depending on the actual planar format, derived natively by hardware.

    buf_index is the index transmitted by the triggering module pointing to the first buffer of a frame.

Programming Restrictions

- For tiled address mode

  Image surface can only aligned to multiples of 256, thus the following restrictions.
  - START_ADDR, START_ADDR_U, START_ADDR_V need to be multiples of 256.
  - BUF_STRIDE, UV_BUF_STRIDE need to be multiples of 256
  - LINE_STRIDE, UV_LINE_STRIDE need to be multiples of 16
  - ADDR_H_OFFSET needs to be even in yuv planar format, or a multiple of bytes per pixel in other formats. If H_DIRECTION=DECREMENT, however, it should point to last valid byte, which is an odd offset..
  - ADDR_V_OFFSET needs to be multiple of 2 in YUV planar format, unless H_DIRECTION=DECREMENT, but with no restrictions on other color formats
- For linear address mode

  Image surface can be aligned 2, 4, or 8 bytes, depending on the color formats.

  As an additional restriction for display, START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16. When a surface is not aligned to 16 bytes, program START_ADDR with the memory surface address with its least 4 significant bits zeroed out and add these 4 address bits to the original H_OFFSET. (So the formulae in Starting Address Calculation above still hold)
  - For all formats:

    START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16.

    For 16-bpp formats,

    (START_ADDR+H_OFFSET) need to be a multiple of 2.

    For 32-bpp formats,

    (START_ADDR+H_OFFSET) needs to be a multiple of 4.
  - For yuv planar formats:

    BUF_STRIDE, UV_BUF_STRIDE:

    BUF_STRIDE[2:1]=UV_BUF_STRIDE[1:0]

    or as a stricter constraint: BUF_STRIDE be a multiple of 8, UV_BUF_STRIDE be a multiple of 4.

LINE_STRIDE, UV_LINE_STRIDE:

LINE_STRIDE and UV_LINE_STRIDE need to be at least 16.

LINE_STRIDE needs to be a multiple of 8, UV_LINE_STRIDE needs to be a multiple of 4.

ADDR_H_OFFSET: Needs to be even unless H_DIRECTION=DECREMENT, in which case should point to the last byte pixel, which is at an odd offset.

ADDR_V_OFFSET: Needs to be even unless V_DIRECTION=DECREMENT, in which case should point to the last valid line, which is at an odd offset

- Memory allocation for non-host triggered case:

  When a window buffer is not controlled by host (software) then a frame may be stored in multiple buffers. In this case, the buffers must be contiguous in the memory because display will use the same luma or chroma line strides for all lines in the frame.

  Also buffer wraparound must not occur in the middle of the displayed part of the frame. The controlling module will send frame start and frame end indicators (flags) to display module to indicate the beginning and end of frame. Buffer start address is latched when frame start flag is active but the actual buffer start address is not switched until frame end flag is active. In the case where one buffer corresponds to one frame then frame start and frame end flag are active every time a buffer index is sent.

Offset: 0x800 │ Byte Offset: 0x2000 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	D_START_ADDR: Window D Start Address. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

21.16.2 DC_WINBUF_D_START_ADDR_NS_0

Window D Shadowed Start Address

Offset: 0x801 │ Byte Offset: 0x2004 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	D_START_ADDR_NS: Window D Shadowed Start Address. This is ARM set shadow of Start Address.

21.16.3 DC_WINBUF_D_ADDR_H_OFFSET_0

Window D Horizontal address offset

Offset: 0x806 │ Byte Offset: 0x2018 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	D_ADDR_H_OFFSET: Window D Horizontal address offset. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies horizontal offset of Y plane. The horizontal offsets of U/V plane is derived by hardware.

21.16.4 DC_WINBUF_D_ADDR_H_OFFSET_NS_0

Window D Shadowed Horizontal address offset

Offset: 0x807 | Byte Offset: 0x201c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	D_ADDR_H_OFFSET_NS: Window D Shadowed Horizontal address offset. This is ARM set shadow of ADDR_H_OFFSET

21.16.5 DC_WINBUF_D_ADDR_V_OFFSET_0

Window D Vertical address offset

Offset: 0x808 | Byte Offset: 0x2020 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	D_ADDR_V_OFFSET: Window D Vertical address offset. This is the vertical coordinate. For YUV planar pixel format, this specifies the vertical coordinate of Y plane. The vertical coordinate of U/V plane is derived by hardware.

21.16.6 DC_WINBUF_D_ADDR_V_OFFSET_NS_0

Window D Shadowed Vertical address offset

Offset: 0x809 | Byte Offset: 0x2024 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	D_ADDR_V_OFFSET_NS: Window D Shadowed Vertical address offset. This is ARM set shadow of ADDR_V_OFFSET

21.16.7 DC_WINBUF_D_UFLOW_STATUS_0

Window D FIFO Underflow Status Register

Offset: 0x80a | Byte Offset: 0x2028 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
30	X	COUNT_OFLOW: Flag bit that indicates that the underflow event counter has overflowed. There were too many events. If COUNT_OFLOW is set, UFLOW_COUNT is meaningless. Cleared on write.
23:0	X	UFLOW_COUNT: Underflow count. This field indicates the number of contiguous groups of output pixels for which there was no data in the FIFO. For example, if the valid from the FIFO is low for 10 consecutive cycles and then goes high, the counter will increment by one. Reset to zero on write.

21.16.8 DC_WINBUF_D_START_ADDR_HI_0

Window D Higher 32 bits of Start Address

Makes the start address 64 bits by adding the higher 32 bits below.

Offset: 0x80d | Byte Offset: 0x2034 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	D_START_ADDR_HI: Window D Start Address. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

21.16.9 DC_WINBUF_D_START_ADDR_HI_NS_0

Window D Shadowed Higher 32 bits of Start Address

Offset: 0x80e │ Byte Offset: 0x2038 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	D_START_ADDR_HI_NS: Window D Shadowed Start Address. This is ARM set shadow of Start Address.

21.16.10 DC_WINBUF_D_UFLOW_CTRL_0

When the underflow debug mode is enabled. Instead of sending out the last valid pixel, DBG_PIXEL is sent out.

If D_UFLOW_CYA is set, the underflow recovery logic for simple windows is bypassed and replaced with an oflow-pop logic present in Tegra 3 styled windows.

Offset: 0x824 │ Byte Offset: 0x2090 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	D_UFLOW_CYA: 0 = DISABLE 1 = ENABLE
0	0x0	D_UFLOW_CTRL_DBG_MODE: 0 = DISABLE 1 = ENABLE

21.16.11 DC_WINBUF_D_UFLOW_DBG_PIXEL_0

Offset: 0x825 │ Byte Offset: 0x2094 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	D_UFLOW_DBG_PIXEL

21.16.12 DC_WINBUF_D_SPOOL_UP_0

Spool up time configuration for different windows related logic.

SPOOL_UP_CTRL = MAX - This is the current Tegra K1 behavior. This allows for memfetch to start fetching for a window (irrespective of its relative position on the screen), at the very beginning of the VBlank of the next frame. Since the spool up time is maximum, this should have the least probability of underflow of the display pipe. However, on the down side, since all three windows would start fetching at the same time, and since display is a high priority client for the MC, it has a high potential to starve out other clients.

SPOOL_UP_EDGE :- By default the memfetch start signal generated by the hvtgen logic is one line clock wide.

For SPOOL_UP_CTRL = MAX:

- If SPOOL_UP_EDGE is programmed to NEGEDGE, it ensures that if any act_req is sent during the time vcounter = 0 (at the beginning of the frame). The activate value is loaded into the active state and the memfetch would see the latest updated value.

The downside of programming SPOOL_UP_EDGE to NEGDGE is 1 line clock worth of spool up is lost. This is required based upon Tegra compatibility.

- If SPOOL_UP_EDGE is programmed to POSEDGE, the memfetch starts fetching at the very beginning of the frame start pulse (1 line clock wide) and gives maximum spool up time. However, this may give test failure and potential Tegra compatibility issues as described above.

Offset: 0x827 | Byte Offset: 0x209c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
28:16	X	D_SPOOL_UP_DURATION
1	0x0	D_SPOOL_UP_EDGE: 0 = NEGEDGE 1 = POSEDGE
0	0x0	D_SPOOL_UP_CTRL. 0 = MAX 1 = PROGRAMMABLE

21.16.13 DC_WINBUF_D_LATENCY_THRESHOLD_0

Offset: 0x829 | Byte Offset: 0x20a4 | Read/Write: R/W | Reset: 0x0000ffff (0b00x00000000000001111111111111111)

Bit	Reset	Description

30	DISALLOW	D_RDY4LATENCY_SPOOLUP_CTRL: 0 = DISALLOW 1 = ALLOW
28:16	0x0	D_RDY4LATENCY_SPOOLUP_DURATION
15:0	0xffff	D_RDY4LATENCY_THRESHOLD

21.16.14 DC_WINBUF_D_MEMFETCH_DEBUG_STATUS_0

Memfetch Debug Status

Offset: 0x82a | Byte Offset: 0x20a8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxx00xxxxxxx0)

Bit	Reset	Description
9	0x0	D_RSP_FIFO_NON_IDLE: Response FIFO idle at end of frame. 0= response FIFO is idle at end of frame. 1= response FIFO is not idle at end of frame
8	0x0	D_REQ_FIFO_NON_IDLE: Request FIFO idle at end of frame. 0= request FIFO is idle at end of frame. 1= request FIFO is not idle at end of frame
0	0x0	D_UNDERFLOW_LINE0: Underflow of line0. 0= No underflow. 1= line0 underflowed

21.16.15 DC_WINBUF_D_MEMFETCH_CONTROL_0

Memfetch Control Register

Offset: 0x82b | Byte Offset: 0x20ac | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	D_MEMFETCH_CLK_GATE_OVERRIDE: Disable clock-gating of memfetch for a controller (all three windows)

Bit	Reset	Description
		0 = DISABLE 1 = ENABLE
0	0x0	D_MEMFETCH_RESET: Reset memfetch for a controller (all three windows) 0 = DISABLE 1 = ENABLE

21.16.16 DC_WINBUF_D_SCRATCH_REGISTER_0_0

Offset: 0x82d │ Byte Offset: 0x20b4 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	D_SCRATCH_REGISTER_0: Scratch register 0

21.16.17 DC_WINBUF_D_SCRATCH_REGISTER_1_0

Offset: 0x82e │ Byte Offset: 0x20b8 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	D_SCRATCH_REGISTER_1: Scratch register 1

21.17 Window T (WIN_T) Registers

These registers control window T parameters.

The registers under DC_WIN are double buffered.

21.17.1 DC_WIN_T_WIN_OPTIONS_0

Window T Options

Class: Display Window Settings

Display Window T parameters

Offset: 0x700 │ Byte Offset: 0x1c00 │ Read/Write: R/W │ Reset: 0x000000X0 (0bx0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
30	0x0	T_WIN_ENABLE: Window T Window enable 0 = DISABLE 1 = ENABLE
6	X	T_COLOR_EXPAND: Window T 12/15/16/18-to-24 bpp color expansion. This bit should be enabled only for 12-bpp B4G4R4A4, 15-bpp B5G5R5A, 16-bpp B5G6R5, 18-bpp B6G6R6 color modes. If enabled, the color conversion is performed prior to horizontal scaling. 0 = DISABLE 1 = ENABLE

21.17.2 DC_WIN_T_COLOR_DEPTH_0

Window T Color Depth. For YCbCr data format, Cb and Cr are 8-bit unsigned values. For YUV data format, U and V are 8-bit signed values. YCbCr422R is similar to YCbCr422P but the Cb and Cr are shared vertically.

YUV422R is similar to YUV422P, but the U and V are shared vertically. YCbCr422RA is the same as YCbCr422R in memory and YUV422RA is the same as YUV422R in memory but while reading from memory, for YCbCr422RA and YUV422RA, chroma averaging is applied for each pixel pair so that they can be processed as YUV422 by the display pipeline.

For YCbCr422R and YUV422R, every other chroma pixels are not used (discarded) by the display pipeline. B6x2G6x2R6x2A8 is similar to B8G8R6A8 but with the 2 LSBs zeroed out. R6x2G6x2B6x2A8 is similar to R8G8B6A8 but with the 2 LSBs zeroed out.

Some formats have NVCF_ or T_ prefix aliases for NVidia surface format naming convention, wherein left-to-right component names correspond to MSB to LSB bits within a word. In old names without NVCF_ or T_, left-to-right component names generally map LSB to MSB within a word.

Offset: 0x703 │ Byte Offset: 0x1c0c │ Read/Write: R/W │ Reset: 0x0000000c (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx0001100)

Bit	Reset	Description

21.17.3 DC_WIN_T_POSITION_0

Window T Position

This register defines the H position and size of Window T after scaling (if there is any).

Offset: 0x704 │ Byte Offset: 0x1c10 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	T_V_POSITION: Window T V Position. This is specified with respect to the top edge of active display area.
12:0	X	T_H_POSITION: Window T H Position. This is specified with respect to the left edge of active display area.

21.17.4 DC_WIN_T_SIZE_0

Window T Size

This register defines the V position and size of Window T after scaling (if there is any).

> **Note:** Programming on window size should guarantee the whole window is inside the active area, otherwise extra rows/columns will be fetched and discarded which affects performance.

Offset: 0x705 | Byte Offset: 0x1c14 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	T_V_SIZE: Window T V Size (lines). This is the vertical size after scaling.
12:0	X	T_H_SIZE: Window T H Size (pixels). This is the horizontal size after scaling.

21.17.5 DC_WIN_T_LINE_STRIDE_0

Window T Line Stride

Offset: 0x70a | Byte Offset: 0x1c28 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	T_LINE_STRIDE: Window T Line Stride. This is stride (in bytes) for all non-planar data formats. If the memory surface is tiled, the stride needs to be a multiple of 16. If H_DIRECTION of window T is set to DECREMENT, the stride also needs to be a multiple of 16. For planar YUV or YCbCr data formats, this is stride (in bytes) for the luma plane with the restriction that it must be in multiples of 8 (16 if tiled or in horizontal flipping) For tiled surface this value may affect starting address of a window. Refer to the comment of START_ADDR for detail.

21.17.6 DC_WIN_T_BLEND_LAYER_CONTROL_0

Offset: 0x716 | Byte Offset: 0x1c58 | Read/Write: R/W | Reset: 0x01000000 (0bxxxxxxx10000000000000000000000)

Bit	Reset	Description

9:8	0x0	T_BLEND_FACTOR_SRC_ALPHA_MATCH_SELECT: 0 = ZERO 1 = K1 2 = K2
6:4	0x0	T_BLEND_FACTOR_DST_COLOR_MATCH_SELECT: 0 = ZERO 1 = ONE 2 = K1 3 = K2 4 = K1_TIMES_DST 5 = NEG_K1_TIMES_DST 6 = NEG_K1_TIMES_SRC 7 = NEG_K1
2:0	0x0	T_BLEND_FACTOR_SRC_COLOR_MATCH_SELECT: 0 = ZERO 1 = ONE 2 = K1 3 = K1_TIMES_DST 4 = NEG_K1_TIMES_DST 5 = K1_TIMES_SRC

21.17.8 DC_WIN_T_BLEND_ALPHA_1BIT_0

Offset: 0x719 | Byte Offset: 0x1c64 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	T_BLEND_WEIGHT1: This is used only for 1-bit alpha and alpha value of 1
7:0	0x0	T_BLEND_WEIGHT0: This is used only for 1-bit alpha and alpha value of 0.

21.18 WINBUF_T Registers

The registers under DC_WINBUF are triple-buffered.

21.18.1 DC_WINBUF_T_START_ADDR_0

Window T Start Address

Overview

START_ADDR, BUF_STRIDE, LINE_STRIDE, ADDR_H_OFFSET, ADDR_V_OFFSET combined, specify the starting address of a window buffer in the memory surface. Generally, START_ADDR is programmed with the starting address of the memory surface. H/V_OFFSET specifies the address offsets of the pixel at the beginning of the window, with respect to the starting address of the memory surface. (There is an exception to that when memory surface is not well aligned, see “For linear address mode” under Programming Restrictions below.)

Note that "beginning of the window" here means the top-left corner of a window in normal mode, top-right corner in horizontal flipping, bottom-left corner in vertical flipping, and bottom-right in horizontal+vertical flipping.

Starting Address Calculation

These formulae are same for both tiled and linear modes. However, for linear mode, the addresses calculated are real physical addresses. For tiled mode, these addresses will be translated to the real physical addresses by the memory controller client before being used.

- When a window is host triggered, the starting address of a window is calculated as follows by hardware.
  - non-YUV-planar modes

    starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar modes

    Y-starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    U-starting-address = START_ADDR_U + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    V-starting-address = START_ADDR_V + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by hardware.
- When a window is non-host triggered, starting address of a window buffer is calculated as below.
  - non-YUV-planar mode

    starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar mode:

    Y-starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    U-starting-address = START_ADDR_U + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    V-starting-address = START_ADDR_V + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    where denom1/denom2 are equal to 1 or 2 depending on the actual planar format, derived natively by hardware.

    buf_index is the index transmitted by the triggering module pointing to the first buffer of a frame.

Programming Restrictions

- For tiled address mode

  Image surface can only aligned to multiples of 256, thus the following restrictions.

  - START_ADDR, START_ADDR_U, START_ADDR_V need to be multiples of 256.
  - BUF_STRIDE, UV_BUF_STRIDE need to be multiples of 256
  - LINE_STRIDE, UV_LINE_STRIDE need to be multiples of 16
  - ADDR_H_OFFSET needs to be even in yuv planar format, or a multiple of bytes per pixel in other formats. If H_DIRECTION=DECREMENT, however, it should point to last valid byte, which is an odd offset..
  - ADDR_V_OFFSET needs to be multiple of 2 in YUV planar format, unless H_DIRECTION=DECREMENT, but with no restrictions on other color formats

- For linear address mode

  Image surface can be aligned 2, 4, or 8 bytes, depending on the color formats.

  As an additional restriction for display, START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16. When a surface is not aligned to 16 bytes, program START_ADDR with the memory surface address with its least 4 significant bits zeroed out and add these 4 address bits to the original H_OFFSET. (So the formulae in Starting Address Calculation above still hold)

  - For all formats:

    START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16.

    For 16-bpp formats,

    (START_ADDR+H_OFFSET) need to be a multiple of 2.

    For 32-bpp formats,

    (START_ADDR+H_OFFSET) needs to be a multiple of 4.

  - For YUV planar formats:

    BUF_STRIDE, UV_BUF_STRIDE:

    BUF_STRIDE[2:1]=UV_BUF_STRIDE[1:0]

    or as a stricter constraint: BUF_STRIDE be a multiple of 8, UV_BUF_STRIDE be a multiple of 4.

    LINE_STRIDE, UV_LINE_STRIDE:

    LINE_STRIDE and UV_LINE_STRIDE need to be at least 16.

    LINE_STRIDE needs to be a multiple of 8, UV_LINE_STRIDE needs to be a multiple of 4.

    ADDR_H_OFFSET: Needs to be even unless H_DIRECTION=DECREMENT, in which case should point to the last byte pixel, which is at an odd offset.

    ADDR_V_OFFSET: Needs to be even unless V_DIRECTION=DECREMENT, in which case should point to the last valid line, which is at an odd offset

- Memory allocation for non-host triggered case:

  When a window buffer is not controlled by host (software) then a frame may be stored in multiple buffers. In this case, the buffers must be contiguous in the memory because display will use the same luma or chroma line strides for all lines in the frame.

  Also buffer wraparound must not occur in the middle of the displayed part of the frame. The controlling module will send frame start and frame end indicators (flags) to display module to indicate the beginning and end of frame. Buffer start address is latched when frame start flag is active but the actual buffer start address is not switched until frame end flag is active. In the case where one buffer corresponds to one frame then frame start and frame end flag are active every time a buffer index is sent.

Offset: 0x800 | Byte Offset: 0x2000 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	T_START_ADDR: Window T Start Address. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

21.18.2 DC_WINBUF_T_START_ADDR_NS_0

Window T Shadowed Start Address

Offset: 0x801 | Byte Offset: 0x2004 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	T_START_ADDR_NS: Window H Shadowed Start Address. This is ARM set shadow of Start Address.

21.18.3 DC_WINBUF_T_ADDR_H_OFFSET_0

Window T Horizontal address offset

Offset: 0x806 | Byte Offset: 0x2018 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	T_ADDR_H_OFFSET: Window T Horizontal address offset. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies horizontal offset of Y plane. The horizontal offsets of U/V plane is derived by hardware.

21.18.4 DC_WINBUF_T_ADDR_H_OFFSET_NS_0

Window T Shadowed Horizontal address offset

Offset: 0x807 | Byte Offset: 0x201c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	T_ADDR_H_OFFSET_NS: Window T Shadowed Horizontal address offset. This is ARM set shadow of ADDR_H_OFFSET

21.18.5 DC_WINBUF_T_ADDR_V_OFFSET_0

Window T Vertical address offset

Offset: 0x808 | Byte Offset: 0x2020 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	T_ADDR_V_OFFSET: Window T Vertical address offset. This is the vertical coordinate. For YUV planar pixel format, this specifies the vertical coordinate of Y plane. The vertical coordinate of U/V plane is derived by hardware.

21.18.6 DC_WINBUF_T_ADDR_V_OFFSET_NS_0

Window T Shadowed Vertical address offset

Offset: 0x809 | Byte Offset: 0x2024 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	T_ADDR_V_OFFSET_NS: Window T Shadowed Vertical address offset. This is ARM set shadow of ADDR_V_OFFSET

21.18.7 DC_WINBUF_T_UFLOW_STATUS_0

Window T FIFO Underflow Status Register

Offset: 0x80a | Byte Offset: 0x2028 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
30	X	COUNT_OFLOW: Flag bit that indicates that the underflow event counter has overflowed. There were too many events. If COUNT_OFLOW is set, UFLOW_COUNT is meaningless. Cleared on write.
23:0	X	UFLOW_COUNT: Underflow count. This field indicates the number of contiguous groups of output pixels for which there was no data in the FIFO. For example, if the valid from the FIFO is low for 10 consecutive cycles and then goes high, the counter will increment by one. Reset to zero on write.

21.18.8 DC_WINBUF_T_START_ADDR_HI_0

Window T Higher 32 bits of Start Address

Makes the start address 64 bits by adding the higher 32 bits below.

Offset: 0x80d | Byte Offset: 0x2034 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	T_START_ADDR_HI: Window T Start Address. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

21.18.9 DC_WINBUF_T_START_ADDR_HI_NS_0

Window T Shadowed Higher 32 bits of Start Address

Offset: 0x80e | Byte Offset: 0x2038 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	T_START_ADDR_HI_NS: Window T Shadowed Start Address. This is ARM set shadow of Start Address.

21.18.10 DC_WINBUF_T_UFLOW_CTRL_0

When the underflow debug mode is enabled. Instead of sending out the last valid pixel, DBG_PIXEL is sent out.

If T_UFLOW_CYA is set, the underflow recovery logic for simple windows is bypassed and replaced with an oflow-pop logic present in Tegra 3 styled windows.

Offset: 0x824 │ Byte Offset: 0x2090 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	T_UFLOW_CYA: 0 = DISABLE 1 = ENABLE
0	0x0	T_UFLOW_CTRL_DBG_MODE: 0 = DISABLE 1 = ENABLE

21.18.11 DC_WINBUF_T_UFLOW_DBG_PIXEL_0

Offset: 0x825 │ Byte Offset: 0x2094 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	T_UFLOW_DBG_PIXEL

21.18.12 DC_WINBUF_T_SPOOL_UP_0

Spool up time configuration for different windows related logic.

SPOOL_UP_CTRL = MAX - This is the current Tegra K1 behavior. This allows for memfetch to start fetching for a window (irrespective of its relative position on the screen), at the very beginning of the VBlank of the next frame. Since the spool up time is maximum, this should have the least probability of underflow of the display pipe. However, on the down side, since all three windows would start fetching at the same time, and since display is a high priority client for the MC, it has a high potential to starve out other clients.

SPOOL_UP_EDGE :- By default the memfetch start signal generated by the hvtgen logic is one line clock wide.

For SPOOL_UP_CTRL = MAX:

- If SPOOL_UP_EDGE is programmed to NEGEDGE, it ensures that if any act_req is sent during the time vcounter = 0 (at the beginning of the frame). The activate value is loaded into the active state and the memfetch would see the latest updated value.

  The downside of programming SPOOL_UP_EDGE to NEGDGE is 1 line clock worth of spool up is lost. This is required based upon Tegra compatibility.
- If SPOOL_UP_EDGE is programmed to POSEDGE, the memfetch starts fetching at the very beginning of the frame start pulse (1 line clock wide) and gives maximum spool up time. However, this may give test failure and potential Tegra compatibility issues as described above.

Offset: 0x827 │ Byte Offset: 0x209c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
28:16	X	T_SPOOL_UP_DURATION
1	0x0	T_SPOOL_UP_EDGE: 0 = NEGEDGE 1 = POSEDGE

Bit	Reset	Description
0	0x0	T_SPOOL_UP_CTRL. 0 = MAX 1 = PROGRAMMABLE

21.18.13 DC_WINBUF_T_LATENCY_THRESHOLD_0

Offset: 0x829 | Byte Offset: 0x20a4 | Read/Write: R/W | Reset: 0x0000ffff (0b00x00000000000001111111111111111)

Bit	Reset	Description
31	DISABLE	T_RDY4LATENCY_THRESHOLD_ENABLE: 0 = DISABLE 1 = ENABLE
30	DISALLOW	T_RDY4LATENCY_SPOOLUP_CTRL: 0 = DISALLOW 1 = ALLOW
28:16	0x0	T_RDY4LATENCY_SPOOLUP_DURATION
15:0	0xffff	T_RDY4LATENCY_THRESHOLD

21.18.14 DC_WINBUF_T_MEMFETCH_DEBUG_STATUS_0

Memfetch Debug Status

Offset: 0x82a | Byte Offset: 0x20a8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxx00xxxxxxx0)

Bit	Reset	Description
9	0x0	T_RSP_FIFO_NON_IDLE: Response FIFO idle at end of frame. 0= response FIFO is idle at end of frame. 1= response FIFO is not idle at end of frame
8	0x0	T_REQ_FIFO_NON_IDLE: Request FIFO idle at end of frame. 0= request FIFO is idle at end of frame. 1= request FIFO is not idle at end of frame
0	0x0	T_UNDERFLOW_LINE0: Underflow of line0. 0= No underflow 1= line0 underflowed

21.18.15 DC_WINBUF_T_MEMFETCH_CONTROL_0

Note: MEMFETCH_CLK_GATE_OVERRIDE should only be enabled AFTER the vertical scaler settings in the active copy - VDDA_INCREMENT is properly set up.

Memfetch Control Register

Offset: 0x82b | Byte Offset: 0x20ac | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	T_MEMFETCH_CLK_GATE_OVERRIDE: Disable clock-gating of memfetch for a controller (all three windows) 0 = DISABLE 1 = ENABLE
0	0x0	T_MEMFETCH_RESET: Reset memfetch for a controller (all three windows) 0 = DISABLE 1 = ENABLE

21.18.16 DC_WINBUF_T_SCRATCH_REGISTER_0_0

Offset: 0x82d │ Byte Offset: 0x20b4 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	T_SCRATCH_REGISTER_0: Scratch register 0

21.18.17 DC_WINBUF_T_SCRATCH_REGISTER_1_0

Offset: 0x82e │ Byte Offset: 0x20b8 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

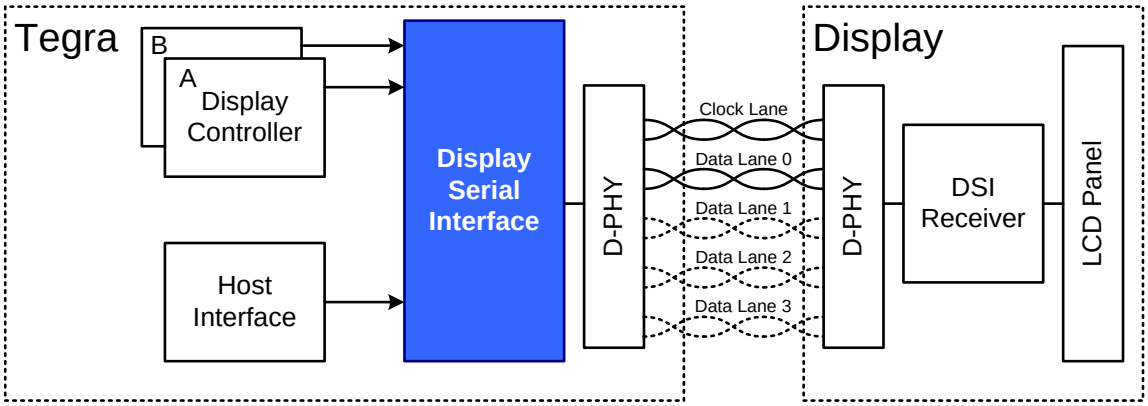
Bit	Reset	Description
31:0	0x0	T_SCRATCH_REGISTER_1: Scratch register 1

[THIS PAGE INTENTIONALLY LEFT BLANK]

22.0 MIPI-DSI (DISPLAY SERIAL INTERFACE)

The Display Serial Interface (DSI) is a MIPI standard serial bitstream that provides a low pin-count interface to a display panel. DSI reduces both package pin-count and I/O power consumption compared with parallel solutions. It transfers pixel data from either one of the display controllers (internal to the Tegra® K1 device) to an external third-party LCD module. The physical positioning of the DSI module in relation to other units/devices in the system is shown in Figure 69.

Figure 69: System Block Diagram of Single DSI Unit



DSI is a replacement for the MIPI DPI and DBI standards and follows the use cases of these interfaces. From a data transport point of view, MIPI DPI is an interface similar to a traditional raster-based isochronous display interface, and DBI is an asynchronous packet based transfer mechanism. DSI behaves like MIPI DPI when in Video Mode, and implements a Command Mode to handle the DBI interface. Any implementation must implement both these modes of operation.

22.1 Features

- Each DSI interface has 1 clock lane and 4 data lanes
- Maximum 1.5 GHz HS transmit rate
- Maximum 10 MHz LP receive rate
- Supports up to 8 PHY lanes with each DSI instance/channel supporting 1, 2, 3, 4 data lanes in Ganged mode configuration
- Video Mode with display controller as master
- Command Mode with host and/or display controller as masters
- Maximum Video Mode resolution is 16:9 AR up to and including (3200x2000), 60 fps at 24 bpp
- Maximum Command Mode packet length is 1920 words

22.2 Functionality

22.2.1 Display Controller Interface

The interface between the display controller and the DSI unit consists of pixel data, Sync data, and a Line-Type code.

DSI captures the state of the line type code every line. This information is then used to look up a pre-programmed packet sequence that corresponds to that line type. There are several different line types to select from.

22.2.2 Packet Poster

The packet poster determines which packets will be sent on what video line when the DSI is in any of the 3 video modes and is being controlled by the display controller. The functions that this sub-unit performs are:

- Line type look-up
- Packet sequence generation
- Pixel data / packet stream integration

There are currently 6 valid line types that can be encoded on the 3 bits from the display controller. The other 2 line types are reserved for future use. The line type coding is shown in the following table.

Table 80: Line Type Descriptions

Line Type	Description
0	Blank line starting with VS
1	Blank line starting with VE
2	Blank line starting with HS
3	Active line
4	First blank line after active
5	First active line
6, 7	Reserved

The packet sequences corresponding to each line type are held in a pair of 32-bit registers. Each register holds three packet descriptors, and each packet descriptor has the following information:

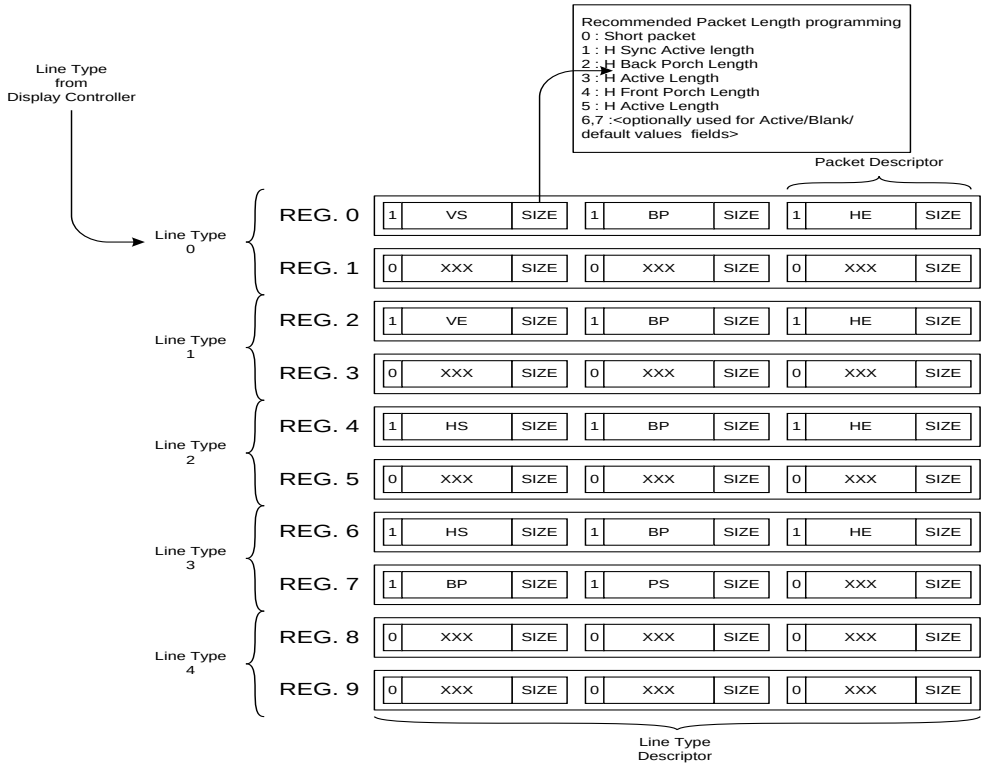
- Valid bit
- 6-bit packet ID
- 3-bit length index

The valid bit simply states whether or not a packet should be generated from that descriptor. A zero valid bit implies that no more packets in this packet sequence should be generated. Thus, the valid bit acts like a null terminator for the list of packet descriptors.

The packet ID is simply the MIPI DSI packet ID value. Software can therefore program any sequence of packets required for that line type.

Rather than have a 16-bit packet length field for every packet descriptor, the length is replaced by a 3-bit index which addresses the full 16-bit length for that packet type. This length is held elsewhere in separate length registers. A complete picture of the packet description data structures is shown in the following figure. This diagram shows typical packet mnemonics for the packets to be generated for video mode with sync pulses. By changing the programming of the packet sequences, any of the video modes, including burst mode, can be realized.

Figure 70: Line Type Look-up and Packet Sequence Descriptors



22.2.3 Host Interface

While many displays use a raster-based packet stream, in some applications it is more efficient to have a frame store in the display device itself and to only update the contents of the frame store when the required pixels have changed. For these types of displays, there is a software-accessible interface for sending command packets using the DSI command mode operation. This mode should also be used to access control and status registers within the display device.

The Host interface consists of a small FIFO for holding packet information and a special register for writing data into the FIFO. In this way, several packets may be queued up by software and sent in one HS burst. This is more efficient that sending the packets one at a time.

When very long sequences of packets are required to be sent – for example, when the host interface is emulating video mode, or where a large amount of data needs to be sent to the display device in one packet – it is possible for the host to use the large video line-store FIFO.

22.2.4 Clocking

The clocks in the DSI include:

- Host Clock = 300 MHz {Maximum frequency}
- Application/Lane Management Byte Clock = function of lanes, pixel clock, pixel depth. 10 to 187.5 Mbps
- Fixed LP receive clock = 20 to 216 MHz
- Lane Bit clock = 40 to 500 MHz differential clock, DDR data (80 to 1500 bps).

More details on pixel clock/byte_clock selection are explained in the next section.

Pixel Clock / DSI Byte Clock Ratios

When running the DSI interface in one of the two non-burst video modes, the relationship between the DSI D-PHY bit-rate clock, the DSI byte-rate lane clock, and the display controller pixel clock must be exact. This ensures that precise raster timing information is conveyed to the display peripheral.

There is always a fixed ratio of 8:1 between the D-PHY bit clock and the lane management layer byte clock since there are 8 bits in each byte that are serialized. Therefore, only relationships between pixel clock and byte clock and between pixel clock and bit clock will be discussed.

The relationship between pixel clock and byte clock is shown in Table 81. As can be seen, for some modes, these ratios are not simple powers of 2.

Table 81: Pixel Clock: Byte Clock for Various Modes

Lanes	Pixel Data Format			
	16 bpp	18 bpp (packed)	18 bpp	24 bpp
1	1:2	4:9	1:3	1:3
2	1:1	8:9	2:3	2:3
3	3:2	12:9	1:1	1:1
4	2:1	16:9	4:3	4:3
5	5:2	20:9	5:3	5:3
6	3:1	8:3	2:1	2:1
7	7:2	28:9	7:3	7:3
8	4:1	32:9	8:3	8:3

Because the pixel clock is effectively derived from the D-PHY bit clock, it can be more instructive to look at the number by which you must divide the bit clock to get the correct pixel clock. This information is shown in Table 82. Here, the numbers look reasonable except for the problematic cases of 16bpp over a 3-lane link and 18 bpp (packed) over a 4 lane link. For these two situations, you cannot simply divide the bit rate clock by some integer to arrive at the pixel clock. Moreover, if you need a 50:50 duty cycle for the pixel clock, then you will need to toggle the pixel clock every N/2 bit clock cycles, where N is the number in Table 82. However, if you do this, 18 bpp (packed) over 2 lanes also becomes a problem.

Table 82: Value to Divide Bit Clock by to Get Pixel Clock

Lanes	Pixel Data Format			
	16 bpp	18 bpp (packed)	18 bpp	24 bpp
1	16	18	24	24
2	8	9	12	12
3	16 / 3	6	8	8
4	4	9 / 2	6	6
5	16/5	18/5	24/5	24/5
6	8/3	3	4	4
7	16/7	18/7	24/7	24/7
8	2	9/4	3	3

Table 83: Value of Shift Clock Divider to Get Pixel Clock (Non-Burst Mode)

Lanes	Data Format (16 bpp)	Data Format (18 bpp)	Data Format (24 bpp)
1	14	16	22
2	6	7	10
3	3.333334	4	6
4	2	2.5	4
5	1.6	1.8	2.4
6	0.666667	1	2
7	1.14285714	1.285714286	1.714285714
8	0	0.25	1

Note: The fractional values in the above table cannot be supported through configuration fields because of a possible limitation in programming the shift divider for deriving the pixel clock from the byte clock in non-burst mode, that is, the SHIFT_CLK_DIVIDER field of the DC_DISP_DISP_CLOCK_CONTROL_0 field. This limitation occurs only in non-burst video mode.

To resolve these issues, derive the display controller pixel clock from a separate PLL and then lock that PLL to the DSI D-PHY PLL using a phase comparator and the appropriate divide ratios obtained from the tables.

DSI PLL – Clock Mux

In the Tegra K1 device, the DSI implements a clock mux for the clock selection of the write clock domain to the line buffer and its upstream path in the DSI.

A single DSI instance receives a pixel data stream from either of the display controller heads. The single bit register field dsi_vid_src in the dsi_clk domain selects the active display head. The selected display pixel clock provides the necessary clocking to the front end of the DSI.

In cases where the Host transmission uses the line buffer, dsi_clk can provide the necessary clocking using the single bit register field pkt_wr_fifo_sel.

22.3 Modes of Operation

The DSI operates in two transmission modes: Video and Host/Command

22.3.1 Video Mode

Communication with the peripheral is by isochronous data transfer similar to a typical video interface. There is no Bus Turn Around permitted in Video Mode, though there is a mandatory period of LP operation at least once per frame. There are three different sub-modes of Video Mode. These are outlined below:

Non-Burst Mode with Start and End

In this mode, the DSI must match the timing of a traditional video raster as closely as possible. This means all information about the start and end of parameters like vertical and horizontal sync, front and back porches must be conveyed to the receiving peripherals via the timing of the transmission of the High-Speed sync packets.

Non-Burst Mode without Start and End

This is like Non-Burst Mode with Start and End, except that the Sync-Active and Sync-End packets are not sent. Pixels must still be delivered at the correct rate.

Burst Mode

Only the timing of Sync-Start packets is required to be accurately conveyed in this mode. The data rate of the pixel data is arbitrary and is typically higher than the pixel rate of the peripheral.

22.3.2 Host/Command Mode

Communication with the peripheral is by asynchronously timed and variable length packets. The packets may contain video data (Display Controller/Host) or control data. In Command Mode, return (read) data can be requested from the peripheral. The DSI will issue a Bus Turn Around (BTA) request and relinquish control of the bus to the peripheral.

22.4 FIFO Buffers

22.4.1 Video Mode Operation

22.4.1.1 Writing Data

The following packets are written into the large data FIFO based on the various triggering events described.

Table 84: FIFO Trigger Events

Trigger Event	Packet
Leading edge of Vertical Sync.	VSync Start
Trailing edge of Vertical Sync	VSync End
Leading edge of Horizontal Sync, *unless* simultaneous with leading or trailing edge of vertical sync	HSync Start
Trailing edge of Horizontal Sync	HSync End
Immediately following VS, HS, VE or HE packets. Packet Word Count determined by display controller timing parameters.	Blanking packet
Immediately following blanking packet	Pixel Stream packet (16, 18, or 24 bits/pixel)

22.4.1.2 Reading Data

The initiation of the reading of the FIFO is triggered by a delayed version of the horizontal sync pulse from the display controller. The delay should be sufficient that the FIFO will not completely drain as reading of the FIFO continues. However, the delay should not be so long as to cause the FIFO to overflow with data.

22.4.2 Command Mode Operation

22.4.2.1 Writing Data from the Display Controller

Upon receipt of the leading edge of Vertical Sync, the display controller sends whatever DCS command packets are required to initialize the display to receive pixels. Then, as pixels start to arrive from the display controller, a DCS Long Write packet is sent – one per line – which contains the pixel data for that line. No synchronization or blanking packets should be sent. Data packets continue to be sent until the end of the active period. Like video mode packets, there is no need to calculate ECC or CRC words, as this is performed by the hardware on the other side of the data FIFO.

The Packet Sequence registers behave in the same manner as they do for Video Mode packet generation with the following exceptions:

- For Long packets, a DCS command ID byte must be inserted as the first byte of the data payload of the packet, ahead of the pixel data. The packet header Word Count must be 1 more than the number of bytes in the pixel data to

take into account this extra byte. It is the responsibility of software to make sure the packet length is programmed correctly.

- For Line Type 4, any data contained in the Host Data FIFO should be appended to the end of any packets defined in the Packet Sequence for Line Type 4. In this way, the Host may send DCS commands to the Display Peripheral while the Display Controller is sending pixel information to the Display Peripheral.

22.4.2.2 Writing Data from the Host

The host should choose which data FIFO – small or large – to use prior to sending packet information. The large data FIFO is only available if the display controller is not currently using it. The software is responsible for constructing whatever packets are required for the desired operation and should be written into the FIFO via the host. There is no need for the software to compute ECC or CRC words, because this is performed by the hardware on the other side of the data FIFO.

22.4.2.3 Reading Data

The initiation of the reading of data from the FIFO is triggered by a FIFO threshold. Once the threshold is reached, the D-PHY starts to drain the FIFO, and the packets are sent to the display. The threshold should be set such that there is no danger of either FIFO overflow from excessive data from the host or display controller, or FIFO underflow caused by a lack of sufficient data in the FIFO.

22.5 Programming Guidelines

The packet timing diagrams in this section use the following key:

Figure 71: Video Mode Timing Diagram Key

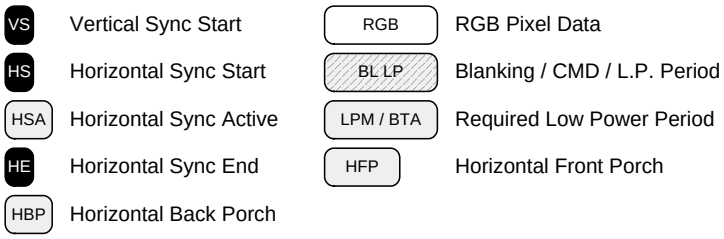


Table 85: Timing Diagram Parameter List

Parameter	Description
tHBP	Horizontal Back Porch period
tHACT	Horizontal Active period
tVBP	Vertical Back Porch period
tVACT	Vertical Active period
tVFP	Vertical Front Porch period
tL	Total line period

22.5.1 Initialization

The start-up and shut-down procedures vary depending on what mode of operation is required. Examples of programming sequences for the main modes are given below.

22.5.1.1 Video Mode Start-up

All 3 video modes – Burst, Non-Burst and Non-Burst with Sync Ends –have the same start-up sequence with a slight variation between Burst and Non-Burst modes:

- Set up the clocks. This involves configuring and enabling the DSI PLL (PLLD). For Non-Burst and Non-Burst with Sync End modes, the Display Controller must also be programmed to take its pixel clock from the DSI PLL. For Burst Mode, the Display Controller can take its pixel clock either from the DSI PLL or from another clock source. Program the PLLD registers with the correct OSC_FREQ and program the PLLD_BASE register. In addition, the PLLP must be running in order to provide the LP receive clock. Program the PLLP registers with the correct OSC_FREQ and program the PLLP_BASE register.
- Depending on the sub-mode, the various Packet Sequence registers and Packet Length registers must be programmed.
- Set the `VID_TX_TRIG_SRC` field in the `DSI_CONTROL` register to `SOL` to select which display controller will source the video data.
- Enable the DSI
- Program the display controller to produce the raster size required
- Enable the display controller

When the display controller starts sending SOL and data, the DSI automatically starts creating and transmitting packets to the display device.

22.5.1.2 Command Mode Start-up

- Set up the clocks. Program and enable the DSI PLL (PLLD). In addition, the PLLP must be running in order to provide the LP receive clock. Program the PLLP registers with the correct OSC_FREQ and program the PLLP_BASE register. Unlike the Video modes, the selection of the PLLD output clock frequency is essentially arbitrary. The clock frequency should be based on the expected data throughput and the requirements of the particular display device. Program the PLLD registers with the correct OSC_FREQ and program the PLLD_BASE register. In addition, the PLLP must be running in order to provide the LP receive clock. Program the PLLP registers with the correct OSC_FREQ and program the PLLP_BASE register.
- Set the HOST_TX_TRIG_SRC field in the HOST_DSI_CONTROL registers to `IMMEDIATE`. Set any other state required.
- Enable DSI.

The DSI should now be ready to accept command packets written to the DSI_WR_DATA register.

22.5.2 Video Mode Programming

The programming model has been designed to accommodate current video mode sequences and potentially future variation. Each line of video output is associated with a “line type”. This line type is automatically generated by the display controller hardware according to the following table.

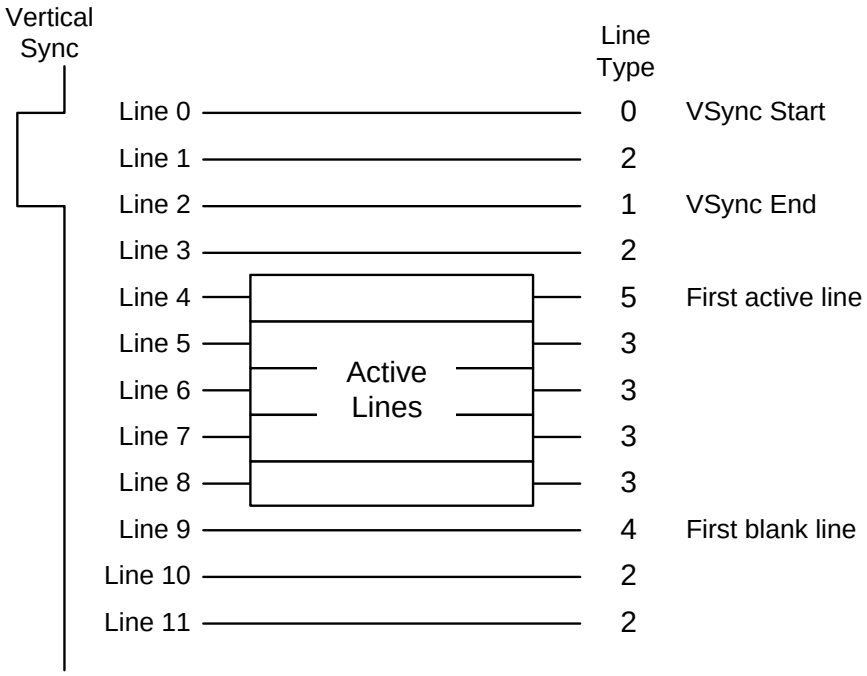
Table 86: Recommended Line Types

Line Type	Description	Typical Raster Position
0	Blank line starting with VS	First line of the raster
1	Blank line starting with VE	Line corresponding to Vsync end.
2	Blank line starting with HS	Vertical blanking line
3	Active line starting with HS	Active line
4	First blank line after active	First blank line after active
5	First active line	First active line

Line Type	Description	Typical Raster Position
6, 7	Reserved	

Figure 72 illustrates a typical raster showing the relationship between various events in the raster and the line types.

Figure 72: Example Video Raster Showing Line Types



The line type acts like a pointer to a data structure containing the information about the "*packet sequence*" for that line type. The packet sequence information is actually held within a pair of registers. For example, the packet sequence for line type 0 is held in the pair of registers DSI_PKT_SEQ_0_LO and DSI_PKT_SEQ_0_HI. Each pair of packet sequence registers contains all the information required to generate up to 6 packets. This is sufficient to generate any packet sequence for any DSI video line. The information stored for each packet is shown in the following table:

Table 87: Packet Sequence Description Fields

Field	No. bits	Description
PKT_*_SIZE	3	Pointer to packet size register
PKT_*_ID	6	Packet ID as defined in the MIPI DSI spec.
PKT_*_EN	1	Enable. Determines which packets are active.

Using the same pair of registers as an example, Table 88 shows how all six packet descriptors fit into the pair of 32-bit packet sequence registers.

Table 88: Packet Sequence 0 Registers

Register	Field	Bits	Description
DSI_PKT_SEQ_0_LO	PKT_00_SIZE	2:0	Packet 0 Size
	PKT_00_ID	8:3	Packet 0 ID
	PKT_00_EN	9	Packet 0 Enable
	PKT_01_SIZE	12:10	Packet 1 Size
	PKT_01_ID	18:13	Packet 1 ID

Register	Field	Bits	Description
	PKT_01_EN	19	Packet 1 Enable
	PKT_02_SIZE	22:20	Packet 2 Size
	PKT_02_ID	28:23	Packet 2 ID
	PKT_02_EN	29	Packet 2 Enable
	SEQ_0_FORCE_LP	30	End in LP state
DSI_PKT_SEQ_0_HI	PKT_03_SIZE	2:0	Packet 3 Size
	PKT_03_ID	8:3	Packet 3 ID
	PKT_03_EN	9	Packet 3 Enable
	PKT_04_SIZE	12:10	Packet 4 Size
	PKT_04_ID	18:13	Packet 4 ID
	PKT_04_EN	19	Packet 4 Enable
	PKT_05_SIZE	22:20	Packet 5 Size
	PKT_05_ID	28:23	Packet 5 ID
	PKT_05_EN	29	Packet 5 Enable

Finally, the SIZE field in the packet descriptor is used as a pointer to a 16-bit "*packet length*" field in the packet length registers. An indirect pointer is used rather than storing the packet length directly in the packet descriptor because the packet lengths are physically large – 16 bits – but there is a lot of re-use. There are only a few different lengths used in a typical raster layout. Thus, it is more efficient to hold the lengths in separate length registers and then to simply refer to them with a short pointer. This allows the storing of 36 packet descriptors in only 6 pairs of packet sequence registers.

Note that one of the packet length registers is reserved for short packets. If a SIZE field in the packet descriptor is programmed to 0, this packet is likely a short packet. Short packets are fixed in length to 4 bytes including the packet header byte and ECC byte. In the context of video mode, they are essentially reserved for timing packets. All other packet length registers can be used to determine the length of any associated long packet.

The SEQ_0_FORCE_LP bit is used to determine if the link should be placed in the LP state at the end of the packet transmission. In Burst Mode operation, the link always drops back into LP state at the end of the HS packet transmission on a line. However, for Non-Burst Modes, the HS transmission may continue to the next line. It is important the that the hardware state machine that generates packets not attempt to go to the LP state, but should instead prepare for the next sequence of packets associated with the next video line and keep the line in the HS transmission state.

The packet length registers are shown in Table 89. The packet size pointer in the packet descriptor can point to any of the available length registers – with the one exception of short packets, whose SIZE field must point to length register 0. It is recommended that the suggested packet length assignment for various length registers is followed to reduce confusion when debugging packet descriptors and packet sequences.

Table 89: Packet Length Registers and Assignments

Register	Field	Suggested Assignment
DSI_PKT_LEN_0_1	LENGTH_0	Must be used for short packets
	LENGTH_1	Horizontal sync active length (HSA)
DSI_PKT_LEN_2_3	LENGTH_2	Horizontal back porch length (HBP)
	LENGTH_3	Horizontal active length (ACTIVE)
DSI_PKT_LEN_4_5	LENGTH_4	Horizontal front porch length (HFP)
	LENGTH_5	–Horizontal active length (ACTIVE)
DSI_PKT_LEN_6_7	LENGTH_6/7	<EOTP/other packet IDs>

When programming the length registers, remember that these contain byte counts, not pixel counts. Therefore, the DSI pixel format, number of DSI lanes in use and the finite (non-zero) size of the packet header and CRC words should be taken into

account when programming these values – especially for blanking packets since all of these parameters affect the number of bytes that should be used to emulate a specific blanking time. The equations required to determine the byte count in the packets are given in the examples that follow. The identification of the length given in the tables and equations has been included in three video mode examples so that the values in the examples can be easily tied to the registers.

22.5.3 SOL Delay Programming

In order to ensure that the pixel FIFO from display to DSI does not underflow when in video mode, it is necessary to delay the start of packet generation by the DSI by a fixed amount from the arrival of the SOL signal from the display. This is especially true of Burst-Mode, because the DSI byte clock can be very much faster than display pixel clock. If no delay is applied, the DSI will very quickly consume all the pixels in the FIFO and the FIFO will underflow. The SOL_DELAY registers are used to set this delay.

22.5.3.1 Non-Burst Mode

In non-burst mode, the rate at which the DSI consumes pixels is the same as the rate at which the display module produces them, so it is merely sufficient to ensure that enough pixels have been fed into the FIFO to overcome the internal latency. This internal latency is approximately 8 pixel clock cycles. However, SOL_DELAY is programmed in DSI byte clocks, so the pixel format and the number of lanes being used should be taken into account when programming this value. Contact your NVIDIA FAE for details on the relationship between display pixel clock and byte clock. These ratios are then used to determine the value of SOL_DELAY as follows:

SOL_DELAY = (((Sol2VldDly) + 12) * F_{DSI} / Fpixel) + FifoLatency

FifoLatency = Ceil (2 * (F_{DSI} / Fpixel)) + 6

Sol2VldDly = Hsync start to Pixel valid delay

Where F_{DSI} and F_{pixel} are the DSI byte and pixel clocks, respectively.

Alternatively, a fixed value of SOL_DELAY that will work for all pixel formats and numbers of lanes can be programming by taking the worst-case ratio of 1:3 (pixel:byte) clock and multiplying by 8 to give SOL_DELAY = 24.

22.5.3.2 Burst Mode

In Burst mode, not only must the pixel format, number of lanes, and the DSI / pixel clock ratio be taken into account, but also the horizontal back porch time (including Hsync) and the Horizontal active time. So, for Burst mode:

- When EOTp packets are enabled:

  SOL_DELAY = (((Sol2VldDly + 4 + Tactive + 1) * FDSI / Fpixel) –

  ((Tactive + 1) * FDSI_NB / Fpixel_NB))) + FifoLatency

- When EOTp packets are not enabled:

  SOL_DELAY = (((Sol2VldDly + 4 + Tactive) * FDSI / Fpixel) –

  ((Tactive) * FDSI_NB / Fpixel_NB))) + FifoLatency

That is,

FifoLatency = Ceil (2 * (FDSI / Fpixel)) + 6

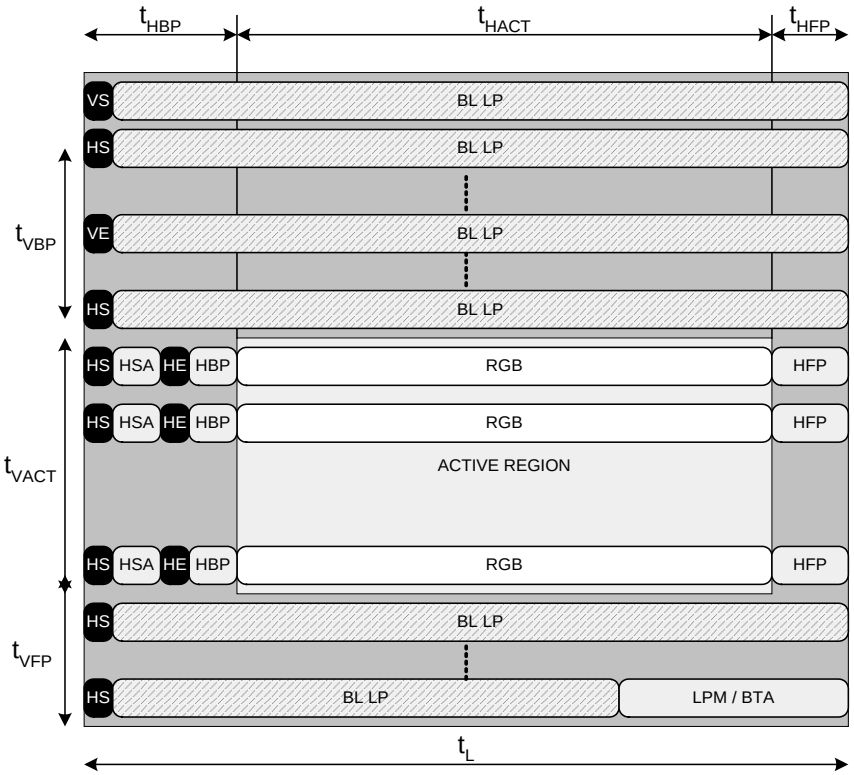
Sol2VldDly = Hsync start to Pixel valid delay

Where the ratio F_{DSI_NB} / F_{pixel_NB} is determined by the clock ratio tables for Non-Burst mode, according to the pixel format used and the number of active lanes.

22.5.4 Non-Burst Mode with Start and End

This mode conveys traditional raster synchronization information across the link to the peripheral by sending both start and end sync packets.

Figure 73: Timing Diagram for Video Non-Burst Mode with Start and End



During the Vertical Active period, all packets should be concatenated into a single HS transmission for the duration of the Vertical Active period.

The figure below shows how a single line is constructed from multiple packets.

Figure 74: Non-Burst Mode with Start and End Packet Timing Detail

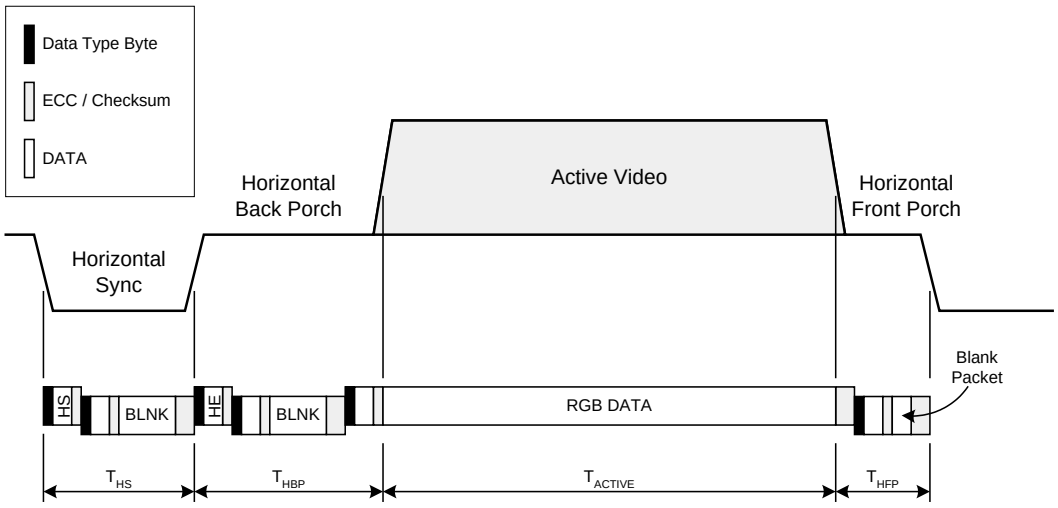


Table 90: Payload Size Table - Non-Burst Mode with Start and End

Packet	Payload Size (Bytes)
HSA	(T_{HS} * B) – 10
HBP	(T_{HBP} * B) – 14
ACTIVE	(T_{ACTIVE} * B)
HFP	(T_{HFP} * B) – 8

B = 2, 2.25 or 3, depending on pixel format.

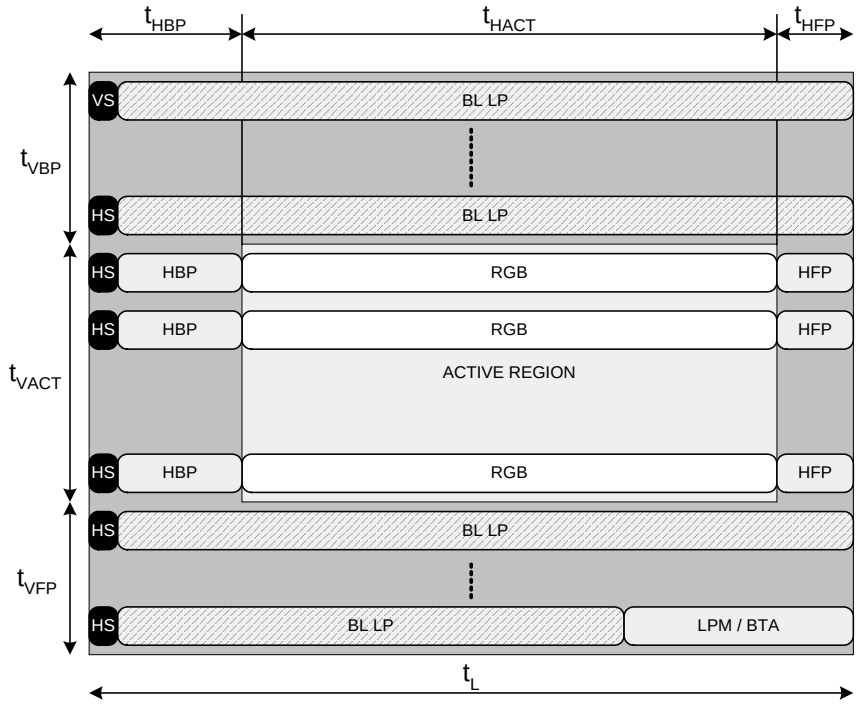
Table 91: Line Type Packet Sequences - Non-Burst with Sync Ends

LT	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len
0	VS	0	EOT	7								
1	VE	0	EOT	7								
2	HS	0	EOT	7								
3	HS	0	BLNK	1	HE	0	BLNK	2	RGB	3	BLNK	4
4	HS	0	EOT	7								
5	HS	0	BLNK	1	HE	0	BLNK	2	RGB	3	BLNK	4

22.5.5 Non-Burst Mode (without Ends)

This mode relaxes the requirement to mimic the generation of sync pulses and merely mandates that the start of the line is indicated and that the pixels appear at the same rate and in the same area of the raster as a tradition raster structure.

Figure 75: Timing Diagram for Video Non-Burst Mode



During the Vertical Active period, all packets should be concatenated into a single HS transmission for the duration of the Vertical Active period.

The figure below shows how a single line is constructed from multiple packets.

Figure 76: Non-Burst Mode Packet Timing Detail

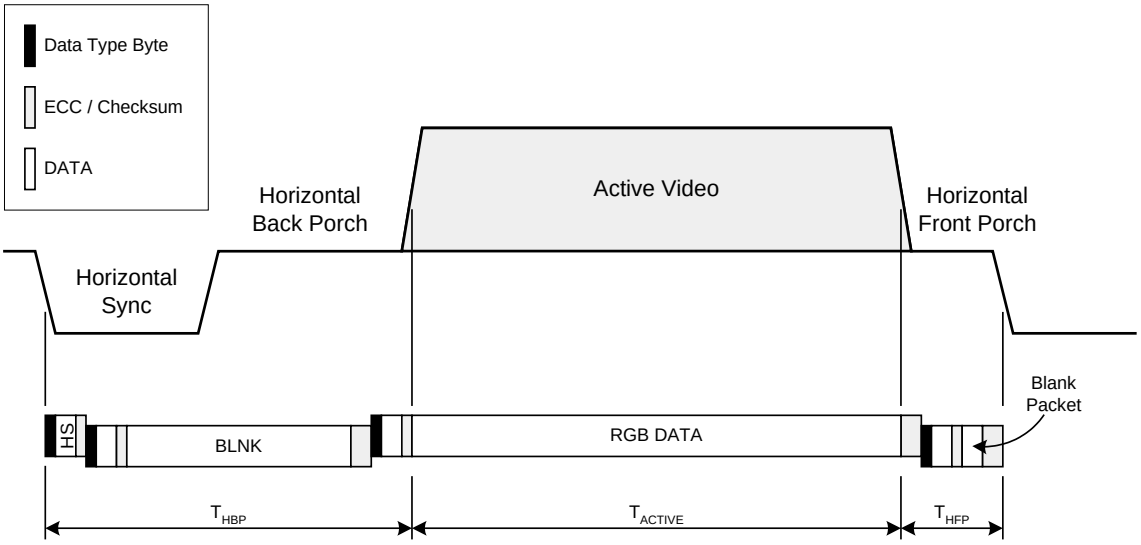


Table 92: Payload Size Table - Non-Burst Mode

Packet	Payload Size (Bytes)
HBP	(T_{HBP} * B) – 14
ACTIVE	(T_{ACTIVE} * B)
HFP	(T_{HFP} * B) – 8

B = 2, 2.25, or 3, depending on pixel format.

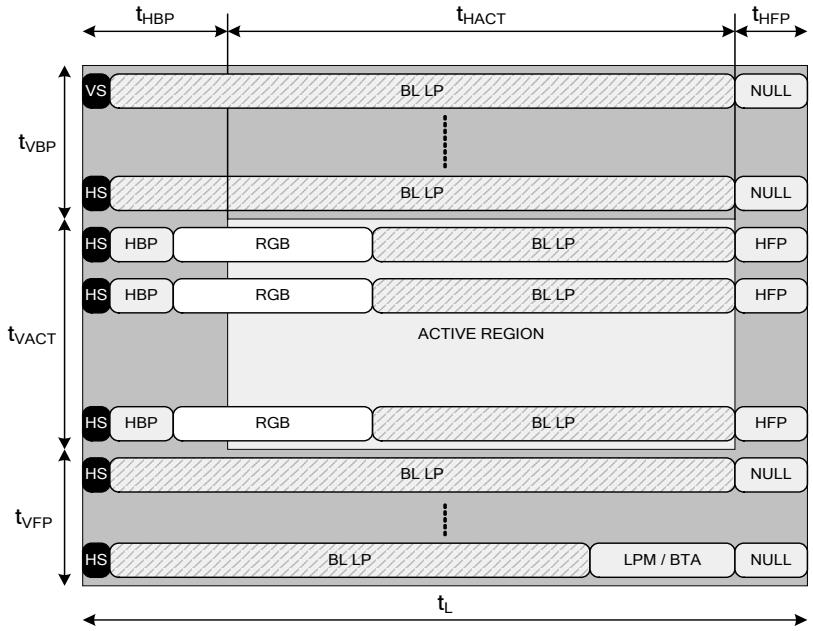
Table 93: Line Type Packet Sequences – Non Burst

LT	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len
0	VS	0	EOT	7								
1	HS	0	EOT	7								
2	HS	0	EOT	7								
3	HS	0	BLNK	2	RGB	3	BLNK	4				
4	HS	0	EOT	7								
5	HS	0	BLNK	2	RGB	3	BLNK	4				

22.5.6 Burst Mode

In Burst Mode, the only attempt to match the raster structure is with the timing of the sync start events. The actual RGB pixel data is transmitted at whatever rate is convenient. This means that the HS, HBP, and RGB packets become compressed with respect to the timing of the underlying raster. This allows some period of idle time for each line that can be used for the transmission of other packets.

Figure 77: Timing Diagram for Video Burst Mode



During the Vertical Active period, packets on an individual line should be concatenated into a single HS transmission. However, unlike Non-Burst Mode, the bus should go idle – if possible – at the end of this transmission. This will allow additional non-video packets to be sent simultaneously with the video stream. The NULL and HFP packets may be optional. Check the latest MIPI DSI specification for clarification.

Table 94: Line Type Packet Sequences - Burst Mode

LT	ID	Len	ID	Len	ID	Len	ID	Len
0	VS	0	EOT	7				
1	HS	0	EOT	7				
2	HS	0	EOT	7				
3	HS	0	BLNK	2	RGB	3	EOT	7
4	HS	0	EOT	7				
5	HS	0	BLNK	2	RGB	3	EOT	7

Notes:

- Burst mode always forces the LP packet field to LP mode. DSI_DSI_PKT_SEQ_0_LO/HI_0/1/2/3/4/5[SEQ_0_FORCE_LP] = 1’b1
- The register programming updates in video mode that impact the raster timing (DSI_DSI_PKT_SEQ_*_LO/HI_*, video mode control fields DSI_DSI_CONTROL_0) are assumed to be static with respect to the display controller. On-the-fly updates are not supported.

22.5.7 Sequence while Switching the Modes/Updates to Raster Timing

This programming sequence must be followed when switching the modes/updates to raster timing:

1. Disable the DC2DSI interface path (DC_DISP_DISP_WIN_OPTIONS [DSI_ENABLE] = 1’b0)
2. Disable the DSI (DSI_LEG_EN disable)
3. Update the DSI configuration registers.
4. Enable the DC2DSI interface path (DC_DISP_DISP_WIN_OPTIONS [DSI_ENABLE] = 1’b1).

5. Enable the DSI (DSI_LEG_EN enable)

22.5.8 Command Mode Programming

There are two sources of command mode packet sequences:

- Display Controller
- Host Interface

Only one of these sources will be active at any particular time.

22.5.8.1 Command Mode from Host

In this mode of operation, all packets sent over the DSI interface are determined by software. There may be hardware assistance in the generation of error correction codes (ECCs) and cyclic redundancy checks (CRCs), but all other data is passed unaltered to the DSI physical layer.

Host Packet Writes

Packets are written to the hardware by writing to the DSI_WR_DATA register. The data written is passed into the DSI Host transmit FIFO. If the data is a packet header and the ECC_ENABLE field in the HOST_DSI_CONTROL register is set to ENABLE, then the MSBs of the 32-bit packet header word are replaced with a hardware-computed ECC byte prior to being written into the FIFO. If this field is set to DISABLE, then no action is taken by the hardware and the packet header is written unchanged.

If the packet is a long packet, then the packet payload should be written to the register after the packet header is written. If the CS_ENABLE field of the HOST_DSI_CONTROL register is set to ENABLE, then the hardware computes the check-sum and appends it to the packet information. If this field is set to DISABLE, then software must append the correctly computed check-sum to the packet data.

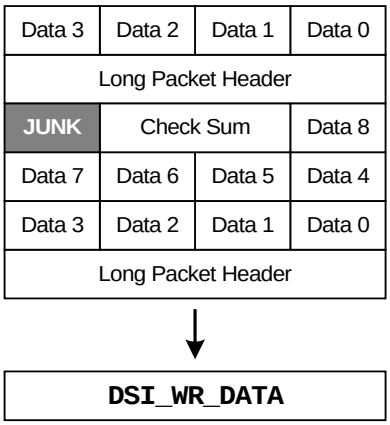
Rules:

1. Software should make sure packets are transmitted in their entirety and that once transmission starts, the FIFO contains enough data to finish a transition on a packet boundary. This can be achieved by only initiating a transmission – either explicitly or indirectly – once all data required for a transmission has been written to the transmit FIFO.
2. In Type-1 Display modules (i.e., the display device includes the full frame buffer to hold image data), the complete image data can be written to the frame buffer via the Host command mode. Software configures the register field to enable the Frame buffer selection for transfer of high-resolution image data.
   DSI_HOST_DSI_CONTROL[PKT_WR_FIFO_SEL]

   Note: The maximum length of the long packet supported is 1920 words including header, payload, and CRC.

3. Packets should be written such that the packet header is always written in one 32-bit word and is never split across writes. In other words, if the end of a packet does not fall on a 32-bit word boundary (if the payload has an odd length, for example), then the header for the next packet should not border the last packet, but should realign with the register. See Figure 78 for an example.

Figure 78: Packet Alignment for Writes to DSI_WR_DATA



Note: For unaligned word transfers, the host transactions are split into multiple host transfers at the unaligned boundary.

Host Packet Transmission

The source that controls when the Host write FIFO starts to drain (flush) is programmable. Selectable source is:

- Explicit FLUSH bit in a control register

Immediate (HOST_TX_TRIG_SRC == IMMEDIATE**)**

As the name implies – if a '1' is written to the `DSI_HOST_TRIGGER` field of the `DSI_TRIGGER` register, then transmission of the data in the Host write FIFO will start immediately. It is recommended that all data required for transmission is written to the DSI_WR_DATA register prior to setting this bit.

22.5.8.2 Command Mode from Display Controller

This mode of operation allows the display controller to write pixel data packets to a DBI-like device that does not require data to be sent in an isochronous raster structure like a DPI device. The data coming from the display controller is sent in an isochronous manner, but the commands sent will be DCS control commands, rather than Video Mode timing and blanking packets.

Setup

There are six steps to operating in this mode:

1. Program the Peripheral display device using DCS commands via the Host Command interface. It is important to send the set_column_address, set_page_address, and set_pixel_format commands. These effectively define the area to which you will be writing pixels.
2. Program the DSI_INIT_SEQ_CONTROL and DSI_INIT_SEQ_DATA_* registers in the DSI interface with the appropriate values. Any commands required to be sent once per frame and *every* frame by way of setup prior to the pixel data being sent should be put in here.
3. Program the `DSI_DATA_FORMAT` field of the DSI_CONTROL register to the required pixel format. Note that `BIT18NP` should not be programmed – see the section below on pixel format restrictions.
4. Program the DSI_PKT_SEQ_* registers. Program the registers in the following way:
   - Packet Sequence registers for Line Types 0, 1, 2, and 4 should all be programmed with 0 in all the Packet Enable fields. In other words, there should not be any packets generated for these line types.
   - Packet Sequence registers for Line Types 3 and 5 should be programmed with a DCS Long Write packet.

5. Program the DCS command ID register to have a write_start command associated with Line Type 5 (First line of active) and a write_continue command associated with Line Type 3 (all other active lines).
6. Enable the display. When Vertical syncs arrive from the display, the initialization sequence should be sent, and for every active line, the pixel data will be sent in a DCS Long Write packet.

Pixel Format Restrictions

The MIPI DCS specification allows for up to 6 different pixel data formats to be transmitted in a write_start or write_continue command. These pixel formats are listed in Table 95. The DSI supports 3 of these pixel formats.

The formats supported are also shown in the “supported” column of Table 95. Do not set `BIT18NP` as a pixel format. There is no DCS equivalent of this format, so undefined behavior may result.

Table 95: DCS Pixel Format Support

DCS ID	DCS Format	Supported	Name
0	reserved	N/A	-
1	3bpp	N	-
2	8bpp	N	-
3	12bpp	N	-
4	reserved	N/A	-
5	16bpp	Y	BIT16P
6	18bpp	Y	BIT18P
7	24bpp	Y	BIT24P

Simultaneous Host Command Packets

It is necessary, from time to time, to send a DCS command to the display peripheral in a “side-band” fashion while the display controller is continuing to send DCS write commands with pixel information. Line Type 4 (first blank line) is reserved to indicate to the hardware when it should attempt to send any DCS command packets requested by software.

If it is desired to send a DCS command in this way, the DCS command packet should be written in its entirety (header, ECC, DCS command, payload, CSC) into the Host Command FIFO. The HOST_TX_TRIG_SRC field should then be set to `IMMEDIATE`.

The DSI hardware will then send the entire contents of the FIFO out on the DSI interface on the first line of blanking. Sending the data on this line guarantees the Host packet transmission will have enough time to complete before the next packet generated by the Display Controller is generated.

> **Note:** There is no BTA permitted in this mode, so no ACK, ACK with error report, or read return data will be generated.

If the host transfer is enabled during the frame video blanking interval, the following sequence needs to be performed at the end of the frame:

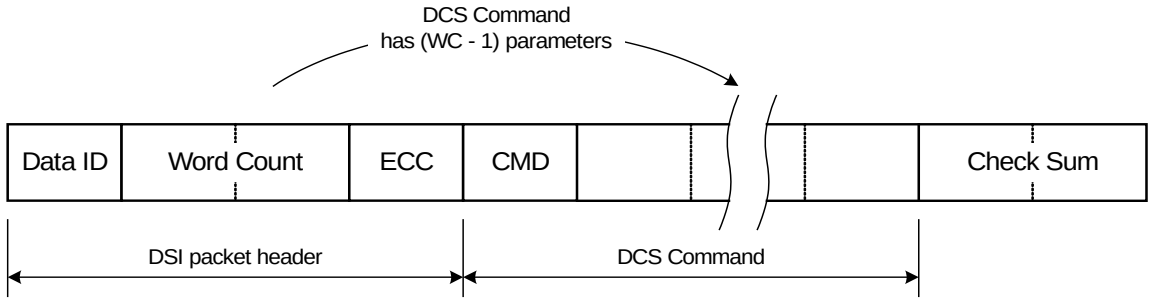
1. Wait for an end of frame event from the display controller.
2. Set the increment syncpt soft reset; that is, program the INCR_SYNCPT_SOFT_RESET field in the DSI_INCR_SYNCPT_CNTRL_0 register to 1’b1.
3. Clear the increment syncpt soft reset; that is, program the INCR_SYNCPT_SOFT_RESET field in the DSI_INCR_SYNCPT_CNTRL_0 register to 1’b0.
4. Continue with the subsequent configuration.

22.5.9 Display Command Set (DCS) Packets

DCS is a legacy control command set that is used to program various control registers present in typical LCD panels used in cell phones. Historically, the commands would be sent to the display over a MIPI DBI interface. Since MIPI DSI is meant to replace both DPI and DBI, it must also transport these control commands.

There are several DCS-specific commands in the MIPI DSI specification that can be used to send DCS commands to the Peripheral Display Device. However, the most useful is probably the DCS Long Write packet since it can be used to send commands with more than one parameter. The DCS command is embedded with an MIPI DSI Long Packet as follows: The DCS Command Byte and all the DCS Command Parameters (payload) are concatenated and sent in the Payload of the MIPI DSI Long Packet. The Word Count of the DSI packet conveys the total size of the DSC packet. As usual, a 2-byte CS footer is appended to the DSI Long Packet. The next figure below shows how a DCS Long Write packet is constructed..

Figure 79: DCS Command Placement in DSI Long Packet



16 bpp Byte Ordering in 16 bpp Format for Video/Command Mode

The DSI specification suggests a different byte order in the 16 bpp video and command mode data bit order, i.e., data packing in:

Video mode [16:0] -> {B[4-0],G[5-3]},{G[2-0],R[4-0]} (Default)

Command mode [16:0] -> {G[2-0],B [4-0]},{R[4-0],G[5-3]} (SwapEn)

The byte order can be configured through the DSI_DSI_CONTROL_0 register, DFMT_16BPP_SWAP_EN field. By default, the video mode order is selected and the command mode can be selected by the programing DFMT_16BPP_SWAP_EN to 1.

Frame Synchronization Between Identical Command Mode Displays

When stretching a single surface across multiple identical displays, frame synchronization can be achieved to avoid visual artifacts due to timing drifts across both the displays.

DCS command “adjust_vsync_timing” provides a mechanism for adjusting the command mode display vsync/frame sync timing with respect to another identical display. Vsync can be shifted, i.e., delayed/advanced by the specified number of scan lines.

Host Command Mode Byte Transmission

Command mode operation primarily involves sending the commands and data to the peripheral (the display device). The host processor indirectly controls activity at the peripheral by sending commands, parameters, and data to the display controller. Command Mode operation requires a bidirectional interface capabilities.

Command mode transfers are classified into,

- HS/LP mode

  Host command mode transmission can be enabled in High Speed and Low Power modes. Follow this programming sequence to configure the DSI to enable command mode transactions.

- Configure DSI_DSI_CONTROL_0 [DSI_HOST_ENABLE]
- LP/HS mode of transmission is selected by configuring the DSI_HIGH_SPEED_TRANS in the DSI_HOST_DSI_CONTROL_0 register.
- Enable checksum/Ecc mode via DSI_HOST_DSI_CONTROL_0[CS_ENABLE], …, DSI_HOST_DSI_CONTROL_0[ECC_ENABLE].
- Write the host data to the register DSI_DSI_WR_DATA_0. Once all the command packets are pushed into the FIFO, trigger the start of the transaction via the HOST_TX_TRIG_SRC field in the DSI_HOST_DSI_CONTROL_0 register.

- Raw Mode

  Host command mode transmission also supports RAW data bytes to be transferred to the display device. In Raw mode, the data written to the host is transferred with no concept of packets and the DSI hardware does not decode the packet headers and ECC/CS computation is not performed.

  In order to send the RAW data bytes (debug / diagnostic workaround mode):

  - Program the number of bytes to be transferred to the DSI_RAW_DATA_BYTE_COUNT register. The byte count programmed is equal to the total number of raw bytes (not to be interpreted as the byte count of a packet).
  - Write raw data bytes to the DSI Host.
  - Enable RAW_DATA in the DSI_HOST_DSI_CONTROL_0 register.

22.5.10 High-Speed Clock Configurations

In High Speed mode, the Host provides a low-swing, differential DDR clock signal for high-speed data transfers. The high-speed clock lane is configurable via the DSI_HS_CLK_CTRL] field in the DSI_DSI_CONTROL register.

- Free Running Mode /Continuous

  The D-Phy clock lane operates in HS free running or continuous mode; i.e., used in systems where the D-Phy clock lane acts as a clock source to the display devices eliminating the need for an alternate oscillator clock source.

- TX Mode/Discontinuous Mode

  The D-Phy clock lane operates in burst mode or discontinuous mode; i.e., the D-Phy clock lane remains active only during the HS transmission and stops the clock lane when there are no high-speed transmissions active in any of the data lanes.

Notes:

1. The Host programs the total horizontal blank period to meet the following criteria to provide enough time for HS <-> LP transitions.

   (HBLANK) >= (number_of_lanes * (HS_Trail + HS-Exit + CLK_POST + CLK_TRAIL + HS_EXIT + TLPX + TLPX + TCLK_PREPARE + TCLK_ZERO + TCLK_PRE + 1 + TLPX + THS_PREPARE + TDAT_ZERO + 1))

   The parameters in this equation are defined in the DSI_DSI_PHY_TIMING registers.

2. The DSI_HS_CLK_CTRL field in the DSI_DSI_CONTROL_0 register control field for the HS clock lane is programmed when the DSI_HIGH_SPEED_TRANS control field in the DSI_DSI_CONTROL_0 register is programmed for HS packet transmission of packets.
3. The HS clock lane state transitions from continuous to discontinuous with soft reset assertion.

22.5.11 Ultra-Low Power Sequence

In this procedure, starting from the Stop state, the transmit side drives the TX-ULPS-Rqst state (LP-10) and then drives the TX-ULPS State (LP-00). After this, the clock lane enters the Ultra-Low Power state. If an error occurs, and an LP-01 or LP-11 is detected immediately after the TX-ULPS-Rqst state, the Ultra-Low Power state entry procedure is aborted, and the receive side waits for or returns to the Stop state, respectively.

The Clock lane and Data lanes can be configured to enter and exit ULPS independently/simultaneously:

- Independent control of the ULPS

  The Clock needs to be in the HS state, sending the active clock when data lanes are entering ULPS, When entering ULPS, the data lanes enter the ULPS first, followed by the clock lanes. Similarly, when exiting ULPS, the Data lanes exit the ULPS first, followed by the clock lanes.

  DSI_ULTRA_LOW_POWER_CONTROL register configures the control to enter the ULPS on particular clock/Data lane.

  ULPS Entry

  - Program the data lane to enter ULP sequence, wait for syncpt.
  - Program the clock lane to enter ULP sequence and, wait for syncpt

  ULPS Exit

  - Program the data lanes to exit the sequence, wait for syncpt
  - Program the clock lanes to exit the sequence, wait for syncpt
- Simultaneous control of the ULPS

  The DSI_ULTRA_LOW_POWER field in the HOST_DSI_CONTROL register controls the ULPS for all lanes (clock and data lanes 0-3) simultaneously.

Notes:

- The DSI_TWAKEUP field in the DSI_PHY_TIMING_2 register defines the length of the exit interval in multiples of 512 byte clocks common for all lanes (Clock/Data).
- The ULPM entry sequence always starts from the NORMAL state. Software should place the control fields in the NORMAL state after the exit sequence after the last operation is done. That is, in case of a ULPM sequence on clock, data lanes, you are recommended to program the register to the NORMAL state after the data lane exit sequence.

22.5.12 End of Transmission Packet (EOTp)

The DSI specification defines a dedicated End of Transmission packet (EoTp) at the protocol layer to indicate the end of HS transmission. For backwards compatibility with earlier DSI systems, this EoTp can be enabled or disabled.

For host transactions during the video mode, EOTp is programmed in the Packet Sequence register, and host data is sent on the interface followed by the last video packet byte, including the EOTp packet as the last word. That is, software programs the EOTP packet as part of the host data during host transactions during video mode.

22.5.13 Host Command Packet During Video Mode Transmission

DSI supports transmission of host command packets during vertical blanking in Video mode.

Host packet transmission during vertical blank time is possible and programmable through the DSI_VID_MODE_CONTROL register to enable and select the line type to trigger the host command packets during video mode. The 0/1/2/4 line types with single short packet transmission as part of video raster can enable simultaneous host transfer in Video mode.

Video blank line types are:

- Line Type = 0 - Blank line starting with VS
- Line Type = 1 - Blank line starting with VE
- Line Type = 2 - Blank line starting with HS
- Line Type = 4 - First Blank line after active starting with HS.

The programming sequence to enable host transactions during Video mode is:

1. Choose the line type 0/1/2/4 (Video Blanking) for simultaneous host transfers during Video mode. Program the DSI_LINE_TYPE field in the DSI_DSI_VID_MODE_CONTROL_0 register to FOUR.
2. Simultaneous host transfers are enabled during Video mode via the Video mode control field. Program the DSI_CMD_PKT_VID_ENABLE field in the DSI_DSI_VID_MODE_CONTROL_0 to 1'b1.
3. Write host data transactions to the host data buffer via the DSI_DSI_WR_DATA_0 register.

HS Packet	Host Data Packets (<= 64 Words)

4. Trigger host transmission when the complete host data for transmission is pushed into the buffer. Program the DSI_HOST_TRIGGER field in the DSI_DSI_TRIGGER_0 to 1'b1.
5. Wait for FRAME_DONE syncpt from the display controller.
6. Set the increment syncpt soft reset; that is, program the INCR_SYNCPT_SOFT_RESET field in the DSI_INCR_SYNCPT_CNTRL_0 register to 1'b1.
7. Clear the increment syncpt soft reset; that is, program the INCR_SYNCPT_SOFT_RESET field in the DSI_INCR_SYNCPT_CNTRL_0 register to 1'b0.

Notes:

- The host packet data transmission cannot be enabled in Video burst mode, where NULL_PACKETs are included with the HSYNC packet.
- Checksum/ECC computation for the host packets can be performed by either the hardware or software by programming the CS/ECC_Enable fields in the DSI_HOST_DSI_CONTROL_0 register.
- After a single VSYNC/VSYNCEND/HSYNC short packet is transmitted, if the Host transmission is enabled, software-constructed Host data packets are transmitted.
- The length of the Host FIFO data is limited to 64 words deep.
- Host data should be pushed into the Host FIFO before the frame is triggered.
- Host packets must be aligned to a word boundary. For host packets ending on an unaligned word boundary, there is support for a maximum of 4 such consecutive packets transferring in a worst-case configuration scenario and relaxed for other configurations. In the worst-case configuration scenario, the number of lanes is 4, and the Host packets end on Byte 0 (that is, a single byte is written in the last word).

  For an unaligned word boundary, if the end of a packet does not fall on a 32-bit word boundary, then the header for the next packet should not border the last packet (see the figure showing packet alignment for writes to DSI_WR_DATA).

22.5.14 Ganged Mode (Odd-Even/Left-Right) Programming

The Tegra K1 DSI supports Ganged mode. This section assumes that the reader is familiar with the DSI specification and normal video mode programing guidelines.

Odd-Even

For Odd-Even Ganged mode, the programming guidelines are based on these assumptions/limitations:

1. Both partitions have a single PLLD and clock source (DSI instances)

2. For VNB, all data lanes end in the same clock cycle aligned to the number of configured lanes.
3. The number of pixels in the 18 bpp packed case is always a multiple of four.
4. The number of active pixels from the display controller is not greater than 4096 pixels.

Programming guidelines/sequence and equations for Odd-Even Ganged mode are listed below:

1. Required inputs are: image resolution, data format, and optional number of lanes
2. Compute the pixel clock frequency from the given resolution :

   pixel frequency = (TotalHorizontalPeriod * TotalVerticalPeriod * FrameRate) / 10^6
3. Determine the shift clock divider value and ganged mode imagesplit information from the number of pixels, data format, and pixel frequency:

   pixel frequency = DSI clock (byte frequency) * 4/clock divider
4. Symmetrical split is possible for all resolutions. Determine the possibility of an asymmetrical split.

   Let n1 = number of lanes for the first partition, and n2 = number of lanes for the second partition from step 3.

   totalNumLanesInGangedMode = n1 + n2
5. Compute the correction pixels needed to align the totalNumPixels, totalNumBytes with totalNumLanesInGangedMode. From Limitation #2 and #3:
   - The pixelsNeededToInitiallyAlign should be such that updated totalNumPixels is a multiple of LCM (total Num Lane sInGangedMode,X)
   - totalNumBytes = totalNumPixels*bytesPerPixel is a multiple of totalNumLanesInGangedMode.

   Note:
   - LCM – least common multiple (X=4 for 18bpp packed, otherwise X=1)

     If remainder is non-zero/ganged alignment and was not successful (from Step 9), add ‘n’ number of additional active pixels (zeros/random data) so that the updated image active width is divisible by the LCM above. This is needed to support image split as determined in (Step 4).
   - Add the additional correction/dummy pixels to HFP, determine the new pixel frequency, and compute the byte frequency using the clock divider. Use this information to program the PLLD and shift clock divider. It is okay to add dummy active pixels since panels provide an option using a register field that can be configured to drop/discard the padded pixels.
   - Update the total number of pixels now with the newly added active pixels to ensure the total number of active pixels does not exceed 4096 pixels. In case the total number of pixels exceeds 4096 pixels, then the frame is considered to not support asymmetrically split for the given configuration (i.e., frame rate and split configurations).
   - In the 18 bpp packed format case, you cannot achieve alignment over a definite set of iterations for a given frame rate. If the alignment is not achieved within 50-60 pixels, the pixel alignment is assumed to not be possible for the frame for symmetric split at that frame rate.
6. Determine if the (first partition width) : (second partition width) ratio = n1/n2. If successful, proceed to the next step. If not, ganged width alignment is not successful. Repeat from step 5 by adding more active pixels that still meet the requirement mentioned there.

   splitFactor (for first partition)= n1/ totalNumLanesInGangedMode;

   First Partition Width (active pixels)= CEIL(spliFactor*image width)

   Pixels per line of first Partition = CEIL(splitFactor*totalNumPixels)

   second partition active width = imagewidth – first partition width

   pixels per line of second partition = totalNumPixels - Pixels per line of first Partition

Note:

- In consideration of constraint #4, software will ensure that the total number of pixels does not exceed 4096 pixels. If the total number of pixels exceeds 2570 pixels, then the frame does not support asymmetrically split for the given configuration, i.e., frame rate and split configurations.
- The number of active pixels added is limited to no more than 60 pixels. If this value exceeds 60 in these iterations, the input image cannot be split as per the split ratio (cannot deviate much from the selected frame rate).

7. Determine the new pixel frequency (new active pixels and HFP correction) and compute the byte frequency using the clock divider. Use this information to configure the clock parameters for PLLD clock generation and the shift clock divider.
8. Determine the factors of the first partition width and second partition width.

   Select ‘x’ from the factors of the first partition and ‘y’ from the factors of the second partition such that x:y = n1/n2. The minimum of 1:1 (symmetrical) is possible for any image.

   - The first group of pixels: ganged start pointer = 0, valid width = x and low width = y
   - The second group: ganged start pointer = x, valid width = y, low width = x
9. In Ganged mode, the packet sequence programming includes HSYNC, HACT, and HFP (total Horizontal blanking period) packets.

   HACT payload size = Total Actual Image Bytes on Data lanes

   Initial HFP payload size = totalNumBytesForTheSelectedPartition - numActBytesToBeSent - 16 (16 is because of 4 Bytes - HSYNC, (4+2) Bytes - HACT, (4+2) Bytes - HFP)
10. Compute the correction bytes (per line of partition) to align with the line width and number of lanes (per partition), limitation #2

    correctionBytesPerLane = CEIL(totalNoOfPixelsPerHorzLine *(FDSI/ Fpixel) – (BPP/ Gangedmode_lanes))

    totalNumBytesForTheSelectedPartition = (correctionBytesPerLane * numOfLanesForSelectedPartition)

    total Horizontal Blank(Bytes) = totalNumBytesForTheSelectedPartition - 16 + correctionBytesForAlignment
11. Ganged mode register programming
    - Even Partition Programming

      DSI_DSI_GANGED_MODE_CONTROL_0[DSI_GANGED_MODE_EN] = 1;

      DSI_DSI_GANGED_MODE_START_0[DSI_GANGED_START_POINTER] = 0

      DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_HIGH_WIDTH] = Even partition active width

      DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_LOW_WIDTH] = Even partition inactive/low width.
    - Odd Partition Programming

      DSI_DSI_GANGED_MODE_CONTROL_0[DSI_GANGED_MODE_EN] = 1;

      DSI_DSI_GANGED_MODE_START_0[DSI_GANGED_START_POINTER] = High width of Even partition

      DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_HIGH_WIDTH] = odd partition active width.

      DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_LOW_WIDTH] = odd partition inactive/low width
12. SOL delay calculation:

    SolFactor = ((Sol2VldDly + 6) * (FDSI / Fpixe)) + 6;

    sol_delay = Ceil (TotalHorzPixelWidth * (FDSI / Fpixel)) -

Ceil (((SplitFactor * TotalHorzPixelWidth) * BPP) / Gangedmode_lanes) + SolFactor;

Final_sol_delay = (dcs_mode) ? (sol_delay + 20) : sol_delay

DSI_DSI_SOL_DELAY_0 = Final_sol_delay

Note:

- Sol2VldDly = Hsync start to Pixel valid delay
- totalNoOfPixelsPerHorzLine = Total Number of horizontal pixel count.
- SplitFactor = DSI_partition_lanes / Gangedmode_lanes.
- Gangedmode_lanes = Total number of lanes required in Ganged mode transfer
- DSI_partition_lanes = Total lanes in current partition/channel.
- BPP = Bytes per pixel

Left-Right:

For Left-Right Ganged mode, the programming guidelines are based on these assumptions/limitations:

- Both partitions have a single PLLD and clock source (DSI instances)
- For VNB, all data lanes end in the same clock cycle aligned to the number of configured lanes (per DSI specification).
- The number of pixels in the 18 bpp packed case is always aligned to 4 pixels (per DSI specification).
- The number of active pixels from the display controller is not greater than 4096 pixels.

Programming guidelines/sequence and equations for Left-Right Ganged mode are listed below:

1. Required inputs are Image resolution,data format, and optional number of lanes
2. Compute the pixel clock frequency from the given resolution
   pixel frequency = (TotalHorizontalPeriod * TotalVerticalPeriod * FrameRate) / 10^6
3. Determine the possible shiftclock divider value and ganged mode image split the information from the number of pixels, data format, and pixel frequency.

   pixel frequency = DSI clock (byte frequency * 4/clock divider)
4. Symmetrical split is possible for all resolutions. Determine the possibility of the asymmetrical split.
5. Let n1=number of lanes for first partition and n2 = number of lanes for second partition from step 3

   Total number of DSI data lanes required for video refresh:
   totalNumLanesInGangedMode = n1 + n2
6. Compute the correction/additional pixels needed to align the total number of pixels and total number of bytes with totalNumLanesInGangedMode.

   From Limitation #3:

   - The pixelsNeededToInitiallyAlign should be such that an updated totalNumPixels is a multiple of LCM (totalNumLanesInGangedMode,X)
   - totalNumBytes = totalNumPixels*bytesPerPixel
     Ensure the total number of bytes is a multiple of totalNumLanesInGangedMode

   Note: For the least common multiple (LCM), X = 4 for 18 bpp packed; otherwise X = 1

   In the 18 bpp packed format, in case the alignment does not complete over a definite set of iterations for a given frame rate, check that the total additional pixels added to the align is not greater than 50-60 pixels. If this range is exceeded, the pixel alignment is not possible, and the frame is not considered to be asymmetrically split for the 18 bpp packed case (for that frame rate).

Add the additional correction pixels to the HFP, determine a new pixel frequency, and compute the byte frequency using the clock divider. Use this information to configure the clock parameters for PLLD clock generation and the shift clock divider.

7. Determine the number of pixels per split on updatedPixelCount from step 6:
   - o Determine the first partition width, and then the remaining pixels will be in the second partition.

     splitFactor (for first partition)= n1/ totalNumLanesInGangedMode

     First Partition Width (active pixels)= CEIL(splitFactor*image width)

     Pixels per line of the first partition = CEIL(splitFactor*totalNumPixels)

     second partition active width = imagewidth – first partition width

     pixels per line of the second partition = totalNumPixels - Pixels per line of the first partition.

     Note: For 18 bpp packed, software should recheck if each of the widths determined above is multiple of 4. Otherwise, adjust the active pixels of the partition (increase) to align to 4 pixels and correspondingly decrease the pixels in the HFP (to still meet the line time) accordingly. Adjust pixels in the second partition as well.

     numActBytesToBeSent = partition active width * bytesPerPixel

     totalNumBytesForTheSelectedPartition = pixels per line of selected partition * bytesPerPixel

8. In Ganged mode, the packet sequence programming includes HSYNC, HACT, and HFP (total horizontal blanking period) packets.

   HACT payload size = Total Actual Image Bytes on Data lanes

   Initial HFP payload size = totalNumBytesForTheSelectedPartition - numActBytesToBeSent - 16

   (16 is because of 4 bytes - HSYNC, (4+2) Bytes - HACT, (4+2) Bytes - HFP)

9. Compute the correction bytes (per line of partition) to align with line width and number of lanes (per partition) (limitation #2)

   Correction Bytes added per lane (correctionBytesPerLane) = CEIL(totalNoOfPixelsPerHorzLine *(FDSI/ Fpixel) – (BPP/ Gangedmode_lanes))

   Correction Bytes added per partition (totalNumBytesForTheSelectedPartition) = correctionBytesPerLane * numOfLanesForSelectedPartition

   total Horizontal Blank(Bytes) = totalNumBytesForTheSelectedPartition – 16 + correctionBytesForAlignment

10. Ganged mode register programming
    - o Left Partition Programming

      DSI_DSI_GANGED_MODE_CONTROL_0[DSI_GANGED_MODE_EN] = 1;

      DSI_DSI_GANGED_MODE_START_0[DSI_GANGED_START_POINTER] = 0;

      DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_HIGH_WIDTH] = Total horizontal active width

      DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_LOW_WIDTH] = Total horizontal width – Total horizontal active width.
    - o Right Partition Programming

      DSI_DSI_GANGED_MODE_CONTROL_0[DSI_GANGED_MODE_EN] = 1;

      DSI_DSI_GANGED_MODE_START_0[DSI_GANGED_START_POINTER] = leftPartitionWidth (for right partition)

      DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_HIGH_WIDTH] = Total horizontal active width

DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_LOW_WIDTH] = Total horizontal width – Total horizontal active width.

11. SOL delay:

    SolFactor = ((Sol2VldDly + 6) * (FDSI / Fpixe)) + 6;

    sol_delay = Ceil (TotalHorzPixelWidth * (FDSI / Fpixel)) -

    Ceil (((SplitFactor * TotalHorzPixelWidth) * BPP) / Gangedmode_lanes) + SolFactor;

    Final_sol_delay = (dcs_mode) ? (sol_delay + 20) : sol_delay

    DSI_DSI_SOL_DELAY_0 = Final_sol_delay

Note:

- Sol2VldDly = Hsync start to Pixel valid delay
- totalNoOfPixelsPerHorzLine = Total Number of horizontal pixel count.
- SplitFactor = DSI_partition_lanes / Gangedmode_lanes.
- Gangedmode_lanes = Total number of lanes required in Ganged mode transfer
- DSI_partition_lanes = Total lanes in current partition/channel.
- BPP = Bytes per pixel

22.5.14.1 Recommended Packet Sequence

Packet	Payload Size (Bytes)
ACTIVE	(T_{ACTIVE} * B)
HFP	(T_{HFP} * B) – 8

- B = 2, 2.25 or 3, depending on pixel format.
- N = Number of Lanes used.

Table 96: Recommended Payload Size - Ganged Mode

LT	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len
0	VS	0								
1	HS	0								
2	HS	0								
3	HS	0	RGB	3	BLNK	4				
4	HS	0								
5	HS	0	RGB	3	BLNK	4				

22.5.14.2 Alternate Packet Sequence

Packet	Payload Size (Bytes)
ACTIVE	(T_{ACTIVE} * B)
HFP	(T_{HFP} * B) – 8

- B = 2, 2.25 or 3, depending on pixel format.

- N = Number of Lanes used.

Table 97: Optional Payload Size- Ganged Mode

LT	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len
0	VS	0								
1	HS	0								
2	HS	0								
3	HS	0	BLNK	2	RGB	3	BLNK	4		
4	HS	0								
5	HS	0	BLNK	2	RGB	3	BLNK	4		

22.5.15 Soft Reset Programming

Soft reset is asserted in the DSI through the LEG_DSI_ENABLE control field of the DSI_DSI_POWER_CONTROL_0 register. When soft reset is asserted, the DSI controller transitions the internal states to default mode. When it is asserted between valid transactions, the current transaction is halted, the internal states are moved to default mode, and a new transaction starts by programming the desired values following the programming sequence explained in the other sections.

Note: For Host transmissions enabled through the DSI_HOST_TRIGGER field of the DSI_DSI_TRIGGER_0 register, soft reset cannot be issued between a transaction, and software will write 1'b0 to the register to clear the trigger bit.

22.5.16 Function Programming

22.5.16.1 ECC Generation

For precise details on the calculation of the ECC field of the packet header, reference should be made to the MIPI Alliance Standard for Display Serial Interface. However, this is an overview of how the ECC can be created quite simply.

Each bit of the ECC byte is the result of XORing a number of bits from the packet header together. Which header bits contribute to which ECC bit is contained in a special table which can be used to calculate the ECC as follows:

```
const UCHAR ecc_parity[24] = { 0x07, 0x0b, 0x0d, 0x0e, 0x13, 0x15, 0x16, 0x19,
                               0x1a, 0x1c, 0x23, 0x25, 0x26, 0x29, 0x2a, 0x2c,
                               0x31, 0x32, 0x34, 0x38, 0x1f, 0x2f, 0x37, 0x3b
                             };
ULONG packet_header;
UCHAR ecc_byte;
UINT  i;

// Assume bottom 24 bits of packet_header
// contains header ID and byte count, then ...

ecc_byte = 0;
for (i = 0; i < 24; i++) {
  ecc_byte ^= ((packet_header >> i) & 1) ? ecc_parity[i] : 0x00;
}
packet_header |= (ULONG)(ecc_byte) << 24;
```

Note that the table in the DSI specification actually contains 64 entries. Since short packets have been fixed in length to be the same as a long packet header since the original specification was written, there will now always be just 24 data bits in the packet header, so only 24 entries are needed.

22.5.16.2 CRC Insertion

The DSI checksum used for long packets is derived using the generator polynomial $x^{16}+x^{12}+x^5+x^0$. Details of this can be found in section 9.6 of the MIPI DSI specification. To understand how the CRC is generated, think of the packet data as consisting of a continuous serialized stream of bits, rather than a sequence of 8-bit bytes. When thought of in this way, it is relatively straight forward to generate the CRC. Reproduced below is an abridged version of the example C code contained in Appendix B of the MIPI DSI specification.

```
// Polynomial, bit reversed form (since DSI transmits LSB first) …
const unsigned short CRC16GenerationCode = 0x8408;

unsigned short CalculateCRC16( unsigned char *DataStream_ptr, unsigned short NumberOfDataBytes)

{
  unsigned short ByteCounter;
  unsigned char  BitCounter;
  unsigned char  CurrentData;
  unsigned short CRC16Result = 0xFFFF;

  if (NumberOfDataBytes > 0) {
    for (ByteCounter = 0; ByteCounter < NumberOfDataBytes; ByteCounteer++) {
      CurrentData = DataStream_ptr[ByteCounter];
      for (BitCounter = 0; BitCounter < 8; BitCounter++) {
        if ((CRC16Result & 0x0001) ^ (CurrentData ^ 0x0001))
          CRC16Result = ((CRC16Result >> 1) & 0x7FFF) ^ CRCGenerationCode;
        else
          CRC16Result =  (CRC16Result >> 1) & 0x7FFF;
        CurrentData = (CurrentData >> 1) & 0x7F;
      }
    }
  }
  return CRC16Result;
}
```

This code may not be very high-performance due to the inner for loop which iterates over bits, rather than bytes. While it is instructive and could form the basis of a reference piece of code, it is not recommended where performance is important. There are many documented methods of performing this calculation in parallel in order to speed up the computations. These methods are beyond the scope of this document.

22.5.17 Read Data Return

DSI is a bidirectional interface. Data is returned from the peripheral display device only after the display controller has requested information by issuing a Bus Turn Around (BTA). All returned data is written into a FIFO that can be read using Host reads of a DSI register.

22.5.17.1 Reading Peripheral Registers

A typical application of a BTA is in the reading of a register from the display peripheral. This is achieved in the following way:

1. Set up the DSI interface to be in Host-driven command mode.

2. Set the DSI_MAX_THRESHOLD to 3.
3. Set the HOST_TX_TRIG_SRC field of the HOST_DSI_CONTROL register to FIFO_LEVEL.
4. Set the PKT_BTA field of the HOST_DSI_CONTROL register to ENABLE.
5. Write a DCS READ command packet (see section 8.8.8.2 of the MIPI DSI specification) into the Command FIFO by writing to the DSI_WR_DATA register.

This will result in the transmission of a DCS READ packet to the peripheral, the initiation of a BTA and – assuming the peripheral received the packet without error – the return of the requested data to the Host Read Return FIFO. The data can then be read from the FIFO by reading the DSI_RD_DATA register.

22.5.17.2 Bus Turn Around

- BTA is only supported for Host driven Command Mode interface. There will be no BTA during video mode transmission.
- Whether or not a BTA is initiated is controlled by the PKT_BTA field of the HOST_DSI_CONTROL register.
- The DSI Read Return FIFO is 4 bytes wide and 8 entries deep, so 32 bytes in total. this is enough to hold 8 short packets, or a mixture of short and long packets. The length of long packets must be severely restricted.
- Hardware does not perform ECC or CS checks on the read return data. Entire packets are simply made available to software to perform whatever checks they desire.
- There is the ability to increment a sync point counter on the arrival of the returned data or on the receipt of an error report in the event there was a problem with the read packet transaction.
- Software will ensure to program the byte clock frequency dsi_clk greater than 52 MHz, when performing BTA transactions.

22.5.17.3 BTA – Response Time Parameter

When a peripheral receives a READ Request, it is expected that a Bus Turn Around will immediately follow to extend support for the display device that cannot handle the request immediately after the Read request is issued.

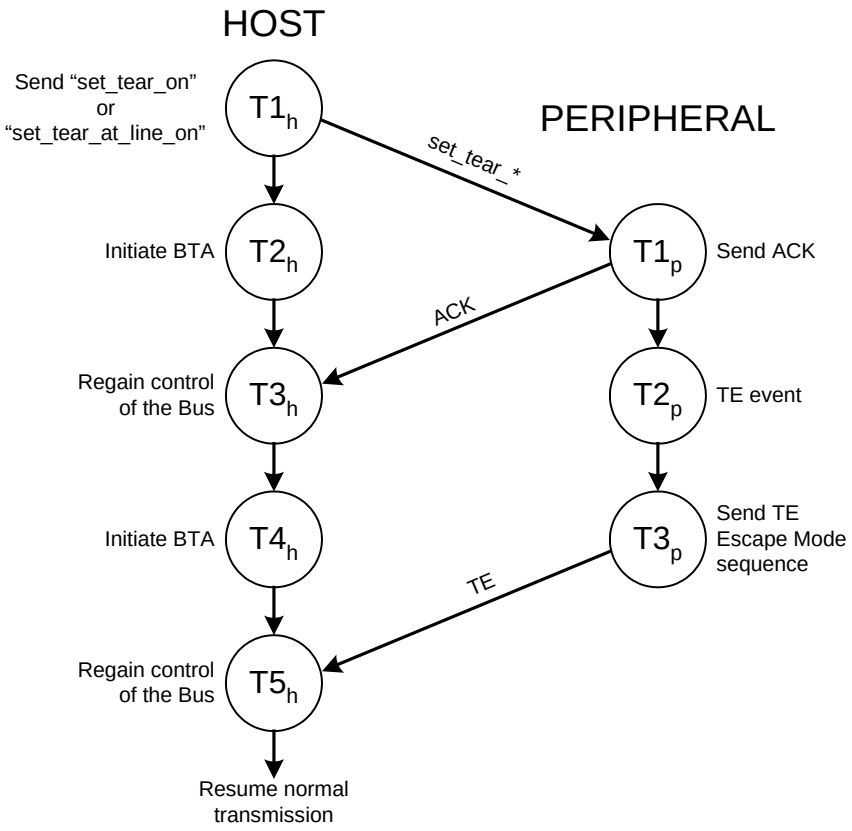
The DSI_DSI_BTA_TIMING_0 register defines DSI_TPKTBTA to allow a programmable delay between the end of host transmission and generation of BTA request for extending support for the display devices with slow response.

Note: Valid programmable values for all the DSI_DSI_BTA_TIMING_0 register fields (DSI_TTAGO/DSI_TTASURE/DSI_TTAGET/DSI_TPKTBTA) are 0 to 254. Invalid value is 255.

22.5.18 Tearing Effect

In order to synchronize the update of a Command Mode display with data from the Host, a signal from the display can be sent to indicate when it is safe to proceed with the transmission of new data. This is the Tearing Effect reporting signal. Refer to section 8.12 “TE Signaling in DSI” of the DSI specification for more details.

Figure 80: Tearing Effect State Transition Diagram



Programmatically, this is achieved in the following way:

1. Send SET_TEAR_ON or SET_TEAR_AT_LINE_ON command with the PKT_BTA field in the HOST_DSI_CONTROL register set to ENABLE. This is state T1h.
2. Wait for ACK to come back from the peripheral. This is states T2h and T3h.
3. Set the IMM_BTA field in the HOST_DSI_CONTROL register set to ENABLE. This will cause the D-PHY to go into BTA without having to send a command first. This is state T4h.
4. Wait for TE return byte from the peripheral. This is state T5h.

22.5.19 Pad Calibration Programming

- Configure the MIPI calibration clock to operate at 72 MHz via programming the register CLK_RST_CONTROLLER_PLLP_BASE_0 register.
- Enable the mipi calibration clock via Set CLK_ENB_MIPI_CAL to 1.
- Release reset to mipi_cal logic by deasserting SWR_MIPI_CAL_RST to 0
- Configure the DSI pad/Bias pads to appropriate values

  DSI_PAD_CONTROL_3_0= 0x0

DSI_PAD_CONTROL_4_0 = 0x0

MIPI_CAL_MIPI_BIAS_PAD_CFG0_0 = 0x0;

MIPI_CAL_MIPI_BIAS_PAD_CFG1_0 = 0x00020000

MIPI_CAL_MIPI_BIAS_PAD_CFG2_0 = 0x00000000

- Configure MIPI calibration settings for DSI pads for setup MIPI_CAL_DSI* _MIPI_CAL_CONFIG [*SELDSI*/ *OVERIDEDSI*/ *HSPDOSDSI*/ *HSPUOSDSI*/ *TERMOSDSI*].

  MIPI_CAL_DSI*_MIPI_CAL_CONFIG_0

- Enable all the DSI lanes that require calibration driving LP_11 state.
- MIPI calibration start via - MIPI_CAL_MIPI_CAL_CTRL_0[MIPI_CAL_STARTCAL]
- Monitor the status via MIPI_CAL_CIL_MIPI_CAL_STATUS_0[*].

22.5.20 Error Reporting

There is no actual error recovery circuitry in the hardware, only error reporting. Any error that is reported via a protocol-level packet will be processed like all other return data and will be written to the data return FIFO for processing by the Host / Software.

Low level hardware errors such as bus contention will not be flagged, but will increment counters that can be queried by software so as to determine the reliability of the link.

22.5.20.1 Acknowledge with Error Report

The peripheral device (display) can be instructed to return an error report along with an acknowledge at the end of a transmission sequence. This is achieved by setting the PKT_BTA field in the HOST_DSI_CONTROL register to ENABLE. When this is done, there are several outcomes as shown in Table 98.

Table 98: Peripheral Response to Various Conditions

Condition	Non-Read Packet	Read Packet
No error	ACK	Read Data
Corrected single bit error	ACK with ERR	Read Data + ACK with ERR
Non-corrected multi-bit error	ACK with ERR	ACK with ERR
SOT, EOT, VI ID or other D-PHY error	ACK with ERR	ACK with ERR

It is the responsibility of software to read this data from the packet returned in the packet return FIFO and process as required. No action will be taken by the hardware based on the error report returned in the ACK packet.

ACK Return

If a BTA request is enabled and there is no error, then the peripheral will return an ACK trigger to the DSI hardware. This single byte trigger has the value 0x84. Since the return FIFO is 32 bits wide, the 0x84 value will be placed in the bottom 8 bits of the FIFO.

Read Data

If a read command packet is sent, then BTA request should be enabled to allow the peripheral to return the read data. If no error occurs in the transmission of the read packet, or a corrected single bit error occurs, then the read data will be returned to the host DSI hardware in the form of a read packet. The precise form will depend on the type of read packet transmitted. Refer to the MIPI DSI specification, section 8.10 for details.

If a corrected error occurs during the transmission of the read command, the requested read data will be returned in the normal way, but an ACK with Error report packet will be appended to the read return data packet.

ACK with Error Report

The error report is contained in the 16 payload bits of a special short packet returned by the peripheral. The bits allocations of the packet data are detailed in section 8.9.5 of the MIPI DSI specification but are repeated here for convenience.

Table 99: Error Report Bit Assignments

Bit	Description
0	SOT error
1	SOT sync error
2	EOT sync error
3	Escape Mode Entry Command error
4	Low-Power Transmit Sync Error
5	HS Receive Timeout error
6	False Control Error
7	RESERVED
8	ECC Error, single bit (corrected)
9	ECC Error, multi-bit (not corrected)
10	CS Error (long packet only)
11	DSI data type not recognized
12	DSI Virtual Channel ID invalid
13	RESERVED
14	RESERVED
15	RESERVED

22.5.21 Time Outs

There are three compulsory and one optional time out counters required by the MIPI DSI specification for Processors (display controller). Each timer will consist of a simple counter which will count DSI byte clocks. The counters will reset to 0 on an event and will then simply increment their count every DSI byte clock cycle. If the event that the time out is protecting occurs before the time out reaches its terminal count, the counter will simply stop counting and hold its value. If the counter reaches software programmed maximum count before the expected event occurs, the counter will stop counting and hold its count value. Any action that is required by the MIPI DSI specification upon reaching the time out will also be performed by the hardware.

Table 100: Time-out Counter Summary

Time Out Name	Abbreviation	Start Condition	Length Greater Than	Action
HS Transmit TO	HTX_TO	SOT	Longest HS sequence	EOT + LP-11
LP Receive TO	LRXH_TO	LP Rx start	LTXP_TO (on periph.)	LP-11
Turn Around TO	TA_TO	BTA start	BTA response time	LP-11
Peripheral Reset	PR_TO	Reset Entry CMD	Peripheral resp. time	None.

In the table, the Peripheral Reset time out is the only timer that is optional. All the other timers are required by the MIPI DSI specification. Note that under “Action”, the listed operations are forced on the interface by the D-PHY under the instruction of the protocol layer (hardware). In the case of the optional Peripheral Reset time out, there is no action since this time out simply

exists to issue a reset to the peripheral. Once the reset command is issued, the only further action required is to wait for an appropriate length of time to allow the peripheral to go through its reset sequence.

In the case of the HTX_TO, LRXH_TO and TA_TO time outs, the reaching of a terminal count will not only cause the action as listed in Table 100, but will also cause a tally counter to increment so that software can read the register and determine if any of the time outs have occurred. Software will be able to reset these tally counters to 0 by writing to the tally register. The value written will be irrelevant. The PR_TO will report its operation in a different manner. When the PR_TO counter is actually counting, there will be a status bit that reads as '0'. When the PR_TO terminal count is reached and time out ends, the status bit will become '1'. This will allow software to determine when the peripheral has been reset.

Table 101: Time Out and Tally Registers

Register	Field	Description
DSI_TIMEOUT_0	HTX_TO	High Speed Transmit time out duration
	LRXH_TO	Low Power Receive time out duration
DSI_TIMEOUT_1	TA_TO	Turn Around time out duration
	PR_TO	Peripheral Reset duration
DSI_TO_TALLY	HTX_TALLY	High Speed Transmit time out Tally
	LRXH_TALLY	Low Power Receive time out Tally
	TA_TALLY	Turn Around time out Tally
	P_RESET_STATUS	Peripheral Reset Status: 0= Reset, 1 = Ready

22.6 MIPI-DSI Registers

Refer to "Reading Register Tables" in the Introduction section for the register table protocol as well as recommendations for accessing registers.

22.6.1 DSI_INCR_SYNCPT_0

Offset: 0x0 | Byte Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = COND_4 5 = COND_5 6 = COND_6 7 = COND_7 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15 16 = COND_16 17 = COND_17 18 = COND_18 19 = COND_19 20 = COND_20 21 = COND_21 22 = COND_22 23 = COND_23 24 = COND_24

Bit	Reset	Description
		25 = COND_25 26 = COND_26 27 = COND_27 28 = COND_28 29 = COND_29 30 = COND_30 31 = COND_31
7:0	0x0	INDX: syncpt index value

22.6.2 DSI_INCR_SYNCPT_CNTRL_0

Offset: 0x1 | Byte Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxxx0)

Bit	Reset	Description
8	0x0	INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal states of the client syncpt block will be reset. To do a soft reset, first set SOFT_RESET of all affected Host1x clients, then clear all SOFT_RESETs.

22.6.3 DSI_INCR_SYNCPT_ERROR_0

Offset: 0x2 | Byte Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

22.6.4 DSI_CTXSW_0

Context switch register. Should be common to all modules. Includes the current channel/class (which is writable by software) and the next channel/class (which the hardware sets when it receives a context switch).

Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS (see vmod/chexample). Software sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be pre-loaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module, and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts.

Another way to avoid context switch interrupts is to set the AUTO_ACK bit. This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 0x8 | Byte Offset: 0x20 | Read/Write: R/W | Reset: 0xf000f800 (0bxxxxxxxxxxxxxxxx11111x0000000000)

Bit	R/W	Reset	Description
31:28	RO	X	NEXT_CHANNEL: Next requested channel
25:16	RO	X	NEXT_CLASS: Next requested class

Bit	R/W	Reset	Description
15:12	RW	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	RW	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests 0 = MANUAL 1 = AUTOACK
9:0	RW	0x0	CURR_CLASS: Current working class

Note: **PACKET DEFINITIONS**

Packet for Display Controller -> DSI communication:

Line Type is used to convey the type of video line from the display controller to the DSI block. The line type implies the generation of one of the associated packet sequences as defined in the DSI packet sequence registers (see below). Used to construct packet headers. All packet headers are now 32-bits wide regardless of whether they are short or long packets. Used for validation infrastructure only.

22.6.5 DSI_DSI_RD_DATA_0

DSI Read Return Data

Offset: 0x9 │ Byte Offset: 0x24 │ Read/Write: RO │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_RD_DATA: Each read to this register will pop 32 bits from the 32-bit wide read return data FIFO. The FIFO has NV_DSI_HOST_DATA_RETURN_FIFO_DEPTH entries.

22.6.6 DSI_DSI_WR_DATA_0

Host FIFO Write Input

Offset: 0xa │ Byte Offset: 0x28 │ Read/Write: R/W │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_WR_DATA: Each write to this register will push 32 bits into the 32-bit wide Host data FIFO. FIFO has NV_DSI_HOST_DATA_FIFO_DEPTH entries

22.6.7 DSI_DSI_POWER_CONTROL_0

Display Power Control

DSI Enable

Offset: 0xb │ Byte Offset: 0x2c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	LEG_DSI_ENABLE: DSI interface Enable 0 = DISABLE : Disable DSI 1 = ENABLE : Enable DSI

22.6.8 DSI_INT_ENABLE_0

Interrupt Enable Register

Offset: 0xc │ Byte Offset: 0x30 │ Read/Write: R/W │ Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1)

Bit	Reset	Description
0	0x1	CTXSW_INT_ENABLE: Context Switch Interrupt Enable 0 = DISABLE : interrupt disabled 1 = ENABLE : interrupt enabled

22.6.9 DSI_INT_STATUS_0

Interrupt Status Register

Offset: 0xd │ Byte Offset: 0x34 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CTXSW_INT: Context switch interrupt status (clear on write)

22.6.10 DSI_INT_MASK_0

Interrupt Mask

Setting bits in this register mask the corresponding interrupt but does not clear a pending interrupt and does not prevent a pending interrupt to be generated. Masking an interrupt also does not clear a pending interrupt status and does not prevent a pending interrupt status to be generated.

Offset: 0xe │ Byte Offset: 0x38 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CTXSW_INT_MASK: Context Switch Interrupt Mask 0 = MASKED : interrupt masked 1 = NOTMASKED : interrupt not masked

22.6.11 DSI_HOST_DSI_CONTROL_0

DSI Control Register When Input is from HOST

Offset: 0xf │ Byte Offset: 0x3c │ Read/Write: R/W │ Reset: 0x00000043 (0bxxxxxxxxxx00x000xx00xx0001000011)

Bit	Reset	Description
21	0x0	FIFO_STAT_RESET: write only bit to clear FIFO underflow/overflow flags. If a new underflow/overflow event occurs during the same time, current access cannot clear the status bits
20	0x0	CRC_RESET: Write only bit. When written with a 1, causes the Verification CRC generator to reset to 0xFFFF_FFFF. If written with 0, it has no effect.
18:16	0x0	DSI_PHY_CLK_DIV: Phy clock divider value for byte clock 0 = DIV1 1 = DIV2
13:12	0x0	HOST_TX_TRIG_SRC: Controls the source of the trigger to start sending packets. 0 = SOL : Start of Line signal from the Display Controller. 1 = FIFO_LEVEL : How full the FIFO is. Level determined elsewhere. 2 = IMMEDIATE : Determined by a write to the DSI_HOST_TRIGGER field of the DSI_TRIGGER register
9:8	0x0	DSI_ULTRA_LOW_POWER: Ultra Low Power 0 = NORMAL 1 = ENTER_ULPM 2 = EXIT_ULPM
7	0x0	PERIPH_RESET: Initiate an Escape Mode Peripheral Reset. 0 = DISABLE : Causes an Escape Mode Command to be sent to reset the 1 = ENABLE : External display device. Also starts the PR_TO counter. PR_TO state can

Bit	Reset	Description
		be checked with the P_RESET_STATUS field in the DSI_TO_TALLY register. Hardware clears this bit upon completion of issuing "Trigger Reset" OR called "Reset Entry" command is sent out.
6	0x1	RAW_DATA: Host raw data mode. In this mode. All data is sent exactly as written. No attempt to decode packet headers is made. This bit will also override the function of the ECC and CS ENABLE fields. No ECC or CS will be generated. This mode is intended as a debug / diagnostic workaround mode only. 0 = DISABLE : Normal mode. 1 = ENABLE : Enable raw data transmission.
5	0x0	DSI_HIGH_SPEED_TRANS: DSI high speed transmission of packets 0 = LOW : Low speed - Note: Unlikely ever to be used. 1 = HIGH : High speed
4	0x0	PKT_WR_FIFO_SEL: Host Write FIFO Select. In video mode, software shall not program PKT_WR_FIFO_SEL=VIDEO. 0 = HOST : Write data to the small host data FIFO only. 1 = VIDEO : Write data to both the host and video line store FIFO, in series. Note: Software shall only program PKT_WR_FIFO_SEL field in Host mode.
3	0x0	IMM_BTA: Generate BTA immediately, e.g., for Tearing Effect reporting. Note: This will generate a BTA and pass control of the D-PHY to the remote peripheral without the need to send any packet. Once the BTA is initiated on interface this bit gets cleared. Later on Host syncpt opdone is returned when the remote peripheral has responded and relinquished control of the bus. 0 = DISABLE : Do not generate BTA 1 = ENABLE : Generate BTA immediately, without waiting for a packet.
2	0x0	PKT_BTA: Generate BTA at the end of Host packets 0 = DISABLE : Do not generate BTA 1 = ENABLE : Generate BTA after the next packet is sent.
1	0x1	CS_ENABLE: enable Hardware Check Sum (CS) for Host packets Note: when CS is disabled, Host is responsible for generating proper CRC and adding the 2-byte CRC to the end of the packet after the payload. 0 = DISABLE : Disable hardware generation of CS (Host must calculate CS). 1 = ENABLE : Enable hardware generation of CS.
0	0x1	ECC_ENABLE: Enable hardware Error Correction Code (ECC) for Host packets Note: when ECC is disabled, Host is responsible for generating proper ECC byte for header 0 = DISABLE : Disable hardware generation of ECC (Host must calculate ECC). 1 = ENABLE : Enable hardware generation of ECC.

22.6.12 DSI_DSI_CONTROL_0

General DSI Control Register

Offset: 0x10 │ Byte Offset: 0x40 │ Read/Write: R/W │ Reset: 0x00000000 (0b00xxxxxxxxx0xx00xx00xx00xx000000)

Bit	Reset	Description
31	0x0	DSI_DBG_ENABLE: Control signal to turn off clock monitoring when enabled for debug, on every DSI byte clock debug signal toggle. Also TX CRC computation aid will turn on.
30	0x0	DFMT_16BPP_SWAP_EN: DSI specification supports different bit ordering (only 16 BPP) in command mode. Command Mode (Default) : 16BPP[15:0] -> B[4-0]G[5-0]R[4-0]; Command Mode (SWAP_EN) : 16BPP[15:0] -> G[2-0]B[4-0]R[4-0]G[5-3]
20	0x0	DSI_HS_CLK_CTRL: Control for the HS clock lane 0 = CONTINUOUS : HS clock is on all the time. 1 = TX_ONLY : HS clock is only active during HS transmissions.
17:16	0x0	DSI_VIRTUAL_CHANNEL: Virtual channel ID. The virtual channel is sent as part of the packet header and used to distinguish multiple displays.

Bit	Reset	Description
13:12	0x0	DSI_DATA_FORMAT: Pixel Data format transmitted. Note that although the pixel format is specified in the packet header ID for RGB data packets, this information is ignored by the hardware. Only the information used in this register is used in the construction of RGB data packets. 0 = BIT16P : 16 bpp RGB Packed. 2 bytes used per pixel 1 = BIT18NP : 18 bpp RGB Not-packed. 3 bytes used per pixel 2 = BIT18P : 18 bpp RGB Packed. 2.25 bytes used per pixel 3 = BIT24P : 24 bpp RGB Packed. 3 bytes used per pixel
9:8	0x0	VID_TX_TRIG_SRC: Controls the source of the trigger to start sending packets. 0 = SOL : Start of Line signal from the Display Controller. 1 = FIFO_LEVEL : How full the FIFO is. Level determined elsewhere. 2 = IMMEDIATE : Determined by a write to the DSI_VID_TRIGGER field of the DSI_TRIGGER register
5:4	0x0	DSI_NUM_DATA_LANES: Number of D-PHY data lanes used by Display for HS transmission. 0 = ONE : 1 data lane. 1 = TWO : 2 data lanes. 2 = THREE : 3 data lanes. 3 = FOUR : 4 data lanes.
3	0x0	VID_DCS_ENABLE: Enable for insertion of DCS commands during Display Controller generated packets. When enabled, the DCS commands defined in the LT3_DCS_CMD and LT5_DCS_CMD fields of the DSI_DCS_CMDS register will be inserted in long packets defined in packet sequence 3 and 5. 0 = DISABLE : No DCS commands will be inserted. 1 = ENABLE : DCS command IDs will be inserted as described above.
2	0x0	DSI_VID_SOURCE: Source of video pixels 0 = DISPLAY_0 : Pixels come from "display" 1 = DISPLAY_1 : Pixels come from "displayb"
1	0x0	DSI_VID_ENABLE: Video DSI Interface Enable 0 = DISABLE : Disable 1 = ENABLE : Enable
0	0x0	DSI_HOST_ENABLE: Host DSI Interface Enable 0 = DISABLE : Disable 1 = ENABLE : Enable

22.6.13 DSI_DSI_SOL_DELAY_0

Number of Byte-Clock Counts to Wait after Reception

Offset: 0x11 | Byte Offset: 0x44 | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	SOL_DELAY: Start Of Line before generating output packets.

22.6.14 DSI_DSI_MAX_THRESHOLD_0

Maximum Threshold Registers for DSI Related Packets

Offset: 0x12 | Byte Offset: 0x48 | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	MAX_THRESHOLD: Start draining FIFO once this threshold is met. This register can be used for DBI mode when line packet data exceeds the size of the data FIFO.

22.6.15 DSI_DSI_TRIGGER_0

Manual Transmission Trigger Register

Offset: 0x13 | Byte Offset: 0x4c | Read/Write: R/W | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
1	X	DSI_HOST_TRIGGER: A 1 written to this bit will start host transmission when HOST_DSI_CONTROL.HOST_TX_TRIG_SRC is set to IMMEDIATE. Hardware auto clears on operation completion
0	X	DSI_VID_TRIGGER: A 1 written to this bit will start video transmission when DSI_CONTROL.VID_TX_TRIG_SRC is set to IMMEDIATE. Hardware auto clears on operation completion

22.6.16 DSI_DSI_TX_CRC_0

Transmission CRC

Offset: 0x14 | Byte Offset: 0x50 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	TX_CRC: Long Packet CRC appended to the end of long packets. This CRC is that result of generating a CRC from all transmitted bytes. If DSI_HOST_ENABLE == ENABLE, then a CRC is generated from all bytes transmitted from the Host interface in Command Mode. If DSI_VID_ENABLE == ENABLE, then a CRC is generated from all bytes transmitted during a frame of video when in Video Mode. Note that the hardware will capture the CRC into a separate internal register so that it can continue to calculate the CRC for the next frame without having to wait for software to read the current result.

22.6.17 DSI_DSI_STATUS_0

DSI Status Register

Offset: 0x15 | Byte Offset: 0x54 | Read/Write: RO | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
10	X	DSI_IDLE: Indicated that the DSI is IDLE.
9	X	LB_UNDERFLOW: Indicates that a Line buffer underflow event happened
8	X	LB_OVERFLOW: Indicates that a Line buffer overflow event happened
4:0	X	RD_FIFO_COUNT: Count of how many data words are left in the Host Read Data Return FIFO. Typically, software knows how much data to read from the DSI_RD_DATA register after a Read packet / BTA has been sent / requested, since these transactions are initiated by software. However, under error conditions, insufficient data may have been read from the FIFO. Software should therefore check this field to make sure it is 0 after reading all the information it expected to get.

22.7 Initialization Sequence Registers

22.7.1 DSI_DSI_INIT_SEQ_CONTROL_0

DSI Initialization Sequence Control

Offset: 0x1a | Byte Offset: 0x68 | Read/Write: R/W | Reset: 0x0000XX00 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
14:8	X	DSI_FRAME_INIT_BYTE_COUNT: Frame Initialization Sequence Byte Count. This parameter specifies the number of frame initialization sequence cycles to send. If programmed to 0, there is no frame initialization cycle generated. Valid programmable values: 0 to 64. Invalid programmable values: 65 to 127.
0	0x0	DSI_SEND_INIT_SEQUENCE: Send Initialization Sequence (IS) 0 = DISABLE 1 = ENABLE

22.7.2 DSI_DSI_INIT_SEQ_DATA_0_0

DSI Init Sequence Write Data 0

Offset: 0x1b | Byte Offset: 0x6c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_0: DSI Init Sequence Write Data bits 31:0

22.7.3 DSI_DSI_INIT_SEQ_DATA_1_0

DSI Init Sequence Write Data 1

Offset: 0x1c | Byte Offset: 0x70 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_1: DSI Init Sequence Write Data bits 31:0

22.7.4 DSI_DSI_INIT_SEQ_DATA_2_0

DSI Init Sequence Write Data 2

Offset: 0x1d | Byte Offset: 0x74 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_2: DSI Init Sequence Write Data bits 31:0

22.7.5 DSI_DSI_INIT_SEQ_DATA_3_0

DSI Init Sequence Write Data 3

Offset: 0x1e | Byte Offset: 0x78 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_3: DSI Init Sequence Write Data bits 31:0

22.7.6 DSI_DSI_INIT_SEQ_DATA_4_0

DSI Init Sequence Write Data 4

Offset: 0x1f | Byte Offset: 0x7c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_4: DSI Init Sequence Write Data bits 31:0

22.7.7 DSI_DSI_INIT_SEQ_DATA_5_0

DSI Init Sequence Write Data 5

Offset: 0x20 | Byte Offset: 0x80 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_5: DSI Init Sequence Write Data bits 31:0

22.7.9 DSI_DSI_INIT_SEQ_DATA_7_0

DSI Init Sequence Write Data 7

Offset: 0x22 | Byte Offset: 0x88 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_7: DSI Init Sequence Write Data bits 31-0

22.8 Packet Sequence Registers

These registers allow the construction of arbitrary packet sequences associated with various video line types as sent from the Display Controller to the DSI block.

The first digit of the pair of digits in each field below is the sequence number, and the second digit denotes the packet number within each sequence. For example, field PKT_23_ID, defines the ID for packet 3 in sequence 2.

22.8.1 DSI_DSI_PKT_SEQ_0_LO_0

DSI Packet Sequence 0 LO Half

Offset: 0x23 | Byte Offset: 0x8c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
30	X	SEQ_0_FORCE_LP: For packet sequence 0, forces the D-PHY to go to LP mode after the last packet of the sequence has been transmitted. 0 = DISABLE 1 = ENABLE
29	X	PKT_02_EN: Packet 2 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_02_ID: Packet 2 Packet ID
22:20	X	PKT_02_SIZE: Packet 2 size pointer
19	X	PKT_01_EN: Packet 1 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_01_ID: Packet 1 Packet ID
12:10	X	PKT_01_SIZE: Packet 1 size pointer
9	X	PKT_00_EN: Packet 0 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_00_ID: Packet 0 Packet ID
2:0	X	PKT_00_SIZE: Packet 0 size pointer

22.8.2 DSI_DSI_PKT_SEQ_0_HI_0

DSI Packet Sequence 0 HI Half

Line Type 0 is associated with the first line in the frame and should contain a packet sequence that starts with a VS packet.

Offset: 0x24 | Byte Offset: 0x90 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
29	X	PKT_05_EN: Packet 5 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_05_ID: Packet 5 Packet ID
22:20	X	PKT_05_SIZE: Packet 5 size pointer
19	X	PKT_04_EN: Packet 4 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_04_ID: Packet 4 Packet ID
12:10	X	PKT_04_SIZE: Packet 4 size pointer
9	X	PKT_03_EN: Packet 3 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_03_ID: Packet 3 Packet ID
2:0	X	PKT_03_SIZE: Packet 3 size pointer

22.8.3 DSI_DSI_PKT_SEQ_1_LO_0

DSI Packet Sequence 1 LO Half

Line Type 1 is associated with the last line of Vertical Sync and should contain a packet sequence that starts with a VE packet.

Offset: 0x25 | Byte Offset: 0x94 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
30	X	SEQ_1_FORCE_LP: For packet sequence 1, forces the D-PHY to go to LP mode after the last packet of the sequence has been transmitted. 0 = DISABLE 1 = ENABLE
29	X	PKT_12_EN: Packet 2 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_12_ID: Packet 2 Packet ID

2:0	X	PKT_53_SIZE: Packet 3 size pointer

22.9 DCS Command and Packet Length Registers

22.9.1 DSI_DSI_DCS_CMDS_0

DCS command IDs used for Line Types 3 and 5. These command IDs are inserted at the start of the data payload of DCS long packets when the Display Controller is being used to transmit DCS commands.

Offset: 0x33 | Byte Offset: 0xcc | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
15:8	X	LT5_DCS_CMD: DCS command for Line Type 5.
7:0	X	LT3_DCS_CMD: DCS command for Line Type 3.

22.9.2 DSI_DSI_PKT_LEN_0_1_0

DSI Packet Lengths 0 and 1

Offset: 0x34 | Byte Offset: 0xd0 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	LENGTH_1: Packet length 1 (in bytes)
15:0	X	LENGTH_0: Packet length 0 (in bytes)

22.9.3 DSI_DSI_PKT_LEN_2_3_0

DSI Packet Lengths 2 and 3

Offset: 0x35 | Byte Offset: 0xd4 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	LENGTH_3: Packet length 3 (in bytes)
15:0	X	LENGTH_2: Packet length 2 (in bytes)

22.9.4 DSI_DSI_PKT_LEN_4_5_0

DSI Packet Lengths 4 and 5

Offset: 0x36 | Byte Offset: 0xd8 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	LENGTH_5: Packet length 5 (in bytes)
15:0	X	LENGTH_4: Packet length 4 (in bytes)

22.9.5 DSI_DSI_PKT_LEN_6_7_0

DSI Packet Lengths 6 and 7

Offset: 0x37 | Byte Offset: 0xdc | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	LENGTH_7: Packet length 7 (in bytes)
15:0	X	LENGTH_6: Packet length 6 (in bytes)

22.10 Physical Interface Timing Registers

The DSI PHY timing registers must be initialized before the interface is enabled. Based on the equations provided in the table below, all PHY timing parameters should be programmed in the timing registers. T_{byte} refers to just the DSI controller clock.

Table 102 D-PHY Timing Values

Parameter	MIPI D-PHY Spec Value	Programmed Value
THS-PREPARE	(40 ns + 4*UI , 85 ns + 6*UI)	Min - (40 + (4 T_{bit}))) / T_{byte} Max - ((85 + 6 T_{bit})) / T_{byte}
THS-ZERO	105 ns + 6*UI min.	(105 + (6 T_{bit})) / T_{byte} -2
THS-TRAIL	max(8*UI, 60 ns + 4*UI)	3 + max(8 T_{bit}, 60 + 4 T_{bit}) / T_{byte}
THS-EXIT	100 ns min.	100 / T_{byte}
TLPX	50 ns min.	50 / T_{byte}
TCLK-ZERO	300 ns along with TCLK-PREPARE	260/ T_{byte}
TCLK-PREPARE	(38 ns, 95 ns)	THS-PREPARE timing should guarantee to meet both these timing requirements
TCLK-POST	60 ns + 52*UI min.	(60 + (52 T_{bit})) / T_{byte} - 2
TCLK-TRAIL	60 ns min.	60 / T_{byte}
TCLK-PRE	8 UI	8 T_{bit}
TTA-GO	4 * TLPX	3 * TLPX
TTA-SURE	(TLPX, 2 * TLPX)	TLPX - 1
TTA-GET	5 * TLPX	4 * TLPX
TWAKEUP	1 ms	1 ms/10 ns x 512 {in terms of 512 byte clocks}

Notes:

- T_{byte} = Period of one byte clock in nanoseconds.
- T_{bit} = Period of one bit time in nanoseconds. (T_{bit} = T_{byte} / 8)
- All figures and time periods are in nanoseconds.
- All timing register values are multiples of byte clock period, T_{byte}.
- All fractional results are truncated. No rounding.

22.10.1 DSI_DSI_PHY_TIMING_0_0

DSI D-PHY Timing Register 0

Offset: 0x3c │ Byte Offset: 0xf0 │ Read/Write: R/W │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	DSI_THSDEXIT: Time to drive LP11 after HS **Note:** Valid programmable values for all the fields in this register (i.e., DSI_THSPREPR/DSI_TDATZERO/DSI_THSTRAIL/DSI_THSDEXIT) are 0 to 254. Invalid value is 255.
23:16	X	DSI_THSTRAIL: Time to drive HS flipped bit at EOT
15:8	X	DSI_TDATZERO: Time to drive HS0 before SOT

Bit	Reset	Description
7:0	X	DSI_THSPREPR: Time to drive LP00 before HS data

22.10.2 DSI_DSI_PHY_TIMING_1_0

DSI D-PHY Timing Register 1

Offset: 0x3d | Byte Offset: 0xf4 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	DSI_TCLKTRAIL: Time to drive HS0 before the clock goes to LP1 **Note:** Valid programmable values for all the fields in this register (i.e., DSI_TTLPX/DSI_TCLKZERO/DSI_TCLKPOST/ DSI_TCLKTRAIL) are 0 to 254 Invalid value is 255.
23:16	X	DSI_TCLKPOST: Time to drive clock after the last HS data
15:8	X	DSI_TCLKZERO: Time to drive LP00 before HS clock
7:0	X	DSI_TTLPX: LP period

22.10.3 DSI_DSI_PHY_TIMING_2_0

DSI D-PHY Timing Register 2

Offset: 0x3e | Byte Offset: 0xf8 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
23:16	X	DSI_TCLKPREPARE: Time to drive LP0 before CLK_ZERO starts off on the clock lane. **Note:** Valid programmable values for the following register fields (i.e., DSI_TCLKPRE/DSI_TCLKPREPARE) are 0 to 254. Invalid value is 255
15:8	X	DSI_TCLKPRE: Time to run clock before enabling data lane
7:0	X	DSI_TWAKEUP: LP period when exiting ULPM, in units of 512 byte clocks.

22.10.4 DSI_DSI_BTA_TIMING_0

DSI D-PHY Bus-Turn-Around Timing

Offset: 0x3f | Byte Offset: 0xfc | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	DSI_TPKTBTA: Programmable Time delay between end of Host packet transmission and generation of Pkt BTA in PKT_BTA mode (i.e., HOST_DSI_CONTROL[2]) - Generate BTA at the end of Host packets **Note**: Valid programmable values for all the fields in this register (i.e., DSI_TTAGO/DSI_TTASURE/DSI_TTAGET/ DSI_TPKTBTA) are 0 to 254. Invalid value is 255.
23:16	X	DSI_TTAGET: Time to Drive LP00 at end of BTA (5 * TTLPX)
15:8	X	DSI_TTASURE: Time to Receive LP00 at end of BTA (2 * TTLPX)
7:0	X	DSI_TTAGO: Time to drive LP00 at start of BTA (4 * TTLPX)

22.11 Contention Recovery Timers

These registers control the length of time - in units of 512 DSI byte clocks – that can elapse before the hardware will decide that a bus contention error has occurred.

There are several counters to deal with various forms of error that may occur. For details, refer to the MIPI DSI Specification, section 7.2.2.

22.11.1 DSI_DSI_TIMEOUT_0_0

DSI Time Out Terminal Count Register 0

Offset: 0x44 │ Byte Offset: 0x110 │ Read/Write: R/W │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	LRXH_TO: Low Power Receive (Host) Time Out terminal count
15:0	X	HTX_TO: High Speed Transmit Time Out terminal count

22.11.2 DSI_DSI_TIMEOUT_1_0

DSI Time Out Terminal Count Register 1

Offset: 0x45 │ Byte Offset: 0x114 │ Read/Write: R/W │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	PR_TO: Peripheral Reset duration.
15:0	X	TA_TO: Turn Around Time Out terminal count

22.11.3 DSI_DSI_TO_TALLY_0

DSI Time Out Tally Register

Each time one of the time-out counters reaches its terminal count, it will increment the associated tally register.

Offset: 0x46 │ Byte Offset: 0x118 │ Read/Write: R/W │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	R/W	Reset	Description
24	RO	X	P_RESET_STATUS: Peripheral Reset time out status 0 = IN_RESET 1 = READY
23:16	RW	X	TA_TALLY: Turn Around time out tally
15:8	RW	X	LRXH_TALLY: LP Rx time out tally
7:0	RW	X	HTX_TALLY: HS Tx time out tally

22.12 Physical Pad Control Registers

22.12.1 DSI_PAD_CONTROL_0

DSI PHY Configuration Register

Software can program this register to work with different panels.

Offset: 0x4b │ Byte Offset: 0x12c │ Read/Write: R/W │ Reset: 0x010f010f (0bxxxxxxx1xxxx1111xxxxxxx1xxxx1111)

Bit	Reset	Description
24	0x1	DSI_PAD_PULLDN_CLK_ENAB:1= Enable pad pulldown for clock bit at power on
19:16	0xf	DSI_PAD_PULLDN_ENAB:1= Enable pad pulldown for data bits at power on
8	0x1	DSI_PAD_PDIO_CLK: Power down for clock bit, drivers, receivers, and contention detectors
3:0	0xf	DSI_PAD_PDIO: Power down for data bit, drivers, receivers, and contention detectors

22.12.2 DSI_PAD_CONTROL_CD_0

Contention Detection Logic Enable Signals

Offset: 0x4c │ Byte Offset: 0x130 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxx000xxxxxxx0xxxx0000)

Bit	Reset	Description
18:16	0x0	DSI_PAD_CDDNADJ: Level adjust on low limit of detection. Tie to 0 (DSI emu, miniTMC control). 000 = 0.3V 001 = 0.375V 010 = 0.45V 011 = 0.525V 100 = 0.3V 101 = 0.225V 110 = 0.15V 111 = 0.075V

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_15: DSI Init Sequence Write Data bits 31:0

23.0 HIGH-DEFINITION MULTIMEDIA INTERFACE

The High-Definition Multimedia Interface (HDMI) receives pixels from the Display Controller and audio from the HDA. It combines and transmits them together.

23.1 Features

- HARDWARE_N feature enabled
- TMDS I/O macro with controls
- Interlaced video format support
- YUV444 output (BT.601 and BT.709 formats)
- HDMI in power-gated partition SOR
- Display CMU, allowing color management
- Output range scaling for RGB
- Vendor-specific infoframe supported
- Audio features for HD audio include:
    - 2, 6, or 8 channels of LPCM (i.e., uncompressed linear PCM)
    - 16, 20, or 24 bits per sample
    - 32, 44.1, 48, 88.2, 96, 176.4, 192 K samples/second

23.2 Programming Guidelines

The overall sequence to start up HDMI is:

- Program power, pin mux, clocks, resets, etc.
- Copy HDCP keys from KFUSE to HDMI
- Program display timing registers, etc.
- Program HDMI registers and Serial Output Resource (SOR) sequencer
- Start HDMI SOR
- Start display

Since audio is entirely asynchronous to HDMI or the display, the HDA module can be started any time.

23.2.1 Power

Turn on the necessary power supplies (these need to be enabled in the PMIC via I^2C):

- AVDD_HDMI_PLL
- AVDD_HDMI
- Onboard 5V for DDC/HDMI_INT/CEC

Set HDMI I/O logic to exit deep power down mode: make sure the HDMI bit in the APBDEV_PMC_IO_DPD_STATUS_0 register and the HV bit in the APBDEV_PMC_IO_DPD2_STATUS_0 register were cleared (see the registers in the PMC section).

23.2.2 DDC / I2C

DDC I^2C is used for E-EDID reading, HDCP, and other communication with downstream HDMI device. I^2C has no connection to HDMI block; the platform defines which I^2C engine is connected to the DDC.

23.2.3 Hot Plug

HDMI_INT is a pad that feeds the GPIO block and the PMC. It has no connection to the HDMI block. It operates as a general-purpose I/O pin.

23.2.4 Clocks

HDMI uses two main clocks:

- hdmi_clk: variable from 25.2 MHz to 300 MHz based on the video pixel rate. The frequency and source must be identical to the display's pixel clock. (i.e., display and HDMI clocks are isochronous).
- hda2hdmi_bitclk: fixed 24 MHz HD Audio bit clock. Same source as HDA Controller's bitclk. The HDA Controller clock enable should not affect it.

And three others:

- display2hdmi_pclk and displayb2hdmi_pclk: Copy of display pixel clocks for display2hdmi and displayb2hdmi pixel buses. Only used to write display data into FIFOs.
- host1x2hdmi_clk: Copy of host1x clock for host interface; only used to write host1x transactions into the FIFO.

All three main clocks have common first-level gate: the CAR CLK_ENB_HDMI register. hdmi_audio_clk has a second level gate controlled by hardware, which is gated.

The display controllers and HDMI have separate clock source registers. However, they must be programmed to the same source and the same frequency. Typical settings for a 13 MHz oscillator using PLLD are listed in the following table:

Pixel Clk (MHz)	PLLD Frequency	PLL M	PLL N	HDMI_ CLK_ DIVISOR	Display SHIFT_ CLK_ DIVIDER	HDMI_CLK_SRC	DISP1_CLK_SRC
27	216/2	13	216	0x6 (/4)	0x6 (/4)	PLLD_OUT0	PLLD_OUT0
74.25	594/2	13	594	0x6 (/4)	0x6 (/4)	PLLD_OUT0	PLLD_OUT0
148.5	594/2	13	594	0x2 (/2)	0x2 (/2)	PLLD_OUT0	PLLD_OUT0
297	594/2	13	594	0x0 (/1)	0x0 (/1)	PLLD2_OUT0	PLLD2_OUT0

In addition, the HDA module must use the same oscillator as display and HDMI, since audio and video clock frequencies must be a fixed, known ratio. For HDA Audio, HDA2CODEC_2X clock must be enabled and configured for 48 MHz.

23.2.5 Display Timing

Frame timing is controlled by the display. HDMI has certain requirements, however, imposed by both the module itself and the HDMI standards.

HDMI gets the following signals from the display:

- h_blank – derived in hardware from h_ref_to_sync, h_sync_width, h_back_porch, h_disp_active, h_front_porch
- v_blank – derived in hardware from v_ref_to_sync, v_sync_width, v_back_porch, v_disp_active, v_front_porch
- h_sync – derived from h_ref_to_sync, h_sync_width
- v_sync – derived from v_ref_to_sync, v_sync_width
- video_preamble – derived from h_pulse2_control, h_pulse2_position.

EIA (CEA-861-B) Formats	ref_to_sync	sync_width	back_porch	disp_active	front_porch
480P_60 (2,3)					
horizontal	1	62	60	720	16
vertical	1	6	30	480	9
720P_60 (4)					
horizontal	1	40	220	1280	110
vertical	1	5	20	720	5
720P_50 (19)					
horizontal	1	40	220	1280	440
vertical	1	5	20	720	5
640x480_60 (1)					
horizontal	1	96	48	640	16
vertical	1	2	33	480	10
576p_50 (17/18)					
horizontal	1	64	68	720	12
vertical	1	5	39	576	5
1080p_60 (16)					
horizontal	1	44	148	1920	88
vertical	1	5	36	1080	4
2160p_30					
horizontal	1	88	296	3840	176
vertical	1	10	72	2160	8
1080i_60 (5)					
horizontal	1	44	148	1920	88
vertical	1	5	15	540	2

The video_preamble uses h_pulse2, with the following settings:

disp_signal_options0.h_pulse2_enable	ENABLE
h_pulse2_control.h_pulse2_mode	NORMAL
h_pulse2_control.h_pulse2_polarity	HIGH
h_pulse2_control.h_pulse2_v_qual	VACTIVE
h_pulse2_control.h_pulse2_last_end	END_A
h_pulse2_position.h_pulse2_start_a	h_ref_to_sync + h_sync_width + h_back_porch - 10
h_pulse2_position.h_pulse2_end_a	h_pulse2_start_a + 8

Miscellaneous registers required:

DISP_TIMING_OPTIONS.VSYNC_H_POSITION	1
DISP_CLOCK_CONTROL.PIXEL_CLK_DIVIDER	PCD1
DISP_COLOR_CONTROL.DITHER_CONTROL	DISABLE
DISP_WIN_OPTIONS.HDMI_ENABLE	ENABLE

23.2.6 Display Datapath

23.2.6.1 Dither

Dithering should be disabled, since HDMI uses a full 8 bits per component.

23.2.6.2 Component Range

For most HDMI resolutions (i.e., everything except VGA 640x480), R/G/B should be scaled to lie in the [16, 235] nominal range; See the HDMI specification, section 6.6. The range scaling can be done in either of two places. For Tegra® 4 and Tegra 4i processor compatibility; CMU is recommended. For Tegra K1 code, CSC2 is recommended.

1. In the CMU block:

```
proc cmu_lut1_flt2fix {flt} {
    set fx [expr floor($flt * 4095.0 + 0.5)]
    if {$fx > 4095} {
        error "cmu_lut1_flt2fix out of range input $flt"
    }
    return $fx
}
proc cmu_lut2_flt2fix {flt} {
    set fx [expr floor($flt * 255.0 + 0.5)]
    if {$fx > 255} {
        error "cmu_lut1_flt2fix out of range input $flt"
    }
    return $fx
}
proc srgb_ungamma {x args} {
    if {$x <= 0.03928} {
        set y [expr $x/12.92]
    } else {
        set y [expr pow(($x + 0.055)/1.055, 2.4)]
    }
    return [cmu_lut1_flt2fix $y]
}
proc rec709_gamma_offset16 {x args} {
    if {$x <= 0.018} {
        set y [expr $x * 4.5]
    } else {
        set y [expr 1.099 * pow($x, 0.45) - 0.099]
    }
    set lut2 [expr 16 + [cmu_lut2_flt2fix $y]]
    return [expr min(255, max($lut2, 0))]
}

#
# program CMU to convert to limited-range RGB with Rec. 709 gamma.
# Display pipe should be using full-range RGB.
# [0..255] is mapped to [16,235].
# NOTE: sRGB primaries and whitebpoint are same as 709, so matrix is just scale.
# We could do everything in LUT as well.
#
proc cmu_to_rec709_rgb219 {} {
    set scale [expr 219.0 / 255.0]
    set mat "
```

```
        $scale 0.0    0.0    \
        0.0    $scale 0.0    \
        0.0    0.0    $scale \
    "
    cmu_lut1 srgb_ungamma
    cmu_csc $mat
    cmu_lut2 rec709_gamma_offset16
    DISP_COLOR_CONTROL.CMU_ENABLE ENABLE
}
```

2. In the CSC2 block:

```
CSC2_CONTROL.OUTPUT_COLOR_SELECT = RGB
CSC2_CONTROL.LIMIT_RGB_COLOR = ENABLE
```

For most HDMI modes, pixel values 0 and 255 must be removed; HDMI's NV_PDISP_INPUT_CONTROL.ARM_VIDEO_RANGE = LIMITED enables this.

23.2.6.3 Gamma

Most content uses sRGB gamma which is not quite the same as Rec. 709 gamma used by HDMI for most modes. Post-composite gamma can be changed in the CMU. The above code illustrates these.HDMI basics.

23.2.7 HDMI Basics

- Select display a/b source with NV_PDISP_HDMI_SRC_SELECT
- If appropriate to the platform, program HDCP timing dividers, based on the HDMI pixel clock. For Tegra K1 platforms, ROM I^2C clock frequency should be 200 KHz.
- Program SOR reference clock, based on the HDMI pixel clock – see the NV_PDISP_SOR_REFCLK register description in this section. For example,

```
dispclk_div_8_2 = int(dispclk_freq / 1000000.0 * 4)
NV_PDISP_SOR_REFCLK.DIV_INT = dispclk_div_8_2 >> 2
NV_PDISP_SOR_REFCLK.DIV_FRAC = dispclk_div_8_2 & 0x3
```

- Program SOR sequences for power up and power down.

23.2.8 TMDS Macro Configuration

The table below provides register values for various modes. Registers not listed should use their initial (reset) values.

HDMI Register	480p (27 MHz)	720p (74.25 MHz)	1080p (148.5 MHz)	1080i (74.25 MHz)	2160p (297 MHz)
HDMI_NV_PDISP_SOR_PLL0_0	0x01003010	0x01003110	0x01003310	0x01003110	0x01003F10
HDMI_NV_PDISP_SOR_PLL1_0	0x00301B00	0x00301500	0x00301500	0x00301500	0x00300F00
HDMI_NV_PDISP_SOR_LANE_DRIVE_CURRENT_0	0x1F1F1F1F	0x2C2C2C2C	0x33333333	0x2C2C2C2C	0x37373737
HDMI_NV_PDISP_PE_CURRENT_0	0x00000000	0x00000000	0x00000000	0x00000000	0x00000000
HDMI_NV_PDISP_SOR_IO_PEAK_CURRENT_0	0x03030303	0x07070707	0x0C0C0C0C	0x07070707	0x17171717
HDMI_NV_PDISP_SOR_PAD_CTLS0_0	0x800034BB	0x800034BB	0x800034BB	0x800034BB	0x800036BB
CLK_RST_CONTROLLER_PLLD_MISC_0	0x40400820	0x40400820	0x40400820	0x40400820	0x40400F20

Note: NV_PDISP_SOR_LANE_DRIVE_CURRENT. LANE0..3 are only used if NV_PDISP_SOR_LANE_DRIVE_CURRENT.FUSE_OVERRIDE is TRUE. HDMI TMDS calibration can be performed and burned into fuses, but are not currently.

23.2.9 HDA Controller Initialization

Basic operations:

- HDA IPFS initialization, FPCI and HDA configuration, and memory spaces allocated
- Deassert soft reset, bring up link. AZA.GCTL.CRST = DEASSERT, and wait for reset completion by spinning until CRST = DEASSERT. Wait 4 frame times (poll AZA.WALCLK for 2000 ticks to elapse)
- Verify internal codec (and external if desired) have been detected by reading AZA.WAKEEN.SDIWAKE3 for internal codec, and SDIWAKE1 for external.

23.2.10 HDA Audio Codec Initialization

When HDA is the audio source, the codec must be initialized before audio can flow. The internal codec uses industry-standard verbs, so in theory, the out-of-box driver should correctly discover and configure the codec. See the HD Audio specification. Below is a summary of the necessary verbs:

1. AOC widget: SET_CONV_STREAM_CHAN with desired output stream ID
2. AOC widget: SET_CONV_FMT to desired audio format (sampling frequency, sample depth, number of channels)
3. AOC widget: SET_DIGITAL_CONV_CONTROL1
   - Bit 0: 1 (DigEn=1)
   - Bit 3..6: channel status pre/copy/audio/pro bits
   - Bit 7: channel status CC bit 7 (called GEN_LEVEL)
4. AOC widget: SET_DIGITAL_CONV_CONTROL2:
   - Bit 6:0: channel status CC bits 6:0
5. Pin widget: SET_CONVERTER_CHANNEL_TO_DIGITAL_SLOT_MAPPING= 0x22 and SET_CONVERTER_CHANNEL_TO_DIGITAL_SLOT_MAPPING= 0x33 to undo default swap of channels 2 and 3
6. AOC widget: SET_STRIPE_CONTROL to select number of lanes. Recommend programming to 2 lanes all the time.
7. Pin widget: SET_PIN_WIDGET_CTRL = 0x40, to enable output and use PCM packets.
8. If desired to use HDA for info packets, program them with SET_DIP_INDEX/SET_DIP_DATA and enable with SET_DIP_XMIT_CTRL.

23.2.11 HDMI Audio

Two methods of generating the CTS portion of ACR packets are supported:

- In “Force SW CTS”, software computes CTS for the current audio and pixel clocks and writes it to registers.
- In “Hardware CTS”, hardware computes CTS automatically.

Likewise, two methods for generating N portion are supported.

- In “SW N”, software programs current desired N into 0441_SUBPACK_HIGH register and AUDIO_N.VALUE.
- In “HW N”, software programs all the ACR_*_SUBPACK_HIGH per-frequency N, then hardware chooses the one to use.

1. Set NV_PDISP_HDMI_ACR_CTRL (all fields) to 0
2. Reset N counter: HDMI.NV_PDISP_AUDIO_N.RESETF = ASSERT, GENERATE=ALTERNATE, LOOKUP per table
3. Based on pixel clock and audio sample clock frequencies, program the appropriate ACR N value into NV_PDISP_HDMI_ACR_0441_SUBPACK_HIGH (see HDMI 1.2a specification, section 7.2.3). LSB of N goes in SB6, and MSB into SB4.
4. Likewise, program the appropriate ACR CTS value into NV_PDISP_HDMI_ACR_0441_SUBPACK_LOW. The LSB of CTS goes in SB3, and the MSB into SB1.

5. Program the computed AVAL into the appropriate SOR_AUDIO_AVAL_ register
6. Set NV_PDISP_AUDIO_N.VALUE = N – 1 (from above)
7. Set NV_PDISP_HDMI_ACR_*_SUBPACK_HIGH.ENABLE = YES.
8. Set NV_PDISP_HDMI_SPARE = 0x10000 OR'd with bits 0 and 1
9. Bring the N counter of reset: set HDMI.NV_PDISP_AUDIO_N.RESETF = DEASSERT
10. Program the audio source with SOR_AUDIO_CNTRL0.SOURCE_SELECT = HDAL for HDA, or AUTO. AUTO automatically selects HDA if HDMI's internal HDA codec has been enumerated by HDA controller.
11. Enable HDMI audio: Set HDMI_CTRL.ENABLE = EN, HDMI_GENERIC_CTRL.AUDIO = EN, AUDIO_ENGINE.PWRDWN=0

Note:	CTS and N values depend on the ratio of the actual pixel clock and audio clock rates. The chip's clock generators cannot create every frequency exactly. For example 25.2 MHz (for 640x480p@60) cannot be exactly generated – 25.25 is the result. Thus CTS and N must be adjusted accordingly.

23.2.12 Other HDMI Configurations

1. Set HDMI_CTRL.MAX_AC_PACKET based on horizontal blanking width. Using display timing registers, MAX_AC_PACKET = floor((H_SYNC_WIDTH + H_BACK_PORCH + H_FRONT_PORCH – HDMI_CTRL.REKEY – 18) / 32)
2. Program and enable Audio InfoFrames. When using HDA audio, its contents come from verbs sent to the internal codec.
3. Program and enable AVI InfoFrames. When using HDA Audio, this *may* come from the HDA Codec if desired, using one of its Generic packets. If so, do not enable the HDMI one:
   - Set HDMI_AVI_INFOFRAME_HEADER = 0x000D0282
   - Program checksum, PB1, PB2, PB3 in HDMI_AVI_INFOFRAME_SUBPACK0_LOW. PB4 contains the video format code from the CEA-861-D specification. See HDMI and EIA/CEA-861-D for all the fields. CRC is computed over header and PB1…PB13 as above.
   - Program PB4…PB6 in HDMI_AVI_INFOFRAME_SUBPACK0_HIGH, and PB7..PB13 in HDMI_AVI_INFOFRAME_SUBPACK1_LOW / HIGH.
   - Set HDMI_AVI_INFOFRAME_CTRL.ENABLE = EN
4. For HDMI 1.4 3D, program and enable the GENERIC InfoFrame to send an HDMI Vendor-Specific InfoFrame. When using HDA Audio, this *might* come from the HDA Codec, if desired, using one of its Generic packets. If so, do not enable the HDMI one.
   - Set HDMI_GENERIC_HEADER = 0x00LL0181 where LL is length of packet – 0x05 for the basic version described here.
   - HDMI_GENERIC_SUBPACK0_LOW.PB1/PB2/PB3 = 0x03/0c/00 (IEEE registration ID)
   - PB4 = 0x40 (Hdmi_video_format = 3d_structure present)
   - PB5 = 0x00 (3D_Structure = Frame packing)
   - PB6...PB27 = 0 (no 3D_Ext_Data for Frame packing)
   - Compute checksum over header and PB1..PB27 and put in PB0, as above.
   - HDMI_GENERIC_CTRL.ENABLE=EN. OTHER, SINGLE, HBLANK= DIS.
   - Be sure to keep HDMI_GENERIC_CTRL.AUDIO = EN

23.2.13 Start HDMI SOR

1. Enable TMDS macro with SOR_PLL0.PWR=0, VCOPD=0, PULLDOWN=0. Observe the power sequencing requirement. After PWR is cleared, you must wait 10 microseconds before setting PDBG=0.
2. Write SOR_PWR with NORMAL_STATE = PU, SAFE_STATE = PD, SETTING_NEW = TRIGGER.
3. Write SOR_PWR with the same settings but with SETTING_NEW = DONE.
4. Poll SOR_PWR for SETTING_NEW = DONE.
5. Write SOR_STATE2 with ASY_OWNER=HEAD0, SUBOWNER=3, ASY_PROTOCOL=SINGLE_TMDS_A, ASY_HSYNCPOL=POSITIVE_TRUE, ASY_VSYNCPOL=POSITIVE_TRUE, ASY_DEPOL=POSITIVE_TRUE.
6. Write SOR_STATE1 with ASY_HEAD_OPMODE=AWAKE, ASY_ORMODE=NORMAL, ATTACHED=0, ARM_SHOW_VGA=0.
7. Write SOR_STATE0 with UPDATE=0.
8. Write SOR_STATE0 with UPDATE=1.
9. Write SOR_STATE1 with ATTACHED=1.
10. Write SOR_STATE0 with UPDATE=0.

23.2.14 Start Display

- Set DISP_WIN_OPTIONS.HDMI_ENABLE = ENABLE.
- Start the display with DISPLAY_COMMAND.DISPLAY_CTRL_MODE and DISPLAY_POWER_CONTROL.

23.3 Audio / Display Driver Communication

HDMI combines video and audio and so the display and audio drivers need to coordinate. The HDA Codec and HDMI implement the methods defined in the audio specifications.

23.3.1 Hot-Plug and ELD (EDID-like data)

When the HDMI driver receives notification of a hot-plug interrupt, it reads the downstream TV's E-EDID ROM. The EDID contains audio-related data, so the audio driver needs it, too. The HDMI can send the hot-plug event and EDID buffer to the Audio driver via the HDA Codec.

Note:	See register comments in SOR_AUDIO_HDA_PRESENSE and SOR_AUDIO_HDA_ELD_BUFWR later in this section.

23.3.2 Copy-Protection

The audio driver can query copy-protection state (i.e., HDCP enabled), and request that HDCP be enabled by the HDMI driver.

Note:	See SOR_AUDIO_HDA_CP register and CP_REQUEST interrupt in INT_STATUS later in this section.

23.3.3 InfoPacket

In HDA mode, the Audio InfoFrame data is provided by the internal HDA Codec, not by the HDMI_AUDIO_INFOFRAME* registers. The SET_DIP_INDEX/SET_DIP_DATA verbs write this data.

Three generic infopackets are provided by the HDA Codec, in addition to the exiting generic packet.

23.3.4 Miscellaneous

For Audio to HDMI signaling, the HDA Codec has SCRATCH verbs that are reflected in the HDMI SOR_AUDIO_HDA_CODEC_SCRATCH* registers and CODEC_SCRATCH* interrupts.

For HDMI to Audio signaling, HDMI SOR_AUDIO_HDA_SCRATCH* registers, when written, are reflected to the HDA Codec GET_NV_SCRATCH_REGN_FROM_DISP verb and cause an Unsolicited Response (interrupt in the HDA Controller).

23.4 Clock Use Cases

Tegra K1 HDMI has the following clock sources. All five are required for HDMI operation.

DISP1 or DISP2	Display controller (pixel clock)
HDMI	HDMI controller (pixel clock)
HDA2CODEC_2X	HDA interface clock (48 MHz)
HDA2HDMICODEC	HDMI audio clock
HDA	HDA controller

23.5 CTS/N/AVAL Algorithm

```
void get_hda_cts_n(
// inputs:
NvU32 audio_freq_hz /* Fs */,
NvU32 pixclk_freq_hz /* Fpix */,
// outputs:
NvU32 &best_cts, NvU32 &best_n, NvU32 &best_a)
{
    // Ideal ACR interval is 1000 hz (1 ms);
    // acceptable is 300 hz .. 1500 hz
    const int min_n = 128 * audio_freq_hz / 1500;
    const int max_n = 128 * audio_freq_hz / 300;
    const int ideal_n = 128 * audio_freq_hz / 1000;

    float min_err = 100.0;

    best_n = 0;
    best_cts = 0;
    best_a = 0;

    for (int n = min_n; n <= max_n; n ++)
    {
        float cts_f = pixclk_freq_hz * (float)n / (128.0 * (float)audio_freq_hz);
        int cts = (int)(cts_f + 0.5); // round to nearest integer
        float err = fabs(cts_f - (float)cts);
        float aval_f = 24000000.0 * (float)n / (128.0 * (float)audio_freq_hz);
        int aval = (int)aval_f; // truncate (round toward zero)
        if ((float)aval == aval_f &&
(err < min_err ||
            ((err == min_err) && (abs(n - ideal_n) < abs((int)best_n - ideal_n)))))
        {
            min_err = err;
            best_n = (NvU32)n;
            best_cts = (NvU32)cts;
            best_a = (NvU32)aval;
        }
    }
```

```
    assert(best_n != 0 && best_cts != 0);
    assert((double)best_cts ==
     ((double)pixclk_freq_hz * best_n) / (128.0 * audio_freq_hz));

}
```

23.6 HDMI Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

23.6.1 HDMI_CTXSW_0

Channel IDs

Context switch register. Should be common to all modules. Includes the current channel/class (which is writable by software) and the next channel/class (which the hardware sets when it receives a context switch).

Context switch works like this: Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS (see vmod/chexample). Software sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be pre-loaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts. Another way to avoid context switch interrupts is to set the AUTO_ACK bit.

This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 0x0 │ Byte Offset: 0x0 │ Read/Write: R/W │ Reset: 0xXXXXf800 (0bxxxxxxxxxxxxxxxx11111x0000000000)

Bit	R/W	Reset	Description
31:28	RO	X	NEXT_CHANNEL: Next requested channel
25:16	RO	X	NEXT_CLASS: Next requested class
15:12	RW	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	RW	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests 0 = MANUAL 1 = AUTOACK
9:0	RW	0x0	CURR_CLASS: Current working class

23.6.2 HDMI_NV_PDISP_SOR_STATE0_0

Writing a 1 to this field causes a 1-cycle pulse, which is used to activate the fields in registers NV_PDISP_SOR_STATE[1,2].

The ATTACHED field in SOR_STATE1 is flopped to create the read-only field "ATTACHED" in the NV_PDISP_SOR_TEST register.

Offset: 0x1 | Byte Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	UPDATE

23.6.3 HDMI_NV_PDISP_SOR_STATE1_0

Offset: 0x2 | Byte Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx00000)

Bit	Reset	Description
4	0x0	ARM_SHOW_VGA

3:0	HEAD0	NONE	ASY_OWNER: 0 = NONE 1 = HEAD0

23.6.5 HDMI_NV_PDISP_HDMI_AUDIO_EMU0_0

HDMI_AUDIO_EMU

HDMI_AUDIO_EMU0 and HDMI_AUDIO_EMU1 are used to program the S/PDIF transmitter during RTL simulation and emulation. This is strictly for verification. This register is write-only.

Offset: 0x1a │ Byte Offset: 0x68 │ Read/Write: WO │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	REGX

23.6.6 HDMI_NV_PDISP_HDMI_AUDIO_EMU_RDATA0_0

HDMI_AUDIO_EMU_RDATA0 is read-only.

Offset: 0x1b │ Byte Offset: 0x6c │ Read/Write: RO │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	RDATA

23.6.7 HDMI_NV_PDISP_HDMI_AUDIO_EMU1_0

HDMI_AUDIO_EMU1 and EMU2 allow control over S/PDIF transmitter clock ratios (which are fixed in the GPU). They do indirect addressing.

EMU1 has the address, and EMU2 has the data.

To write:

1. Write data register with data

2. Write address register with bit 31=1, and address in 15:0

3. Write address register with bit 31=0

To read:

1. Write address register with bit 31=0 and address in 15:0

2. Read back address register to introduce delay allowing read data to propagate

3. Read data register

Offset: 0x1c │ Byte Offset: 0x70 │ Read/Write: R/W │ Reset: 0x00000000 (0b0xxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description

Bit	Reset	Description
31:0	0x0	DATA

23.6.9 HDMI_NV_PDISP_HDMI_AUDIO_INFOFRAME_CTRL_0

This is the register space for the HDMI block. Refer to HDMI Version 1.1. Refer to IEC60958-1 for general information and IEC60958-3 for consumer specifications for related audio information.

Additional notes regarding the ACR packet:

There are several methods that can be used to generate the N and CTS values in the Audio Clock Regeneration packet. The details of these methods are described here.

Full Software control: Software controls the contents of the possible ACR packets. Software writes the contents of the ACR_XXXX_SUBPACK_HIGH and ACR_XXXX_SUBPACK_LOW for all seven audio frequencies.

Software selects a method in ACR_CTRL to determine the audio sampling frequency

1. Measured in the audio block (MEASURE)
2. Read from the channel status information encoded in the audio stream (PACKET)

3. Defined by software (FREQS)

Software writes _YES to the ENABLE field of the SUBPACK_HIGH registers to allow that pair of registers to be used as the ACR packet. The audio sampling frequency specified in ACR_CTRL will select one of the seven pairs of SUBPACK registers to use as the ACR packet. This packet is sent on every Frame 27 of the audio block if that pair's ENABLE field is _YES.

Hardware controlled CTS: Software provides the N value and the hardware measures the CTS value. This is described in the HDMI_SPARE comments and mentioned in all other affected registers.

Software writes _ENABLE to HDMI_SPARE_HW_CTS to enable this feature.

Software writes 1 to HDMI_SPARE_CTS_RESET_VAL. This controls what the internal CTS counter resets to when it starts the next round of measurement. Resetting to zero was not correct, and adding a few bits of control helped to fine tune the measurement.

Software sets all ENABLEs in ACR_CTRL to _NO. (The easy way to do this is just to write zero to the whole register.)

Software writes the value of N in two places:

1. ACR_0441_SUBPACK_HIGH_SB[4/5/6]: It is written here so that the ACR packet contains the correct information for N.

2. AUDIO_N_VALUE: It is written here so that the audio block knows what N to use while it is measuring CTS. (Software does not need to write N to these places if Hardware Selected N is used.)

Software enables the sending of ACR_0441_SUBPACK* by setting ACR_0441_SUBPACK_ENABLE to _YES. (This pair of registers is used for all audio frequencies when Hardware controlled CTS is enabled.)

Software writes _USE_HW_CTS_VAL to ACR_0441_SUBPACK_LOW_SB1.

Hardware selected N: Software provides the possible N values whenever the pixel clock frequency changes. Hardware looks up the correct N value from a table stored in priv registers.

Software writes the 7 possible N values into the 7 AUDIO_NVAL registers. This is based on pixel clock frequency.

Software enables this feature by setting AUDIO_N_LOOKUP to _ENABLE. Hardware will use the audio sampling frequency detected by the audio block to select the correct N value.

NOTE: This is not the audio sampling frequency reported by the channel status information in the audio stream. Hardware will ignore whatever if written in the SUBPACK_HIGH registers when this feature is enabled and send the value of N it selected in these bytes of the ACR packet. CTS can come from the SUBPACK_LOW registers or the Hardware controlled CTS.

Audio frequency notes: There are several places in the HDMI and Audio registers where the audio sampling frequency is reported or set. Here is a breakdown of all such fields.

In SPDIF audio encoding, one bit of each audio sample is part of the "channel status" information. The bits from all 192 audio samples combine to form the 192 bit channel status packet. For consumer applications, only the first 40 bits have defined values. These bits are included in the encoded HDMI audio packet. Four of these bits contain the audio sampling frequency as reported by the audio source. See the IEC60958-3 specification for more information.

SPDIF_CHN_STATUS1 and SPDIF_CHN_STATUS2 are read-only registers that contain the 40 bits of channel status data read from the last audio block. The audio frequency the audio stream reports can be read from SPDIF_CHN_STATUS1_SFREQ. This is the sampling frequency that ACR_CTRL refers to with _PACKET.

SPDIF_CHN_STATUS1_ORIGINAL is the original sampling frequency of the audio. If the source of the audio stream changed the sampling frequency from its original frequency for any reason, the original sampling frequency is reported here.

AUDIO_CNTRL0_SAMPLING_FREQ is the sampling frequency measured by the audio block. It counts the number of dispclks periods that occur between to specific points in the audio stream. It compares this count to the thresholds in the AUDIO_FS registers to determine what the audio sampling frequency is. This is the sampling frequency that ACR_CTRL refers to as

_MEASURE. This is the sampling frequency used to determine the correct value of N when Hardware selected N is enabled (see AUDIO_N).

The CHANNEL_STATUS1 and CHANNEL_STATUS2 registers are for debug. They can be used to replace the channel status bits that were in the original SPDIF stream with user-defined bits. CHANNEL_STATUS1_SFREQ can be used to report a different sampling frequency to downstream devices.

ACR_CTRL_FREQS can be written to select a specific pair of SUBPACK registers to send as your ACR packet. ACR_CTRL_FREQS_ENABLE must be set to _YES for this to have any effect.

The HDMI Audio InfoFrame, AVI InfoFrame, and Generic InfoFrame have nearly identical priv register interfaces. The next five registers control the Audio InfoFrame as described in section 8.2.2 of the HDMI specification.

HDMI_AUDIO_INFOFRAME_CTRL

This register controls the frequency and generation of audio InfoFrame packets. The contents of the packet should be written into the header (HDMI_AUDIO_INFOFRAME_HEADER) and subpacket (HDMI_AUDIO_INFOFRAME_SUBPACK0_LOW, HDMI_AUDIO_INFOFRAME_SUBPACK0_HIGH) registers.

ENABLE: Setting this field to _YES will initiate InfoFrame generation. Setting this bit to _NO will disable InfoFrame generation at the beginning of the next frame. The frequency of InfoFrame generation is controlled by OTHER and SINGLE fields.

OTHER: Setting this field to _EN while SINGLE is set to _DIS will cause InfoFrame to be transmitted to every other frame.

SINGLE: Setting this field to _EN while OTHER is set to _DIS will cause InfoFrame to be transmitted exactly once.

If OTHER and SINGLE fields are both set to _DIS, an InfoFrame will be generated every frame. Software should never set OTHER and SINGLE both to _EN.

See chapter 8.2.2 - Audio InfoFrame, in the HDMI specification for more information

CHKSUM_HW: Hardware provides a way to calculate the checksum for the InfoFrames.

_ENABLE will enable the hardware calculation to be passed to the packet

_DISABLE:

- Uses the register value defined in NV_PDISP_SOR_HDMI_AUDIO_INFOFRAME_SUBPACK0_LOW_PB0 for the S/PDIF
- Uses the checksum provided by the Azalia codec for the Azalia audio formats.

Usage: Normal Operation

Offset: 0x1e │ Byte Offset: 0x78 │ Read/Write: R/W │ Reset: 0x00000200 (0bxxxxxxxxxxxxxxxxxxxxxxx10xxx0xxx0)

Bit	Reset	Description
9	ENABLE	CHKSUM_HW: CHKSUM_HW is an optional feature for software to use. Not required to be enabled. 0 = DISABLE 1 = ENABLE
8	0x0	SINGLE: 0 = DIS 1 = EN
4	0x0	OTHER: 0 = DIS 1 = EN

Bit	Reset	Description
0	0x0	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

23.6.10 HDMI_NV_PDISP_HDMI_AUDIO_INFOFRAME_STATUS_0

HDMI_AUDIO_INFOFRAME_STATUS

The SENT bit will be set to _DONE, after the first packet is sent. After the ENABLE bit in INFOFRAME_CTRL is set to _NO, the SENT bit will be set to _WAITING after the start of the next frame to indicate that it is safe to change the contents of the packet header and subpacket registers.

Usage: Normal Operation

Offset: 0x1f │ Byte Offset: 0x7c │ Read/Write: RO │ Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	SENT: 1 = DONE 0 = WAITING

23.6.11 HDMI_NV_PDISP_HDMI_AUDIO_INFOFRAME_HEADER_0

HDMI_AUDIO_INFOFRAME_HEADER

This register should be written with the value of the HDMI Audio InfoFrame header. This header is described in table 8-4 of chapter 8.2.2 of the HDMI specification. HB0, HB1, and HB2 are defined fields of the header from the specification.

Offset: 0x20 │ Byte Offset: 0x80 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxx000000000000000000000000)

Bit	Reset	Description
23:16	0x0	HB2
15:8	0x0	HB1
7:0	0x0	HB0

23.6.12 HDMI_NV_PDISP_HDMI_AUDIO_INFOFRAME_SUBPACK0_LOW_0

HDMI_AUDIO_INFOFRAME_SUBPACK0_LOW

This register should be written with the lower 4 bytes of the HDMI Audio InfoFrame. PB0, PB1, PB2, and PB3 are defined fields from the specification. See chapter 8.2.2 - Audio InfoFrame, Table 8-5, in the HDMI specification for more information

Offset: 0x21 │ Byte Offset: 0x84 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:24	0x0	PB3
23:16	0x0	PB2
15:8	0x0	PB1
7:0	0x0	PB0

23.6.13 HDMI_NV_PDISP_HDMI_AUDIO_INFOFRAME_SUBPACK0_HIGH_0

HDMI_AUDIO_INFOFRAME_SUBPACK0_HIGH

This register should be written with the upper 2 bytes of the HDMI Audio InfoFrame. PB4 and PB5 are defined fields from the specification. See chapter 8.2.2 - Audio InfoFrame, Table 8-5, in the HDMI specification for more information

Offset: 0x22 │ Byte Offset: 0x88 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	PB5
7:0	0x0	PB4

23.6.14 HDMI_NV_PDISP_HDMI_AVI_INFOFRAME_CTRL_0

The following registers are used to send a 14-byte packet intended for sending AVI InfoFrame packet as described in section 8.2.1 of the HDMI specification.

HDMI_AVI_INFOFRAME_CTRL

This register controls the frequency and generation of AVI InfoFrame packets. The fields of this register are identical to HDMI_AUDIO_INFOFRAME_CTRL. See chapter 8.2.1 - Auxiliary Video information (AVI) InfoFrame, in the HDMI specification for more information

Offset: 0x23 │ Byte Offset: 0x8c │ Read/Write: R/W │ Reset: 0x00000200 (0bxxxxxxxxxxxxxxxxxxxxxxxx10xxx0xxx0)

Bit	Reset	Description
9	ENABLE	CHKSUM_HW: CHKSUM_HW is an optional feature for software to use. Not required to be enabled 0 = DISABLE 1 = ENABLE
8	DIS	SINGLE: 0 = DIS 1 = EN
4	DIS	OTHER: 0 = DIS 1 = EN
0	NO	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

23.6.15 HDMI_NV_PDISP_HDMI_AVI_INFOFRAME_STATUS_0

HDMI_AVI_INFOFRAME_STATUS

The SENT bit will be set to _DONE, after the first packet is sent. After the ENABLE bit in INFOFRAME_CTRL is set to _NO, the SENT bit will be set to _WAITING after the start of the next frame to indicate that it is safe to change the contents of the packet header and subpacket registers.

Offset: 0x24 │ Byte Offset: 0x90 │ Read/Write: RO │ Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	SENT: 1 = DONE 0 = WAITING

23.6.16 HDMI_NV_PDISP_HDMI_AVI_INFOFRAME_HEADER_0

HDMI_AVI_INFOFRAME_HEADER

This register should be written with the value of the HDMI AVI InfoFrame header. This header is described in table 8-1 of chapter 8.2.1 of the HDMI specification. HB0, HB1, and HB2 are defined fields of the header from the specification.

Offset: 0x25 │ Byte Offset: 0x94 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxx000000000000000000000000)

Bit	Reset	Description
23:16	0x0	HB2
15:8	0x0	HB1
7:0	0x0	HB0

23.6.17 HDMI_NV_PDISP_HDMI_AVI_INFOFRAME_SUBPACK0_LOW_0

HDMI_AVI_INFOFRAME_SUBPACK0_LOW

This register should be written with the lower 4 bytes of the HDMI AVI InfoFrame. PB0, PB1, PB2, and PB3 are defined fields from the specification. See chapter 8.2.1 - Auxiliary Video information (AVI) InfoFrame, Table 8-2, in the HDMI specification for more information.

Offset: 0x26 │ Byte Offset: 0x98 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:24	0x0	PB3
23:16	0x0	PB2
15:8	0x0	PB1
7:0	0x0	PB0

23.6.18 HDMI_NV_PDISP_HDMI_AVI_INFOFRAME_SUBPACK0_HIGH_0

HDMI_AVI_INFOFRAME_SUBPACK0_HIGH

This register should be written with bytes 4-6 of the HDMI AVI InfoFrame. PB3, PB5, and PB6 are defined fields from the specification. See chapter 8.2.1 - Auxiliary Video information (AVI) InfoFrame, Table 8-2, in the HDMI specification for more information.

Offset: 0x27 │ Byte Offset: 0x9c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

Bit	Reset	Description
23:16	0x0	PB6
15:8	0x0	PB5
7:0	0x0	PB4

23.6.19 HDMI_NV_PDISP_HDMI_AVI_INFOFRAME_SUBPACK1_LOW_0

HDMI_AVI_INFOFRAME_SUBPACK1_LOW

This register should be written with bytes 7-10 of the HDMI AVI InfoFrame. PB7, PB8, PB9, and PB10 are defined fields from the specification. See chapter 8.2.1 - Auxiliary Video information (AVI) InfoFrame, Table 8-2, in the HDMI specification for more information.

Offset: 0x28 │ Byte Offset: 0xa0 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:24	0x0	PB10
23:16	0x0	PB9
15:8	0x0	PB8
7:0	0x0	PB7

23.6.20 HDMI_NV_PDISP_HDMI_AVI_INFOFRAME_SUBPACK1_HIGH_0

HDMI_AVI_INFOFRAME_SUBPACK1_HIGH

This register should be written with bytes 11-13 of the HDMI AVI InfoFrame. PB11, PB12, and PB13 are defined fields from the specification. See chapter 8.2.1 - Auxiliary Video information (AVI) InfoFrame, Table 8-2, in the HDMI specification for more information.

Offset: 0x29 │ Byte Offset: 0xa4 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

Bit	Reset	Description
23:16	0x0	PB13
15:8	0x0	PB12
7:0	0x0	PB11

23.6.21 HDMI_NV_PDISP_HDMI_GENERIC_CTRL_0

The following registers are used to send a 28-byte packet intended for sending any packet type. These registers will most likely be used for debug purposes.

HDMI_GENERIC_CTRL

This register controls the frequency and generation of generic InfoFrame packets. The fields of this register are identical to HDMI_AUDIO_INFOFRAME_CTRL except where noted below.

HBLANK: If HBLANK is set to _EN, then this packet will be sent (once) during the next horizontal blanking interval. The packet will still be sent at most once per frame. Software can poll GENERIC_STATUS_SENT to determine when the packet has been sent.

Using HBLANK is intended to mimic Audio Sample Packets and ACR Packets and therefore sending of the actual audio packets should be disabled by setting AUDIO to _DIS. This feature is used for debug purposes only.

To mimic an audio packet:

- begin
- wait for GENERIC_STATUS_SENT=_WAITING
- write next 4 audio samples to GENERIC_HEADER/GENERIC_SUBPACK registers
- set HBLANK = _EN
- wait for GENERIC_STATUS_SENT=_SENT
- set HBLANK = _DIS
- end

AUDIO: Audio packet transmission will be stopped when set to _DIS. Normal audio packet transmission will be allowed when set to _EN. This is used during debug to disable normal audio when using HBLANK.

Offset: 0x2a │ Byte Offset: 0xa8 │ Read/Write: R/W │ Reset: 0x00010000 (0bxxxxxxxxxxxxxxxx1xxx0xxx0xxx0xxx0)

Bit	Reset	Description
16	EN	AUDIO: Set to 1 in audio mode and 0 in DVI mode. 0 = DIS 1 = EN
12	DIS	HBLANK: 0 = DIS 1 = EN
8	DIS	SINGLE: 0 = DIS 1 = EN
4	DIS	OTHER: 0 = DIS 1 = EN
0	NO	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

23.6.22 HDMI_NV_PDISP_HDMI_GENERIC_STATUS_0

HDMI_GENERIC_STATUS

The SENT bit will be set to _DONE, after the first packet is sent. After the ENABLE bit in INFOFRAME_CTRL is set to _NO, the SENT bit will be set to _WAITING after the start of the next frame to indicate that it is safe to change the contents of the packet header and subpacket registers.

Offset: 0x2b │ Byte Offset: 0xac │ Read/Write: RO │ Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	SENT: 1 = DONE 0 = WAITING

23.6.23 HDMI_NV_PDISP_HDMI_GENERIC_HEADER_0

HDMI_GENERIC_HEADER

This register should be written with the contents of the packet header.

Offset: 0x2c │ Byte Offset: 0xb0 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

7:0	0x0	PB21

23.6.31 HDMI_NV_PDISP_HDMI_GENERIC_SUBPACK3_HIGH_0

HDMI_GENERIC_SUBPACK3_HIGH

Bytes 25-27 of the packet are written into this register.

Offset: 0x34 │ Byte Offset: 0xd0 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

Bit	Reset	Description
23:16	0x0	PB27
15:8	0x0	PB26
7:0	0x0	PB25

23.6.32 HDMI_NV_PDISP_HDMI_ACR_CTRL_0

HDMI_ACR_CTRL

The Audio Clock Regeneration (ACR) packet contains the N and CTS values that the HDMI sink requires to recreate the audio clock. This mechanism is described in chapter 7.2 of the HDMI specification.

If software needs to specify N and CTS directly, this register is used to select the audio sampling frequency detection mechanism. The sampling rate is used to index one of the seven ACR_XXXX_SUBPACK_LOW/HIGH registers which must be written with the correct value of N and CTS. N and CTS are determined by the current audio sampling frequency and the pixel clock frequency:

CTS = (PixelClock*N) / (128*AudioSamplingFrequency)

The selected sampling rate must point to a valid entry (i.e., one of the 7 listed below) and the selected ACR_XXXX_SUBPACK_HIGH_ENABLE must be set to enable sending the packet.

When software is controlling N and CTS directly, the ACR packet is sent every 27th audio frame (of 0 to 191) of the audio block. The sampling frequency read from the channel status bits is not available until the 27th audio frame.

PACKET_ENABLE: Set this to _YES to use the channel status information read from the incoming SPDIF audio stream to determine the sampling frequency.

MEASURE_ENABLE: Set this to _YES to use the sampling frequency measured in the in the audio block to determine the sampling frequency. This is the sampling frequency that is read from AUDIO_CNTRL0_SAMPLING_FREQ.

FREQS_ENABLE: Set this to _YES to use the sampling frequency written into the _FREQS field of this register.

FREQS: This is the audio sampling frequency that will be used when FREQS_ENABLE is _YES.

When Hardware is used to measure CTS, all ENABLE fields of this register should be set to _NO.

All four subpackets contain the same ACR packet.

Offset: 0x35 │ Byte Offset: 0xd4 │ Read/Write: R/W │ Reset: 0x02010000 (0bxxxx0010xxxxxxx1xxxxxxx0xxxxxxx0)

Bit	Reset	Description

16	YES	FREQS_ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN
8	NO	MEASURE_ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN
0	NO	PACKET_ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

23.6.33 HDMI_NV_PDISP_HDMI_ACR_0320_SUBPACK_LOW_0

HDMI_ACR_0320_SUBPACK_LOW

Contains bytes 1-3 of the 32 kHz ACR packet. This is the CTS value.

See table 5-11 in chapter 5.3.3 in the HDMI specification for more information.

Offset: 0x36 │ Byte Offset: 0xd8 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000xxxxxxxx)

Bit	Reset	Description
31:24	0x0	SB1
23:16	0x0	SB2
15:8	0x0	SB3

23.6.34 HDMI_NV_PDISP_HDMI_ACR_0320_SUBPACK_HIGH_0

HDMI_ACR_0320_SUBPACK_HIGH

Contains bytes 4-6 of the 32 kHz ACR packet. This is the N value. See table 5-11 in chapter 5.3.3 in the HDMI specification for more information.

ENABLE: _YES allows this packet to be sent. When set to _NO, this ACR packet will not be sent even if the sampling frequency defined in ACR_CTRL points to this register set.

Offset: 0x37 │ Byte Offset: 0xdc │ Read/Write: R/W │ Reset: 0x00000000 (0b0xxxxxxx00000000000000000000000)

Bit	Reset	Description
31	NO	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN
23:16	0x0	SB4
15:8	0x0	SB5
7:0	0x0	SB6

23.6.35 HDMI_NV_PDISP_HDMI_ACR_0441_SUBPACK_LOW_0

HDMI_ACR_0441_SUBPACK_LOW

Contains bytes 1-3 of the 44.1 kHz ACR packet. This is the CTS value. If Hardware measured CTS is enabled, SB1 should be set to zero. See table 5-11 in chapter 5.3.3 in the HDMI specification for more information.

Offset: 0x38 │ Byte Offset: 0xe0 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000xxxxxxx)

Bit	Reset	Description
31:24	0x0	SB1: 0 = USE_HW_CTS_VAL
23:16	0x0	SB2
15:8	0x0	SB3

23.6.36 HDMI_NV_PDISP_HDMI_ACR_0441_SUBPACK_HIGH_0

HDMI_ACR_0441_SUBPACK_HIGH

Contains bytes 4-6 of the 44.1 kHz ACR packet. This is the N value. See table 5-11 in chapter 5.3.3 in the HDMI specification for more information.

If Hardware measured CTS is enabled, ACR_0441_SUBPACK_HIGH_N should be written with the N value for the current audio sampling frequency.

If the hardware N value selection is enabled, the N value does not need to be written to this register.

ENABLE: _YES allows this packet to be sent. This should be set to _YES when hardware measured CTS is being used. When set to _NO, this ACR packet will not be sent even if the sampling frequency defined in ACR_CTRL points to this register set.

Offset: 0x39 │ Byte Offset: 0xe4 │ Read/Write: R/W │ Reset: 0x00000000 (0b0xxxxxxx00000000000000000000000)

HDMI_ACR_1920_SUBPACK_HIGH

Contains bytes 4-6 of the 192 kHz ACR packet. This is the N value. See table 5-11 in chapter 5.3.3 in the HDMI specification for more information.

ENABLE: _YES allows this packet to be sent. When set to _NO, this ACR packet will not be sent even if the sampling frequency defined in ACR_CTRL points to this register set.

Offset: 0x43 │ Byte Offset: 0x10c │ Read/Write: R/W │ Reset: 0x00000000 (0b0xxxxxxx00000000000000000000000)

Bit	Reset	Description
31	NO	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN
23:16	0x0	SB4
15:8	0x0	SB5
7:0	0x0	SB6

23.6.47 HDMI_NV_PDISP_HDMI_CTRL_0

HDMI_CTRL

REKEY: REKEY is the number of clocks required for HDCP rekey, starting from when DE is deasserted. No HDMI packets can be sent during this time. Due to a two cycle delay in hardware, REKEY should be set to two less than the desired value.

AUDIO_LAYOUT: AUDIO_LAYOUT controls layout (HB1[4]) of the Audio Sample Packet Header. Two different layouts are supported in the HDMI specification. The hardware only supports layout _2CH (2 channel audio). This should not need to be programmed beyond its init value of _2CH.

See Section 5.3.4 of the HDMI specification.

AUDIO_LAYOUT_SELECT: For projects with integrated audio codec, the AUDIO_LAYOUT information is automatically detected by hardware (default). We can override this capability and fall back on AUDIO_LAYOUT based selection by setting AUDIO_LAYOUT_SELECT to _SW_BASED.

If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in the project specification, this field has no meaning, and only AUDIO_LAYOUT field will take effect.

SAMPLE_FLAT: SAMPLE_FLAT controls the values of (HB2[3:0]) of the Audio Sample Packet Header and should be _CLR. See Section 5.3.4 of the HDMI specification.

MAX_AC_PACKET: Set MAX_AC_PACKET to the maximum number of 32-pixel packets that will fit in the horizontal blanking interval. This controls the maximum number of audio packets, ACR packets, GCP packets, InfoFrames, etc. that will be sent during the horizontal blanking period.

MAX_AC_PACKET <= Floor[((HBLANK-REKEY-18)/32)]

CT_SELECT: Diagnostic workaround bit to decide whether the value of "coding type" will be hardware based or software based. The CT field is required in the construction of Audio InfoFrame packet (HDMI Specification, section 8.2.2). By default, the CT field is constructed by software. However, by setting this bit, the CT field in the construction of the Audio InfoFrame packet comes as a sideband signal from the HDA codec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field is reserved.

CC_SELECT: Diagnostic workaround bit to decide whether the value of "channel count" will be hardware based or software based. The CC field is required in the construction of Audio InfoFrame packet (HDMI Specification, section 8.2.2). By default, the CC field is constructed by software. However,by setting this bit, the CC field in the construction of the Audio InfoFrame packet comes as a sideband signal from the HDA codec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field is reserved.

SF_SELECT: Diagnostic workaround bit to decide whether the value of "sampling frequency" will be hardware based or software based. The SF field is required in the construction of Audio InfoFrame packet (HDMI Specification, section 8.2.2). By default, the SF field is constructed by software. However, by setting this bit, the SF field in the construction of the Audio InfoFrame packet comes as a sideband signal from the HDA codec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field is reserved.

SS_SELECT: Diagnostic workaround bit to decide whether the value of "sample size" will be hardware based or software based. The SS field is required in the construction of Audio InfoFrame packet (HDMI Specification, section 8.2.2). By default, the SS field is constructed by software. However, by setting this bit, the SS field in the construction of the Audio InfoFrame packet comes as a sideband signal from the HDA codec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field is reserved.

CA_SELECT: Diagnostic workaround bit to decide whether the value of "channel allocation" will be hardware based or software based. The CA field is required in the construction of Audio InfoFrame packet (HDMI Specification, section 8.2.2). By default, the CA field is constructed by software. However, by setting this bit, the CA field in the construction of the Audio InfoFrame packet comes as a sideband signal from the HDA codec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field is reserved.

ENABLE: Set to _YES to enable HDMI for this head. Set to _NO to disable HDMI for this head.

Offset: 0x44 │ Byte Offset: 0x110 │ Read/Write: R/W │ Reset: 0x00020038 (0bx0x00000xxx00010xxx0x0x0x0111000)

23.6.48 HDMI_NV_PDISP_HDMI_VSYNC_KEEPOUT_0

HDMI_VSYNC_KEEPOUT

Defines the start and end of the VSYNC keepout period where HDMI packets should not be sent. This is defined in chapter 2.7 the HDCP 1.1 specification.

END: Defines the end of the keepout period. This is measured in pixels after the active edge of VSYNC. This is defined in the specification and should not need to be written beyond its initialized value.

START: Defines the start of the keepout period. This is measured in pixels after the active edge of VSYNC. This is defined in the specification and should not need to be written beyond its initialized value.

ENABLE: When set to _YES, the keepout window is respected and no HDMI packets are sent in the period of time between START and END. This bit should be set to _YES. When set to _NO, the keepout window is ignored and HDMI packets may be sent regardless of the keepout window.

Offset: 0x45 │ Byte Offset: 0x114 │ Read/Write: R/W │ Reset: 0x819a028a (0b1xxxxx0110011010xxxxxx1010001010)

25:16	0x19a	START
9:0	0x28a	END

23.6.49 HDMI_NV_PDISP_HDMI_VSYNC_WINDOW_0

HDMI_VSYNC_WINDOW

Defines the start and end of the window of opportunity where the HDCP EESS signaling occurs. This is defined in chapter 2.7 of the HDCP 1.1 specification.

END: Defines the end of the window of opportunity. This is measured in pixels after the active edge of VSYNC. This is defined in the specification and should not need to be written beyond its initialized value.

START: Defines the start of the window of opportunity. This is measured in pixels after the active edge of VSYNC. This is defined in the specification and should not need to be written beyond its initialized value.

ENABLE: _YES will allow EESS signaling during the window of opportunity. _NO will prevent EESS signaling.

Offset: 0x46 │ Byte Offset: 0x118 │ Read/Write: R/W │ Reset: 0x82000210 (0b1xxxxx1000000000xxxxxx1000010000)

9:0	0x210	END

23.6.50 HDMI_NV_PDISP_HDMI_GCP_CTRL_0

The following registers are used to send a single-byte packet intended for sending the general control packet as described in section 5.3.6 of the HDMI specification. This control packet is used to control the AVMUTE flag.

HDMI_GCP_CTRL

This register controls the frequency and generation of GCP packets. The fields of this register are identical to HDMI_AUDIO_INFOFRAME_CTRL.

All four subpackets contain the same GCP packet.

Offset: 0x47 │ Byte Offset: 0x11c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxx0xxx0)

Bit	Reset	Description
8	DIS	SINGLE: 0 = DIS 1 = EN

0	NO	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

23.6.51 HDMI_NV_PDISP_HDMI_GCP_STATUS_0

HDMI_GCP_STATUS

The SENT bit will be set to _DONE, after the first packet is sent. After the ENABLE bit in INFOFRAME_CTRL is set to _NO, the SENT bit will be set to _WAITING after the start of the next frame to indicate that it is safe to change the contents of the packet header and subpacket registers.

Offset: 0x48 │ Byte Offset: 0x120 │ Read/Write: RO │ Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	SENT: 1 = DONE 0 = WAITING

23.6.52 HDMI_NV_PDISP_HDMI_GCP_SUBPACK_0

HDMI_GCP_SUBPACK

This register should be written with the contents of the general control packet.

See chapter 5.3.6 of the HDMI specification for more information.

Offset: 0x49 │ Byte Offset: 0x124 │ Read/Write: R/W │ Reset: 0x00000001 (0bxxxxxxxx00000000000000000000001)

Bit	Reset	Description
23:16	0x0	SB2
15:8	0x0	SB1
7:0	0x1	SB0: 1 = SET_AVMUTE 16 = CLR_AVMUTE

23.6.53 HDMI_NV_PDISP_HDMI_CHANNEL_STATUS1_0

HDMI_CHANNEL_STATUS1

This register is used for debug purposes only. Normally, the channel status bits encoded in the SPDIF sample stream are passed directly into the HDMI audio packet. HDMI_CHANNEL_STATUS1/2 can be used to override these bits with user defined values.

If STATUS2_ENABLE is set to _YES, then the 40-bit contents of CHANNEL_STATUS2/1 is inserted into the Cl and Cr bits of the audio sample packets for audio frames 0-39. Cl and Cr contain the channel status bits. See chapter 5.3.4 of the HDMI specification for information on Cr and Cl.

The fields in SPDIF_CHN_STATUS1/2 correspond to the fields in CHANNEL_STATUS1/2 for all values except for the ABCDM field. The values read from SPDIF_CHN_STATUS1/2 can be passed directly into the fields for CHANNEL_STATUS1/2 without any manipulation. This could be used if the user only needs to force one of the fields to a specific value and leave the rest untouched. Information on the channel status bits can be found in Chapter 5 of the IEC60958-3 specification.

ABCDM: This is the first byte of the channel status information. These bits have several meanings. See chapter 5.2.1 of IEC60958-3 for more information.

CODE: This byte defines the Category Code of the input device. This code indicates what type of equipment is generating the input. See 5.3.1 of the IEC60958-3 specification for the values of codes.

SOURCE: Source number of the audio.

CHANNEL: Channel number of the audio. The channel number inserted into channel 2 will be STATUS1_CHANNEL + 1

SFREQ: The reported sampling frequency of the audio stream.

ACCURACY: Transmitter Clock accuracy.

- LVL1 High accuracy mode: Transmitted sampling frequency is within a tolerance of +/-50*10^-6
- LVL2 Normal accuracy mode: Transmitted sampling frequency is within a tolerance of +/-1000*10^-6
- LVL3 Variable pitch shifted clock mode: Only specially designed receivers can receive the signal in this mode.
- OTHER: Interface frame rate not matched to sampling frequency: This is for all other modes that do not have an embedded sampling frequency clock.

Offset: 0x4a │ Byte Offset: 0x128 │ Read/Write: R/W │ Reset: 0xf2ffffff (0b11110010111111111111111111111111)

7:0	0xff	ABCDM

23.6.54 HDMI_NV_PDISP_HDMI_CHANNEL_STATUS2_0

HDMI_CHANNEL_STATUS2

MAX_LENGTH: Reports if the maximum audio sample word length is 20 bits or 24 bits.

LENGTH: Reports the audio sample word length of this block. The value of these bits is dependent on the value of MAX_LENGTH

If MAX_LENGTH = _20 then refer to the MAX20_* defines.

If MAX_LENGTH = _24 then refer to the MAX24_* defines.

All other bit combinations are reserved.

ORIGINAL: Defines the original sampling frequency of the audio stream.

ENABLE: _YES: override the channel status data with the value of these registers. _NO: Send the original channel status data

Offset: 0x4b │ Byte Offset: 0x12c │ Read/Write: R/W │ Reset: 0x000000f1 (0b0xxxxxxxxxxxxxxxxxxxxxxxx11110001)

23.6.55 HDMI_NV_PDISP_HDMI_EMU0_0

HDMI_EMU0 and 1 do indirect addressing. EMU0 has the address, and EMU1 has the data.

To write:

1. Write the data register with data.

2. Write the address register with bit 31=1, and the address in bits 15:0.

3. Write the address register with bit 31=0.

To read:

1. Write the address register with bit 31=0 and the address in bits 15:0.

2. Read back the address register to introduce delay allowing the read data to propagate.

3. Read the data register.

Offset: 0x4c │ Byte Offset: 0x130 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

23.6.58 HDMI_NV_PDISP_HDMI_SPARE_0

HDMI_SPARE

HW_CTS - If this is set to _ENABLE, Hardware measured CTS will be enabled. This method is more accurate than using software controlled CTS. The HDMI block will count the number of TMDS clocks that occur during the interval 1/(128 * audio sample rate) and use the value as CTS and issue the ACR Packet at each interval. When hardware measured CTS is enabled, all ENABLE fields of ACR_CTRL must be set to _NO. Also, ACR_0441_SUBPACK_HIGH_ENABLE must be set to _YES.

ACR_0441_SUBPACK_HIGH_N should be written with the value of N for the current sampling frequency.

The N value must also be written into AUDIO_N_VALUE (See the AUDIO register section for more details).

The value of N can be determined from the current audio sampling frequency, the current pixel clock rate, and tables 7-1. 7-2, and 7-3 in the HDMI specification. In most cases the value in the "Other" row can be used.

FORCE_SW_CTS: When HW_CTS = ENABLE, it uses measured CTS. However, when the audio clock / video clock ratio is known, this is undesirable. Currently, HW_CTS cannot be disabled.

When FORCE_SW_CTS=ENABLE along with HW_CTS=ENABLE, the HW_CTS is used to control transmission of ACR packets, but the CTS is programmed by software in the ACR_0441_SUBPACK_LOW registers.

SUPRESS_SP_B: Default SUPRESS_SP_B=0 is to disable B bits in audio sample packets, for non-present samples. Setting SUPRESS_SP_B=1 restores the old behavior.

CTS_RESET_VAL: When an ACR packet is sent, the CTS counter is reset to the value in this field. This should be set to the INIT value of 1

ACR_PRIORITY: This controls the priority of the ACR packet with respect to Audio Sample packets. This should be set to _HIGH.

LOW: ACR packets will have lower priority than Audio Sample packets

HIGH: ACR packets will have higher priority than Audio Sample packets

Software needs to make sure these registers are set when audio is active:

- HDMI_SPARE_HW_CTS = _HW_CTS_ENABLE
- HDMI_SPARE_CTS_RESET_VAL = 1
- HDMI_SPARE_ACR_PRIORITY = _HIGH
- ACR_CTRL_*_ENABLE = _NO
- ACR_0441_SUBPACK_HIGH_ENABLE = _YES
- ACR_0441_SUBPACK_HIGH_N = N
- AUDIO_N_VALUE = N
- ACR_0441_SUBPACK_LOW_SB1 = _USE_HW_CTS_VAL

HDMI_SPARE: 0:0 rw HW_CTS init=DISABLE

enum (DISABLE,ENABLE)

1:1 rw FORCE_SW_CTS init=DISABLE

enum (DISABLE,ENABLE)

2:2 rw SUPRESS_SP_B init=SUPRESS

enum (SUPRESS, KEEP)

18:16 rw CTS_RESET_VAL init=1

31:31 rw ACR_PRIORITY init=HIGH

enum (HIGH, LOW)

Offset: 0x4f │ Byte Offset: 0x13c │ Read/Write: R/W │ Reset: 0x00010000 (0b00000000000000010000000000000000)

Bit	Reset	Description
31:0	0x10000	Reserved.

23.6.59 HDMI_NV_PDISP_HDMI_SPDIF_CHN_STATUS1_0

HDMI_SPDIF_CHN_STATUS1

HDMI_SPDIF_CHN_STATUS1/2 contains the value of the channel status bits extracted from the incoming S/PDIF audio data stream. See IEC60958-3 chapter 5 for more information on these fields.

USE Specifies consumer use (CONSUMER) or professional (PRO) use of the channel status block. SPDIF_CHN_STATUS1/2 assumes consumer use.

TYPE: Specifies the type of data the audio word represents.

- PCM: Audio sample word represents linear PCM samples
- OTHER: Audio sample word is something other than liner PCM (i.e., compressed audio)

COPYRIGHT: Copyright status of the audio.

- YES: Copyright is asserted
- NO: Copyright is not asserted

D: The values of these bits have different meanings based on the value of _TYPE.

If _TYPE==_PCM, then:

- NO_PREEMPHASIS: 2 audio channels without pre-emphasis
- PREEMPHASIS: 2 audio channels with 50 microseconds/15 microseconds pre-emphasis

All other states are reserved for future use.

MODE Defines one of four possible channel status formats for bytes 1-23 of channel status. Currently only the value "0" is defined. This format is assumed for the SPDIF_CHN_STATUS1/2.

CODE: This byte defines the Category Code of the input device. This code indicates what type of equipment is generating the input. See 5.3.1 of the IEC60958-3 specification for the values of codes.

SOURCE: Source number of the audio. If this value is zero then no source number was reported.

CHANNEL: Channel number of the audio. This reports the channel number reported for the first subframe of audio. If this value is zero then the channel number was not reported.

SFREQ: This is the reported sampling frequency of the input audio stream. The value UNDEFINED means that the sampling frequency was not indicated by the audio stream.

ACCURACY: Transmitter Clock accuracy.

- LVL1 High accuracy mode: Transmitted sampling frequency is within a tolerance of +/-50*10^-6
- LVL2 Normal accuracy mode: Transmitted sampling frequency is within a tolerance of +/-1000*10^-6
- LVL3 Variable pitch shifted clock mode: Only specially designed receivers can receive the signal in this mode

- OTHER: Interface frame rate not matched to sampling frequency: This is for all other modes that do not have an embedded sampling frequency clock.

23.6.61 HDMI_NV_PDISP_CRC_CONTROL_0

CRC_CONTROL

The main CRC enable bit flows along the pipeline. This register controls the injection of this bit at the top of the pipeline. This register is double-buffered. The active value is updated at start of each frame from this 'ARM' register.

Other registers such as SOR_STATE2.ASY_CRCMODE and SOR_*CRC* control the actual CRC logic, once enabled.

ARM_CRC_CONTROL enables or disables computation of CRC, effective at the start of next frame.

Offset: 0x96 │ Byte Offset: 0x258 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	NO	ARM_CRC_ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

23.6.62 HDMI_NV_PDISP_INPUT_CONTROL_0

INPUT_CONTROL

HDMI_SRC_SELECT selects from which of the two display units to take input. This register should be changed only when HDMI is idle.

ARM_RGB_RANGE controls whether R/G/B values of 0 and 255 are permitted (FULL), or removed by clamping to [1,254] (LIMITED).

According to the EIA/CEA-861-B and HDMI specifications, the 640x480 VGA mode uses FULL, and all others use LIMITED.

Note that this does not scale the video or change the black and white points (VGA is [0,255], others are [16,235]). That must be done, if necessary, in display or at the source.

See the HDMI 1.2a specification, section 6.6.

This register is double-buffered and will take effect on next frame boundary.

Offset: 0x97 │ Byte Offset: 0x25c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00) | Default: 0x00000001

3:0	0x8	0x0	PE_CURRENT0

23.6.65 HDMI_NV_PDISP_KEY_CTRL_0

HDCP KEY SRAM Register Control

This is the register space for the HDCP ROM interface control register. This register controls writing the contents of the hdcp_key_data bus (56 bits) into the local key store. The keys are decoded in the Crypto block, and then the key data is presented on the bus.

LOCAL: If this bit is ENABLED the on-chip HDCP key store will be used by the HDCP encryption block. If DISABLED, external Crypto-ROM will be used.

AUTOINC: If this bit is ENABLED, the address written to by the WRITE16 function will auto-increment after the operation is complete. This is the normal operating mode.

WRITE16: If this bit is set to TRIGGER, the HDCP keys module will write all 16 bytes of data from the hdcp_key_data bus (sourced by the CD module) into the local key store. The bytes are written into the store at contiguous bytes pointed to by the ADDRESS field in auto-increment mode, or contiguous bytes pointed to by the LOAD_ADDRESS field otherwise. Poll this bit until it reports DONE to ensure the write is complete.

PKEY_REQUEST_RELOAD: Requests that the private key be requested again from KFUSE. Will autoclear to zero as soon as the requested transfer of the key begins. ,Only PKEY_LOADED will indicate when the key is ready for use.

PKEY_LOADED: Indicates that the private key value has been received from KFUSE and is ready for use.

LOAD_ADDRESS: For the WRITE16 function, this field selects the start byte address of the contiguous locations in the local key store to be written with the hdcp_key_data. This field is ignored if the AUTOINC bit is ENABLED. Addresses start at 0.

ADDRESS: This read-only field reports the next byte address in the local key store to be written to once the TRIGGER bits are DONE. For the WRITE16 operation, the address will increment by 16. Addresses start at 0.

Typical operation is as follows:

1. Write to the register with LOCAL_ENABLED, AUTOINC_DISABLED, WRITE5_INIT, WRITE7_INIT, LOAD_ADDRESS_ZERO.
2. Write the downstream KSV key data into the CD module and decrypt the key (see dev_cd.ref - HDCP_KEY_REG(i) and NV_PCIPHER_CTL1).
3. Write to the register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE5_TRIGGER, WRITE7_INIT, LOAD_ADDRESS_ZERO. Poll for WRITE5_DONE.
4. Write the first downstream key data into the CD module and decrypt the key (see dev_cd.ref - HDCP_KEY_REG(i) and NV_PCIPHER_CTL1).
5. Write to the register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE7_TRIGGER, WRITE7_INIT, LOAD_ADDRESS_ZERO. Poll for WRITE7_DONE.
6. Repeat steps 4 and 5 39 more times. There are always 40 keys and one KSV value.

If upstream key authentication is required do the following:

7. Write the upstream KSV key data into the CD module and decrypt the key.

8. Write to the register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE5_TRIGGER, WRITE7_INIT, LOAD_ADDRESS_ZERO. Poll for WRITE5_DONE.
9. Write the first upstream key data into the CD module and decrypt the key (see dev_cd.ref - HDCP_KEY_REG(i) and NV_PCIPHER_CTL1).
10. Write to the register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE7_TRIGGER, WRITE7_INIT, LOAD_ADDRESS_ZERO. Poll for WRITE7_DONE.
11. Repeat steps 9 and 10 39 more times. There are always 40 keys and one KSV value.

This will leave the store as follows (the required format):

- Byte 0 to Byte 4: downstream KSV
- Byte 5 to Byte 11: 1st downstream key
- Byte 12 to Byte 18: 2nd downstream key

  ...
- Byte 278 to Byte 284: 40th downstream key
- Byte 285 to Byte 289: upstream KSV
- Byte 290 to Byte 296: 1st upstream key

  ...
- Byte 563 to Byte 569: 40'th upstream key

0	DISABLE	CODEC_SCRATCH0_ENABLE: 0 = DISABLE 1 = ENABLE

23.6.78 HDMI_NV_PDISP_HDMI_VSI_INFOFRAME_CTRL_0

HDMI_VSI_CTRL

This register controls the frequency and generation of the Vendor Specific infoframe packets. The Vendor Specific Infoframe packet contains supplemental information about the raster type. The fields of this register are identical to HDMI_AVI_INFOFRAME_CTRL except where noted below.

The Vendor Specific Infoframe is described in Appendix H of the HDMI 1.4a specification.

- ENABLE

  Setting this field to _YES will initiate infoframe generation. Setting this bit to _NO will disable infoframe generation at the beginning of the next frame.

The frequency of infoframe generation is controlled by OTHER and SINGLE fields.

- OTHER

  Setting this field to _EN while SINGLE is set to _DIS will cause infoframe to be transmitted every other frame.
- SINGLE

  Setting this field to _EN while OTHER is set to _DIS will cause infoframe to be transmitted exactly once.

If OTHER and SINGLE fields are both set to _DIS, infoframe will be generated every frame. Software should never set both OTHER and SINGLE to _EN.

- CHKSUM_HW: Hardware provides a way to calculate the Checksum for the infoframes.
  - _ENABLE will enable the hardware calculation to be passed to the packet
  - _DISABLE will use the register value defined in SF_HDMI_VSI_SUBPACK0_LOW_PB0 for the checksum.
- VIDEO_FMT

  The Vendor Specific Infoframe contains an HDMI_Video_Format Field. This field specifies how the remaining bytes in the infoframe should be interpreted by the specification. When switching to a 3D stereo format, the HDMI_Video_Format field and the 3D_Structure field need to be set appropriately. This priv register field selects whether hardware or software will set those fields.
- _SW_CONTROLLED: The HDMI_Video_Format field and 3D_Structure field will be set by SF_HDMI_VSI_SUBPACK0_HIGH_PB4 and PB5.
- _HW_CONTROLLED: The HDMI_Video_Format field and 3D_Structure field will be set automatically by Hardware based on the state of the NV_917D_Core_Head_SetHdmiCtrl method.

23.7 Serial Output Resource Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

23.7.1 HDMI_NV_PDISP_SOR_PWR_0

This register contains bits that control the power state of the SOR. For simplicity, the sequencer will be used to perform all power control operations in the SOR (even in TMDS where the sequencing is relatively simple). This unifies the approach and makes it easier for the hardware and software to deal with the SOR's. At boot, the software must load and configure the SOR sequencer via the SOR_SEQ_CTL and SOR_SEQ_INST registers below. The sequencer must be properly programmed for power control to work.

NORMAL_STATE: Sets the normal operating state. There are two choices: powered up and powered down. To change this register, software should load in the new value and write SETTING_NEW=TRIGGER. Once the change has been successfully completed, SETTING_NEW will indicate DONE. This is the state that software will want to control in order to power up and down the interface.

NORMAL_START: The execution of the power up and power down sequence can be modified somewhat by choosing to use either the NORM or ALT program entry point.

SAFE_STATE: Sets the safe operating state. There are only two choices: powered up and powered down. To change this register, software should load in the new value and write SETTING_NEW=TRIGGER. Once the change has been successfully completed, the SETTING_NEW will indicate DONE. The execution of the power up and power down sequence can be modified somewhat by choosing to use either the standard or the alternate program entry point. This is the state that the hardware will use whenever it initiates the mode switch/shutdown procedure for HDMI. In general, this should be set to STATE_PD and left there always.

SAFE_START: The execution of the power up and power down sequence can be modified somewhat by choosing to use either the NORM or ALT program entry point.

HALT_DELAY: Once the sequencer gets to the instruction with the HALT=1, the program is essentially complete; that is, the attached unit is powered up or down as was requested. Some panels, however, have a minimum time before their state can be changed again. If the halt instruction has a non-zero delay, this bit will be set while that time expires.

MODE: The currently active state, normal or safe. After reset, the MODE is always SAFE.

SETTING_NEW: This bit is used to trigger a new setting of power mode to take effect. The typical procedure might be something like:

1. Make sure SETTING_NEW==DONE, i.e., not already an outstanding change request. If there is an outstanding change request, software must wait for it to complete.

2. Update the NORMAL and SAFE power mode fields.

3. Write SETTING_NEW=TRIGGER.

4. Poll for SETTING_NEW=DONE. If it does not happen within one frame time, then software may opt to accelerate the change by writing SOR_SEQ_CTL SWITCH=FORCE (be careful not to disturb other settings in that register!).

Usage: boot / initialization / mode switch / normal operation / shutdown

Offset: 0x55 | Byte Offset: 0x154 | Read/Write: R/W | Reset: 0xXX000000 (0b0xxxxxxxxxxxxx00xxxxxxxxxxxxxx00)

Bit	R/W	Reset	Description
31	RW	0x0	SETTING_NEW: 0 = DONE 1 = PENDING 1 = TRIGGER
28	RO	X	MODE: 0 = NORMAL 1 = SAFE
24	RO	X	HALT_DELAY: 0 = DONE 1 = ACTIVE
17	RW	0x0	SAFE_START: 0 = NORMAL 1 = ALT
16	RW	0x0	SAFE_STATE: 0 = PD 1 = PU
1	RW	0x0	NORMAL_START: 0 = NORMAL 1 = ALT
0	RW	0x0	NORMAL_STATE: The normal state depends on the power sequencing state. NORMAL_STATE=1 is correct for powered-up HDMI. 0 is for the powered-down / reset state. 0 = PD 1 = PU

23.7.2 HDMI_NV_PDISP_SOR_TEST_0

This register contains control bits that configure certain aspects of testing mode of the SOR.

TEST_ENABLE: To enable testing:

- 0 = normal operation
- 1 = test mode

In test mode test_fastclkint and test_loadpulse signals from the core are used in place of the internally generated signals.

INVD: Invert the data. Note that combining INVD with the choice of DSRC and TPAT below permits ramp up, ramp down, walking ones, walking zeros, all ones, all zeros.

ACT_HEAD_OPMODE: Report the current OR operating mode.

ATTACHED: Report whether the OR is currently attached to a head.

DSRC: When DSRC=NORMAL, the serializers behave normally and use the encoded RGB data. When DSRC=DEBUG, the serializers load from DEBUGA0, DEBUGA1, DEBUGB0, and DEBUGB1 bits instead of the normal data coming down the pipe. When DSRC=TGEN, the data is taken from the built in test generator.

TPAT: Selects the test generator pattern. When test generator is running, H will be high for 1 in 4 repetitions (of duration 1024 clocks), V will be high for 4 in 16 repetitions coincident with H. Only operates when test mode is enabled.

LO: force all 0s

TDAT: use hardware fixed value

RAMP: test generator output ramps

WALK: test generator output is a walking one

MAXSTEP: 0, 1023, ...

MINSTEP: 511, 512, ...

CRC: The source of the data for CRC computation (for verification) can be either before the high-speed serializer logic, or after the high-speed serializer/deserializer logic.

TESTMUX[7:0]: Test MUX select - output seen on PROBE

Usage: Debug

Offset: 0x56 │ Byte Offset: 0x158 │ Read/Write: R/W │ Reset: 0x00800X00 (0b000000001000xx00xxxxxxxxx0xxxx0x)

Bit	R/W	Reset	Description
31:24	RW	0x0	TESTMUX: 0 = AVSS 2 = CLOCKIN 4 = PLL_VOL 8 = SLOWCLKINT 16 = AVDD 32 = VDDREG 64 = REGREF_VDDREG 128 = REGREF_AVDD
23	RW	0x1	CRC: 0 = PRE_SERIALIZE 1 = POST_DESERIALIZE
22:20	RW	0x0	TPAT: 0 = LO 1 = TDAT 2 = RAMP 3 = WALK 4 = MAXSTEP 5 = MINSTEP
17:16	RW	0x0	DSRC: 0 = NORMAL 1 = DEBUG 2 = TGEN
10	RO	X	ATTACHED: 0 = FALSE 1 = TRUE
9:8	RO	X	ACT_HEAD_OPMODE: 0 = SLEEP 1 = SNOOZE 2 = AWAKE
6	RW	0x0	INVD: 0 = DISABLE 1 = ENABLE
1	RW	0x0	TEST_ENABLE: 0 = DISABLE 1 = ENABLE

23.7.3 HDMI_NV_PDISP_SOR_PLL0_0

These registers configure the main SOR PLL and other frequency-dependent controls. The value loaded is a function of the pixel clock frequency, and whenever the pixel clock changes, these registers must be updated. In general, these registers will be updated during the second interrupt of a mode switch.

PWR: 1 = power down the TMDS PLL

PDBG: 1 = power down the bandgap

VCOPD: 1 = power down the VCO

PDPORT: 1 = power down the output drivers

RESISTORSEL: Selects the internal resistor (0) or external resistor (1).

PULLDOWN: Weak pull-down enable

- 1 = 2Kohm pulldown on all outputs.
- 0 = Weak pulldown disabled.

Note: pulldown is also controlled by the sequencer. the pulldown is derived from an OR of:

NV_PDISP_SOR_PLL0_PULLDOWN and the sequencer control of pulldown. This priv register field does not read the final pull-down value. In other words if software writes NV_PDISP_SOR_PLL0_PULLDOWN to DISABLED and sequencer pulldown is enabled, then an NV_PDISP_SOR_PLL0_PULLDOWN read will return DISABLED (while pulldown might be ENABLED due to sequencer control).

VCOCAP[3:0]: Selects the VCO capacitor and adjusts ring oscillator inter-stage load.

FILTER[3:0]: Selects the loop filter and adjusts the filter resistor value.

ICHPMP[3:0]: Specifies additions to the charge pump current in steps of 0.375 µA.

TMDS_TERM: This bit is used to enable termination. Termination is only used in TMDS mode of operation, and may not be needed at lower operating frequencies (in which case, disabling it saves power).

TERMADJ[3:0]: Termination resistance control.

LOADADJ[3:0]: Load pulse position adjust.

AUX0-AUX7: Most of these bits currently have no assigned function, but are provided to permit control of possible future features of the macro.

- AUX0: No function
- AUX1: No function
- AUX2: No function
- AUX3: Rotate green channel by 1 bit to reduce TMDS EMI
- AUX4: No function
- AUX5: No function
- AUX6: No function
- AUX7: No function

TMDS_ANALOG_X4_HP_B revision:

BG_V17_S[3:0]: Bandgap 1.7V output voltage control

TX_REG_LOAD[1:0]: TX regulator default loading

- 00: 0.5mA (default)
- 01: 1.0mA
- 10: 1.5mA
- 11: 2.0mA

PE_EN: Pre-emphasis enable. PE_EN active only at 1080p, but turn off at 720p

- 0: Disable
- 1: Enable

HALF_FULL_PE: Pre-emphasis half bit time or full bit time (Note 2)

- 0: Half bit time (default)
- 1: Full bit time (for long trace)

S_D_PIN_PE: Pre-emphasis on one single pin or on differential pins (D+ and D-) (Note 2)

- 0: Single pin (default)
- 1: Differential pins

See also the NV_PDISP_PE_CURRENT register below.

16	0x0	AUX0

23.7.6 HDMI_NV_PDISP_SOR_CSTM_0

The class permits the driver to select a number of operating modes for the SOR. Some of these modes (TMDS modes) are well defined and stable. Some modes may require customization by software before they will work. These registers are used for that customization. The fields available for customization are:

- PD_TXDA[3:0]: Bitwise control to power down the data pins of link A. Set to DISABLE to power down the pin.
- PD_TXDB[3:0]: Bitwise control to power down the data pins of link B. Set to DISABLE to power down the pin.
- PD_TXCA: Power down the clock pin of link A. Set to DISABLE to power down the pin.
- PD_TXCB: Power down the clock pin of link B. Set to DISABLE to power down the pin.

UPPER: Designates whether LVDS bank A is the upper, odd, or first pixel. Bank B is always set to !UPPER. The serial output from UPPER=1 will be Clock and A0-A3. The serial output from UPPER=0 (and DUALMODE) will be Clock and A4-A7. The default is bank A has UPPER=1, bank B has UPPER=0.

MODE[1:0]: Controls the digital output encoding applied to the data stream in custom mode and is only used for data muxing at the input of the SOR. This field does not control the TMDS macro.

- 0 = LVDS
- 1 = TMDS
- 2 = Reserved
- 3 = Reserved

LINKACTA, LINKACTB: Enables (1) or disables (0) the digital logic of links A and B

LVDS_EN: Output driver configuration for controlling the encoding of the data and the output common mode control. This does not control the internal clock dividers of the TMDS macro.

- 0 = TMDS
- 1 = LVDS

DUP_SYNC: This field only has an effect when in LVDS mode. When asserted in LVDS mode, it forces the link to use DE, HSYNC, and VSYNC for the encoding and to never use RES, CNTLE, and CNTLF. RES becomes DE. CNTLE becomes HSYNC. CNTLF becomes VSYNC.

NEW_MODE: For backwards compatibility, set register to 0 so the old mode is used. In old mode, for the second link in dual link mode, all the control bits are zeroed out except for VSYNC. When a new mode is used, none of the control bits of the second link for dual-link mode are zeroed out.

BALANCED: For MODE = LVDS, this enables balanced encoding. Balanced mode will selectively invert sets of bits in the serial stream in an attempt to keep the average DC value near zero. Default is unbalanced. Has no effect in other modes.

PLLDIV: Controls the internal clock dividers of the TMDS_MACRO by setting the feedback divider for the high-speed PLL.

- 0 = divide by 7 (LVDS)
- 1 = divide by 10 (TMDS)

ROTCLK[3:0]: Skews the TXC clock to come out earlier. By changing this register value, you can configure the skew between output data (TX data) and output clock (TXC). This field specifies the number of sclk cycles which the output clock should come out earlier than its normal phase. For TMDS, sclk is a 10x pixel clock, so ROTVAL should be between 0-9. For LVDS, sclk is a 7x pixel clock, so ROTVAL should be between 0-7.

ROTDAT[2:0]: Before encoding the 8 bits of each color channel, the 8 bits within each color channel can be right rotated. All color channels are rotated by the same amount. For example, if ROTDAT = 6, then input channel data (r7,r6,r5,r4,r3,r2,r1,r0} would become {r5,r4,r3,r2,r1,r1,r7,r6}.

ROTDAT should be between 0 and 7.

TMDS modes of operation are standard and stable. The table below summarizes the fixed values the hardware uses for the above fields for TMDS operating modes.

	SINGLE TMDS_A	SINGLE TMDS_B	SINGLE TMDS_AB	SINGLE TMDS	Dual TMDS
PD_TXDA[2:0]	0	7	0	0	0
PD_TXDA[3]	1	1	1	1	1
PD_TXDB[2:0]	7	0	0	0	0
PD_TXDB[3]	1	1	1	1	1
PD_TXCA	0	1	0	0	0

	SINGLE TMDS_A	SINGLE TMDS_B	SINGLE TMDS_AB	SINGLE TMDS	Dual TMDS
PD_TXCB	1	0	0	0	1
UPPER	1	1	1	1	1
MODE[1:0]	1	1	1	1	1
LINKACTA	1	0	1	1	1
LINKACTB	0	1	1	1	1
LVDS_EN	0	0	0	0	0
DUP_SYNC	0	0	0	0	0
NEW_MODE	0?	1	1	1	0?
BALANCED	0	0	0	0	0
PLLDIV	1	1	1	1	1
ROTCLK[3:0]	0	0	0	0	0
ROTDAT[2:0]	0	0	0	0	0

The first register defines the total custom mode. This is useful for defining possible new modes of operation as well as for test and characterization in the lab. Which is to say, this is a debug register set. Software should really never need to use it. Also, note that if LVDS_ONLY=TRUE, then this register cannot be used as the hardware will only permit Protocol=LVDS to be enabled. This register is intended to have the same format as the second register.

Usage: boot / initialization / mode switch

Offset: 0x5a │ Byte Offset: 0x168 │ Read/Write: R/W │ Reset: 0x0001c800 (0bx0000000xx0x000111001x0000000000) | Default: 0x02000000

23.7.8 HDMI_NV_PDISP_SOR_CRCA_0

The following three registers are used to fetch CRC's when running VGA mode tests. One contains the valid bit, one contains the actual computed CRC, and the third contains the error (overrun bit). Proper use of these registers is as follows:

1) Poll SOR_CRCA for VALID == TRUE.

2) Reset SOR_CRCA by writing RESET to it.

3) Read SOR_CRCB to get the CRC

Usage: verification

Offset: 0x5c │ Byte Offset: 0x170 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	VALID: 0 = FALSE 1 = TRUE 1 = RESETV

23.7.9 HDMI_NV_PDISP_SOR_CRCB_0

Usage: verification

Offset: 0x5d │ Byte Offset: 0x174 │ Read/Write: RO │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	CRC

23.7.10 HDMI_NV_PDISP_SOR_BLANK_0

This register can be used to override the SOR output resource pixels with blank data.

OVERRIDE: Setting this field to true will override the pixel bus from the RG and output black pixels instead.

TRANSITION: This field controls the timing of the output resource blank override. The choices are IMMEDIATE. The output resource will be blanked or restored to its previous output data immediately.

NEXT_VSYNC The output resource will be blanked or restored to its previous output data at the next vsync.

STATUS This read-only field returns BLANKED when the output resource is sending blank pixels forced by the OVERRIDE bit, otherwise it returns NOT_BLANKED.

Usage: boot / initialization / mode switch / normal operation

Offset: 0x5e │ Byte Offset: 0x178 │ Read/Write: R/W │ Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	R/W	Reset	Description
2	RO	X	STATUS: 0 = NOT_BLANKED 1 = BLANKED
1	RW	0x0	TRANSITION: 0 = IMMEDIATE 1 = NEXT_VSYNC
0	RW	0x0	OVERRIDE: 0 = FALSE 1 = TRUE

23.7.11 HDMI_NV_PDISP_SOR_SEQ_CTL_0

Sequencer control registers for SOR. Up to three pins can be assigned to an SOR for use in controlling the power to an attached LVDS flat panel. The meaning of any particular pin and whether it is actually available to this SOR is controlled in either the host or PCB manager. In addition, the sequencer can override the individual link clock and data power control pins, thereby forcing them all into disabled or tristate mode and it can override the DE signal from the RG (for TMDS mode) to force the link to become inactive.

PU_PC: The program counter for the start of the power up program sequence. Always 0.

PU_PC_ALT: The alternate entry point into the power up program sequence. Defaults to the same value as PU_PC.

PD_PC: The program counter for the start of the power down program sequence. Defaults to 8, evenly dividing the available program space.

PD_PC_ALT: The alternate entry point into the power down program sequence. Defaults to the same default value as PD_PC.

PC: The current value of the program counter (useful for status and debug).

STATUS: Indicates if the sequencer is STOPPED or RUNNING.

SWITCH: If a particular sequencer instruction is waiting for vsync to arrive, writing this bit to FORCE will cause the wait condition to be satisfied immediately.

> **Note:** The sequencer can begin with arbitrary phase relative to the 1 µs timer that is used to advance the internal counters. Thus the actual time delay for the first event can be almost one microsecond less than what is requested. Subsequent instructions in a chain of events do transition on 1 µs boundaries, however. If a minimum specification of "x" µs is required, then it is best to program "x+1" µs of delay.

Usage: boot / initialization / mode switch

Offset: 0x5f │ Byte Offset: 0x17c │ Read/Write: R/W │ Reset: 0xX00X880X (0bx0xxxxxxxxxxxxxx100010000000xxxx)

- 1001110: 27.8mA
- 1001111: 28.2mA
- 1010000: 25.4mA
- ...

1111111: 28.2 mA

By default, FUSE_OVERRIDE is FALSE, meaning that the TMDS current control is driven via calibration data stored in the fuse block. Software can override these defaults by programming FUSE_OVERRIDE to TRUE, and setting each LANEn field to the appropriate value.

23.7.29 HDMI_NV_PDISP_SOR_REFCLK_0

SOR_REFCLK

The HDMI clock is programmable and varies, depending on screen resolution. The NV_PDISP_SOR_SEQ_INSTn instructions (above) can wait for certain time intervals to elapse. Whenever hdmi_clk frequency is changed, this register must be reprogrammed to divide hdmi_clk to produce a 1 µs time reference, otherwise the time intervals requested by NV_PDISP_SOR_SEQ_INSTn will not be accurate.

The format of DIVISOR is an unsigned 8.2 divider. Because this is a simple digital divider, not a PLL, fractional values result in a jitter of one hdmi_clk between successive "1 µs" intervals, but the long-term average works out to the requested divisor. This jitter is OK because the NV_PDISP_SOR_SEQ_INST wait intervals do not need to be exact. If the integer part is written as 0, it will be interpreted the same as "1".

23.8 Test and Debug Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

23.8.1 HDMI_NV_PDISP_SOR_VCRCA0_0

To quickly determine if the TMDS is working properly, a running CRC stamp is kept, which is reset at each VSYNC. For each sub-link, there are up to 40 bits of encoded data that have been re-parallelized from the serial data going out.

These encoded bits of data are broken up into three 16-bit pieces depending on either LVDS or TMDS encoding:

For TMDS, the encoded data is as follows:

- CRCH: {8'b00000000,TMDS_CLK_ENC[9:2]}
- CRCM: {TMDS_CLK_ENC[1:0],TMDS_TX2_ENC[9:0],TMDS_TX1_ENC[9:6]}
- CRCL: {TMDS_TX1_ENC[5:0],TMDS_TX0_ENC[9:0]}

For LVDS, the encoded data is as follows:

- CRCH: {8'b00000000,LVDS_CLK_ENC[6:4]}
- CRCM: {LVDS_CLK_ENC[3:0],,LVDS_A3_ENC[6:0],LVDS_A2_ENC[6:2]}
- CRCL: {LVDS_A2_ENC[1:0],LVDS_A1_ENC[6:0],LVDS_A0_ENC[6:0]}

For each of these pieces, a CRC16 is computed, CRCH for the upper 16-bit piece, CRCM forms the middle 16-bit piece, and CRCL for the lower 16-bit piece. The CRC16 takes in the 16 bits of encoded data plus the CRC16 value of the previous cycle to generate the new CRC16. The CRC equation which is used is:

$x^{16} + x^{11} + x^4 + 1$.

At each VSync, the previously running CRC16 values are captured into the VCRC registers and a previous CRC value of all zeroes is fed into the CRC16 units. This means the running CRC16 is reset at each VSync.

Note:	For power saving, the VCRC is only computed when NV_PDISP_SOR_TRIG != 0. Also, it seems these are not latched at VSync but are free-running.

The VCRC registers for sub-link A

Usage: debug

Offset: 0x72 │ Byte Offset: 0x1c8 │ Read/Write: RO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	CRCM
15:0	X	CRCL

23.8.2 HDMI_NV_PDISP_SOR_VCRCA1_0

Usage: debug

Offset: 0x73 │ Byte Offset: 0x1cc │ Read/Write: RO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	CRCH

23.8.3 HDMI_NV_PDISP_SOR_CCRCA0_0

The CCRC registers contain the CRC value for the encoded link, captured when the trigger event occurred.

The CCRC registers for sub-link A

Usage: debug

Offset: 0x74 | Byte Offset: 0x1d0 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	CRCM
15:0	X	CRCL

23.8.4 HDMI_NV_PDISP_SOR_CCRCA1_0

Usage: debug

Offset: 0x75 | Byte Offset: 0x1d4 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	CRCH

23.8.5 HDMI_NV_PDISP_SOR_EDATAA0_0

EDATA has the encoded data for the serial channels TXC, TX3, TX2, TX1, and TX0. For each link, there are up to 40 bits of encoded data. The encoded bits making up the data are as follows:

For TMDS, the encoded data is as follows:

```
EDATA[39:0] =
{TMDS_CLK_ENC[9:0],
TMDS_TX2_ENC[9:0],
TMDS_TX1_ENC[9:0],
TMDS_TX0_ENC[9:0]}
```

For LVDS, the encoded data is as follows:

```
EDATA[39:0] =
{5'b00000,
LVDS_CLK_ENC[6:0],
LVDS_A3_ENC[6:0],
LVDS_A2_ENC[6:0],
LVDS_A1_ENC[6:0],
LVDS_A0_ENC[6:0]}
```

The EDATA registers can be written to when any of the trigger bits for capture are set high.

The EDATA registers for sub-link A

Usage: debug

Offset: 0x76 | Byte Offset: 0x1d8 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VAL

23.8.6 HDMI_NV_PDISP_SOR_EDATAA1_0

Usage: debug

Bit	Reset	Description
7:0	X	VAL

23.8.7 HDMI_NV_PDISP_SOR_COUNTA0_0

There are three 16-bit counts for each sub-link (TX0, TX1, TX2). The count registers for sub-link A.

Usage: debug

Offset: 0x78 | Byte Offset: 0x1e0 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	TX1
15:0	X	TX0

23.8.8 HDMI_NV_PDISP_SOR_COUNTA1_0

Usage: debug

Offset: 0x79 | Byte Offset: 0x1e4 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	TX2

23.8.9 HDMI_NV_PDISP_SOR_DEBUGA0_0

The debug registers for sub-link A

The following registers control the debug data input to the serializer. These bits are only relevant when TEST_ENABLE is set.

DEBUGA0 has the data for the serial channels TXC, TX3, TX2, TX1, and TX0. For each link, there are up to 40 bits of data to be encoded. The bits to be encoded which make up the data are as follows:

For TMDS, the data to be encoded are loaded as follows:

```
{TMDS_CLK_ENC[9:0], TMDS_TX2_ENC[9:0], TMDS_TX1_ENC[9:0], TMDS_TX0_ENC[9:0]}
 =
 {DEBUGA1, DEBUGA0}
```

For LVDS, the encoded data is as follows:

```
 {5'b00000, LVDS_CLK_ENC[6:0], LVDS_A3_ENC[6:0], LVDS_A2_ENC[6:0],
 LVDS_A1_ENC[6:0], LVDS_A0_ENC[6:0]}
 =
 {DEBUGA1[2:0], DEBUGA0}
```

Usage: debug

Offset: 0x7a | Byte Offset: 0x1e8 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	VAL: 0 = RESETV

23.8.10 HDMI_NV_PDISP_SOR_DEBUGA1_0

Usage: debug

Offset: 0x7b │ Byte Offset: 0x1ec │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	VAL: 0 = RESETV

23.8.11 HDMI_NV_PDISP_SOR_TRIG_0

TRIG specifies the number of pixel clock cycles after the previous VSYNC was detected to capture state data into IDATA, EDATA, CNT, and CCRC. After the trigger has captured data, the trigger gets reset with the next VSYNC and waits TRIG pixel cycles to capture data again. If the TRIG value is greater than the number of cycles between consecutive VSYNCs, then the trigger is not reset while it is still pending to capture data. Once the data has been captured, the trigger is reset with the following VSYNC to capture data again. If TRIG is all zeros, then the trigger is disabled and no capturing occurs.

Usage: debug

Offset: 0x7c │ Byte Offset: 0x1f0 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxx000000000000000000000000)

Bit	Reset	Description
23:0	0x0	VAL: 0 = RESETV

23.8.12 HDMI_NV_PDISP_SOR_MSCHECK_0

The mode switch monitor is used for hardware debug only. To use, the test should set the CTL bit to CLEAR and then to RUN. At the end of the test, the register can be read. The various fields indicate the number of times the following conditions occurred:

- CRC enable went from false to true
- CRC enable went from true to false
- Data enable went from false to true
- Data enable went from true to false

All counts have 4 bits, so the count will clamp at 15.

Usage: debug

Offset: 0x7d │ Byte Offset: 0x1f4 │ Read/Write: R/W │ Reset: 0x80000000 (0b1xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
31	RW	0x1	CTL: 0 = CLEAR 1 = RUN
15:12	RO	X	DATA_ENABLE_T2F
11:8	RO	X	DATA_ENABLE_F2T
7:4	RO	X	CRC_ENABLE_T2F
3:0	RO	X	CRC_ENABLE_F2T

23.9 Audio Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

23.9.1 HDMI_NV_PDISP_AUDIO_N_0

AUDIO_N

N_VALUE: N_VALUE is the N parameter in HDMI Audio Clock Regeneration Packet. This value should be written when hardware measured CTS is enabled. The correct N value can be read from tables 7-1, 7-2, and 7-3 in the HDMI specification.

N_RESET: N_RESET is the reset for the N counter. If software is controlling the value of N, every time the audio stream changes sampling frequency (fs), software (driver) need to reset the N counter by writing _ASSERT to N_RESET followed by writing a _DEASSERT to N_RESET.

If the hardware selected N feature is enabled (N_LOOKUP = _ENABLE), software only needs to reset the N counter when writing to the AUDIO_NVAL registers and when enabling/disabling N_LOOKUP.

1) Set N_RESET = _ASSERT

2) Modify N value registers

3) Set N_RESET = _DEASSERT

Modifying N_VALUE can be done in step 1.

N_GENERATE: N_GENERATE controls how the audio block generates the 128*fs/N pulse, which is related to CTS. The detail of CTS can be found in HDMI 1.1 specification, Chapter 7. This bit is strictly for debugging purposes only.

_NORMAL: This method increments the CTS counter a variable number of times based on the length of the S/PDIF pulse.

_ALTERNATE: This method attempts to recreate the 128*fs clock and increments the CTS counter at regular intervals based on HALF.

N_LOOKUP: When set to _ENABLE, the hardware will select the appropriate value of N to use from one of the AUDIO_NVAL registers. This selection is based on the audio sampling frequency detected by the audio block. This is not the sampling frequency reported in the channel status bits. N_RESET should be toggled when this feature is enabled. When set to _DISABLE, software must program the correct N value into AUDIO_N.

Offset: 0x8c │ Byte Offset: 0x230 │ Read/Write: R/W │ Reset: 0x01000000 (0bxxx0xxx1xxx00000000000000000000)

Bit	Reset	Description
28	0x0	LOOKUP: 1 = ENABLE 0 = DISABLE
24	0x1	GENERATE: 0 = NORMAL 1 = ALTERNATE
20	0x0	RESETF: 1 = ASSERT 0 = DEASSERT
19:0	0x0	VALUE

23.9.2 HDMI_NV_PDISP_SOR_AUDIO_CNTRL0_0

HD Audio (also known as Azalia)

PORT_CONNECTIVITY: This controls the behavior of the Port Connectivity field of the Azalia Configuration Defaults Verb. This can be used to disable a codec that is associated with an SOR that does not connect to a physical port.

- ENABLE: Report 00 in the Port Connectivity field by default. This corresponds to "The Port Complex is connected to a jack"
- DISABLE: Report 01 in the Port Connectivity field by default. This corresponds to "No physical connection for Port" See table 100 and table 101 of the High Definition Audio Specification (Revision 1.0) for more information.

AFIFO_FLUSH: When the DP and HDMI logic are not in the middle of sending an audio packet, they will flush out any entries at the head of the AFIFO that is not tagged as the beginning of a sample. This ensures that the next new audio packet sent will begin on the correct channel. This is a diagnostic workaround bit to disable the flushing.

- ENABLE: Automatically fix the AFIFO if it gets out of alignment
- DISABLE: Do not throw out any AFIFO entries.

SAMPLING_FREQ: This will report the incoming audio stream sampling frequency in the Azalia codec. The HDMI specification only supports 7 audio sample frequencies (fs). Anything other than those 7 fs will be reported as UNKNOWN. See the HDMI 1.1 specification, Table 7-4 (page 77).

SOURCE_SELECT: Determines whether to use the S/PDIF or Azalia (HDAL) audio input. This field has no effect on chips without the HDAL input. The default is AUTO: selects S/PDIF audio until the HDAL audio input is initialized by the external controller

INJECT_NULLSMPL: When the bit is enabled, if the audio format is stereo LPCM as indicated by the stream format in the corresponding output converter widget, the codec inserts null samples into the audio FIFO for each Azalia frame in which it did not receive any samples. This is done only for stereo LPCM and not for any other audio format. This bit should be disabled by default for backwards compatibility.

INPUT_MODE: This bit indicates what the audio data source is. HDA is Azalia data, S/PDIF is S/PDIF data.

SOR_AUDIO_CNTRL0

Offset: 0xac │ Byte Offset: 0x2b0 │ Read/Write: R/W │ Reset: 0xX01X1000 (0bxx0xxxxxxx01xxxxxxx1xxxxxxxxxxx0)

Bit	R/W	Reset	Description
31	RO	X	INPUT_MODE: 0 = HDA 1 = SPDIF
29	RW	DISABLE	INJECT_NULLSMPL: 0 = DISABLE 1 = ENABLE
21:20	RW	SPDIF	SOURCE_SELECT: 0 = AUTO 1 = SPDIF 2 = HDAL
19:16	RO	X	SAMPLING_FREQ: 3 = FREQ_32_0KHZ 0 = FREQ_44_1KHZ 8 = FREQ_88_2KHZ 12 = FREQ_176_4KHZ 2 = FREQ_48_0KHZ 10 = FREQ_96_0KHZ 14 = FREQ_192_0KHZ 1 = FREQ_UNKNOWN

Bit	R/W	Reset	Description
12	RW	ENABLED	AFIFO_FLUSH: 0 = DISABLED 1 = ENABLED
0	RW	ENABLE	PORT_CONNECTIVITY: 0 = ENABLE 1 = DISABLE

23.9.3 HDMI_NV_PDISP_SOR_AUDIO_DEBUG_0

SOR_AUDIO_DEBUG

This register is used for debug purposes only.

FIFO_ERROR: The data is passed from the audio (Azalia or S/PDIF) to the SOR via an async FIFO. This bit indicates that the FIFO is full. There is one bit for each head. This is an indication that the SOR units do not drain away the audio sample data fast enough.

Offset: 0xad │ Byte Offset: 0x2b4 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	NO	FIFO_ERROR: 0 = NO 1 = YES

23.9.4 HDMI_NV_PDISP_SOR_AUDIO_SPARE0_0

This register is a backup register.

SOR_AUDIO_SPARE0

Offset: 0xae │ Byte Offset: 0x2b8 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	Reserved.

23.9.5 HDMI_NV_PDISP_SOR_AUDIO_NVAL_0320_0

SOR_AUDIO_NVAL

The following seven registers are used for HDMI N values for Azalia. These registers should be written with the correct N values for the current pixel clock frequency. These values can be found in tables 7-1, 7-2, and 7-3 of the HDMI specification. These registers are initialized to the value in the "other" row of these tables.

For DisplayPort audio, a value of 2^15 (0x8000) is always used.

VALUE: The correct N value for 32 kHz audio at the current pixel clock frequency should be written here.

Offset: 0xaf │ Byte Offset: 0x2bc │ Read/Write: R/W │ Reset: 0x00001000 (0bxxxxxxxxxxxxx00000001000000000000)

23.9.18 HDMI_NV_PDISP_SOR_AUDIO_HDA_ELD_BUFWR_0

Software Programming Model

In an integrated graphics chip, which includes an NVIDIA® Audio Controller, with support for an NVIDIA audio codec driver, the following is the background and the suggested programming model.

The audio software for the HDMI codec will need information about the audio capabilities of an attached HDMI sink device. This information is stored in the HDMI sink device's EDID. Typically, the EDID flows through a graphics adapter to graphics software, so the graphics adapter hardware will not have knowledge of the EDID contents.

To that end, a new mechanism is defined for passing the HDMI sink device's audio EDID information from the graphics software to the audio software. The data payload containing the audio information will be known as EDID-Like Data (or ELD) and will contain a subset of the HDMI sink devices EDID information.

The ELD information will be valid if the HDMI sink is attached and powered on and the ELD Valid bit is set. The Pin Widget that is associated with this HDMI widget will report if the device is attached and that the ELD memory is populated and valid by reporting Presence Detect of 1 and ELD Valid of 1 to a Pin Sense control command. As with the Presence Detect bit, the changes to the ELD Valid bit can also result in the generation of unsolicited responses.

Each codec implements a 96-byte ELD buffer that is written by the resource manager and read by the audio driver. Once the ELD buffer is written by the resource manager, the valid bit, NV_PDISP_SOR_AUDIO_HDA_PRESENSE_ELDV is set to _VALID to indicate that ELD contents have been initialized by the resource manager. On hot unplug events, NV_PDISP_SOR_AUDIO_HDA_PRESENSE_ELDV is set to _INVALID to erase ELD programming in the audio driver.

Offset: 0xbc │ Byte Offset: 0x2f0 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description

7:0	0x0	DATABYTE

23.9.19 HDMI_NV_PDISP_SOR_AUDIO_HDA_PRESENSE_0

Reports the Hot Plug state and ELD state to the audio driver. Changes to this state can cause an unsolicited response.

ELDV: Indicates whether the data in the ELD buffer is valid and ready to read.

PD: Presence Detect. This should be set to _PRESENT by software upon hot plug and _NOT_PRESENT on unplug.

Offset: 0xbd │ Byte Offset: 0x2f4 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	INVALID	ELDV: 0 = INVALID 1 = VALID
0	NOT_PRESENT	PD: 0 = NOT_PRESENT 1 = PRESENT

23.9.20 HDMI_NV_PDISP_SOR_AUDIO_HDA_CP_0

Reports the Content Protection state requested by the Audio driver. It is at the discretion of the video driver to enable or disable content protection. This is a read-only register set by the Content Protection Control (CP_CONTROL) verb.

REQUEST_STATE

_DONT_CARE: No state change requested

_RESERVED: Unused

_PROTECTION_OFF: Audio driver requests content protection to be disabled.

_PROTECTION_ON: Audio driver requests content protection to be enabled.

		0 = DONT_CARE 2 = PROTECTION_OFF 3 = PROTECTION_ON

23.9.21 HDMI_NV_PDISP_SOR_AUDIO_AVAL_0320_0

When using the Azalia codec, it is difficult to recover the 128*fs clock frequency from the incoming audio stream. Therefore, when using the Azalia codec, these registers must be programmed to emulate the N counter.

When using S/PDIF, the N counter will run at 128*fs (audio sampling frequency) and count to a value determined by the HDMI specification. The Azalia counter will run at 24 MHz at all times, and it needs to count for the same period of time as the N counter would have.

Refer to section 7.2 of the HDMI specification, 1.2.

AVAL values do not need to be programmed by software. Their default values are OK. If the NVAL changes, it will change the N counter frequency. AVAL will need to be changed to match with this new NVAL. Certain resolutions may require different NVALs.

For Mobile chips, the clock is 24 MHz, not 54 MHz. For 44.1, the default N of 6272 gives non-integer AVAL. Choosing N of 4704 instead (nominal CTS 61875) gives an N frequency of 1200 Hz.

48k: 1ms 24000 azaclk cycles (0x5DC0)

44.1k: 1ms/1.2 20000 azaclk cycles (0x4E20)

But this is academic because CTS/N is hardcoded since the pixel clock / audio clock ratios are known and fixed.

At 27 MHz Pixel Clock			
	CTS	**N**	**AVAL**
44.1	22500	4704	20000
88.2	22500	9408	20000
176.4	22500	18816	20000
At 74.25 MHz Pixel Clock			
44.1	61875	4704	20000
88.2	61875	9408	20000
176.4	61875	18816	20000
At 148.5 MHz Pixel Clock:			
44.1	123750	4704	20000

24.0 LVDS/EDP DISPLAY OUTPUT

24.1 Overview

The Tegra® K1 LVDS/eDP Serial Output Resource (SOR) block is a display output controller, with two operating modes, supporting either Low Voltage Differential Signaling (LVDS) or Embedded DisplayPort (eDP). It drives local panels only and does not support an external DP port.

The LVDS/eDP SOR block collects pixels from the output of the display pipeline, formats/encodes them to the LVDS/eDP format, and then streams them to various output devices. The LVDS/eDP block consists of individual resources that can interface with different display devices. An LVDS/eDP block can drive only a single device at any given time and can be connected to any display controller (Head).

24.2 Features

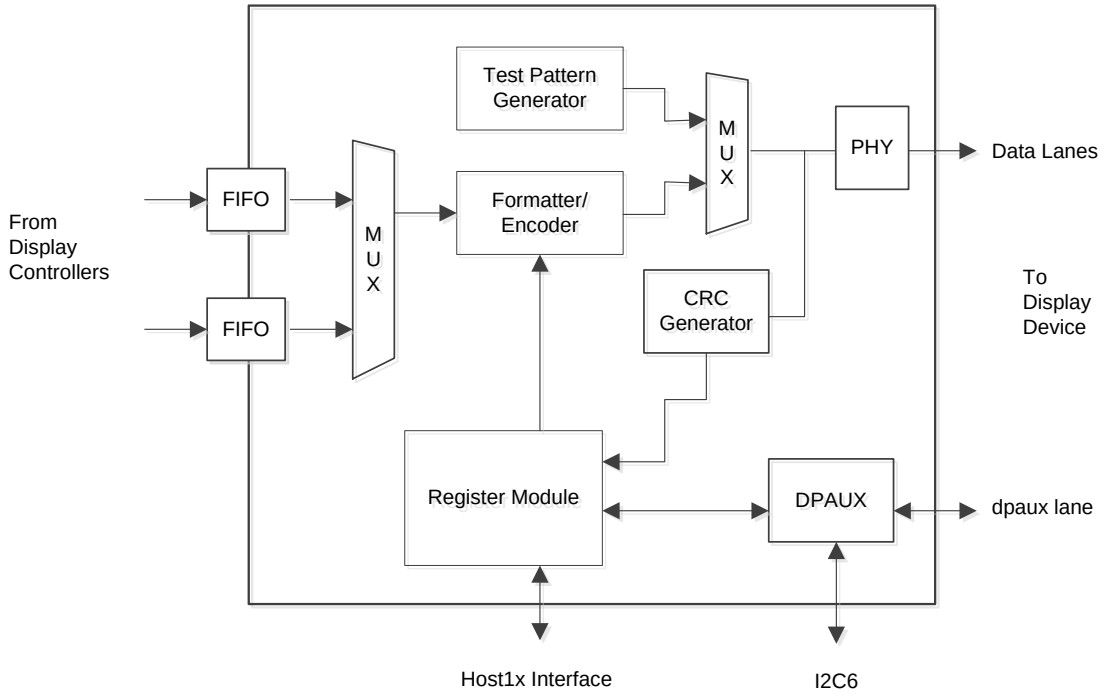
These features are supported in the LVDS/eDP SOR block:

- eDP 1.4
  - 1/2/4 lanes, single link
  - RBR/HBR/HBR2
  - 18/24 bits color depth
  - Up to 450MHz
  - Internal panel:
    - 3200 x 2000 @ 60Hz (2D – portrait/landscape)
    - 1920 x 1080 @ 60Hz (3D – portrait/landscape)
  - -0.5% down spread support
- LVDS
  - 3/4 data lanes + 1 clock lane, single link
  - 18/24 bits color depth
  - Intel 24.0/24.1 single channel format
  - Up to 165 MHz
  - Internal panel:
    - 1920 x 1200 @ 60Hz (2D – portrait/landscape)
  - LVDS direct connect (captive panel)
  - Spread-spectrum capable to -5.0%
  - Additional I2C port for LVDS
- Stereo mode
- Generic infoframe
- Supports DP AUX and HPD
- Single PHY to select LVDS or eDP as output
  - Either a 4-lane eDP or a 5-lane (single-link) LVDS
  - Supports 5.4 GHz eDP or 165MHz pixel clock LVDS

24.3 Functional Description

The LVDS/eDP block has a pixel bus as an input from the display pipe of each head. It also has a small test pattern generator and formatter to encode pixels for specific output devices, a CRC generator, and a bundle interface to the display software interface.

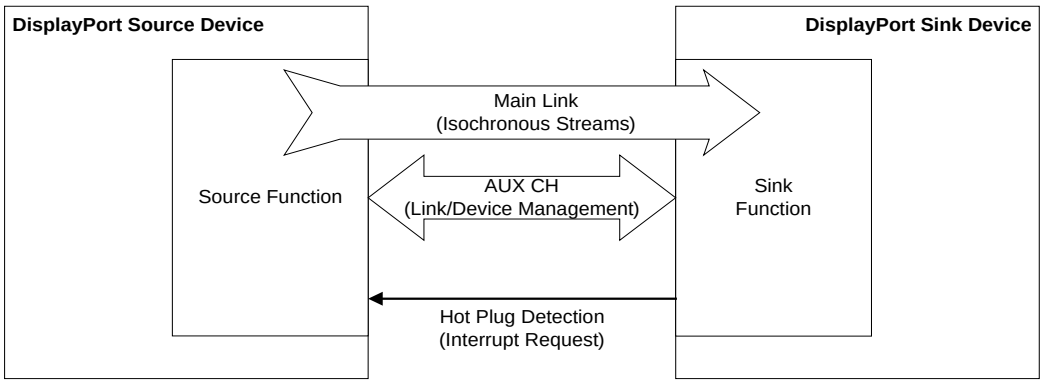
Figure 81: LVDS/eDP High-Level Block Diagram



24.4 DisplayPort Overview

The DisplayPort link consists of Main Link, Auxiliary Channel (AUX CH), and Hot Plug Detect (HPD) channels. Main Link is a unidirectional, high-bandwidth, and low-latency channel used for transport of isochronous streams such as uncompressed video and audio. Auxiliary Channel is a half-duplex, bidirectional channel used for link management and device control. The HPD signal serves as an interrupt request by the sink device. Main Link consists of AC-coupled, doubly terminated differential pairs (called lanes). Three link rates are supported: 5.4 Gbps, 2.7 Gbps, and 1.62 Gbps per lane. The Main Link supports 1, 2, or 4 lanes.

Figure 82: DisplayPort Link



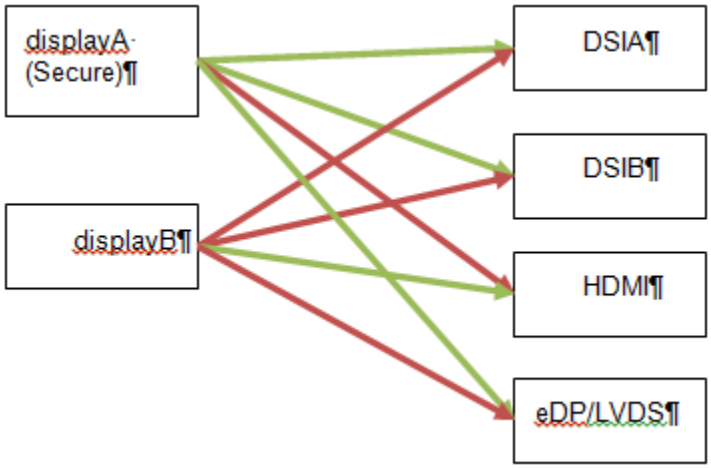
24.5 SOR Security

The eDP/LVDS SOR block does not support TZ_SECURE access.

The ARM TrustZone document requires Secure OS to control the connection of Secure Window to displays.

The typical Secure Display use case is below; green arrows are permitted SOR connections, and red arrows are disabled. All paths can be controlled by the Secure OS using the SECURE_CONTROL registers.

Figure 83: Secure Display Use Case



The TrustZone window will drive an interrupt similar to underflow interrupts from other windows. Mask and status registers related to this window are non-secure.

24.6 LVDS/eDP Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

24.6.1 SOR_CTXSW_0

Context switch register. Should be common to all modules. Includes the current channel/class (which is writable by SW) and the next channel/class (which the hardware sets when it receives a context switch).

Context switch works like this:

Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS (see vmod/chexample). SW sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be pre-loaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts.

Another way to avoid context switch interrupts is to set the AUTO_ACK bit.

This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 0x0 | Byte Offset: 0x0 | Read/Write: R/W | Reset: 0xXXXXf800 (0bxxxxxxxxxxxxxxxx11111x0000000000)

Bit	R/W	Reset	Description
31:28	RO	X	NEXT_CHANNEL: Next requested channel
25:16	RO	X	NEXT_CLASS: Next requested class
15:12	RW	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	RW	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests 0 = MANUAL 1 = AUTOACK
9:0	RW	0x0	CURR_CLASS: Current working class

24.6.2 SOR_NV_PDISP_SOR_SUPER_STATE0_0

The following 2 registers are the equivalent for supervisor methods that GPU HW automatically used to enqueue.

Writing a 1 to this field cause a 1 cycle pulse which is used to activate the fields in registers NV_PDISP_SOR_STATE[1].

Offset: 0x1 | Byte Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	UPDATE

24.6.3 SOR_NV_PDISP_SOR_SUPER_STATE1_0

NV_PDISP_SOR_SUPER_STATE1 contains triple buffered registers. The values written to SUPER_STATE1 are assembly values.

These are promoted to ARMed state when SUPER_STATE0 UPDATE is written.

The ARMed values are then promoted to ACTIVE internally by HW when an internally generated LOADV signal arrives.

The active state is reported in DISP_SOR_PWR and DISP_SOR_TEST registers

ATTACHED

- YES : Attach SOR to a display head
- NO : Detach SOR from display head

ASY_ORMODE

- SAFE: SOR is in safe low power state and not sending any active data.
- NORMAL : SOR is actively sending data

ASY_HEAD_OPMODE

- SLEEP : Display is not sending pixels and SOR will stop reading pixels from FIFOs
- SNOOZE : This should never be set by SW.
- AWAKE : Display is sending active pixels to SOR

Offset: 0x2 | Byte Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
3	NO	ATTACHED: 0 = NO

1:0	0x0	ASY_HEAD_OPMODE: 0 = SLEEP 1 = SNOOZE 2 = AWAKE

24.6.4 SOR_NV_PDISP_SOR_STATE0_0

Writing a 1 to this field cause a 1 cycle pulse which is used to promote the activate the fields in registers NV_PDISP_SOR_STATE[1], NV_PDISP_HEAD_STATE[0-5].

Offset: 0x3 | Byte Offset: 0xc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	UPDATE

24.6.5 SOR_NV_PDISP_SOR_STATE1_0

SOR Control Register

ASY_PIXELDEPTH

This sets the pixel depth and the only valid values are BPP_18_444 and BPP_24_444.

ASY_REPLICATE

This is used to enable/disable pixel replication for HDMI. This should always be set to OFF for Tegra as SOR0 does not support HDMI.

ASY_DEPOL

This field needs to be set based on the DE polarity as needed by the panel

ASY_VSYNCPOL

This field needs to be set based on the VSYNC polarity as needed by the panel

ASY_HSYNCPOL

This field needs to be set based on the HSYNC polarity as needed by the panel

ASY_CRCMODE

This field controls the pixels (LVDS) or symbols (eDP) that get CRCed.

- ACTIVE_RASTER --> Only active regions of the raster are CRCed
- COMPLETE_RASTER--> Entire raster (active + blanking) will be CRCed.
- NON_ACTIVE_RASTER --> Only non-active regions of the raster are CRCed

ASY_SUBOWNER

This field should always set to NONE.

ASY_OWNER

This field controls the display pipe that is being connected to the SOR. Note that the ARMED value of this filed is promoted only when SOR gets attached.

- HEAD0 --> When SOR needs to be connected to display internal head : displaya
- HEAD1 --> When SOR needs to be connected to display external head : displayb
- NONE --> When it is not connected to any heads

Offset: 0x4 | Byte Offset: 0x10 | Read/Write: R/W | Reset: 0x00000040 (0bxxxxxxxxxxxx00000000000000001000000)

3:0	NONE	ASY_OWNER: 0 = NONE 1 = HEAD0 2 = HEAD1

24.6.6 SOR_NV_PDISP_HEAD_STATE0_0

Head Control Register

INTERLACED

Should always be set to PROGRESSIVE as INTERLACED is not supported

RANGECOMPRESS

Compresses the range of an RGB signal with black at 0, white at nominal 255 to the range required for CEA ranged RGB output, i.e., black at 16, white at 235. This control gives the driver a very quick way to compress RGB levels to be compatible with those required for output to TV via the TV encoder and/or to HDMI.

DYNRANGE

Sets the dynamic range for the output. VESA is the full 0 to maximum range. CEA mode will clip the output to fit within CEA range. Display Port has a restriction that BPP_18_444 RGB mode must use VESA.

COLORSPACE

Should always be set to RGB. YUV_601/YUV_709 are not supported

This is an array of 2 identical register entries; the register fields below apply to each entry.

Offset: 0x5..0x6 | Byte Offset: 0x14..0x18 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx000000)

Bit	Reset	Description
5:4	PROGRESSIVE	INTERLACED: 0 = PROGRESSIVE 1 = INTERLACED
3	DISABLE	RANGECOMPRESS: 0 = DISABLE 1 = ENABLE
2	VESA	DYNRANGE: 0 = VESA 1 = CEA
1:0	RGB	COLORSPACE: 0 = RGB 1 = YUV_601 2 = YUV_709

24.6.7 SOR_NV_PDISP_HEAD_STATE1_0

This register sets the size of the raster

VTOTAL

This field is the total number of lines in a frame of the raster.

HTOTAL

This field is the total number of pixels in a line of the raster.

This is an array of 2 identical register entries; the register fields below apply to each entry.

Offset: 0x7..0x8 | Byte Offset: 0x1c..0x20 | Read/Write: R/W | Reset: 0x01011000 (0bx000000100000001x001000000000000)

Bit	Reset	Description
30:16	0x101	VTOTAL
14:0	0x1000	HTOTAL

24.6.8 SOR_NV_PDISP_HEAD_STATE2_0

This register sets the location of the horizontal and vertical sync end

VSYNC_END

This field is the total number of lines after which vertical sync ends

HSYNC_END

This field is the total number of pixels after which horizontal sync ends

This is an array of 2 identical register entries; the register fields below apply to each entry.

Offset: 0x9..0xa | Byte Offset: 0x24..0x28 | Read/Write: R/W | Reset: 0x00000001 (0bx0000000000000000x0000000000000001)

Bit	Reset	Description
30:16	0x0	VSYNC_END
14:0	0x1	HSYNC_END

24.6.9 SOR_NV_PDISP_HEAD_STATE3_0

This register sets the location of horizontal and vertical blank end.

VSYNC_END

This field is the total number of lines after which vertical sync ends

HSYNC_END

This field is the total number of pixels after which horizontal sync ends

This is an array of 2 identical register entries; the register fields below apply to each entry.

Offset: 0xb..0xc | Byte Offset: 0x2c..0x30 | Read/Write: R/W | Reset: 0x00010011 (0bx0000000000000001x0000000000010001)

Bit	Reset	Description
30:16	0x1	VBLANK_END
14:0	0x11	HBLANK_END

24.6.10 SOR_NV_PDISP_HEAD_STATE4_0

This register sets the location of the horizontal and vertical blank start.

This is an array of 2 identical register entries; the register fields below apply to each entry.

Offset: 0xd..0xe | Byte Offset: 0x34..0x38 | Read/Write: R/W | Reset: 0x00110100 (0bx0000000000010001x0000000100000000)

24.6.11 SOR_NV_PDISP_HEAD_STATE5_0

The following fields need to be set only for interlaced mode

This is an array of 2 identical register entries; the register fields below apply to each entry.

Offset: 0xf..0x10 | Byte Offset: 0x3c..0x40 | Read/Write: R/W | Reset: 0x00000001 (0bx0000000000000000x0000000000000001)

Bit	Reset	Description
30:16	0x0	VBLANK_END_2
14:0	0x1	VBLANK_START_2

24.6.12 SOR_NV_PDISP_SOR_CRC_CNTRL_0

CRC_CONTROL

The main CRC enable bit flows along the pipeline. This register controls the injection of this bit at the top of the pipeline.

This register is double-buffered. The active value is updated at start of each frame from this 'arm' register.

Other registers such as SOR_STATE2.ASY_CRCMODE and SOR_*CRC* control the actual CRC logic, once enabled.

ARM_CRC_CONTROL enables or disables computation of CRC, effective at the start of next frame.

Offset: 0x11 | Byte Offset: 0x44 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	NO	ARM_CRC_ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

24.6.13 SOR_NV_PDISP_SOR_DP_DEBUG_MVID_0

This register reports the MVID value calculated by HW

Offset: 0x12 | Byte Offset: 0x48 | Read/Write: RO | Reset: 0x00XXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:0	X	VALUE

24.6.14 SOR_NV_PDISP_SOR_CLK_CNTRL_0

LINK_SPEED

Programs the link speed for DP and LVDS i.e. it selects the multiplier used by the analog macro PLL.

For DP and TMDS, logic in the SOR will receive a version of this clock that is divided by 10. For LVDS, logic in the SOR will receive a version of this clock that is divided by 7. This field should only be changed when MODE_BYPASS is set to DP_SAFE or when the SOR is in safe mode.

It may take up to 200 microseconds for the PLLs in the analog macro to settle after this setting is changed.

Changing this field will require DP link re-training.

- G1_62: Selects the 1.62GHz link clock; PLL generates 1.62 GHz from 270MHz (multiplier = 6)
- G2_7 : Selects the 2.70GHz link clock; PLL generates 2.70GHz from 270MHz (multiplier = 10)
- G5_4 : Selects the 5.40GHz link clock; PLL generates 5.40GHz from 270MHz (multiplier = 20)
- _LVDS: Link speed is 7*pixel clock used for LVDS (multiplier = 7)

CLK_SEL

The DP_SINGLE_LVDS macro has four input clocks. This field selects which clock is used for the internal logic. When the SOR is operating in DP mode, this should be set to one of the _DPCLK settings. When the SOR is operating in LVDS mode, this should be set to one of the _PCLK settings. This field should only be changed when the SOR is asleep or the

Please allow 200 microseconds for the PLLs in the macro to settle after changing this setting.

DIFF_PCLK and DIFF_PCLK inputs to macro are tied off. So SW should only set to _SINGLE_(DP|P)CLK

- _SINGLE_PCLK: Single ended pclk from the VPLLs

- _DIFF_PCLK: Differential Pclk
- _SINGLE_DPCLK: Single ended 270MHz clock
- _DIFF_DPCLK: Differential 270MHz clock

Offset: 0x13 | Byte Offset: 0x4c | Read/Write: R/W | Reset: 0x00000018 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx0011000)

24.6.15 SOR_NV_PDISP_SOR_CAP_0

Serial output resource

The registers are defined as if all the SORs are fully featured (e.g., dual link). If a feature is not supported, the register remains accessible, i.e., writes will not hang, and reads will always return the default value.

Each SOR unit consists of two sub-links designated A and B. In single link operation, the A and/or B sub-link is active. In dual link modes, both links are active. SOR units consist of either one or two links operating in the following combinations:

- Sub-link A(single link mode)
- Sub-link B(single link mode)
- Sub-link AB (dual single link copy mode)
- Sub-links A+B (dual link mode)

Driver level control of the SOR is accomplished through methods in the core channel of the display engine. However, certain aspects of SOR operation are chip, process, voltage, and pixel clock dependent. These need to be controlled via registers by the VBIOS or RM during mode configuration. In addition, the preset LVDS mode may occasionally require some tweaking (to handle certain odd panels), so registers are provided to customize the support of LVDS.

This register reports the innate capabilities of the SOR. Note that depending on the actual board build configuration, these values may not be exactly the same ones reflected in the overall capabilities structure reported through the class. With the exception of the last bit, the values assumed by these fields are automatically produced by the hardware. The last bit represents the state of a fuse per SOR that can be blown to constrain the SOR to be usable only for LVDS.

This assists the determination of security for HDCP encrypted output operation.

If the fuse is blown for LVDS only, then the SOR module hardware will enforce this. In addition, the fuse value must be taken into account when reporting overall capabilities.

Note: This register definition must be kept coherent with DSI_SOR_CAP(i) !

Usage: boot / initialization

Offset: 0x14 | Byte Offset: 0x50 | Read/Write: RO | Reset: 0xXXXXXX0X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description

0	X	SINGLE_LVDS_18: 0 = FALSE 1 = TRUE

24.6.16 SOR_NV_PDISP_SOR_PWR_0

This register contains bits that control the power state of the SOR. For simplicity, the sequencer will be used to perform all power control operations in the SOR (even in TMDS where the sequencing is relatively simple). This unifies the approach and makes it easier for the hardware and software to deal with the SORs. At boot, the SW must load and configure the SOR sequencer via the SOR_SEQ_CTL and SOR_SEQ_INST registers below. The sequencer must be properly programmed for power control to work.

NORMAL_STATE

Sets the normal operating state. There are two choices: powered up and powered down. To change this register, software should load in the new value and write SETTING_NEW=TRIGGER. Once the change has been successfully completed, the SEQ_CTL_STATUS will indicate STOPPED. This is the state that software will want to control in order to power up and down the interface.

NORMAL_START

The execution of the powerup and powerdown sequence can be modified somewhat by choosing to use either the NORM or ALT program entry point.

SAFE_STATE

Sets the safe operating state. There are only two choices: powered up and powered down. To change this register, software should load in the new value and write SETTING_NEW=TRIGGER. Once the change has been successfully completed, the SEQ_CTL_STATUS will indicate STOPPED. The execution of the powerup and powerdown sequence can be modified somewhat by choosing to use either the standard or the alternate program entry point. This is the state that the hardware will use whenever it initiates the mode switch/shutdown procedure for this device. In general, this should be set to STATE_PD and left there always.

SAFE_START

The execution of the powerup and powerdown sequence can be modified somewhat by choosing to use either the NORM or ALT program entry point.

HALT_DELAY

Once the sequencer gets to the instruction with the HALT=1, the program is essentially complete; i.e., the attached unit is powered up or down as was requested. Some panels, however, have a minimum time before their state can be changed again. If the halt instruction has a non-zero delay, this bit will be set while that time expires.

MODE

The currently active state, normal or safe. After reset, the MODE is always SAFE.

SETTING_NEW

This bit is used to trigger a new setting of power mode to take effect. The typical procedure might be something like:

1. Be sure SEQ_CTL_STATUS=STOPPED, i.e., not already an outstanding change request. (If there is an outstanding change request, SW must wait for it to complete)

2. Update the NORMAL and SAFE power mode fields.

3. Write SETTING_NEW=TRIGGER

4. Poll for SEQ_CTL_STATUS=STOPPED. If it doesn't happen within one frame time, then Software may opt to accelerate the change by writing SOR_SEQ_CTL SWITCH=FORCE (being careful not to disturb other settings in that register).

Note: Software can start polling on SEQ_CTL_STATUS right after writing SETTING_NEW to trigger because SEQ_CTL_STATUS is set to RUNNING after 2 sorclk cycles which will always be less than the reg read delay.

Usage: boot / initialization / mode switch / normal operation / shutdown

Offset: 0x15 | Byte Offset: 0x54 | Read/Write: R/W | Reset: 0xXX000000 (0b0xxxxxxxxxxxxx00xxxxxxxxxxxxxx00)

Bit	R/W	Reset	Description
31	RW	DONE	SETTING_NEW:w1c 0 = DONE 1 = PENDING 1 = TRIGGER
28	RO	X	MODE:

Bit	R/W	Reset	Description

24	RO	X	HALT_DELAY: 0 = DONE 1 = ACTIVE
17	RW	NORMAL	SAFE_START: 0 = NORMAL 1 = ALT
16	RW	PD	SAFE_STATE: 0 = PD 1 = PU
1	RW	NORMAL	NORMAL_START: 0 = NORMAL 1 = ALT
0	RW	PD	NORMAL_STATE: 0 = PD 1 = PU

24.6.17 SOR_NV_PDISP_SOR_TEST_0

This register contains control bits that configure certain aspects of testing mode of the SOR.

TEST_ENABLE

To enable testing

- 0 = normal operation
- 1 = test mode

In test mode test_fastclkint and test_loadpulse signals from the core are used in place of the internally generated signals.

INVD

Invert the data. Note that combining INVD with the choice of DSRC and TPAT below permits ramp up, ramp down, walking one, walking zero, all one, all zero.

ACT_HEAD_OPMODE

Report the current OR operating mode.

ATTACHED

Report whether the OR is currently attached to a head.

DSRC

When DSRC=NORMAL, then the serializers behave normally and use the encoded RGB data. When DSRC=DEBUG, the serializers load from DEBUGA0, DEBUGA1, DEBUGB0, and DEBUGB1 bits instead of the normal data coming down the pipe.

When DSRC=TGEN, the data is taken from the built in test generator.

HEAD_NUMBER

Report the display controller (head) that the SOR is currently attached to.

The ARM state of HEAD_NUMBER is only promoted on an attach event.

When SOR gets detached with HEAD_NUMBER set to NONE this register would still report the head that SOR was connected to before it got detached

TPAT

Selects the test generator pattern. When test generator is running, H will be high for 1 in 4 repetitions (of duration 1024 clocks), and V will be high for 4 in 16 repetitions coincident with H. Only operates when test mode is enabled.

- LO force all 0s
- TDAT uses a hardware fixed value of 1023
- RAMP test generator output ramps
- WALK test generator output is a walking one
- MAXSTEP 0, 1023, ...
- MINSTEP 511, 512, ...

CRC

The source of the data for CRC computation (for verification) can be either before the high-speed serializer logic, or post the high-speed seralizer/deserializer logic.

TESTMUX[7:0]

Test MUX select - output seen on PROBE

Usage: debug

Offset: 0x16 | Byte Offset: 0x58 | Read/Write: R/W | Reset: 0x0080XX00 (0b000000001000xx00xxxxxxxxx0xxxx0x)

Bit	R/W	Reset	Description
6	RW	DISABLE	INVD: 0 = DISABLE 1 = ENABLE
1	RW	DISABLE	TEST_ENABLE: 0 = DISABLE 1 = ENABLE

24.6.18 SOR_NV_PDISP_SOR_PLL0_0

These registers configure the main SOR PLL and other frequency dependent controls. The value loaded is a function of the pixel clock frequency, and whenever pixel clock changes, these registers must be updated. In general, these registers will be updated during the second interrupt of a mode switch.

PWR

- 1 = powerdown the TMDS PLL

VCOPD

- 1 = powerdown the VCO

RESISTORSEL

Selects the internal resistor (0) or external resistor (1).

PULLDOWN

Weak pulldown enable

- 1 = 2Kohm pulldown on all outputs.
- 0 = Weak pulldown disabled.

Note: pulldown is also controlled by the sequencer. the pulldown is derived from an OR of NV_PDISP_SOR_PLL0_PULLDOWN and the sequencer control of pulldown. This priv reg field does not read the final pulldown value. In other words if software writes NV_PDISP_SOR_PLL0_PULLDOWN to DISABLED and sequencer pulldown is enabled, then an NV_PDISP_SOR_PLL0_PULLDOWN read will return DISABLED (while pulldown might be ENABLED due to sequencer control).

VCOCAP[3:0]

Selects the VCO capacitor and adjusts ring oscillator inter-stage load.

FILTER[3:0]

Bits 2:0 select the loop filter and adjusts the filter resistor value.

Bit 3 controls the VCO startup bit for the TMDS_DUAL macro.

- 0 - normal operation (default)
- 1 - forced VCO oscillation mode

ICHPMP[3:0]

Specifies additions to the charge pump current in steps of 0.375uA.

IOCURRENT[5:0]

Used for I/O control.

This field has been replaced by the SOR_LANE_DRIVE_CURRENT registers.

TMDS_TERM

This bit is used to enable termination. Termination is only used in TMDS mode of operation, and may not be needed at lower operating frequencies (in which case, disabling it saves power).

TERMADJ[3:0]

Termination resistance control.

- 0000 - lowest
- ...
- 1000 - default
- ...
- 1111 - highest

COMPOUT

Termination calibration status. Only exists on DisplayPort SORs.

This procedure should be performed on boot time to program TERMADJ correctly. Ideally this should be re-calibrated on Hot Plug Detect as well.

The procedure for termination calibration:

1. Start with the TERM_ADJ = 1000
2. Wait 100µs and check COMPOUT
3. If COMPOUT=1, change the MSB to 0
4. Repeat for the next significant bits until all 4 bits are determined.

SUPPLYLEV[1:0]

Supply voltage level descriptor

LOADADJ[3:0]

Load pulse position adjust

LVDS_CM[1:0]

Common mode control for LVDS

- 00 - 1.25V
- 01 - 1.30V
- 10 - 1.35V
- 11 - 1.20V

COHERENTMODE

Output reference clock selector

- 0 = Non-coherent mode
- 1 = Coherent mode

BGAP_CNTL

Band-gap current setting control.

- 00 = Normal
- 01 = Positive coefficient

- 10 = Negative coefficient
- 11 = Normal + 12.5%

LOCKDET

Status signal indicating whether PLL is locked within the desired resolution.

- 0 = Not locked
- 1 = Locked

MISC_CNTL

Reserved.

DCIR_PLL_RESET

For the Display-over-PCIe feature, a different type of analog macro was used in the SOR.

The PLL in this macro needs to be held in reset during mode switches when the reference clock drops to a safe clock frequency. A signal from the DCIR asserts this reset. NV_PDISP_SOR_PLL2_DCIR_PLL_RESET can be used to override this signal

- OVERRIDE: The signal from the DCIR cannot power down the PLL.
- ALLOW: The signal from the DCIR will be able to power down the PLL.

AUX0-AUX7

Most of these bits currently have no assigned function, but are provided to permit control of possible future features of the macro.

AUX0 gate seq_2all_pll_pulldown from PULLDOWN. this can be used to remove sequencer control to PULLDOWN.

- SEQ_PLL_PULLDOWN_OVERRIDE: Mask the pll_pulldown signal from the SOR sequencer so that it has no effect on the PLL_PULLDOWN port.
- SEQ_PLL_PULLDOWN_ALLOW: Allow the pll_pulldown signal from the SOR sequencer to affect the PLL_PULLDOWN port.

AUX1 Power on override for PLLCAPPD. The PLL in the analog macro will not run unless this is powered on. This can be used if the PLL needs to be powered on before the sequencer runs.

- SEQ_PLLCAPPD_OVERRIDE: Mask the pll_reset signal from the SOR sequencer so that it has no effect on the PLLCPAPPD port of the SOR macro.
- SEQ_PLLCAPPD_ALLOW: Allow the pll_reset signal from the SOR sequencer to assert PLLCAPPD.

AUX2 gate PDBG from sequencer_pd_macro.

This can be used to force the Bandgap to power on.

- OVERRIDE_POWERDOWN: gate the PDBG signal from the sequencer, PDBG can still be set by AUX6
- ALLOW_POWERDOWN:normal operation, the PDBG signal from the sequencer can power down the bandgap

AUX3 rotate grn channel by 1 bit to reduce tmds EMI

- ROTATE_DISABLE: Do not rotate
- ROTATE_ENABLE: Right-rotate green channel by 1 bit

AUX4 has been used to enable duplicate controls for the Dual link HDCP. This is needed for some Dual Link panels.

- DUPLICATE_CTRL_ENABLE: Copy the control bits from the primary link to the secondary.
- DUPLICATE_CTRL_DISABLE: Zero out the ctrl bits on the secondary link.

AUX5 should be set to DUAL_LINK_LVDS for dual link lvds. this field it used to distinguish between single link and dual link LVDS

- DUAL_LINK_LVDS: Used for dual link LVDS.
- SINGLE_LINK_LVDS: Used for single link LVDS.

AUX6 Main power down for bandgap and reference current setting circuitry. (NOTE: This must be BANDGAP_POWERDOWN_DISABLE when in power down mode if 3.3V is seen on the IO_[A/B]_VDD rails)

- BANDGAP_POWERDOWN_DISABLE: Allow the bandgap to power up.
- BANDGAP_POWERDOWN_ENABLE: Force the bandgap to power down.

AUX7 Controls PDPORT in the analog macro which powers down all the output links/lanes. For instance, txd{n/p}0-9 for dual TMDS macro.

- PORT_POWERDOWN_DISABLE: Allow the output ports to be turned on.
- PORT_POWERDOWN_ENABLE: Force the output ports to power down. This will prevent any data from reaching the sink device.

AUX8 Power on enforcement for PLLCAPPD. This can force the PLLCAPPD to be asserted to reset the analog macro.

This can be used to force the PLLCAPPD to be asserted for work arounds where it is inconvenient to run the SOR sequencer.

- SEQ_PLLCAPPD_ENFORCE_ENABLE: Force PLLCAPPD to be asserted.
- SEQ_PLLCAPPD_ENFORCE_DISABLE: Not to force PLLCAPPD, normal state.

AUX9 Overrides LVDSEN programmed by priv register. This can force the LVDSEN to be deasserted.

- LVDSEN_ALLOW: Allow priv register to assert LVDSEN.
- LVDSEN_OVERRIDE: Override LVDSEN to be deasserted, mask the priv register setting for LVDSEN.

Usage: boot / initialization / mode switch

24.6.21 SOR_NV_PDISP_SOR_PLL3_0

SOR_PLL3

This register directly controls the SOR analog macro.

KICKSTART

- _DISABLE: Disable kickstart
- _LOOP_40: short loop-filter 40% of avdd14
- _LOOP_60: short loop-filter 60% of avdd14
- _LOOP_50: short loop-filter 50% of avdd14

AVDD14_LEVEL

Internal regulated 1.4V voltage level control bits

- _1_35V: 1.35V
- _1_40V: 1.40V
- _1_45V: 1.45V
- _1_50V: 1.50V

No other values are valid for this field.

AVDD10_LEVEL

Internal regulated 1.0V voltage level control bits

- _0_95V: 0.95V
- _1_00V: 1.00V
- _1_05V: 1.05V
- _1_10V: 1.10V

No other values are valid for this field.

CLKDIST_MODE

Determines the clock distribution by CMOS buffer or CML buffers:

- _CMOS: CMOS buffers
- _CML: CML buffers

PLLVDD_MODE

Field to determine the PLL voltage. Software needs to program this after power-on.

- _1_8V: 1.8V --> For LVDS
- _3_3V: 3.3V --> For eDP

PLL_BYPASS

Enable the PLL bypass mode, allowing the reference clock to drive the output driver directly to all channels. This would be used for debug purposes only.

- _ENABLE: Force the PLL output onto all lanes.
- _DISABLE: Normal operation

TEST_REFCLK_EN

Enable the TEST_REFCLK to drive the output driver directly, for each individual lane

This is a bit mask with one bit per lane. This field is for debug purposes only and Software should not be using this field.

BG_VREF_LEVEL

Control bits for the bandgap's output voltages

V(bandgap output) = 0.7V * (84% + BG_VREF_LEVEL*2%)

i.e.

- 0000 -> 0.588V
- ...
- 1000 -> 0.7V
- ...
- 1111 -> 0.798V

BG_TEMP_COEF

Control bits for the bandgap's temperature coefficient.

Offset: 0x1a | Byte Offset: 0x68 | Read/Write: R/W | Reset: 0x38002220 (0b00111000000000000x01000100010xx00)

Bit	Reset	Description
31:28	0x3	BG_TEMP_COEF
27:24	0x8	BG_VREF_LEVEL
23:16	0x0	TEST_REFCLK_EN
14	DISABLE	PLL_BYPASS: 0 = DISABLE 1 = ENABLE
13	V3_3	PLLVDD_MODE: 0 = V1_8 1 = V3_3
12	CMOS	CLKDIST_MODE: 0 = CMOS 1 = CML

7:4	V1_45	AVDD14_LEVEL: 0 = V1_35 1 = V1_40 2 = V1_45 3 = V1_50
1:0	DISABLE	KICKSTART: 0 = DISABLE 1 = LOOP_40 2 = LOOP_50 3 = LOOP_60

24.6.22 SOR_NV_PDISP_SOR_CSTM_0

The class permits the driver to select a number of operating modes for the SOR. Some of these modes (TMDS modes) are well defined and stable. Some modes may require customization by software before they will work. These registers are used for that customization. The fields available for customization are:

PD_TXDA[3:0]

Bitwise control to power down the data pins of link A. Set to DISABLE to power down the pin.

PD_TXDB[3:0]

Bitwise control to power down the data pins of link B. Set to DISABLE to power down the pin.

PD_TXCA

Power down the clock pin of link A. Set to DISABLE to power down the pin.

PD_TXCB

Power down the clock pin of link B. Set to DISABLE to power down the pin.

UPPER

Designates whether LVDS bank A is the upper, odd, or first pixel. Bank B is always set to !UPPER. The serial output from UPPER=1 will be Clock and A0-A3. The serial output from UPPER=0 (and DUALMODE) will be Clock and A4-A7. Default is bank A has UPPER=1, bank B has UPPER=0.

MODE[1:0]

Controls the digital output encoding applied to the data stream in custom mode and is only used for data muxing at the input of the SOR. This field does not control the TMDS macro.

- 0: LVDS
- 1: TMDS

LINKACTA, LINKACTB

Enables (1) or disables (0) the digital logic of links A and B

LVDS_EN

Output driver configuration for controlling the encoding of the data and the output common mode control. This does not control the internal clock dividers of the TMDS macro.

- 0 = TMDS
- 1 = LVDS

DUP_SYNC

This field only has an effect when in LVDS mode. When asserted in LVDS mode, it forces the link to use DE, HSYNC, and VSYNC for the encoding and to never use RES, CNTLE, and CNTLF. RES becomes DE. CNTLE becomes HSYNC. CNTLF becomes VSYNC.

NEW_MODE

For backwards compatibility, set register to 0 so the old mode is used. In old mode, for the second link in dual link mode, all the control bits are zeroed out except for vsync. When new mode is used none of the control bits of the second link for dual-link mode are zeroed out.

BALANCED

For MODE = LVDS, this enables balanced encoding Balanced mode will selectively invert sets of bits in the serial stream in an attempt to keep the average DC value near zero. Default is unbalanced. Has no effect in other modes.

PLLDIV

Controls the internal clock dividers of the TMDS_MACRO by setting the feedback divider for the high-speed PLL.

- 0 = divide by 7 (LVDS)
- 1 = divide by 10 (TMDS)

ROTCLK[3:0]

Skews the TXC clock to come out earlier. By changing this register value, you can configure the skew between output data (TX data) and output clock (TXC). This field specifies the number of sclk cycles which the output clock should come out earlier than its normal phase. For TMDS, sclk is 10x pixel clock so ROTVAL should be between 0-9. For LVDS, sclk is 7x pixel clock so ROTVAL should be between 0-7.

For all the TMDS modes, ROTCLK field is programmable using NV_PDISP_SOR_CSTM_ROTCLK.

ROTDAT[2:0]

Before encoding the 8 bits of each color channel, the 8 bits within each same amount. ROTDAT should be between 0 and 7. For example, to support 24.1 LVDS data format, set ROTDAT = 6, then input channel data (r7,r6,r5,r4,r3,r2,r1,r0} would become {r5,r4,r3,r2,r1,r1,r7,r6}.

TMDS modes of operation are standard and stable. The table below summarizes the fixed values the hardware uses for the above fields for TMDS operating modes.

```
                                                DUAL
                SINGLE      SINGLE      SINGLE  SINGLE      DUAL
                TMDS_A      TMDS_B      TMDS_AB TMDS        TMDS
                ------------------------------------------------
PD_TXDA[2:0]  |  0           7           0       0           0   |
PD_TXDA[3]    |  1           1           1       1           1   |
PD_TXDB[2:0]  |  7           0           0       0           0   |
PD_TXDB[3]    |  1           1           1       1           1   |

NEW_MODE      |  0?          1           1       1           0?  |
BALANCED      |  0           0           0       0           0   |
PLLDIV        |  1           1           1       1           1   |
ROTCLK[3:0]   |  X           X           X       X           X   |
ROTDAT[2:0]   |  0           0           0       0           0   |
                ------------------------------------------------
Where X (ROTCLK[3:0]) = NV_PDISP_SOR_CSTM_ROTCLK;
```

The first register defines the total custom mode. This is useful for defining possible new modes of operation as well as for test and characterization in the lab. Software should never need to use it. Also, note that if LVDS_ONLY=TRUE, then this register cannot be used as the HW will only permit Protocol=LVDS to be enabled. This register is intended to have the same format as the second register.

Usage: boot / initialization / mode switch

Offset: 0x1b | Byte Offset: 0x6c | Read/Write: R/W | Reset: 0x0001c800 (0bx0000000xx0x000111001x0000000000)

24.6.24 SOR_NV_PDISP_SOR_CRCA_0

The following registers are used to fetch CRCs when running VGA mode tests. Three registers are used. One contains the valid bit, one contains the actual computed CRC, and the third contains the error (overrun bit). Proper use of these registers is as follows:

1) Poll SOR_CRCA for VALID == TRUE.

2) Reset SOR_CRCA by writing RESET to it.

3) Read SOR_CRCB to get the CRC

Usage: verif

Offset: 0x1d | Byte Offset: 0x74 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	FALSE	VALID:w1c(RST) 0 = FALSE 1 = TRUE 1 = RST

24.6.25 SOR_NV_PDISP_SOR_CRCB_0

Usage: verif

Offset: 0x1e | Byte Offset: 0x78 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	CRC:w1c

24.6.26 SOR_NV_PDISP_SOR_BLANK_0

This register can be used to override the SOR output resource pixels with blank data.

OVERRIDE

Setting this field to true will override the pixel bus from the RG and output black pixels instead.

TRANSITION

This field controls the timing of the output resource blank override. The choices are

- IMMEDIATE The output resource will be blanked or restored to its previous output data immediately.
- NEXT_VSYNC The output resource will be blanked or restored to its previous output data at the next VSYNC.

STATUS

This read-only field returns BLANKED when the output resource is sending blank pixels forced by the OVERRIDE bit, otherwise it returns NOT_BLANKED.

Usage: boot / initialization / mode switch / normal operation

Offset: 0x1f | Byte Offset: 0x7c | Read/Write: R/W | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	R/W	Reset	Description
2	RO	X	STATUS: 0 = NOT_BLANKED 1 = BLANKED
1	RW	IMMEDIATE	TRANSITION: 0 = IMMEDIATE

Bit	R/W	Reset	Description
			1 = NEXT_VSYNC
0	RW	FALSE	OVERRIDE: 0 = FALSE 1 = TRUE

24.6.27 SOR_NV_PDISP_SOR_SEQ_CTL_0

Sequencer control registers for SOR. Up to three pins can be assigned to an SOR for use in controlling the power to an attached LVDS flat panel. The meaning of any particular pin and whether it is actually available to this SOR is controlled in either the host or PCB manager. In addition, the sequencer can override the individual link clock and data power control pins, thereby forcing them all into disabled or trisate mode and it can override the DE signal from the RG (for TMDS mode) to force the link to become inactive.

PU_PC

The program counter for the start of the powerup program sequence. Always 0.

PU_PC_ALT

The alternate entry point into the powerup program sequence. Defaults to the same value as PU_PC.

PD_PC

The program counter for the start of the powerdown program sequence. Defaults to 8, evenly dividing the available program space.

PD_PC_ALT

The alternate entry point into the powerdown program sequence. Defaults to the same default value as PD_PC.

PC

The current value of the program counter (useful for status and debug).

STATUS

Indicates if the sequencer is STOPPED or RUNNING.

SWITCH

If a particular sequencer instruction is waiting for VSYNC to arrive, writing this bit to FORCE will cause the wait condition to be satisfied immediately.

Usage: boot / initialization / mode switch

Offset: 0x20 | Byte Offset: 0x80 | Read/Write: R/W | Reset: 0xX00X880X (0bxxxxxxxxxxxxxxxx100010000000xxxx)

Bit	R/W	Reset	Description
30	RW	X	SWITCH: 0 = WAIT 1 = FORCE
28	RO	X	STATUS: 0 = STOPPED 1 = RUNNING
19:16	RO	X	PC
15:12	RW	0x8	PD_PC_ALT
11:8	RW	0x8	PD_PC
7:4	RW	0x0	PU_PC_ALT

Bit	R/W	Reset	Description
3:0	RO	X	PU_PC

24.6.28 SOR_NV_PDISP_SOR_LANE_SEQ_CTL_0

The SOR_LANE_SEQ_CTL register is used to control the operation of the SOR lane sequencer. The lane sequencer is used to power up or power down the lanes in the analog macro one at a time to prevent spikes on the power rail.

LANE_STATE

This is the current status of each lane's power.

```
        |    DP          TMDS            LVDS
 -------+---------------------------------------
  LANE0 | DPA lane2   LinkA Lane0     LinkA Lane0
  LANE1 | DPA lane1   LinkA Lane1     LinkA Lane1
  LANE2 | DPA lane0   LinkA Lane2     LinkA Lane2
  LANE3 | unused      unused          LinkA Lane3
  LANE4 | DPA lane3   LinkA clock     LinkA clock
  LANE5 | DPB lane2   LinkB Lane0     LinkB Lane0
  LANE6 | DPB lane1   LinkB Lane1     LinkB Lane1
  LANE7 | DPB lane0   LinkB lane2     LinkB Lane2
  LANE8 | unused      unused          LinkB Lane3
  LANE9 | DPB lane3   LinkB clock     LinkB clock
```

DELAY

Number of microseconds to delay between each lanes' power state change. The recommended value is 1 µs.

NEW_POWER_STATE

This controls whether the lanes should be powered up or powered down when this sequencer is triggered by SETTING_NEW_TRIGGER.

- PU: Power up the requested lanes
- PD: Power down to the requested lanes

SEQUENCE

Controls the direction of the power up or power down sequence.

- UP: Lanes are powered up in increasing order
- DOWN: Lanes are powered up in decreasing order

STATE

Whenever this sequencer is running, this field will be set to _BUSY.

SETTING_NEW

This bit can be used to run this sequencer outside of the normal SOR sequencer operation. If the sequencer is already BUSY because of a request from the SOR sequencer, the lane sequencer will wait until that request is complete before servicing this request. It is recommended that this trigger should only be used when the SOR sequencer is not running in order to prevent this type of interaction.

The lane sequencer looks at the current protocol, NV_PDISP_SOR_DP_LINKCTL_ENABLE and whether the request is power-up or power-down to determine what the new lane state should be.

```
DP_LINKCTL_ENABLE   PowerUp   Protocol==DP || New Lane State
-----------------------------------------++----------------
        0             0           X       ||   All lanes
        0             1           0       || Based on Protocol
        0             1           1       || DP_PADCTL_PD_TXD*
        1             X           X       || DP_PADCTL_PD_TXD*
```

Usage: boot / initialization / mode switch

Offset: 0x21 | Byte Offset: 0x84 | Read/Write: R/W | Reset: 0xX0011XXX (0b0xxxxxxxxxx0xxx10001xxxxxxxxxxx)

Bit	R/W	Reset	Description

2	RO	X	LANE2_STATE: 0 = POWERUP 1 = POWERDOWN
1	RO	X	LANE1_STATE: 0 = POWERUP 1 = POWERDOWN

Bit	R/W	Reset	Description
0	RO	X	LANE0_STATE: 0 = POWERUP 1 = POWERDOWN

24.6.29 SOR_NV_PDISP_SOR_SEQ_INST0_0

This register set is used to preload the power-up and power-down sequences. Each step of the program performs the following based on the fields below. First, either delay for WAIT time or until the next leading edge of vertical sync from the RG. The range of WAIT is 0-1023 us or 0-1023 ms. Second, set sequencer outputs (A, B, I/O pin powerdown override etc) to the values specified in the instruction. The meaning and use of pins A and B is chip and board dependent i.e. something the SW will need to know how to configure. Lastly, if HALT==1, stop, otherwise, execute the next instruction.

WAIT_TIME

Amount of time to wait (in either microseconds or milliseconds). Note if WAIT_UNITS=VSYNC, the WAIT_TIME field is ignored.

WAIT_UNITS

Wait delay mode, µs, ms, vsync.

PDPLL

Asserts the PDPLL port on the analog macro, powering down the PLL. This sequencer control can be overridden by NV_PDISP_SOR_PLL2_AUX1_SEQ_PLLCAPPD_OVERRIDE. NV_PDISP_SOR_PLL0_PWR_OFF will force PDPLL to be asserted, regardless of the state of the sequencer.

- YES: Power down the PLL.
- NO: Do not power down the PLL

PDPORT

Asserts the PDPORT port on the SOR analog macro. This powers down all output lanes. This sequencer control can be overridden by NV_PDISP_SOR_DP_LINKCTL_ENABLE. NV_PDISP_SOR_PLL2_AUX7_PORT_POWERDOWN_ENABLE will force PDPORT to be asserted, regardless of the state of the sequencer.

- YES: Power down the port
- NO: Do not power down the port

LANE_SEQ

When set to _RUN, the sequencer will kick off the Lane Sequencer (see NV_PDISP_SOR_LANE_SEQ_CTL). The SOR sequencer will not continue to the next instruction until the lane sequencer completes. The lane sequencer will run before the other commands in the current instruction take effect and before the delay in the current instruction.

When running the Power Up sequence, the lanes to be powered up are determined by the new active protocol. When running the Power Down sequence, all lanes are powered down.

```
DP_LINKCTL_ENABLE   PowerUp   Protocol==DP || New Lane State
-----------------------------------------++---------------
        0             0           X      ||   All lanes
        0             1           0      || Based on Protocol
        0             1           1      || DP_PADCTL_PD_TXD
        1             X           X      || DP_PADCTL_PD_TXD
```

SEQUENCE

This field controls the direction of the lane power up or power down sequence.

- UP: Lanes are powered up or down in increasing order PDTXD_0, PDTXD_1 .. PDTXD_9
- DOWN: Lanes are powered up or down in decreasing order PDTXD_9, PDTXD_8 .. PDTXD_0

PIN_A, PIN_B

State to drive the external pin to. The connection state of these pins is controlled in either the host or the PCB manager.

DRIVE_PWM_OUT_LO

Drive the PWM circuit output low. Note that this driven low condition is applied before the optional PWM_POLARITY control, so that the external pin can actually be driven high or low.

TRISTATE_IOS

Force all output pins to tristate.

- 0 = enable output pins
- 1 = disable/tristate output pins

For chips with the SOR Lane Sequencer, this does not take effect until the Lane Sequencer is run. Since Lane Sequencer runs before the values in the current instruction take effect, TRISTATE_IOS should be set to the desired value on the instruction before LANE_SEQ_RUN.

BLACK_DATA

Override the pixel bus from the RG, and replace the pixels with black.

- 0 = normal data output
- 1 = force black output

BLANK_DE, BLANK_H, BLANK_V

Override the de, hsync, and vsync signals from the rg. The signals will be forced to the inactive, i.e., deasserted state.

- 0 = normal output
- 1 = force signal inactive/deasserted

ASSERT_PLL_RESET

Assert reset to the PLL (PLLCAPPD). This sequencer control can be overridden by NV_PDISP_SOR_PLL2_AUX1_SEQ_PLLCAPPD_OVERRIDE.
NV_PDISP_SOR_PLL2_AUX8_SEQ_PLLCAPPD_ENFORCE_ENABLE will force PLLCAPPD to be asserted, regardless of the state of the sequencer.

- 0 = normal
- 1 = force reset

POWERDOWN_MACRO

Override LINKACTA, LINKACTB and force LVDS/TMDS macro to powerdown state (Only controls PDBG)

- 0 = normal operation
- 1 = force powerdown

PULLDOWN

Weak pulldown enable (Only exists on TMDS/LVDS SORs)

- 1 = 2Kohm pulldown on all outputs.
- 0 = Weak pulldown disabled.

Offset: 0x22 | Byte Offset: 0x88 | Read/Write: R/W | Reset: 0x01008000 (0b00000001000x00001x00xx0000000000)

24.6.45 SOR_NV_PDISP_SOR_PWM_DIV_0

These two registers control the optional PWM function for backlight intensity control. The PWM circuit will be driven off the buffered crystal clock. The first register (SOR_PWM_DIV) prescales the crystal clock and sets the resolution range.

DIVIDE

This field defines the period of the PWM output. Note that a value of 0 has the special meaning to disable PWM output.

pwm freq = reference clock / DIVIDE

DUTY_CYCLE

This specifies the duty cycle of the PWM output. In other words, the number of cycles during PWM period (DIVIDE), hardware will assert high (Hi_PERIOD).

CLK_SEL

SOR PWM can be run at pixel clock. This field selects if PWM is run at crystal clock or pixel clock.

SETTING_NEW

Provides the mechanism to trigger a new configuration for both registers (SOR_PWM_DIV and SOR_PWM_CTL). When updating SOR_PWM_DIV, software must be careful to not overwrite an old value in duty cycle unless doing so is desired. Once a state change has been requested, it must be permitted to complete before attempting to trigger another one.

Examples of computation:

If Fs is the desired frequency:

- DIV_DIVIDE = (reference freq / Fs); DIVIDE > 0 and integer.
- DUTY_CYCLE Range : 1 to DIV_DIVIDE
- To get minimum intensity : DUTY_CYCLE = 1
- To get maximum intensity : DUTY_CYCLE = DIV_DIVIDE

Example 1:

For reference clock 27MHz (Xtal)

Desired : 210Hz (Fs)

DIV_DIVIDE = (27000000/210) = 128571.43

Round down to the 128571 causes desired Freq Fs = 210.0007Hz

Round up to the 128572 causes desired Freq Fs = 209.999Hz

Example 2:

For Crystal 120MHz (pixel clock)

Desired : 50000Hz (Fs)

DIV_DIVIDE = (120000000/50000) = 2400

Usage: boot / initialization

Offset: 0x32 | Byte Offset: 0xc8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

24.6.47 SOR_NV_PDISP_SOR_VCRCA0_0

Test and Debug Registers

To quickly determine if the TMDS is working properly, a running CRC stamp is kept which is reset at each VSYNC. For each sub-link, there are up to 40 bits of encoded data which has been re-parallelized from the serial data going out. These encoded bits of data are broken up into 3 16-bits chunks depending on either LVDS or TMDS encoding:

For TMDS, the encoded data is as follows:

- CRCH: {8'b00000000,TMDS_CLK_ENC[9:2]}
- CRCM: {TMDS_CLK_ENC[1:0],TMDS_TX2_ENC[9:0],TMDS_TX1_ENC[9:6]}
- CRCL: {TMDS_TX1_ENC[5:0],TMDS_TX0_ENC[9:0]}

For LVDS, the encoded data is as follows:

- CRCH: {8'b00000000,LVDS_CLK_ENC[6:4]}
- CRCM: {LVDS_CLK_ENC[3:0],,LVDS_A3_ENC[6:0],LVDS_A2_ENC[6:2]}

- CRCL: {LVDS_A2_ENC[1:0],LVDS_A1_ENC[6:0],LVDS_A0_ENC[6:0]}

For each of these chunks, a CRC16 is computed, CRCH for the upper 16-bit chunk, CRCM for the middle 16-bit chunk, and CRCL for the lower 16-bit chunk.

The CRC16 takes in the 16 bits of encoded data plus the CRC16 value of the previous cycle to generate the new CRC16. The CRC equation which is used is:

x^16 + x^11 + x^4 + 1.

At each VSYNC, the previous running CRC16 values are captured into the VCRC registers and a previous CRC value of all zeroes are fed into the CRC16 units. This means the running CRC16 is reset at each VSYNC.

The VCRC registers for sub-link A

Usage: debug

Offset: 0x34 | Byte Offset: 0xd0 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

15:0	X	CRCL

24.6.51 SOR_NV_PDISP_SOR_EDATAA0_0

EDATA has the encoded data for the serial channels TXC, TX3, TX2, TX1, and TX0. For each link, there are up to 40 bits of encoded data. The encoded bits making up the data are as follows:

For TMDS, the encoded data is as follows:

- EDATA[39:0] =
  - {TMDS_CLK_ENC[9:0],
  - TMDS_TX2_ENC[9:0],
  - TMDS_TX1_ENC[9:0],
  - TMDS_TX0_ENC[9:0]}

For LVDS, the encoded data is as follows:

- EDATA[39:0] =
  - {5'b00000,
  - LVDS_CLK_ENC[6:0],
  - LVDS_A3_ENC[6:0],
  - LVDS_A2_ENC[6:0],
  - LVDS_A1_ENC[6:0],
  - LVDS_A0_ENC[6:0]}

The EDATA registers can be written to when any of the trigger bits for capture are set high.

The EDATA registers for sub-link A

Usage: debug

Offset: 0x3c | Byte Offset: 0xf0 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VAL

24.6.52 SOR_NV_PDISP_SOR_EDATAB0_0

The EDATA registers for sub-link B

Usage: debug

Offset: 0x3e | Byte Offset: 0xf8 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VAL

24.6.53 SOR_NV_PDISP_SOR_COUNTA0_0

There are three 16 bit counts for each sub-link (TX0, TX1, TX2)

The count registers for sub-link A.

Usage: debug

Offset: 0x40 | Byte Offset: 0x100 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	TX1
15:0	X	TX0

24.6.54 SOR_NV_PDISP_SOR_COUNTB0_0

The count registers for sub-link B.

Usage: debug

Offset: 0x42 | Byte Offset: 0x108 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	TX1
15:0	X	TX0

24.6.55 SOR_NV_PDISP_SOR_DEBUGA0_0

The debug registers for sub-link A

The following registers control the debug data input to the serializer. These bits are only relevant when TEST_ENABLE is set.

DEBUGA0 has the data for the serial channels TXC, TX3, TX2, TX1, and TX0. For each link, there up to 40 bits of data to be encoded. The bits to be encoded which make up the data are as follows:

For TMDS, the data to be encoded are loaded as follows:

- {TMDS_CLK_ENC[9:0], TMDS_TX2_ENC[9:0], TMDS_TX1_ENC[9:0], TMDS_TX0_ENC[9:0]} = {DEBUGA1, DEBUGA0}

For LVDS, the encoded data is as follows:

- {5'b00000, LVDS_CLK_ENC[6:0], LVDS_A3_ENC[6:0], LVDS_A2_ENC[6:0], LVDS_A1_ENC[6:0], LVDS_A0_ENC[6:0]} = {DEBUGA1[2:0], DEBUGA0}

Usage: debug

Offset: 0x44 | Byte Offset: 0x110 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	RST	VAL: 0 = RST

24.6.56 SOR_NV_PDISP_SOR_DEBUGB0_0

The debug registers for sub-link B

Usage: debug

Offset: 0x46 | Byte Offset: 0x118 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	RST	VAL: 0 = RST

24.6.57 SOR_NV_PDISP_SOR_TRIG_0

TRIG specifies the number of pixel clock cycles after the previous VSYNC was detected to capture state data into IDATA, EDATA, CNT, and CCRC. After the trigger has captured data, the trigger gets reset with the next VSYNC and waits TRIG pixel cycles to capture data again. If the TRIG value is larger than the number of cycles between consecutive VSYNCs, then the trigger is not reset while it is still pending to capture data. Once the data have been captured, the trigger is reset with the following VSYNC to capture data again. If TRIG is all zeros, then the trigger is disabled and no capturing occurs.

Usage: debug

Offset: 0x48 | Byte Offset: 0x120 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

Bit	Reset	Description
23:0	RST	VAL: 0 = RST

24.6.58 SOR_NV_PDISP_SOR_MSCHECK_0

The mode switch monitor is used for hardware debug only. To use, the test should set the CTL bit to CLEAR and then to RUN. At the end of the test, the register can be read. The various fields indicate the number of times the following conditions occurred:

- CRC enable went from false to true
- CRC enable went from true to false
- data enable went from false to true
- data enable went from true to false

All counts are 4 bits, so the count will clamp at 15.

Usage: debug

Offset: 0x49 | Byte Offset: 0x124 | Read/Write: R/W | Reset: 0x8000XXXX (0b1xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
31	RW	RUN	CTL: 0 = CLEAR 1 = RUN
15:12	RO	X	DATA_ENABLE_T2F
11:8	RO	X	DATA_ENABLE_F2T
7:4	RO	X	CRC_ENABLE_T2F
3:0	RO	X	CRC_ENABLE_F2T

24.6.59 SOR_NV_PDISP_SOR_XBAR_CTRL_0

This register controls the crossbar between the SOR and the TMDS analog macro.

There are 2 links per SOR and 4/5 TMDS channels per link. Within the same link, the crossbar are fully connected (i.e. each output channel can be connected to any channel). The crossbar output can also be driven to zero by setting XSEL_* to

XSEL_*_ZERO. Also, the two links can be swapped by setting LINK_SWAP to one. This crossbar can also be bypassed by setting BYPASS to one.

Usage: boot / initialization

Offset: 0x4a | Byte Offset: 0x128 | Read/Write: R/W | Reset: 0x8d111a23 (0b10001101000100010001101000100011)

Bit	Reset	Description
31:29	0x4	LINK1_XSEL_4: 7 = ZERO
28:26	0x3	LINK1_XSEL_3: 7 = ZERO
25:23	0x2	LINK1_XSEL_2: 7 = ZERO
22:20	0x1	LINK1_XSEL_1: 7 = ZERO
19:17	0x0	LINK1_XSEL_0: 7 = ZERO
16:14	0x4	LINK0_XSEL_4: 7 = ZERO
13:11	0x3	LINK0_XSEL_3: 7 = ZERO
10:8	0x2	LINK0_XSEL_2: 7 = ZERO
7:5	0x1	LINK0_XSEL_1: 7 = ZERO
4:2	0x0	LINK0_XSEL_0: 7 = ZERO
1	0x1	LINK_SWAP
0	0x1	BYPASS

24.6.60 SOR_NV_PDISP_SOR_XBAR_POL_0

This register controls the polarity of the channels going into the crossbar. Each input channel can be inverted individually by setting the corresponding bit to one.

Usage: boot / initialization

Offset: 0x4b | Byte Offset: 0x12c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0000000000)

Bit	Reset	Description

4	NORMAL	POL_LINK0_4: 0 = NORMAL 1 = INVERT
3	NORMAL	POL_LINK0_3: 0 = NORMAL 1 = INVERT
2	NORMAL	POL_LINK0_2: 0 = NORMAL 1 = INVERT
1	NORMAL	POL_LINK0_1: 0 = NORMAL 1 = INVERT
0	NORMAL	POL_LINK0_0: 0 = NORMAL 1 = INVERT

24.6.61 SOR_NV_PDISP_SOR_DP_LINKCTL0_0

PROGRAMMING NOTE: The SOR_DP registers are doubly indexed. The first index selects the SOR, the second index selects port within the SOR. Some DP SORs will support DPA port and DPB port. The capability bits for each SOR will determine what ports exist. The field NV_PDISP_SOR_DP_LINKCTL_ENABLE is used to enable a specific port on a given OR.

SOR_DP_LINKCTL

ENABLE

- _YES The current DP port is enabled and data will be driven to the associated pins
- _NO The current DP port is not enabled and the port will be powered down.

Each DP SOR has two DP ports, but only one can be active at any given time. Only one of the SOR_DP_LINKCTL_ENABLE fields should be set to _YES. Whichever set of SOR_DP registers has ENABLE set to YES will be the set that controls the DP hardware.

This field must be set to _YES before the first test pattern is sent out for link training. If this field is ever set to _NO, the link must be re-trained before it can be used again.

A certain number of active symbols are metered out every transfer unit to maintain a constant data rate. Since hardware has limited precision to represent the number to active symbols, an error will add up over the line width. TUSIZE is programmed to minimize the error to a value that is close to zero or can be handled by the buffer available in the hardware to sustain the slightly higher or lower data rate than the calculated value.

TUSIZE

Transfer unit size - Valid range 64 to 32

A certain number of active symbols are metered out every transfer unit to maintain a constant data rate. Since hardware has limited precision to represent the number to active symbols, an error will add up over the line width. TUSIZE is programmed to minimize the error to a value that is close to zero or can be handled by the buffer available in the hardware to sustain the slightly higher or lower data rate than the calculated value.

SYNCMODE

- _DISABLE = Link clock and stream clock asynchronous

- _ENABLE = Link clock and stream clock synchronous

This bit is used to specify whether the link clock and pixel clock are synchronous or not. This bit is included in the Main Stream Attribute data. The DP hardware treats all pixel clocks as asynchronous, so this should be left as _DISABLE.

ENHANCED_FRAME

- _DISABLE = Enhanced Framing symbol sequence for BS, SR, CPBS, and CPSR not supported.
- _ENABLE = Enhanced Framing symbol sequence for BS, SR, CPBS, and CPSR supported.

Enhanced Framing is required for HDCP over DP. This should be set to _ENABLE when the SOR is being used for DP and HDCP is enabled.

LANE_COUNT

- _ZERO = no lanes, DP disabled
- _ONE = One lane
- _TWO = Two lanes
- _FOUR = Four lanes

This field controls the lane configuration of the DP datapath. Power controls for individual lanes are in NV_PDISP_SOR_DP_PADCTL. For one-lane configuration, Lane0 is used. For 2-lane configuration, Lane0 and Lane1 are used. Source may choose any lane count as long as it does not exceed the capability of DisplayPort receiver as indicated in the receiver capability field. This field should only be changed when the SOR is asleep.

COMPLIANCE TEST PATTERN

This field is not implemented in Hardware

FORCE IDLE PATTERN

This is a diagnostics bit which when set will force the hardware to send idle pattern on all lanes enabled. By default, the DP hardware will automatically send out the idle pattern if the OR goes to sleep while the link is still trained. This field provides an additional override if needed.

- _NO - don't force idle pattern
- _YES - force idle pattern

Offset: 0x4c | Byte Offset: 0x130 | Read/Write: R/W | Reset: 0x00000100 (0b0xx0xxxxxxx00000x0xxx0x1000000x0)

24.6.62 SOR_NV_PDISP_SOR_LANE_DRIVE_CURRENT0_0

SOR_LANE_DRIVE_CURRENT

Transmitter main output drive level. Used to set transmitter main output drive level for each of the four lanes.

bit<7> is dummy

bit<6:3> is decoded into each 3.2mA unit

bit<2:0> are mapped to binary weighted units of 1.6mA, 0.8mA, 0.4mA. Each step is 400uA; the max setting=x100 0111=28mA

- x000 0000 -> 0mA
- ...
- x100 0111 -> 28mA max
- ...
- x111 1111 -> maxed out

Voltage is for single-ended output amplitude with double 50 ohm termination. Voltage is independent of termination control.

This register will be used during link training to set the voltage swing as requested by the sink device. The value to set for the drive current is dependent on the current value of the pre-emphasis in SOR_LANE_PREEMPHASIS. There is a separate LEVEL define for each valid pre-emphasis value..

Note: When DP is active, the LANE0_DP_LANE2 field should be used for lane2 and LANE2_DP_LANE0 should be used for lane0.

Offset: 0x4e | Byte Offset: 0x138 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description

7:0	0x0	LANE0_DP_LANE2: 17 = P0_LEVEL0 21 = P1_LEVEL0 26 = P2_LEVEL0 34 = P3_LEVEL0 26 = P0_LEVEL1 32 = P1_LEVEL1 39 = P2_LEVEL1 34 = P0_LEVEL2 43 = P1_LEVEL2 51 = P0_LEVEL3

24.6.63 SOR_NV_PDISP_SOR_LANE4_DRIVE_CURRENT0_0

SOR_LANE4_DRIVE_CURRENT

Non-DP SORs contain five total lanes; four data lanes and one clock. There was not enough room in one register to fit all five lanes. LANE4 controls the fifth lane.

Offset: 0x50 | Byte Offset: 0x140 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	LANE4

24.6.64 SOR_NV_PDISP_SOR_LANE_PREEMPHASIS0_0

SOR_LANE_PREEMPHASIS

Transmitter main output pre-emphasis for each of the four lanes.

bit<7> is dummy

bit<6:3> is decoded into each 1.6mA unit

bit<2:0> is mapped to binary weighted units of 0.8mA, 0.4mA, 0.2mA. Each step is 200 µA; the maximum setting=x010 1111 = 9.4mA, if the main driver is not borrowing; the main driver has higher priority to borrow.

- x000 0000 -> 0mA
- ...
- x010 1111 -> 9.4mA max
- ...
- x111 1111 -> maxed out

This register will be used during link training to set the pre-emphasis level of each lane as requested by the sink device. The sink device may request this value to be changed during Training Pattern 1 or Training Pattern 2 during link training.

The pre-emphasis value for a given level is dependent on the drive current setting.

Note: when DP is active, the LANE0_DP_LANE2 field should be used for lane2 and LANE2_DP_LANE0 should be used for lane0.

Offset: 0x52 | Byte Offset: 0x148 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

7:0	0x0	LANE0_DP_LANE2

24.6.67 SOR_NV_PDISP_SOR_DP_CONFIG0_0

SOR_DP_CONFIG

This register contains various other controls which affect the behavior of the DP logic.

WATERMARK

This field defines the number of symbols that the DP logic will wait for at the beginning of a line before ending blanking. This number will be based on the pixel rate, the link speed, bits per pixel, tusize and line active width.

IDLE_BEFORE_ATTACH

When a head is attached to the SOR while in DisplayPort mode, the OR will send out five idle patterns before acknowledging the attach command. The DP spec requires that at least five idle patterns are sent before changing any timing parameters. This give the hardware time to calculate a new M value if the pclk frequency changed.

- _ENABLE: wait 5 idle patterns after attach before acknowledging it
- _DISABLE: acknowledge attach right away.

This register is for debug purposes only; it should be set to _ENABLE all the time for production.

RD_RESET_VAL

When training pattern 2 begins, the running disparity of the 8B10B encoding is reset. The DP spec defines that the disparity of the first symbol sent out should be negative. By resetting the 8B10B running disparity to positive, the first symbol sent out will have a negative disparity.

- _POSITIVE: The internal running disparity is reset to positive, so the first 10b symbol sent out will have negative disparity.

- _NEGATIVE: The internal running disparity is reset to negative, so the first 10b symbol send out will have positive disparity.

This value is not expected to change unless we encounter a panel that expects a different disparity.

ACTIVESYM_COUNT, ACTIVESYM_FRAC and ACTIVESYM_POLARITY:

These three fields control the number of active symbols sent out every transfer unit. Hardware maintains a TU count which is used for metering. ACTIVESYM_COUNT is the number of symbols sent out every transfer irrespective of the tu count. Based on the ACTIVESYM_POLARITY which can be 0 or 1, we can send extra symbol for a particular TU based on the ACTIVESYM_FRAC (active fraction). If active polarity is 0 and ACTIVESYM_FRAC is say 5, hardware send an extra symbols every 5th TU. If active polarity is 1 and ACTIVESYM_FRAC is 5, hardware will send an extra symbols every TU except for the 5th TU.

For instance if the number of active symbols per TU is calculated to be 17.2, ACTIVESYM_COUNT is set to 17. Fractional value is 0.2 = 1/5 which translates to 1 symbol every 5 TUs. This translates to ACTIVESYM_FRAC of 5 and ACTIVESYM_POLARITY of 0.

For instance if the number of active symbols per TU is calculated to be 17.8, ACTIVESYM_COUNT is set to 17. Fractional value is 0.8 = 4/5 which translates to 1 symbol every TU except for the 5th TU. This translates to ACTIVESYM_FRAC of 5 and ACTIVESYM_POLARITY of 1.

ACTIVESYM_COUNT, ACTIVESYM_FRAC and ACTIVESYM_POLARITY:

These three fields control the number of active symbols sent out every transfer unit. Hardware maintains a TU count which is used for metering. ACTIVESYM_COUNT is the number of symbols sent out every transfer irrespective of the tu count. Based on the ACTIVESYM_POLARITY which can be 0 or 1, we can send extra symbol for a particular TU based on the ACTIVESYM_FRAC (active fraction). If active polarity is 0 and ACTIVESYM_FRAC is say 5, hardware send an extra symbols every 5th TU. If active polarity is 1 and ACTIVESYM_FRAC is 5, hardware will send an extra symbols every TU except for the 5th TU.

For instance if the number of active symbols per TU is calculated to be 17.2, ACTIVESYM_COUNT is set to 17. Fractional value is 0.2 = 1/5 which translates to 1 symbol every 5 TU's. This translates to ACTIVESYM_FRAC of 5 and ACTIVESYM_POLARITY of 0.

For instance if the number of active symbols per TU is calculated to be 17.8, ACTIVESYM_COUNT is set to 17. Fractional value is 0.8 = 4/5 which translates to 1 symbol every TU except for the 5th TU. This translates to ACTIVESYM_FRAC of 5 and ACTIVESYM_POLARITY of 1.

24.6.68 SOR_NV_PDISP_SOR_DP_MN0_0

SOR_DP_MN

This register contains controls to tweak the values used for M and N in the Main Stream Attribute data. These controls are for debugging purposes and possible workarounds. See Section 2.3.3 of the DisplayPort specification for more detailed descriptions of M and N.

N_VAL

This is the value that will be used for calculating M. This value is not used in the Main Stream Attributes. Main Stream attributes always send 2^15 for Nvid. This should not need to be programmed beyond its default value. If this value needs to be changed, it should be done while the OR is detached. Otherwise, the calculated M value will be incorrect for some time, or until the next mode switch.

M_DELTA

This defines an offset that will be used to modify the calculated M value. This should not need to be programmed beyond its default value.

M_MOD

Describes how the M_DELTA field should be applied to the M value.

- _NONE: The M_DELTA is ignored and not used.
- _INC: The M_DELTA value is added to M.
- _DEC: The M_DELTA value is subtracted from M.

This should not need to be programmed beyond its default value.

Offset: 0x5a | Byte Offset: 0x168 | Read/Write: R/W | Reset: 0x00008000 (0b00xx00000000000010000000000000000)

Bit	Reset	Description
31:30	NONE	M_MOD: 0 = NONE 1 = INC 2 = DEC
27:24	0x0	M_DELTA
23:0	0x8000	N_VAL

24.6.69 SOR_NV_PDISP_SOR_DP_PADCTL0_0

SOR_DP_PADCTL

This register directly controls the DP pads. Some values in this register are only valid in DP mode when NV_PDISP_SOR_DP_LINKCTL_ENABLE == _YES.

PD_TXD_

Individual controls to power down the lanes. NV_PDISP_SOR_DP_LINKCTL_LANE_COUNT sets the number of lanes that are active in the DP datapath. These fields control power to the macro pins. When reducing the number of active lanes, the inactive lanes should be powered down before the lane configuration is changed. See section 5.1.2 of the DP Specification.

If a lane is powered down, link training will need to be done before that lane can be used again.

- _YES: Force the lane to power down
- _NO: Enable power to the lane. Do not power down.

Only valid in DP mode when NV_PDISP_SOR_DP_LINKCTL_ENABLE == _YES.

COMMONMODE_TXD_

This is used to force the lanes to output the common mode voltage. This is required before link training begins. Section 3.5.3.3 of the DP specification dictates that the lanes must be precharged to the common mode voltage for at least 10 microseconds before beginning link training. Please see the DP specification for more information:

Note: when DP is active, the TXD_0_DP_TXD_2 field should be used for lane2 and TXD_2_DP_TXD_0 should be used for lane0.

- _DISABLE: Normal operation
- _ENABLE: Force the lanes to output the common mode voltage

TX_PU_VALUE

TX pull-up current source drive

- x000xxxx -> 0mA
- x001xxxx -> 1mA
- x010xxxx -> 2mA
- x011xxxx -> 3mA
- x100xxxx -> 4mA
- x101xxxx -> 5mA
- x110xxxx -> 6mA

TX_PU

- _ENABLE: Pull-up current sources enabled
- _DISABLE: Pull-up current sources disabled

VCMMODE

VCM pin mode select

- _TRISTATE:tristate (default)
- _TEST_MUX:under test-mux control
- _WEAK_PULLDOWN:0 V weak pull-down
- _STRONG_PULLDOWN: 0V strong pull-down

This is a test mode pin, it does not need to be programmed by software.

REG_CTRL

Internal regulator control. These are spare input bits to the analog macro that have no defined function currently.

PAD_CAL_PD

Powerdown control for the pad calibration logic.

- _POWERDOWN: Power down
- _POWERUP:Normal operation

VCO_2X

This is a VCO startup diagnostics control input to the DP analog macro.

- _ENABLE: forced VCO oscillation mode
- _DISABLE: normal VCO operation

SPARE

Spare PLL control bits.

This field maps to ports SPAREPLL_1 to SPAREPLL_7 of the DP/LVDS macro. Some bits in this field are used only for debug. Some bits are used for VCO Gain Calibration and LOADADJ calibration.

The field names used below are the names of the ports on the macro.

SPARE_1: Maps to "vcolimit_sel":

- when vcolimit_sel=0, the clamp counter counts 128 cycles <-> 474ns @270Mhz;
- when vcolimit_sel=1, the clamp counter counts 32 cycles <-> 118ns @ 270MHz.

SPARE_2: Maps to "loadadj_sync_en":

- when loadadj_sync_en=0,the loadadj-calibration code is reset to 0000;
- when loadadj_sync_en=1,the loadadj-calibration code is swept and the best value is used.
- Used during LOADADJ calibration. Must be set to 0 and then to 1 to trigger the calibration sequence.

SPARE_3: Maps to "loadadj_bypn":

- when loadadj_bypn=0, the loadadj-calibration block is bypassed;
- when loadadj_bypn=1, the loadadj-calibration block is being used.
- Used during LOADADJ calibration to select the auto-cal value instead of the register value.

SPARE_4: Maps to "vcocalib_enb":

- when vcocalib_enb=0,enable vco-calibration, sweep the vcogain<3:0> code and the best value is used.
- when vcocalib_enb=1, reset the vco-calibration block.
- Used during VCO Gain Calibration. Must be set to 1 and then back to 0 to trigger the calibration sequence.

SPARE_5: Maps to "vcocalib_overwrb":

- when vcocalib_overwrb=0, overwrite/disable the vco-calibration block;
- when vcocalib_overwrb=1, enable the vco-calibration block.
- Used during VCO Gain Calibration.

SPARE_6: Maps to "vcocalib_ts0":

- when vcocalib_ts0=0, vco-calibration block counts 96 cycles <-> 355ns @270MHz;
- when vcocalib_ts0=1, vco-calibration block counts 128 cycles <-> 474ns @270Mhz

SPARE_7: Maps to "vcolimit_disable":

- when vcolimit_disable=0, enable the VCO-protection clamp;
- when vcolimit_disable=1, disable the VCO-protection clamp.

Offset: 0x5c | Byte Offset: 0x170 | Read/Write: R/W | Reset: 0x00800000 (0b00000000100000000000000000000000)

24.6.70 SOR_NV_PDISP_SOR_DP_DEBUG0_0

SOR_DP_DEBUG register is meant for debug purposes. It indicates of underflows or overflows at various point in the main link datapath.

- _NO indicates that no error of this type has occurred.
- _YES indicates that an error of the given type occurred at least once.

This is a write-1-to-clear register, i.e. to clear the _ERROR bits, just write _RESET to the bit you want to clear.

LANE0/1/2/3_FIFO_UNDERFLOW

When active symbol control is enabled (controlled by NV_PDISP_SOR_DP_CONFIG_ACTIVESYM_CNTL), a programmed value of active symbols are transmitted every transfer unit. This error is set when active symbol control is enabled and lane FIFOs underflow.

LANE0/1/2/3_PIXPACK_OVERFLOW

This error indicates that pixel packing registers have overflowed. This would happen if the incoming data rate (at pixel clock) is much faster than outgoing data rate (at link clock).

LANE0/1/2/3_STEER_ERROR

These bits indicate that an unexpected error has occurred in the steering logic causing imbalance in the number of bits in the lanes.

SPKT_OVERRUN

If the watermark is attained while a secondary packet is still being scanned out, then this bit will be set. All secondary packets should complete before Blank End needs to be set.

LANE0/1/2/3_FIFO_OVERFLOW

This error is set if the lane FIFOs overflow. This error would point to incorrect programming of tusize, active sym parameters. These params control the rate at which the lane FIFOs are read.

If these params are smaller than expected values, symbols will keep accumulating in the lane FIFO during the course of a horizontal line and would eventually cause an overflow.

24.6.71 SOR_NV_PDISP_SOR_DP_SPARE0_0

NV_PDISP_SOR_DP_SPARE

This is an extra register in the DP SORs that can be used for future features

SEQ_ENABLE

Used to enable the sequencer in DP mode. This needs to be set for eDP where we need to run sequencer to control backlight.

PANEL

Specify whether the DP panel is external or internal (notebook panel)

- EXTERNAL: An external DP panel is connected, normal operation status will report an internal link, and the scrambler will reset to 0xFFFE instead of 0xFFFF

SOR_CLK_SEL

This is used for SOR testbench. Specify whether to use a safe clock or the macro clock as the SOR clock.

SAFE_SORCLK: Use the safe clock as the SOR clock

MACRO_SORCLK: Use the macro clock as the SOR clock

Offset: 0x60 | Byte Offset: 0x180 | Read/Write: R/W | Reset: 0x00000002 (0b00000000000000000000000000000010)

Bit	Reset	Description
31:3	0x0	REG
2	SAFE_SORCLK	SOR_CLK_SEL: 0 = SAFE_SORCLK 1 = MACRO_SORCLK
1	INTERNAL	PANEL: 0 = EXTERNAL 1 = INTERNAL
0	NO	SEQ_ENABLE: 0 = NO 1 = YES

24.6.72 SOR_NV_PDISP_SOR_DP_AUDIO_CTRL_0

SOR_DP_AUDIO_CTRL

ENABLE

This is the global enable/disable field for Audio over DisplayPort. When set to _NO, no audio stream packets, audio timestamp packets, or audio infoframes will be sent. When set to _YES, audio stream packets will be sent whenever audio arrives, and timestamp and infoframe packets will be sent once per frame during hblank.

MUTE

This field controls the AudioMute_Flag in the VB-ID. When muted, audio samples sent to the sink device are not played. This is an override to the audio mute signal coming from the Azalia Codec.

- DISABLE: The mute is not asserted, audio will be audible
- ENABLE: The mute is asserted. The sink device should not play any audio samples that are sent. If SW changes MUTE from ENABLE to AUTO, hardware will take control of unmuting after the new audio infoframe and audio timestamp have been sent.
- AUTO: The mute signal is controlled by hardware. Audio is muted during audio format or audio timing change and unmuted after the new audio infoframe and audio timestamp have been sent.

AUDIO INFOFRAME HEADER_OVERRIDE

HB1-HB3 are fixed values as defined by the DisplayPort specification. This field will let the values in NV_PDISP_HDMI_AUDIO_INFOFRAME_HEADER override the default values. This can be used for Debugging purposes and can be left at DISABLE for production.

- DISABLE: Use the default values of HB0=0x00, HB1=0x84, HB2=0x1B, HB3=0x44
- ENABLE: Replace the contents of the Audio Infoframe Header with the values in NV_PDISP_HDMI_AUDIO_INFOFRAME_HEADER

GENERIC_INFOFRAME_ENABLE

This field allows software to send infoframes (AVI, etc.) other than audio infoframe. When enabled NV_PDISP_SOR_DP_GENERIC_INFOFRAME_HEADER, NV_PDISP_SOR_DP_GENERIC_INFOFRAME_SUBPACK* priv regs is used as infoframe header and packet data. The infoframe is sent once per vertical blanking period.

PACKETID

All secondary data packets have a packet ID in the header. All packets that are associated with the same audio stream need to have the same packet ID. This field is used to set that ID. This field can be used for debugging purposes and can be left at 0 for production.

CT_SELECT (Coding Type), CC_SELECT (Channel Count), SF_SELECT (Sampling Frequency), SS_SELECT (Sample Size), CA_SELECT (Channel/Speaker Allocation)

These fields control the values of several fields in the Audio Infoframe. The Azalia codec will detect these values, and can automatically place the correct values in the Infoframe.

- SW: The Audio Infoframe will contain the value from NV_PDISP_HDMI_AUDIO_INFOFRAME_SUBPACK0*
- HW: The Audio Infoframe will contain the value set by the Azalia codec.

NEW_SETTINGS

All the fields/settings in this register will not take effect until NEW_SETTINGS is set to _TRIGGER. When the new settings are active, this field will automatically be set to _DONE. If hardware is sending an audio packet when this is set to trigger, then it will wait for the completion of the packet before the new settings are activated. Hence the max delay from TRIGGER to DONE will be time to complete an audio packet (56* (1/162 * 10^6) = 0.35 µs).

Offset: 0x62 | Byte Offset: 0x188 | Read/Write: R/W | Reset: 0x00Xf0001 (0b0xxxxxxxxxx111110000000000xx00x1)

0	RW	YES	ENABLE: 0 = NO 1 = YES

24.6.73 SOR_NV_PDISP_SOR_DP_AUDIO_HBLANK_SYMBOLS_0

SOR_DP_AUDIO_HBLANK_SYMBOLS

The packet generation logic needs to know the length of the hblank period. If there is no room in the current hblank for a new packet, it will be delayed until the next blanking period. This field should be programmed during the second Supervisor interrupt based on the new raster dimensions.

Y = 12/number of lanes

number of symbols/hblank = ((SetRasterBlankEnd.X + SetRasterSize.Width - SetRasterBlankStart.X - 7) * link_clk / pclk) - 3*enhanced_framing - Y

Y accounts for the time required to send BS, VBID, Mvid, Maud.

The value 7 is subtracted to account for reduction in hblank interval in the link clock domain due to uncertainties arising due to pixels crossing async boundary from pixel clock (rg_clk) to link clock (or_clk). Since we use two async FIFOs to transfer pixels from rg_clk to orclk, the uncertainties are effectively doubled. The value has been experimentally determined.

The following formulas can be used to calculate the maximum audio sampling rate that can be supported by DisplayPort given the current raster dimensions. DisplayPort has much more bandwidth during blanking periods than HDMI has, so hblank size is less of an issue.

- number of free symbols/hblank = ((SetRasterBlankEnd.X + SetRasterSize.Width - SetRasterBlankStart.X - 7) * link_clk / pclk - 2 - (3*enhanced_framing)) * #lanes - 12
- Size of a packet for 2ch audio = 20 symbols (up to 2 samples)
- Size of a packet for 8ch audio = 40 symbols
- Size of an audio packet header plus control symbols = 2*#lanes + 8 symbols (assuming < 32 samples per line)
- number of packets/hblank for 2ch audio = Floor ((number of free symbols/hblank - (2*#lanes + 8) / 20)
- number of packets/hblank for 8ch audio = Floor ((number of free symbols/hblank - (2*#lanes + 8) / 40)

Maximum audio sample rate possible:

- number of audio samples/line = SetRasterSize.Width * audio_fs / pclk
- number of audio packets needed for 2ch audio = Ceiling(SetRasterSize.Width * audio_fs / (pclk*2))
- number of audio packets needed for 3-8ch audio = SetRasterSize.Width * audio_fs / pclk

If the number of audio packets needed > number of packets/hblank, then that audio frequency is not supported.

Offset: 0x63 | Byte Offset: 0x18c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx00000000000000000)

Bit	Reset	Description
16:0	0x0	VALUE

24.6.74 SOR_NV_PDISP_SOR_DP_AUDIO_VBLANK_SYMBOLS_0

SOR_DP_AUDIO_VBLANK_SYMBOLS

The packet generation logic needs to know the length of a line during VBLANK. If there is no room in the current line for a new packet, it will be delayed until the next line. This field should be programmed during the second Supervisor interrupt based on the new raster dimensions.

Y accounts for the time required to send main stream attributes.

25 accounts for reduction of the vblank interval in the link clock domain due to active region transmission spilling on to the vblank region. Note this happen only on the first vblank line while transitioning from active to blanking. This value is

experimentally determined. This might need some adjustment if NV_PDISP_SOR_AUDIO_DEBUG_BLANK_COUNT_ERROR is triggered. Note that this value will not exceed TUSIZE.

Y = (36/number of lanes) + 3;

number of symbols/line in vblank = ((SetRasterBlankStart.X - SetRasterBlankEnd.X - 25) * link_clk / pclk) - Y - 1

Offset: 0x64 | Byte Offset: 0x190 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxx00000000000000000000)

24.6.83 SOR_NV_PDISP_SOR_DP_TPG_0

NV_PDISP_SOR_DP_TPG

This register is used to control the training patterns needed during link training. This should be set after the SOR clock has been set up and the lanes have been precharged.

There is one field per lane. If the same test pattern is to be sent on all lanes, they must all be switched to that pattern at the same time in order to stay in sync

Link Training Pattern Setting

- _NOPATTERN Training not in progress (or disabled)
- _TRAINING1 Training Pattern 1
- _TRAINING2 Training Pattern 2
- _TRAINING3 Training Pattern 3
- _D102 D10.2 test pattern (unscrambled) transmitted (same as Training Pattern 1)
- _SBLEERRATE Symbol Error Rate measurement pattern transmitted
- _PRBS7 PRBS7 transmitted
- _CSTM Custom 80 bit test pattern defined in NV_PDISP_SOR_DP_LQ_CSTM
- _HBR2_COMPLIANCE HBR2 Compliance Eye pattern. Repetition of scrambled 0s before 8b10b encoding. Sends SR periodically as defined in NV_PDISP_SOR_DP_TPG_CONFIG_HBR2_COMPLIANCE_PERIOD

This is used for HBR2 electrical compliance.

SCRAMBLEREN

- _DISABLE- DisplayPort transmitter disables scrambler
- _ENABLE_GALIOS - DisplayPort transmitter scrambles data symbols before transmission
- _ENABLE_FIBONACCI - This enables a different type of scrambler. This will probably not be used.

CHANNEL_CODING

This bit set to _ENABLE when DisplayPort receiver supports the Main Link channel coding specification as specified in ANSI X3.230-1994, clause 11. This is reserved for future expansion if a different coding scheme is used later.

See section 2.9.3.6 for more information about the different test patterns. For convenience, table 2-76 is provided here to specify the required SCRAMBLEREN and CHANNELCODING values for each pattern.

```
                | Requires        | Requres
Pattern         | Channel Coding? | Scrambling?
----------------+-----------------+------------
TRAINING1       | Yes             | No
TRAINING2       | Yes             | No
TRAINING3       | Yes             | No
D102            | Yes             | No
SBLERRATE       | Yes             | Yes
PRBS7           | No              | No
CSTM            | No              | No
HBR2_COMPLIANCE | Yes             | Yes
```

24.6.84 SOR_NV_PDISP_SOR_DP_TPG_CONFIG_0

NV_PDISP_SOR_DP_TPG_CONFIG

Additional controls for the DP Test Pattern Generator.

HBR2_COMPLIANCE_PERIOD

The HBR2 compliance pattern is a series of 0s that are scrambled and 8b10b encoded. Periodically, the Scrambler Reset Sequence is sent to keep the source and sink in sync. This field controls how many total symbols there are between the start of a new Scrambler Reset Sequence. This will be defined by a DPCD register on the sink test equipment.

Offset: 0x6e | Byte Offset: 0x1b8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx00000000000000000)

Bit	Reset	Description

24.6.85 SOR_NV_PDISP_SOR_DP_LQ_CSTM0_0

NV_PDISP_SOR_DP_LQ_CSTM

These registers are used to program a custom 80-bit test pattern used for link quality purposes in DP1.2. When NV_PDISP_SOR_DP_TPG is set to CSTM, the 80 bit pattern in these registers is send repetitively on the link. NV_PDISP_SOR_DP_TPG_LANE*_CHANNELCODING and NV_PDISP_SOR_DP_TPG_LANE*_SCRAMBLEREN should be set to _DISABLE in order to send out this pattern unaltered. For the HBR2 Compliance Eye Pattern, these three registers should all be set to 0, while NV_PDISP_SOR_DP_TPG_LANE*_CHANNELCODING and NV_PDISP_SOR_DP_TPG_LANE*_SCRAMBLEREN are set to _ENABLE.

24.7 DPAUX Registers

24.7.1 DPAUX_CTXSW_0

Context switch register

Should be common to all modules. Includes the current channel/class (which is writable by software) and the next channel/class (which the hardware sets when it receives a context switch).

Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS (see vmod/chexample). Software sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be preloaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts.

Another way to avoid context switch interrupts is to set the AUTO_ACK bit. This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 0x0 | Byte Offset: 0x0 | Read/Write: R/W | Reset: 0xXXXXf800 (0bxxxxxxxxxxxxxxxx11111x0000000000)

Bit	R/W	Reset	Description
31:28	RO	X	NEXT_CHANNEL: Next requested channel
25:16	RO	X	NEXT_CLASS: Next requested class
15:12	RW	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	RW	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests 0 = MANUAL 1 = AUTOACK
9:0	RW	0x0	CURR_CLASS: Current working class

24.7.2 DPAUX_INTR_EN_AUX_0

A DP SOR port can generate 4 types of interrupts:

- PLUG_EVENT: The HPD line has been high for at least DPAUX_HPD_CONFIG_0_PLUG_MIN_TIME microseconds
- UNPLUG_EVENT: The HPD line has gone low for at least DPAUX_HPD_CONFIG_0_UNPLUG_MIN_TIME microseconds
- IRQ_EVENT: After a DP device has been connected, it can generate an interrupt request. This will cause the DP hardware to read the Sink status and then notify the RM with an IRQ_EVENT interrupt.
- AUX_DONE: This interrupt will signify the completion of an AUX transaction.

This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x1..0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
3	DISABLED	AUX_DONE: 0 = DISABLED 1 = ENABLED

24.7.12 DPAUX_DP_AUXADDR_0

DP_AUXADDR

Address register for DisplayPort AUX channel transaction.

This address register describes the 20-bit address that the transaction reads from/writes to the sink AUX register address space. Refer to the DisplayPort specification for more details.

This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x29..0x2c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
19:0	0x0	REG

24.7.13 DPAUX_DP_AUXCTL_0

DP_AUXCTL

Main control register for AUX transactions.

Refer to the DisplayPort specification for more information about AUX channel transactions.

The AUX bus can transmit data at 1Mbps. A single AUX transaction may take up to 648 microseconds to complete:

- 66 µs for precharge, SYNC, COMMAND, ADDRESS, and LENGTH
- 16*8 µs DATA
- 2 µs SYNC/STOP
- 400 µs maximum delay before reply begins
- 34 µs for precharge, SYNC
- 8 µs for REPLY_TYPE
- 8 µs LENGTH
- 2 µs SYNC/STOP

  ---

  648 microseconds

If an HPD_IRQ arrives just before an AUX request occurs, hardware will use the AUX channel to read the Link/Sink status, and then process the software request. This will incur an additional delay of up to 568 microseconds before the software request begins. This brings the total worst-case reply time to 1216 microseconds.

The AUXCTL_SEMA_REQUEST and AUXCTL_SEMA_GRANT bits are the semaphore for the DisplayPort AUX channel. Both VBIOS and RM need to use the AUX channel. The AUX semaphore is requested by writing to AUXCTL_SEMA_REQUEST. The client must check the value of AUXCTL_SEMA_GRANT to see if it was awarded the semaphore.

To obtain the semaphore:

For RM:

```
Write _RM to AUXCTL_SEMA_REQUEST
read AUXCTL_SEMA_GRANT
if (AUXCTL_SEMA_GRANT == _RM)
     RM grabbed the AUX channel successfully
else
     RM failed to control the AUX
```

For VBIOS:

```
Write _VBIOS to AUXCTL_SEMA_REQUEST
read AUXCTL_SEMA_GRANT;
if (AUXCTL_SEMA_GRANT == _VBIOS)
     VBIOS grabbed the AUX channel successfully;
else
     VBIOS failed to control the AUX;
```

To release the semaphore:

After the AUX transaction is finished, software must write _RELEASE to SEMA_REQUEST. This can be used to put the AUX channel back into a good state if it gets corrupted.

This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x2d..0x30 | Read/Write: R/W | Reset: 0x0X000000 (0b0xxxxxxxxx00xxx00000xxx000000000)

Bit	R/W	Reset	Description
31	RW	DEASSERT	RST: This can be used to put the AUX channel back into a good state if it gets corrupted. Set to ASSERT to force a localized reset of the AUX logic. Set to DEASSERT to allow the AUX engine to run 0 = DEASSERT 1 = ASSERT
25:24	RO	X	SEMA_GRANT: The client must check the value of AUXCTL_SEMA_GRANT to see if it was awarded the semaphore. SEMA_GRANT_NONE: AUX channel available SEMA_GRANT_RM: AUX channel obtained by RM SEMA_GRANT_VBIOS: AUX channel obtained by VBIOS SEMA_GRANT_PMU: AUX channel obtained by PMU 0 = NONE 1 = RM 2 = VBIOS 3 = PMU
21:20	RW	RELEASE	SEMA_REQUEST: The AUX semaphore is requested by writing to AUXCTL_SEMA_REQUEST. The process for RM or VBIOS to obtain the AUX channel is: Set to _RM if aux is obtained by RM. Set to _VBIOS if aux is obtained by VBIOS. Set to RELEASE to relinquish control of the AUX channel. 0 = RELEASE 1 = RM 2 = VBIOS 3 = PMU
16	RW	DONE	TRANSACTREQ: Software uses this bit to request an AUX channel transaction. After CMD, CMDLEN, and AUXDATA_WRITE have been set, this field should be set to _TRIGGER (1). After the hardware receives the reply, the hardware clears the TRANSACTREQ to _DONE (0).

Bit	R/W	Reset	Description
			If an unplug event is detected in the middle of a transaction, the current transaction is aborted, and the UNPLUG_EVENT bit will be set in DPAUX_INTR_4. Further transactions while unplugged will still be sent. If DPAUX_HYBRID_PADCTL_MODE is set to _I2C, or DPAUX_HYBRID_SPARE_PAD_PWR is set to _POWERDOWN, no transactions will be sent out. Any transactions in flight will complete. This prevents any interference with the I2C functionality of the pad. At the completion of an AUX transaction, the hardware will write the results into the DPAUX_DP_AUXSTAT register. The reply type should be checked as well as the error bits in this register to determine if the request was successful 0 = DONE 1 = PENDING
15:12	RW	I2CWR	CMD: AUX Command. Refer to Section 2.4, AUX channel syntax, in the DisplayPort specification. I2CWR: I2C write I2CRD: I2C read I2CREQWSTAT: I2C write status request I2CMOTWR: I2C write, Middle of transaction (MOT) I2CMOTRD: I2C read, MOT MOTREQWSTAT: I2C write status request, (MOT) AUXWR: AUX write AUXRD: AUX read 0 = I2CWR 1 = I2CRD 2 = I2CREQWSTAT 4 = MOTWR 5 = MOTRD 6 = MOTREQWSTAT 8 = AUXWR 9 = AUXRD
8	RW	NO	ADDRESS_ONLY: Some I2C-over-AUX operations require address-only transactions. This bit modifies any AUX transaction into an address only transaction. The DP specification only uses Address-only transactions for I2CRD and I2CWR (with or without MOT set). NO: Send the AUX transaction normally. YES: Send an Address-only AUX transaction. Only Command and Address will be sent. The CMDLEN field is ignored; no data will be written. Since no data is written, the ACK/NACK for this command will not contain an M value. The values in DPAUX_DP_AUXSTAT_REPLY_M and DPAUX_DP_AUXSTAT_RX_ERROR will not be accurate after an Address-only transaction. 0 = NO 1 = YES
7:0	RW	0x0	CMDLEN: These bits determine the number of data bytes an AUX channel transaction writes or reads. An AUX transaction can read or write a maximum 16 bytes. Note: This field should be set to N-1, where N is the number of bytes in the transaction.

24.7.14 DPAUX_DP_AUXSTAT_0

DP_AUXSTAT

When an AUX command completes, it will update most fields in this register.

Refer to the DisplayPort specification for more information about AUX channel transaction.

This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x31..0x34 | Read/Write: R/W | Reset: 0xX0XX00XX (0bxxxxxxxxxxxxxxxxxxxxx0000xxxxxxxx)

Bit	R/W	Reset	Description
28	RO	X	HPD_STATUS: Reports the current state of the HPD line, plugged or unplugged. This field is valid at all times, not just at the end of a transaction. This status is based on the value of the GPIO associated with this AUX channel. The connection between GPIO and AUX channel is hard coded, so they must be kept together when assigning them to an SOR link. AUX0 GPIO(1) AUX1 GPIO(19) AUX2 GPIO(15) AUX3 GPIO(21) 0 = UNPLUG 1 = PLUGGED
23:20	RO	X	AUXCTL_STATE: Reports the current state of the AUXCTL state machine. This field is valid at all times, not just at the end of a transaction. 0 = IDLE 1 = SYNC 2 = START1 3 = COMMAND 4 = ADDRESS 5 = LENGTH 6 = WRITE1 7 = READ1 8 = GET_M 9 = STOP1 10 = STOP2 11 = REPLY 12 = CLEANUP
19:16	RO	X	REPLYTYPE: These bits are for status and describe the reply type of the AUX channel command. Refer to Section 2.4.1 of the DisplayPort specification for more information about how to handle each type of reply. ACK: Transaction successful NACK: Transaction failed or is incomplete DEFER: Try again later. I2CNACK: I2C transaction failed or is incomplete I2CDEFER: Try again later. 0 = ACK 1 = NACK 2 = DEFER 4 = I2CNACK 8 = I2CDEFER
11	RW	NOT_PENDING	NO_STOP_ERROR: If the AUX reply from the Sink device did properly terminate with a STOP signal (if the AUX line goes idle), this error bit will be set. There may have been some problem with the connection. The results of the most recent request cannot be guaranteed correct. This bit will remain set until 1 is written to it. 0 = NOT_PENDING 1 = PENDING
10	RW	NOT_PENDING	SINKSTAT_ERROR: After an HPD IRQ, the hardware will automatically read DPCD addresses 0x205-0x200 and place the results in the DPAUX_DP_AUX_SINKSTAT registers. REPLYTYPE is not updated on this type of read, so if the Sink device does not respond with an ACK, this bit will be set. RX_ERROR, TIMEOUT, and NO_STOP can still be set by the automatic read. This bit will remain set until 1 is written to it. 0 = NOT_PENDING 1 = PENDING
9	RW	NOT_PENDING	RX_ERROR: This error reporting bit is set if there is an undefined error detected by the AUX channel. Currently, this is only set if the logic was expecting the sink to send a length value (M), but one was not received. This bit will remain set until 1 is written to it. 0 = NOT_PENDING 1 = PENDING
8	RW	NOT_PENDING	TIMEOUT_ERROR: This error reporting bit is set to PENDING when a timeout has occurred while waiting for a reply. The AUX channel will wait for 400 µs before aborting the AUX transaction. The timeout value is programmable in the

Bit	R/W	Reset	Description
			DPAUX_DP_AUX_CONFIG register. This bit will remain set until 1 is written to it. 0 = NOT_PENDING 1 = PENDING
7:0	RO	X	REPLY_M: These bits show the number of data bytes an AUX channel transaction receives. An AUX transaction can read or write 16 bytes maximum.

24.7.15 DPAUX_DP_AUX_SINKSTATLO_0

All bits of the SINKSTATLO and SINKSTATHI registers are combined into a 6-byte data buffer. This buffer contains sink/link status information from AUX address space from 00200h to 00205h, as specified in the DisplayPort specification. Hardware automatically issues an AUX read to the above address after a HPD IRQ is detected. The 6 bytes of read data are put into this buffer. The buffer is little endian.

This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x35..0x38 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	REG

24.7.16 P_AUX_SINKSTATHI_0

All bits of the SINKSTATLO and SINKSTATHI registers are combined into a 6-byte data buffer. This buffer contains sink/link status information from AUX address space from 00200h to 00205h, as specified in the DisplayPort specification. Hardware automatically issues an AUX read to the above address after a HPD IRQ is detected. The 6 bytes of read data are put into this buffer. The buffer is little endian.

This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x39..0x3c | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	REG

24.7.17 DPAUX_HPD_CONFIG_0

HPD_CONFIG

This register is used to configure the behavior of the HPD plug/unplug events. The INIT values are defined by the DisplayPort specification.

This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x3d..0x40 | Read/Write: R/W | Reset: 0x07d000fa (0b00000111110100000000000011111010)

Bit	Reset	Description
31:16	0x7d0	UNPLUG_MIN_TIME: The HPD line must be low for this long before it is considered an unplug event. The units of this field are in microseconds.
15:0	0xfa	PLUG_MIN_TIME: The HPD line must be high for this long to be considered a plug event. The units of this field are in microseconds.

24.7.18 DPAUX_HPD_IRQ_CONFIG_0

HPD_IRQ_CONFIG

This register controls the size of the HPD IRQ pulse. The INIT value is defined by the DisplayPort specification.

This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x41..0x44 | Read/Write: R/W | Reset: 0x000000fa (0bxxxxxxxxxxxxxxxx0000000011111010)

Bit	Reset	Description
15:0	0xfa	MIN_LOW_TIME: IRQ minimum time. The HPD line must be low for at least this amount of time to be an IRQ. An IRQ will occur if IRQ_MIN_TIME < duration of HPD low pulse < UNPLUG_MIN_TIME.

24.7.19 DPAUX_DP_AUX_CONFIG_0

AUX_CONFIG contains miscellaneous configuration parameters for the AUX channel.

This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x45..0x48 | Read/Write: R/W | Reset: 0x00000190 (0bxxxxxxxxxxxxxxxx0000000110010000)

Bit	Reset	Description
15:0	0x190	TIMEOUT: Sets the wait time, in microseconds, before an AUX transaction will abort and report TIMEOUT in DPAUX_DP_AUXSTAT_TIMEOUT. The default value of 400 µs is specified in the DisplayPort specification.

24.7.20 DPAUX_HYBRID_PADCTL_0

HYBRID_PADCTL

Configuration for the hybrid pads that can be used as AUX/I2C.

This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x49..0x4c | Read/Write: R/W | Reset: 0x00002462 (0bxxxxxxxxxxxxxxxx0010x10001100010)

Bit	Reset	Description
15	DISABLE	I2C_SDA_INPUT_RCV: Active high receiver enable for the I2C pad's DATA channel. 0 = DISABLE 1 = ENABLE
14	DISABLE	I2C_SCL_INPUT_RCV: Active high receiver enable for the I2C pad's CLK channel. 0 = DISABLE 1 = ENABLE
13:12	V0_70	AUX_CMH: Active high 1.0V signal to control the output common mode voltage. 0_60V : VCM = 0.6V (default) 0_64V : VCM = 0.64V 0_70V : VCM = 0.70V 0_56V : VCM = 0.56V 0 = V0_60 1 = V0_64 2 = V0_70 3 = V0_56
10:8	OHM_50	AUX_DRVZ: Active high driver output impedance control. Increasing this value decreases the driver impedance. 0 = OHM_78 1 = OHM_60 2 = OHM_54 3 = OHM_45 4 = OHM_50

Bit	Reset	Description
		5 = OHM_42 6 = OHM_39 7 = OHM_34
7:2	0x18	AUX_DRVI: Active high output driver current control. Increasing the register value increases drive current.
1	ENABLE	AUX_INPUT_RCV: Active high receiver enable for the AUX CH pad. 0 = DISABLE 1 = ENABLE
0	AUX	MODE: Controls whether the pad is in I2C or AUX mode. 0 = AUX 1 = I2C

24.7.21 DPAUX_HYBRID_SPARE_0

PAD_PWR: When a HotPlug is detected on a given DP port, this bit must be set to _POWERUP before any AUX transactions are done. When an Unplug event is detected, this can be written to _POWERDOWN. As long as a DP monitor is connected, the AUX pads should remain powered on because the monitor may send an HPD IRQ, which will require the HW to initiate an AUX read without SW intervention. The logic assumes that the AUX pad will be powered on.

Offset: 0x4d..0x50 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
0	POWERUP	PAD_PWR: Controls the E_PWRD port of the hybrid pad. The pads can consume a lot of power if enabled and should be disabled when not in use. POWERUP: pad has power and can be used for transactions. POWERDOWN: pad is powered down and cannot be used. 0 = POWERUP 1 = POWERDOWN

24.7.22 DPAUX_SCRATCH_REG0_0

SCRATCH_REG0

This register is used in the sor_wrap to control the BFM parameters. For fields such as data/address/cmd_type/data_count, the corresponding values get loaded from the scratch_reg1 registers

Offset: 0x51 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

24.7.23 DPAUX_SCRATCH_REG1_0

SCRATCH_REG1

This register is used for loading data/address/cmd_type/data_count values when the corresponding field in the SCRATCH_REG0 is triggered.

Offset: 0x55 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	REG

24.7.24 DPAUX_SCRATCH_REG2_0

SCRATCH_REG2

This register is used to provide data back to the .tcl tests in cases where tests wait/poll for a particular value.

Offset: 0x59 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	REG: 0 = IDLE 1 = DONE

25.0 HDMI CEC

The HDMI Consumer Electronics Control (CEC) block supports CEC standard communication over an HDMI connection. It supports both remote control of HDMI devices attached to the Tegra® K1 device, and also allows other HDMI devices to control Tegra functions. Refer to the CEC appendix of the HDMI specification for details of this link.

25.1 Functional Description

The CEC module is an APB slave. It is located at address NV_ADDRESS_MAP_APB_CEC_BASE (0x70015000).

The CEC consists of hardware state machines that send and receive bytes over the CEC wire. Its simple host interface allows one byte to be sent and received at a time.

The CEC has interrupts for interrupt-driven input and output, and also permits polling I/O.

25.2 Programming Guidelines

25.2.1 Initialization

25.2.1.1 Clock and Reset

The CEC uses a fixed clock source – the APB bus clock. It also has a clock enable and reset in the CAR block.

- CAR.RST_DEVICES_W.SWR_CEC_RST = DISABLE
- CAR.CLK_OUT_ENB_W.CLK_ENB_CEC = ENABLE

25.2.1.2 Interrupt

The CEC is on PRI interrupt controller bit 3.

CEC INT_MASK should be enabled for TX_* and RX_* interrupts. TX_REGISTER_EMPTY and RX_REGISTER_FULL are the key interrupts; most others are errors.

Refer to the Interrupt Controller section for more information.

25.2.1.3 Pin Mux

The CEC is available on the HDMI_CEC pin. HDMI_CEC pin mux should be configured for:

- PM=0 (primary CEC function)
- PUPD=NORMAL
- TRISTATE=NORMAL
- E_INPUT=ENABLE
- OD=ENABLE.

25.2.2 CEC Timing

Timing parameters are in units of 32 microseconds. See the HDMI specification for CEC timing requirements. In Tegra K1 devices, the registers have default (reset) values as indicated in the following table.

Register	Field	Value	Comment
RX_TIMING_0	RX_START_BIT_MAX_LO_TIME	0x7a	

Register	Field	Value	Comment
	RX_START_BIT_MIN_LO_TIME	0x6d	
	RX_START_BIT_MAX_DURATION	0x93	
	RX_START_BIT_MIN_DURATION	0x86	
RX_TIMING_1	RX_DATA_BIT_MAX_LO_TIME	0x35	
	RX_DATA_BIT_SAMPLE_TIME	0x21	
	RX_DATA_BIT_MAX_DURATION	0x56	
	RX_DATA_BIT_MIN_DURATION	0x40	
RX_TIMING_2	RX_END_OF_BLOCK_TIME	0x50	
TX_TIMING_0	TX_START_BIT_LO_TIME	0x74	
	TX_START_BIT_DURATION	0x8d	
	TX_BUS_XITION_TIME	0x8	
	TX_BUS_ERROR_LO_TIME	0x71	
TX_TIMING_1	TX_LO_DATA_BIT_LO_TIME	0x2f	
	TX_HI_DATA_BIT_LO_TIME	0x13	
	TX_DATA_BIT_DURATION	0x4b	
	TX_ACK_NAK_BIT_SAMPLE_TIME	0x21	
TX_TIMING_2	BUS_IDLE_TIME_ADDITIONAL_FRAME	0x7	
	BUS_IDLE_TIME_NEW_FRAME	0x5	
	BUS_IDLE_TIME_RETRY_FRAME	0x3	

25.2.3 CEC Control

The CEC has several modes but only some are simulated or supported. TX_RX_MODE=ENABLE should be set last.

Register	Field	Value	Comment
SW_CONTROL	MODE	DISABLE	Use HW mode
INPUT_FILTER	FIFO_LENGTH	0	
	MODE	DISABLE	
HW_CONTROL	RX_LOGICAL_ADDRS	*Slave addresses (bitmap)*	If slave, holds addresses
	RX_SNOOP	DISABLE	
	RX_NAK_MODE	BLOCK	
	TX_NAK_MODE	BLOCK	
	FAST_SIM_MODE	DISABLE	SW should use DISABLE
	TX_RX_MODE	ENABLE	Enable last
INT_MASK	TX_*, RX_*	DISABLE/ENABLE	ENABLE to enable interrupt

25.2.4 Transmission

Each message is a series of bytes, and each byte has several flags associated with it.

Register	Field	Value	Comment
TX_REGISTER	DATA	*byte*	8-bit byte
	EOM	1 on last byte	End of message flag
	ADDRESS_MODE	DIRECT/BROADCAST	
	GENERATE_START_BIT	1	
	RETRY_FRAME	0/1	

In general, the first byte contains source and destination addresses, per the CEC specification. The source address is chosen by software as the Tegra address. The destination address is either 15 for broadcast, or less than 15 for a particular slave. The last byte contains EOM=1. When sending to address 15 (broadcast), ADDRESS_MODE must be BROADCAST so that ACK and NAK have correct polarity. If this transmission is a retry of a previous one, RETRY_FRAME should be 1 so that correct retry timing is used.

The TX register interface is unusual in that the interrupt (TX_REGISTER_EMPTY) controls transmission – it's not merely a status signal. To transmit a byte, TX_REGISTER is first written with data, then the INT_STAT.TX_REGISTER_EMPTY interrupt must be cleared. If interrupt service routines are used, they must be careful when clearing an interrupt, because doing so incorrectly could cause a spurious or lost byte.

Transmission pseudo-code:

```
Transmit(unsigned char data, bool eom?, bool broadcast?):
        // enqueue byte
        Write TX_REGISTER: DATA = data,
                EOM = eom?,
                ADDRESS_MODE = broadcast?,
                GENERATE_START_BIT = 1
        // clear interrupt to enable transmission
        Write INT_STAT: TX_REGISTER_EMPTY = 1
        // wait for transmission
        Either Poll INT_STAT.TX_* to go high, or wait for TX_* interrupt.
        If TX_REGISTER_EMPTY=1, transfer is complete.
        If other TX_* interrupts set, then error.
```

Transmission of multi-block frames requires the blocks (bytes) to be sent back-to-back with no idle space between. If software does not provide the bytes in time, hardware will signal a TX_REGISTER_UNDERRUN interrupt and halt transmission (see Error Recovery below).

25.2.5 Reception

The RX_REGISTER_FULL interrupt indicates that a byte has been received and blocks further reception until cleared. If a subsequent byte is received while RX_REGISTER_FULL is high, an RX_REGISTER_OVERRUN error results.

When a byte is received, two additional EOM and ACK flags are provided as well.

Register	Field	Value	Comment
RX_REGISTER	DATA	*byte*	8-bit byte
	EOM	1 on last byte	End of message flag
	ACK	*bit from bus*	Expected value depends on whether broadcast or direct

Once INT_STAT indicates a byte has been received, first read the byte (and flags), and then clear the interrupt.

Reception pseudo-code:

```
Receive( unsigned char &data, bool &eom, bool &ack):
        // wait for data
        Either Poll INT_STAT.RX_REGISTER_FULL, or
                wait for CEC RX_REGISTER_FULL interrupt
        If INT_STAT.RX_* error interrupts set, then error
        data, eom, ack = Read RX_REGISTER.DATA/EOM/ACK
        // clear interrupt to allow further reception
        Write INT_STAT.RX_REGISTER_FULL = 1
```

25.2.6 Error Recovery

In case of transmission error such as UNDERRUN or NAKD, the transmission will stop. Alternatively, the soft reset sequence should be used:

```
tmp = CEC_HW_CONTROL
CEC_HW_CONTROL = 0
CEC_INT_STATUS = 0xffffffff
CEC_HW_CONTROL = tmp
```

25.3 CEC Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

For more information on Consumer Electronics Control (CEC), refer to the CEC appendix of the HDMI specification.

25.3.1 CEC_SW_CONTROL_0

SW controlled mode is not supported. Leave disabled.

Offset: 0x0 | Read/Write: R/W | Reset: 0x000000XX (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
31	RW	DISABLE	MODE: 0 = DISABLE 1 = ENABLE
4	RO	X	FILTERED_RX_DATA_PIN
0	RO	X	RAW_INPUT_DATA_PIN

25.3.2 CEC_HW_CONTROL_0

The following steps are the best way to reset the CEC engine:

1. Set the CEC_HW_CONTROL_TX_RX_MODE to DISABLE
2. Set all the interrupt enable bits in CEC_HW_INTR_EN to DISABLE
3. Wait 1 second (1 second is the maximum CEC bus timeout period from the HDMI specification)
4. Set the CEC_HW_CONTROL_TX_RX_MODE to ENABLE and restart.

Other devices on the bus might have been communicating just fine. When the restart has completed, there might be a few spurious false start bits and other receive bus anomalies before normal operation is resumed.

The CEC_HW_CONTROL register contains the control bits and fields for operating and configuring the HW CEC engine.

Note:	Once the block is enabled, software should not attempt to change these configuration parameters without first disabling the block, except for the RX_LOGICL_ADDRS and RX_SNOOP fields.

RX_LOGICAL_ADDRS

The HDMI specification permits a single physical entity to claim logical addresses reserved for different functions (e.g., "Tuner x" and "Playback device y"). For a PC, it is entirely possible to be a multi-function device, so hardware might need to respond to 2 (or more) logical addresses (as many combinations as make sense). The next fields are used to configure the logical addresses that hardware will respond to. As per the specification, hardware will always respond to the broadcast address. This is a 15-bit field, where each bit position is associated with one of the logical addresses. A '1' in any bit position causes the hardware to respond to the associated logical address (i.e., capture data blocks/frames addressed to the address and properly ack/nak said blocks). To keep things simple, the mapping of bit position to logical address is direct, i.e., bit N maps to logical address N.

RX_SNOOP

When enabled, the hardware will intercept and forward to software all traffic on the CEC bus. It will continue to ack/nak only those addresses that are assigned to it.

RX_NAK_MODE

The HDMI specification is a bit unclear about what the initiator is supposed to do if an intermediate block of a frame is NAK'd, i.e., should the initiator cease transmitting immediately or complete the rest of the frame. The HDMI specification says that a follower may NAK a frame at any time, but the concern is that some initiator might not recover from such an early NAK'd frame. This bit will permit the receive state machine to operate in either mode. The choices are:

- BLOCK which means that a frame will be NAK'd as soon as a RX_REGISTER_OVERRUN is detected
- FRAME which means that the hardware will keep track of any RX_REGISTER_OVERRUNs that occur during frame reception, and NAK only during the last block.

TX_NAK_MODE

The HDMI specification is a bit unclear about what the initiator is supposed to do if an intermediate block of a frame is NAK'd, i.e., should the initiator cease transmitting immediately or complete the rest of the frame. This bit will permit the transmit state machine to operate in either mode. The choices are:

- BLOCK which means transmission will cease at the first NAK'd block
- FRAME which means that transmission will always continue to the end of the frame.

TX_RX_INTERRUPT_ROUTING

The engine generates a single composite interrupt output signal which can then be routed to either PMU or HOST. This bit controls that routing.

TX_RX_MODE

This bit enables or disables the operation of the HW CEC engine. If the TX_RX_MODE is changed to DISABLE, then the HW engine returns to the IDLE state irrespective of what it is doing and drives a 1 onto the CEC bus. If CEC_SW_CONTROL_MODE is ENABLED, the HW CEC engine operation is automatically disabled.

Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0b00xxxxx0xxxxxxx00000000000000000)

Bit	Reset	Description
31	DISABLE	TX_RX_MODE: 0 = DISABLE 1 = ENABLE
30	DISABLE	FAST_SIM_MODE: 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
24	BLOCK	TX_NAK_MODE: 0 = BLOCK 1 = FRAME
16	BLOCK	RX_NAK_MODE: 0 = BLOCK 1 = FRAME
15	DISABLE	RX_SNOOP: 0 = DISABLE 1 = ENABLE
14:0	0x0	RX_LOGICAL_ADDRS: All logical addresses that should be matched. One bit per address.

25.3.3 CEC_INPUT_FILTER_0

The CEC_INPUT_FILTER register is used to configure the HW filtering that is required to deglitch the incoming receive data line. As data arrives into the chip, it is pushed into a 1 bit wide FIFO with a maximum of 64 entries deep. The actual used depth of the FIFO is set using the CEC_INPUT_FILTER_FIFO_LENGTH field. The used length is equal to CEC_INPUT_FILTER_FIFO_LENGTH+1. A datum is pushed into the FIFO once per microsecond tick. The FIFO bits should reset to '1' (the idle condition of the CEC bus).

The filtered output of the FIFO is computed roughly as follows:

```
filterMsk[63:0] = (1 << CEC_INPUT_FILTER_FIFO_LENGTH + 1) - 1;

if (reset || (CEC_INPUT_FILTER_MODE == CEC_INPUT_FILTER_MODE_DISABLE))
    fifo[63:0] = 0xffffffffffffffff;
else if (clock tick time)
    fifo[63:0] = (fifo[63:0] << 1) | rawInputDataPin;

if (reset || (CEC_INPUT_FILTER_MODE == CEC_INPUT_FILTER_MODE_DISABLE))
    filteredRxDataPin = 1;
else if ((clock tick time) && ((fifo & filterMsk) == filterMsk))
    filteredRxDataPin = 1;
else if ((clock tick time) && ((~fifo & filterMsk) == filterMsk))
    filteredRxDataPin = 0;
else
    filteredRxDataPin = filteredRxDataPin;
```

This logic should make sure that the filteredRxDataPin output only transitions to 0 or 1 when all the examined bits in the FIFO are also 0 or 1. Thus the filtered data line will not transition as long as there are glitches in the FIFO. The length of 64 provides a maximum operational length of 64 µs.

Every state transition on the filtered receive data line is reportable to software via the interrupt register described later.

Offset: 0x8 | Read/Write: R/W | Reset: 0x000000XX (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	DISABLE	MODE: 0 = DISABLE 1 = ENABLE
5:0	X	FIFO_LENGTH

25.3.4 CEC_SPARE_0

Spare register for future use.

Offset: 0xc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0x0	SPARES

25.3.5 CEC_TX_REGISTER_0

CEC_HW_TX_REGISTER register

This register is used by software to provide the hardware with the actual data to be transmitted on the bus. Note that hardware will 'blindly' transmit what it is given. For example, it will not check to be sure that a proper legal initiator address has been provided, it will not check to be sure that the maximum frame length of 16 is not violated, etc. These higher level protocol checks are the domain of the SW. In order to facilitate easier software programming and smoother operation, hardware will make its own working copy of the fields in this register, thus quickly freeing up the register for software to write the next block. (Basically, it is a one-deep FIFO with fullness reported via the TX_REGISTER_EMPTY bit).

DATA

The actual 8 bits of address/data to be transmitted on the bus. The data is always transmitted MSB (bit 7) first.

EOM

This is the "end of message" bit for this block of data. This bit is set at the last block of the frame.

ADDRESS_MODE

This bit indicates to the hardware whether this particular block is directly addressed or broadcast addressed (which in turn dictates how hardware is to interpret the ACK/NAK for the block).

GENERATE_START_BIT

Indicates to the hardware that it should precede the transmission of this block of data with a start bit.

RETRY_FRAME

Indicates if the current frame is a retry frame or not. Based on this value, hardware chooses an appropriate bus idle time programmed in TX_TIMING2 register and waits for the bus to be idle before it can attempt to send a start bit. This bit is only meaningful when TX_GENERATE_START_BIT is set.

RETRY FRAME	LAST_FRAM_ SENT_BY_US	WAIT TIME
1	YES	TIMING2_BUS_IDLE_TIME_RETRY_FRAME
1	NO	TIMING2_BUS_IDLE_TIME_RETRY_FRAME
0	NO	TIMING2_BUS_IDLE_TIME_NEW_FRAME
0	YES	TIMING2_BUS_IDLE_TIME_ADDITIONAL_FRAME

If a frame is being sent immediately following the previous frame, hardware waits for "TIMING2_BUS_IDLE_TIME_ADDITIONAL_FRAME". However, if someone else uses the bus before that time elapses, the hardware resets its wait time counter and waits for "TIMING2_BUS_IDLE_TIME_NEW_FRAME".

Offset: 0x10 | Read/Write: R/W | Reset: 0x00010000 (0bxxxxxxxxxxxxxxx01xxx0xxx000000000)

Bit	Reset	Description
17	DISABLE	RETRY_FRAME: 0 = DISABLE 1 = ENABLE
16	ENABLE	GENERATE_START_BIT: 0 = DISABLE 1 = ENABLE
12	DIRECT	ADDRESS_MODE: 0 = DIRECT 1 = BROADCAST
8	0x0	EOM
7:0	0x0	DATA

25.3.6 CEC_RX_REGISTER_0

CEC_HW_RX_REGISTER register

This register is used by hardware to buffer data to the software. When a block of data has been received from the bus, it is stored here for software (and the RX_REGISTER_FULL bit is set). The hardware also has a 'working copy' of the receive register to give software as much time as possible to empty it. When a full block is assembled, hardware places it into RX_REGISTER, so the register is like a 1 deep FIFO.

DATA

The 8 bits of data that were read from the bus.

EOM

The EOM bit read from the bus.

ACK_NAK

The ACK/NAK bit as read from the bus. In some cases (broadcast block) even though the device may have ACK'd the frame, some other device on the bus may NAK the frame, and software would need to know this.

Offset: 0x14 | Read/Write: RO | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
9	X	ACK
8	X	EOM
7:0	X	DATA

25.3.7 CEC_RX_TIMING_0_0

CEC_HW_RX_TIMING0 register

Note: All timing registers must be configured before the HW CEC engine is enabled.

RX_START_BIT_MAX_LO_TIME

nominal 3.9 ms, (3900/32 = 122 intervals) = 3.904 ms

The maximum time the received bus can remain low, and still be considered the beginning of a proper start bit. If the start bit low time overruns this time, the start bit is considered invalid and is ignored.

RX_START_BIT_MIN_LO_TIME

nominal 3.5 ms, (3500/32 = 109 intervals) = 3.488 ms

The minimum time the received bus can remain low and still be considered the beginning of a proper start bit. If the start bit low time underruns this time, the start bit is considered invalid and is ignored.

RX_START_BIT_MAX_DURATION

nominal 4.7 ms, (4700/32 = 147 intervals) = 4.704 ms

The maximum total duration of the start bit from the first detected high-to-low transition to the high-to-low transition that begins the first address bit. If the start bit duration overruns this time, the start bit is considered invalid and is ignored.

RX_START_BIT_MIN_DURATION

nominal 4.3 ms (4300/32 = 134 intervals) = 4.288 ms

The minimum total duration of the start bit from the first detected high-to-low transition to the high-to-low transition that begins the first address bit. If the start bit duration underruns this time, the start bit is considered invalid and is ignored.

Offset: 0x18 | Read/Write: R/W | Reset: 0x86936d7a (0b10000110100100110110110101111010)

Bit	Reset	Description
31:24	0x86	RX_START_BIT_MIN_DURATION
23:16	0x93	RX_START_BIT_MAX_DURATION
15:8	0x6d	RX_START_BIT_MIN_LO_TIME
7:0	0x7a	RX_START_BIT_MAX_LO_TIME

25.3.8 CEC_RX_TIMING_1_0

CEC_HW_RX_TIMING1 register

Note: All timing registers must be configured before the HW CEC engine is enabled.

RX_DATA_BIT_MAX_LO_TIME

nominal 1.7 ms, (1700/32 = 53 intervals) = 1.696 ms

The maximum time the received bus can remain low and still be considered the beginning of a proper start bit. If the start bit low time overruns this time, the start bit is considered invalid and is ignored.

RX_DATA_BIT_SAMPLE_TIME

nominal 1.05 ms, (1050/32 = 33 intervals) = 1.056 ms

The time to sample that data bit.

RX_DATA_BIT_MAX_DURATION

nominal 2.75 ms, (2750/32 = 86 intervals) = 2.752 ms

The maximum total duration of the start bit from the first detected high-to-low transition to the high-to-low transition that begins the first address bit. If the start bit duration overruns this time, the start bit is considered invalid and is ignored.

RX_DATA_BIT_MIN_DURATION

nominal 2.05 ms (2050/32 = 64 intervals) = 2.048 ms

The minimum total duration of the start bit from the first detected high-to-low transition to the high-to-low transition that begins the first address bit. If the start bit duration underruns this time, the start bit is considered invalid and is ignored.

Offset: 0x1c | Read/Write: R/W | Reset: 0x40562135 (0b01000000010101100010000100110101)

Bit	Reset	Description
31:24	0x40	RX_DATA_BIT_MIN_DURATION

Bit	Reset	Description
23:16	0x56	RX_DATA_BIT_MAX_DURATION
15:8	0x21	RX_DATA_BIT_SAMPLE_TIME
7:0	0x35	RX_DATA_BIT_MAX_LO_TIME

25.3.9 CEC_RX_TIMING_2_0

CEC_HW_RX_TIMING2 register

Note: All timing registers must be configured before the HW CEC engine is enabled.

RX_END_OF_BLOCK_TIME

nominal 1.9 ms, (1900/32 = 80 intervals) = 1.9 ms

The time to wait after the start of the final ACK/NAK phase of frame transmission before returning to the idle state. (Needed since the last ACK/NAK bit will not be followed by another high-to-low transition.)

Offset: 0x20 | Read/Write: R/W | Reset: 0x00000050 (0bxxxxxxxxxxxxxxxxxxxxxxxx01010000)

Bit	Reset	Description
7:0	0x50	RX_END_OF_BLOCK_TIME

25.3.10 CEC_TX_TIMING_0_0

The next set of timing registers configures the CEC logic for HW assisted operation. To permit flexible configuration (to support possible semi-compliant devices), the bit timing control and check values are programmable (rather than just directly using the specification values).

While the block itself works on a 1 µs tick, in order to save register space, these timing numbers are specified in units of 32 µs.

First, the registers for the various timing intervals (there are quite a few of them).

CEC_HW_TX_TIMING0 register

Note: All timing registers must be configured before the HW CEC engine is enabled.

For details of exact values and tolerances, refer to the CEC appendix of the HDMI specification.

TX_START_BIT_LO_TIME

nominal 3.7 ms, (3700/32 = 116 intervals) = 3.712 ms

How long to hold the bus lo during the start bit.

TX_START_BIT_DURATION

nominal 4.5 ms, (4500/32 = 141 intervals) = 4.512 ms

The total duration of the start bit

TX_BUS_XITION_TIME

nominal 250 µs, (250/32 = 8 intervals) = 256 µs

Time to wait for bus to settle after transitioning output.

TX_BUS_ERROR_LO_TIME

nominal 3.6 ms (3600/32 = 113 intervals) = 3.616 ms

Time to drive bus low when bus error must be signaled on the bus

Offset: 0x24 | Read/Write: R/W | Reset: 0x71088d74 (0b01110001xxxx10001000110101110100)

31:24	0x71	TX_BUS_ERROR_LO_TIME
19:16	0x8	TX_BUS_XITION_TIME
15:8	0x8d	TX_START_BIT_DURATION
7:0	0x74	TX_START_BIT_LO_TIME

25.3.11 CEC_TX_TIMING_1_0

CEC_HW_TX_TIMING1 register

Note: All timing registers must be configured before the HW CEC engine is enabled.

TX_LO_DATA_BIT_LO_TIME

nominal 1.5 ms, (1500/32 = 47 intervals) = 1.504 ms

How long to hold the bus low when transmitting a '0'.

TX_HI_DATA_BIT_LO_TIME

nominal 0.6 ms, (600/32 = 19 intervals) = 6.08 ms

How long to hold the bus low when transmitting a '1'.

TX_DATA_BIT_DURATION

nominal 2.4 ms, (2400/32 = 75 intervals) = 2.4 ms

The total duration of a data or ACK/NAK bit.

TX_ACK_NAK_BIT_SAMPLE_TIME

nominal 1.05 ms, (1050/32 = 33 intervals) = 1.056 ms

The time to sample that ACK/NAK bit.

Offset: 0x28 | Read/Write: R/W | Reset: 0x214b132f (0b00100001010010110001001100101111)

25.3.12 CEC_TX_TIMING_2_0

CEC_HW_TX_TIMING2 register

This register contains the bus idle time values for the various scenarios indicated in the HDMI specification (section 9.1). Software indicates to the hardware the amount of delay in units of data bit periods, as defined by the CEC_HW_TX_TIMING1_TX_DATA_BIT_DURATION field.

ADDITIONAL_FRAME:

The amount of time the bus needs to be idle before a new frame can be sent immediately after sending a frame. The suggested value is greater than or equal to 7.

NEW_FRAME:

The amount of time the bus needs to be idle before a new frame can be sent if we were not the initiator for the previous frame. The suggested value is greater than or equal to 5.

RETRY_FRAME:

The amount of time the bus needs to be idle before the same frame can be resent. The suggested value is >= 3.

Offset: 0x2c | Read/Write: R/W | Reset: 0x00000357 (0bxxxxxxxxxxxxxxxxxxxxx001101010111)

Bit	Reset	Description
11:8	0x3	BUS_IDLE_TIME_RETRY_FRAME
7:4	0x5	BUS_IDLE_TIME_NEW_FRAME
3:0	0x7	BUS_IDLE_TIME_ADDITIONAL_FRAME

25.3.13 CEC_INT_STAT_0

CEC_HW_INTR register

This register contains the individual interrupt and status bits for the CEC HW unit. The CEC_HW_INTR_EN register contains the corresponding enable bit for each interrupt/status bit in the interrupt register. The interrupt enable determines whether the interrupt propagates to the PMIC as an interrupt, but the interrupt status bit itself is always set if the described condition occurs. Software writes a '1' to any interrupt/status bit in order to clear it.

Because the HW state machine also looks at the state of the interrupt bits when determining what action(s) to take, it is important for software to operate in roughly the following order when processing interrupts from this source:

1. Read the interrupt register to determine what caused the interrupt and what needs to be done.
2. Perform the operations required, e.g., reload TX register, read RX register.
3. Finally, clear the corresponding interrupt bits.

TX_REGISTER_EMPTY

The transmit register is empty, so software is free to write the next block of the frame into the register. For multi-block frames, software must in fact provide the next block before the current block is sent, otherwise a TX_REGISTER_UNDERRUN error will occur. When the TX engines reads from the TX_REGISTER register and stores a local copy, this interrupt is asserted.

TX_REGISTER_UNDERRUN

The transmit register was empty at the time the transmit hardware needed to have the next block ready to send. This is an error condition. The transmitter will have stopped transmitting, and recovery will require resending the entire frame from scratch.

TX_FRAME_OR_BLOCK_NAKD

Hardware sets this bit if any block/frame is NAK'd. If software sees this bit set, it knows it will have to resend the frame later.

TX_ARBITRATION_FAILED

Hardware sets this bit during the address block phase of transmitting a frame, if failed to win arbitration. In this case, transmission will cease, and the HW will flush any pending data in the TX_REGISTER. Software will need to retry the frame from scratch (after the appropriate signal free time, i.e., hardware will not automatically retry).

TX_BUS_ANOMALY_DETECTED

Sometime during block transmission, hardware detected anomalous behavior on the bus (e.g., the bus remained low after transmitter had signaled high). When such an anomaly is detected, the transmitter ceases operation, releases the bus high, and flushes any pending data in the TX_TRANSMIT register.

TX_FRAME_TRANSMITTED

This is asserted at the end of the last data bit, i.e., the ACK bit of the last block is sent. This is just an indication that the last block is sent but does not necessarily mean the transmission was successful. Software should still look for other interrupts to check for any errors.

RX_REGISTER_FULL

The hardware has assembled a complete block from the bus and placed it into the RX_REGISTER. Software should read the block immediately to ensure the RX_REGISTER is empty before hardware has the next block ready to load. When the HW RX engine writes RX data to the RX_REGISTER, this bit is set.

RX_REGISTER_OVERRUN

Software failed to read the RX_REGISTER before hardware had another block of data ready to transfer. Hardware will NAK the block/frame, and the initiator will need to retry later. Software will need to flush the partially accumulated frame.

RX_START_BIT_DETECTED

Whenever the receive engine detects a start bit, it will set this bit. This bit is used for debug.

RX_BUS_ANOMALY_DETECTED

The receiver detected some anomaly (including bus errors) on the bus. A bus error has a specific definition in the HDMI specification, but there are other kinds of anomalies that can occur. All anomalies and bus errors are reported here.

RX_BUS_ERROR_DETECTED

The receiver has detected the specific anomaly called a bus error and then signaled a bus error on the bus per the HDMI specification.

FILTERED_RX_DATA_PIN_TRANSITION_H2L

In direct SW bus drive mode, software needs to be interrupted whenever the state of the received data line transitions. This interrupt is asserted on a 1 to 0 transition.

FILTERED_RX_DATA_PIN_TRANSITION_L2H

In direct SW bus drive mode, software needs to be interrupted whenever the state of the received data line transitions. This interrupt is asserted on a 0 to 1 transition

26.0 MIPI-CSI (CAMERA SERIAL INTERFACE)

This section describes the Camera Serial Interface (CSI), which is based on the MIPI CSI 2.0 standard specification. The MIPI CSI 2.0 standard is available from MIPI to its members at http://www.mipi.org/.

26.1 Functional Description

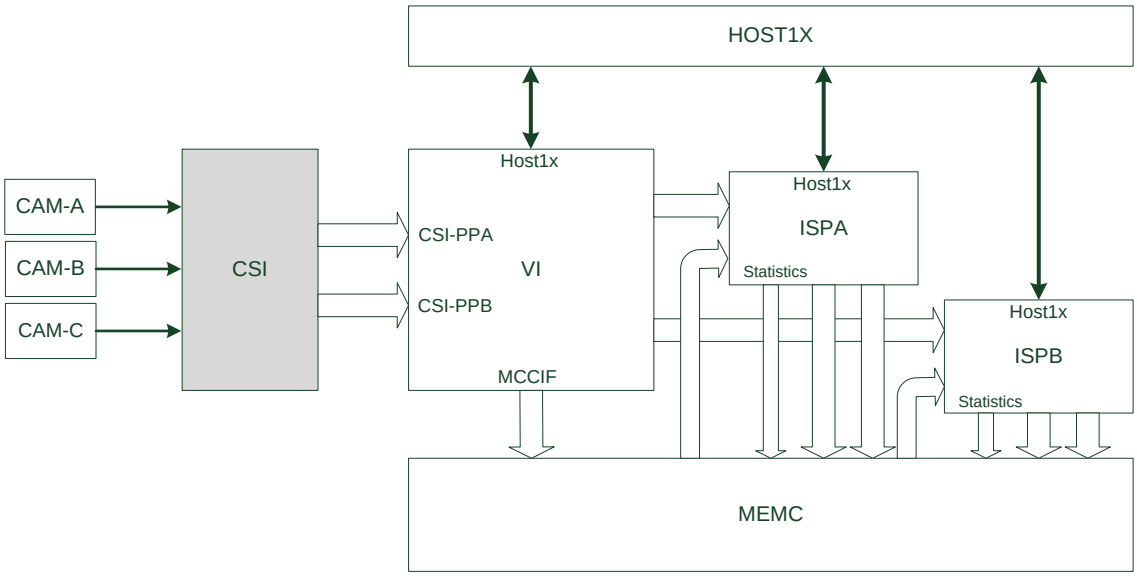
The CSI implements a MIPI compliant CSI receiver that may receive data from an external camera module with a CSI transmitter. The CSI is designed to provide for direct connection to three camera modules and allow any two of the modules to be active simultaneously:

- CSI-A interface supports 1 clock lane and up to 4 data lanes for Camera A.
- CSI-B interface supports 1 clock lane and up to 4 data lanes for Camera B OR a single data lane for Camera C.

The CSI offers both single and multi-camera configuration options. These options include a single camera configuration with a 1 to 4 lane sensor connected to CSI-A or CSI-B or a dual camera configuration with a 1 to 4 lane sensor connected to CSI-A and a 1 lane sensor to CSI-B.

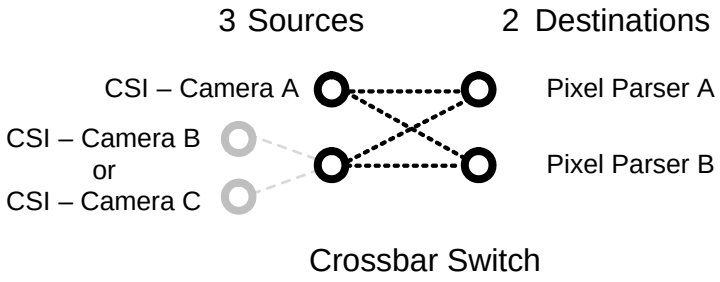
The following figure illustrates the datapaths associated with the Tegra® K1 camera subsystem.

Figure 84: Datapath Through the Tegra K1 Camera Subsystem



A maximum of two data/pixel streams can be processed simultaneously at any given time. The two streams can come from any one or two of the three possible sources, as shown in Figure 85. If the two streams come from a single source, then the streams are separated using a filter indexed on different virtual channel numbers or data types. In case of separation using data types, the normal data type is separated from the embedded data type. Because there are only two pixel parsers (PPA and PPB), the virtual channel and embedded data capability cannot be used at the same time.

Figure 85: Data Source/Destination Options



The CSI may receive data from camera modules through the MIPI serial interface. A test pattern generator has been implemented to assist validation.

The CSI supports single-shot mode and burst capture mode.

The CSI is designed with error resilience.

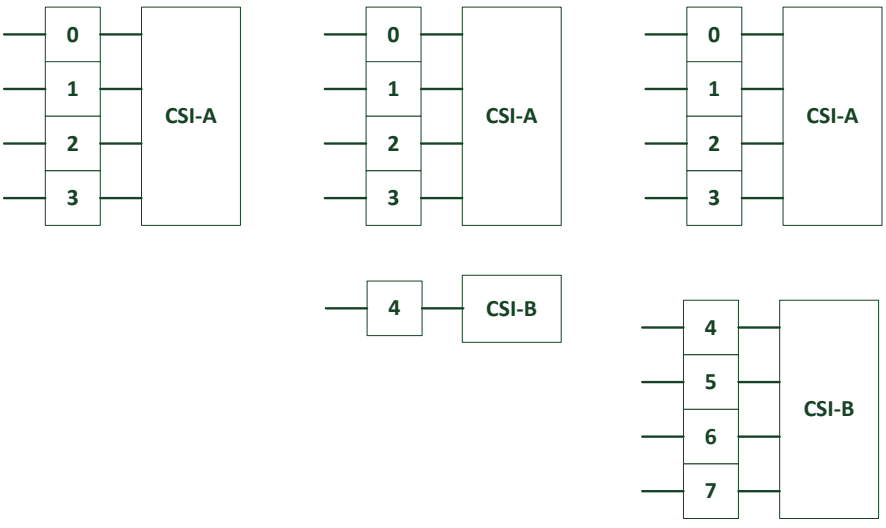
26.1.1 Lane Configurations

The number of MIPI lanes supported provides flexibility in the support of both single and dual camera user models. The typical single and dual camera application targets include high-resolution mono image capture in addition to dual camera image capture configurations:

- 1 x4 (Single camera with 4 lane sensor)
- 1 x4 + 1 x1 (one high resolution camera and another front facing low resolution camera)
- 2 x4 (Dual cameras for stereo with up to 4 lanes for each camera)

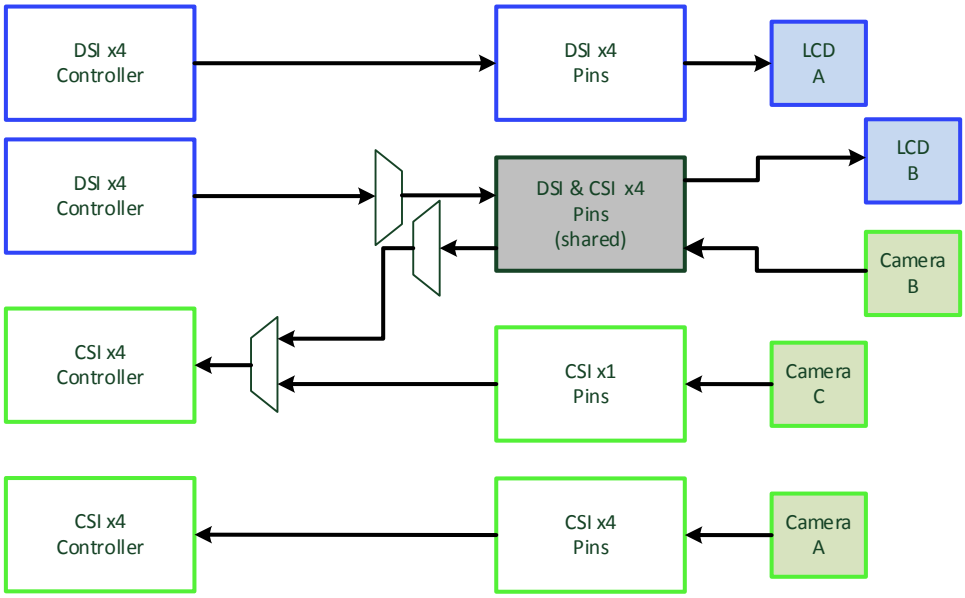
The following figure summarizes the typical camera configurations.

Figure 86: CSI MIPI Lane Configurations



The DSI and CSI controllers share one of the x4 MIPI bricks as shown resulting in several possible configuration options for the CSI depending on the system configuration. In some cases, the DSI x4 brick may not be available and only the CSI dedicated x4 brick will be available for a high-resolution camera interface.

Figure 87: Pin Muxing for DSI and CSI Controllers



26.2 Use Cases

The primary mono and stereo camera user models involve the capture of either pre-processed image data from a camera module in YCbCr 4:2:2 format or as a Raw Bayer stream with 10-bit precision. Additional pixel formats for image data may be accepted; however Raw 10-bit and YCbCr 4:2:2 are used primarily. Depending on the mode of operation, image resolution, and resulting pixel rate, one of several paths through the VI may be used. The use cases supported by the CSI include basic single camera, multiple cameras, embedded data, and virtual channel. The still and video capture sequences involve different single camera and multi-camera configuration options.

Table 103 summarizes the use case categories.

Table 103: Summary of CSI Camera Use Cases

Case	Description	Sources	Destinations
Single Camera Video Capture	Basic preview or video capture using single camera	Camera A or B or C	PPA or PPB
Stereo Camera Video Capture	Stereo pair video capture	Camera A and B	PPA and PPB
Single Camera Still Capture and Preview	Basic high resolution still capture supporting single shot and burst capture and preview	Camera A or B or C	PPA or PPB
Stereo Camera Still Capture and Preview	Stereo camera high resolution still capture and preview	Camera A and B	PPA and PPB
Dual Camera Mono Video Capture	Video feed of front facing camera and user facing camera for video annotation or video preview during Video Conference	Camera A and (B or C)	PPA and PPB
Video Conference Mono Still Capture & Preview*	Video feed of user facing camera for video conference and mono still capture from front facing camera.	Camera A and (B or C)	PPA and PPB
Dual Camera Automotive	Low resolution YUV or RGB video feed from two cameras.	Camera A and (B or C)	PPA and PPB

Case	Description	Sources	Destinations
Virtual Channel	One stream goes to both parsers. Packet filtering based on VC number in header	Camera A and B	PPA and/or PPB
Embedded Data	Mode 1: Each stream goes to one parser and has normal and embedded data	Camera A and/or (B or C)	PPA and PPB
	Mode 2: Embedded data from one stream goes to one pixel parser and the normal data goes to the other.	Camera A or (B or C)	PPA and PPB

The dual camera use cases require two capture streams from two different sensors, each imaging a separate scene. Within the Tegra K1 camera system, it is necessary to process two different images with different algorithm sequences/ISP setup or to receive a preprocessed YCbCr image and deliver the stream to system memory.

26.3 Performance

The following table describes the various MIPI lane configurations and the theoretical maximum Mpixels/s achievable at 100% efficiency for several RAW Bayer pixel precisions and YCbCr 4:2:2.

Table 104: Maximum Capture Rate in MPixels/s for Various CSI Configurations

Link Speed	Number of Lanes	Maximum Mpixels/s with 100% Efficiency				
		RAW8	RAW10	RAW12	RAW14	YCbCr422
600 Mbps	1	75	60	50	42.9	37.5
	2	150	120	100	85.7	75
	3	225	180	150	128.6	112.5
	4	300	240	200	171.4	150
800 Mbps	1	100	80	66.7	57.1	50
	2	200	160	133.3	114.3	100
	3	300	240	200	171.4	150
	4	400	320	266.7	228.6	200
1 Gbps	1	125	100	83.3	71.4	62.5
	2	250	200	166.7	142.9	125
	3	375	300	250	214.3	187.5
	4	500	400	333.3	285.7	250
1.5 Gbps	1	187.5	150	125	107.1	93.8
	2	375	300	250	214.3	187.5
	3	562.5	450	375	321.4	281.3
	4	750	600	500	428.6	375

The following table translates the maximum pixel rate into the maximum achievable frame rate for different sensor resolutions and bit depths.

Table 105: Maximum Capture Rate in FPS for Various CSI Configurations

Link Speed	Pixel Type	Maximum Frame Capture Rate (FPS) with 100% Efficiency											
		800 Mbps				1 Gbps				1.5 Gbps			
		1	2	3	4	1	2	3	4	1	2	3	4
8MP	RAW10	10	20	30	40	12.5	25	37.5	50	18.8	37.6	56.4	75.2
	RAW12	8.3	16.7	25	33.4	10.4	20.8	31.1	41.6	15.6	31.2	46.8	62.4

	RAW14	3.9	7.8	11.7	15.6	4.9	9.8	14.7	19.5	7.7	15.4	23.1	30.8
16MP	RAW10	4.9	9.9	14.8	19.8	6.2	12.4	18.6	24.7	9.4	18.8	28.2	37.6
	RAW12	4.1	8.2	12.4	16.5	5.2	10.3	15.5	20.6	7.8	15.6	23.4	31.2
	RAW14	3.5	7.1	10.6	14.1	4.4	8.8	13.3	17.7	6.7	13.4	20.1	26.8
24MP	RAW10	3.3	6.6	9.8	13.1	4.1	8.2	12.3	16.4	6.3	12.6	18.9	25.2
	RAW12	2.7	5.5	8.2	10.9	3.41	6.8	10.3	13.7	5.2	10.4	15.6	20.8
	RAW14	2.3	4.7	7	9.4	2.9	5.9	8.8	11.7	4.5	9	13.5	18
32MP	RAW10	2.5	5.1	7.6	10.2	3.2	6.4	9.5	12.7	4.7	9.4	14.1	18.8
	RAW12	2.1	4.2	6.4	8.5	2.7	5.3	8	10.6	3.9	7.8	11.7	15.6
	RAW14	1.8	3.6	5.5	7.3	2.3	4.5	6.8	9.1	3.3	6.6	9.9	13.2

To minimize the rolling shutter artifacts a generally accepted minimum still capture target of 1/15th of a second is desired. In many cases, this frame rate can be managed since the high resolution CMOS sensor modules are unlikely to deliver the full resolution image at 15fps maximum. The Zero Shutter Lag (ZSL) user model in which a preview stream and a still capture circular buffer are maintained makes it desirable to achieve the highest frame rate possible to provide good motion video for scene composition.

26.4 Supported CSI to VI Data Formats

The formats of the pixel data presented from the CSI to the VI across the 24-bit bus for each of the pixel parsers are summarized in Table 106.

The Tegra K1 device presents all Raw data to the VI/ISP in its original bit order.

Table 106: CSI to VI Pixel Formats

Format Name	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

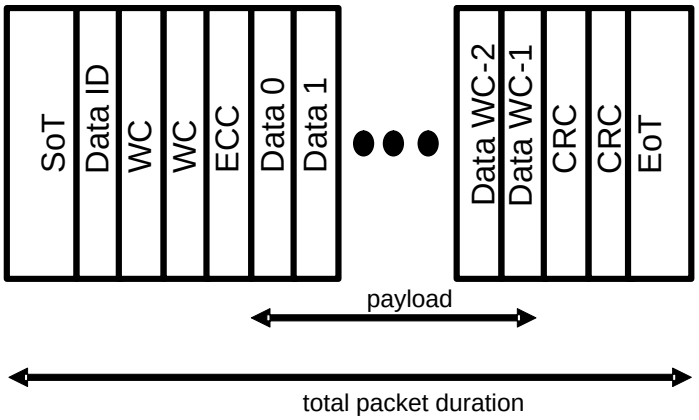
1. The bits marked as '0' are actually don't cares.
2. Odd Line refers to the first line from the CSI unit.

26.5 CSI Packet Structure

The CSI packet structure is illustrated in Figure 88. It has a start-of-transmission sequence (SoT), which contains a 1-byte preamble sequence. The packet is composed of a 4-byte header, a body of word count (WC) bytes, and a 2-byte CRC check. The end-of-transmission (EoT) is indicated by the line state going from high-speed transmission to the LP11 state.

Figure 88: CSI Packet Structure



26.6 CSI Implementation

The CSI interface consists of:

- MIPI D-PHY block
- Control Interface Logic (CIL) for Serial Clock Receiver
- CSI datapath module which is implemented as a sub-module of VI module

In the Tegra K1 implementation, three CSI bricks including the csiab_pad with 4x data lanes, the shared dsib_pad with 4x data lanes, and the csie_pad with 1x data lanes receive serial data from cameras, deserialize them into 8-bit parallel data, and send them to the CSICIL block. The CSICIL block performs packet boundary detection by searching for the packet preamble. The main CSI module receives an 8-bit packet aligned data from CSICIL, performs parity checking on the header, header decoding, CRC check, and pixel parsing. The output is sent out to the VI through the 28-bit bus, which outputs 1 pixel per VI clock.

26.7 Performance Limitations

The performance of the CSI interface is subject to several factors that must all be met. The performance factors that are directly related to the CSI interface are the serial data rate and the internal pixel rate. Maximum serial data rate is expected to be 1Gbps given the ideal system condition. This data rate may be degraded depending on system design and may also be limited by the CSI transmitter in the camera.

For each CSI data lane, the serial data stream received by the CSI PHY is internally converted to a byte stream by the CSI Control Interface Logic (CIL) before further processed by the CSI module that resides as part of the Video Input (VI) module. The CSI byte clock is used to transfer this data byte stream (1 byte per data lane) between the CIL and the CSI datapaths. This CSI byte clock is derived from the received CSI serial clock by dividing the CSI serial clock by 4. So for 1 Gbps serial CSI data rate, the serial clock frequency is 500 MHz and the byte clock frequency is 125 MHz.

The byte stream received by the CSI CIL logic is converted to a pixel stream at 1 pixel per clock in the CSI module. This pixel stream output is further processed by other modules (ISP or the rest of the VI datapath). Depending on where the CSI pixel stream is processed (ISP or VI), the maximum pixel clock frequency is limited by the pixel clock frequency of the modules that process this pixel stream.

Note:	VI/ISP pixel frequency may be lower than CSI output pixel clock frequency and therefore, may limit the actual pixel data rate. Please refer to the ISP and VI specifications.

Note that with multiple data lanes per CSI interface, the maximum serial data link speed may not be achievable due to pixel clock frequency limitations. Also, if two data streams come from the same CSI interface, since the streams are interleaved in time, the pixel clock frequency limitations may also limit the frame rate of the combined streams.

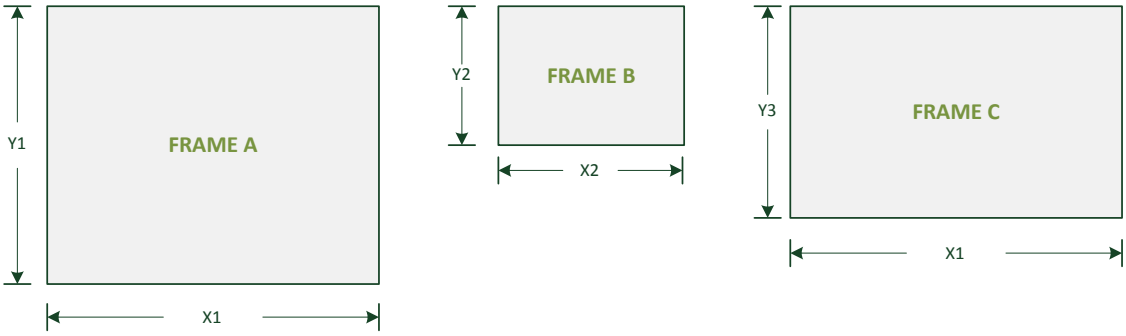
Table 107: Packet Efficiency

	Best* WC=65536	Typical* WC=1024
Payload	524 µs	8192 ns
Overhead	356 ns	356 ns
Efficiency	99.9%	96%

26.8 Frame Size Mismatch Scenarios

Several frame mismatch scenarios can occur during image capture. In these situations, a frame might not have the expected dimensions as shown in the following figure.

Figure 89: Frame Size Variations



Frame A = Full Resolution Image of size (X1,Y1)
Frame B - Preview image of size (X2,Y2) where, Y2 < Y1 & X2 < X1
Frame C - Preview image of size (X1,Y3) where, Y3 < Y1

The following subsections describe the behavior of the CSI (and VI/ISP) in the various frame size mismatch scenarios:

26.8.1 Received Frame Width and Height Matches Programmed Width and Height

When the CSI receives any frame size, it starts capturing the frame. The VI will raise the sync point when it receives the EoF at the right time.

26.8.2 Received Frame Width Does Not Match Programmed Width

Packet Width Mismatch Error

If the CSI receives any frame size in which the width of the incoming frame does not match the programmed value, the error is detected and signaled to the VI. The VI will drop the frame in the case of packet width mismatch errors.

26.8.3 Received Frame Height Does Not Match Programmed Height

CASE 1: Frame Height Mismatch Error - Fewer Rows Than Expected

Example: The CSI is instructed to capture Frame A:

When the sensor receives Frame C, it starts capturing the frame as the width of the frame matches the expected frame width. The CSI will encounter an early EoF. At this time, it will rearm the pixel parser state-machine with the same set of frame capture parameters and wait for the next frame.

If this frame was to be sent to memory, the VI unit will not detect that it is not the right frame and will not raise the sync point. When it receives the next frame from the CSI, it will overwrite the memory buffer (at the buffer location pointed by previous frame parameter).

If this frame was to be sent to the ISP, the VI forwards the EoF control packet to the ISP and indicates that the Frame was too short. The CSI and VI will not pad the frame to make the frame the right size. The ISP unit needs to detect the error condition and should not update the parameter for the next frame and apply the same parameters (as the previous frame) for the next incoming frame from the VI.

CASE 2: Frame Height Mismatch Error - More Rows Than Expected

Example 2: The CSI is instructed to capture Frame C:

When the CSI receives Frame A, it starts capturing the frame as the width of the frame is matched.

For the frame to be sent to memory, the VI marks the last atom of the frame to the memory as a non-posted write. The VI then raises a sync point when the WrAck and EoF at the expected frame size if received. In this case, instead of EoF, the VI will receive more pixel data. On detecting this condition, the VI will not raise the sync point; it drops the rest of the frame and does not corrupt the memory buffer. The CSI will rearm the pixel parser state machine with the same set of frame capture parameters and waits for the next frame. Because the VI is also aware of the expected frame height and detects the frame to be erroneous, it will overwrite the memory buffer with the next frame.

In case this frame was to be sent to the ISP, the VI, when it receives the regular pixel data instead of EoF flag from the CSI, will drop the data and generate an EoF flag to the ISP to terminate the frame and mark it as frame-too-big. The ISP unit needs to detect the error condition; it should not update the parameter for the next frame and will apply the same parameters (as the previous frame) for the next incoming frame from the VI.

26.8.4 Double Buffering of the Configuration Registers

There are two copies of configuration registers: operational and the shadow registers. The shadow registers are updated from the Host1x input when it does not have a pending capture command. The shadow register is copied to the operational register when a frame is successfully captured (at the EoF received at the right time). In the event of a frame size mismatch, the shadow registers are not copied and the current settings remain active for the next incoming frame:

1. **Successful Frame Capture:** The CSI pixel parser (and header parser) sub-units copy the shadow configuration register to the operational configuration register, if it needs to capture the next frame. This configurations need to move along the pipeline with the SoF marker.
2. **Failed Frame Capture (Dropped):** When a frame is dropped for being too big or too small, the shadow registers are not copied over to the operational register and the CSI remains armed for the next frame.

Whenever the CSI drops an incoming frame, whether due to a mismatch in virtual channel, data type, width, or the height, this information is appropriately logged in the status register. This would help in debugging any system issues where the software arms the CSI to capture the frame but eventually times out due to a missing sync point. There is only one copy of this register (per CSI channel) and every subsequent dropped frame will update this status register.

26.9 Error Handling

The CSI is required to tolerate and/or recover stream errors at various levels.

Error Categories	Classification	Type	Description
D-PHY Level Errors	Start of Transmission (SoT) Error	Single-bit error	Corrected an error condition signal from PHY/CIL
		Multi-bit error	Packet discarded
	Control Error	Incorrect line state sequence	XError signal asserted
	Escape Entry Error	Escape command different from 8-bits and escape handshaking incorrect	XError signal asserted
	End of Transmission (EoT) Error	A bit of the payload not on a byte boundary	Unrecoverable error condition signaled to the application layer
Packet Level Errors	Packet Header Error	Single bit error	Detected and corrected by the ECC code
		Multi-bit error	Detected but not corrected; error is flagged and interrupt generated
	Packet Payload Errors	Signaled through CRC Code	Detected but not corrected; error is flagged and interrupt generated
Protocol Decoding Errors	Frame Sync Error	FE is not matched to FS	Frame data is supplied to the VI and an error is signaled as a stream error to the application layer.
	Unrecognized ID	Data ID Error	Packet discarded
CSI Block Specific Errors	Packet Header Mismatch Error	Data ID Error	If the virtual channel ID does not match the programmed value for the corresponding pixel parser then the packet is discarded
		Data Type Error	If the data-type does not match the programmed value for the corresponding pixel parser then the packet is discarded
	FIFO Overflow	Backpressure	Frame is dropped
	Packet Word Count Mismatch	Packet longer than word count	Packet is dropped
		Packet shorter than word count	Packet is dropped
	Frame Height Mismatch	Frame larger than programmed size	Frame data is supplied to the VI until EoF and then the pixel parser is re-armed. VI will receive or drop the additional data depending on destination (MEMC or ISP)
		Frame smaller than programmed size	The pixel parser is rearmed on EoF and waits for the next frame
	Padding Congestion	Data received during Frame padding	Padding removed for Tegra K1

26.10 Other Architectural Constraints

The following specifies other architectural constraints for this design:

- Because there are only 2 pixel parsers, embedded data and virtual channel cannot be supported simultaneously.
- Embedded data in a frame can be output in the same output port as the pixel data stream; however, in some cases where image processing or data reformatting is performed in VI/ISP, this embedded data may be accidentally processed in VI/ISP. Currently, VI/ISP cannot differentiate between embedded data or pixel data. Refer to the VI chapter for more information on the options for managing embedded data.

26.11 CSI Datapath Module

The CSI datapath consists of two input ports and two output ports. There are two datapaths for pixel stream processing; therefore, at any time, a maximum of two input ports may be active simultaneously.

The components of the CSI datapath include:

- Two input ports from: CSI A interface and CSI B interface. Each port is capable of carrying a stream with CSI compatible data format.
- Two asynchronous input buffers (FIFOs) to receive streams from the CSI A interface and the CSI B interface.
- Three header parsers for searching packet header and to perform error detection and correction of CSI header.
- Two pixel parsers with corresponding output ports. Each pixel parser can convert a CSI packet data stream to output a pixel stream. Each output port consists of a maximum 24 bits of data per clock. Depending on the output data format options, one or two pixels per clock may be sent.

26.11.1 Header Parser

CSI pixel stream processing mainly consists of header parser and pixel parser. There are 3 header parsers: header parser A, header parser B, and header parser H.

Header parser A is enabled when CSI A interface is selected as input source. Similarly, header parser B is enabled when CSI B interface is selected as input source.

In general the header parser is used for:

- Detecting long and short packet headers and deciding what to do with the packet. This includes performing error detection and correction on the packet header prior to making decision and dealing with uncorrectable packet header.
- Skipping extra data on longer than expected data packets.
- Skipping next packet on imminent input buffer overflow when the pixel parser is busy processing current packet.

When enabled, the header parser will interpret CSI packet header, perform error detection and correction. If the packet header is uncorrectable, then an error is flagged and interrupt generated. If good or correctable CSI packet header is found, then the header parser will check the Data Identifier (DI) byte in the packet header and check the 2-bit Virtual Channel (VC) identifier and the 6-bit Data Type (DT) within this Data Identifier byte and will also check the 2-byte Word Count (WC) value in the packet header. If the virtual channel ID does not match the expected (programmed) value for the corresponding pixel parser then the packet is discarded. If the virtual channel ID matches the expected (programmed) value for the corresponding pixel parser then the header parser must decide what to do with the packet depending on the Data Type and the Word Count value. For long packet, if the Data Type does not match the expected (programmed) value for the corresponding pixel parser then the packet is discarded. If the Data Type of the long packet matches the expected (programmed) value for the corresponding pixel parser, then the corresponding pixel parser is notified to process the remaining packet data and checksum.

When first enabled, the header parser must always search for Frame Start packet which is a CSI short packet. When frame start packet/signal is found, the header parser will notify the corresponding pixel parser so that it can prepare to process a new frame and output frame start code.

26.11.1.1 Data Type

There are 64 possible data types based on the 6-bit Data Type value.

Data Type	Description
0x00 – 0x07	Synchronization Short Packet Data Types
0x08 – 0x0F	Generic Short Packet Data Types
0x10 – 0x17	Generic Long Packet Data Types
0x18 – 0x1F	YUV Data
0x20 – 0x27	RGB Data
0x28 – 0x2F	RAW Data
0x30 – 0x37	User Defined Byte-based Data
0x38 – 0x3F	Reserved

26.11.1.2 Short Packets

There are 16 possible short packets based on Data Type value.

Data Type	Description
0x00	Frame Start Code
0x01	Frame End Code
0x02	Line Start Code (Optional)
0x03	Line End Code (Optional)
0x04 – 0x07	Reserved

26.11.1.3 Long Packets

CSI long packets are data packets which always consist of 1 line of data per packet with exception of arbitrary data packets. There are various data types defined. Please refer to the Input Data Format section for a summary of CSI data formats and their corresponding CSI module internal output format.

Generic long packets need special handling. There are 3 generic long packet types defined: null packet (DT=0x10), blanking data packet (DT=0x11), and embedded data packet (DT=0x12). There are also 5 reserved generic long packet types (DT=0x13 to 0x17). The header parser should discard all null packets and all reserved generic long packets.

Blanking data packets may contain blank color or blank image information. The transmission of blanking data packet is optional in the CSI2.0 specification. Null and blanking data are defined in the CSI2.0 specification mainly to accommodate a receiver which is timing sensitive and requires line start/end for every line in the frame. As a CSI receiver, this product does not have such blank timing sensitivity and it typically does not process blank data and does not store it to memory. Blanking data packet can therefore be discarded by the header parser.

However, some module may have a requirement for specific number of “blank” or extra lines at the end of vertical active area, such as the ISP module, which requires input active scan area to be about 6 lines larger than output active area. If a module that takes CSI output stream requires extra lines at the end of active image then blanking packet data can be used to generate these additional lines. In the future, there might be other reasons to process blank data. So, an option should be provided to accept and process blanking data. In the absence of better definition of blanking data format in the CSI specification, if software decides that blanking data cannot be discarded then, the pixel parser should assume that the blanking data format is the same as the programmed expected data type of the pixel stream.

The current CSI2.0 specification specifies that embedded data packets consists of 8-bit arbitrary data. This embedded data is, typically not the same pixel color as the image data. It might be used to send headers/status for JPEG/MPEG compressed data at the beginning or end of image data or in between image data lines. It might also be used to send closed caption text information or other type of information.

The exact use of embedded data is not clear, and therefore in most cases, embedded data is probably not used, or if sent by the transmitter, the embedded data packets can simply be discarded. If for some reason, it is important to receive the embedded data, there are other options that should be supported. Since there are two pixel parsers, if there is only one video source, it is best to direct embedded data to the other pixel parser which does not process the normal image data. In this way, the embedded data can be treated the same way as 8-bit arbitrary/compressed image data and can be output in 8-bit/clock or 16-bit/clock format. If there are two video sources that occupy both the pixel parsers, then embedded data if it has to be stored to memory, needs to be output in the same channel as the image data as 8-bit/16-bit data. But this also means that the module that receives output of CSI module and does image processing must have the ability to differentiate embedded data and not do image processing on this data prior to writing it to memory.

26.11.1.4 Top or Bottom Field Tag

During frame start, a tag is passed from CSI to VI to indicate top or bottom field. The 1-bit tag is at the least significant bit of the CSI output bus. If the bit is “1”, the field is top, but bottom otherwise.

26.12 Test Pattern Generator (TPG)

The test pattern generator is a configurable resource introduced to improve hardware verification capability for the Tegra CSI. Because a provision for inserting pixel data from the Host interface is not available, the hardware verification of the CSI and VI unit is difficult. The only sources of pixel data that can exercise the CSI are image sensors. In general, the sensor data cannot be controlled, making any self-checking test impossible. Test pattern generation modes offered by sensors are also ineffective because they have limited control.

There are two separate test pattern generators that can be configured to provide for the generation of synthetic image data, which is delivered to the PPA and PPB input FIFOs. The image data is multiplexed into the CSI data patch between lane-merging logic and the data FIFOs. Programmable configuration parameters are available to allow variation in pixel data, data type, and spacing between various packets. In the real system, the LP state transition between any two CSI packets guarantees some idle time between the lines. This spacing between the lines from the pattern generator should be programmed to a minimum of 8 cycles, as the later stages of VI expects some idle cycles between the lines in order for it not to overflow.

A difference engine architecture is employed which can generate almost arbitrary patterns that consist of frequency sweeps or intensity ramps in both the horizontal and vertical directions. In addition, by using selected bits from the difference engine variables as addresses, a color patchwork pattern can be generated. The output from the difference engine is modeled off of a second-order partial differential equation of the form:

$$\varphi_{out} = \varphi + x \cdot \frac{d\varphi}{dx} + x^2 \cdot \frac{d^2\varphi}{dx^2}$$

Where:

$$\varphi = PHASE$$

$$\frac{d\varphi}{dx} = FREQ$$

$$\frac{d^2\varphi}{dx^2} = FREQ\_RATE$$

The PHASE, FREQ, and FREQ_RATE variables may be programmed to create a variety of different test patterns and are either used directly or as an index into a look-up table (LUT). Table 108 summarizes the configuration parameters for the TPG.

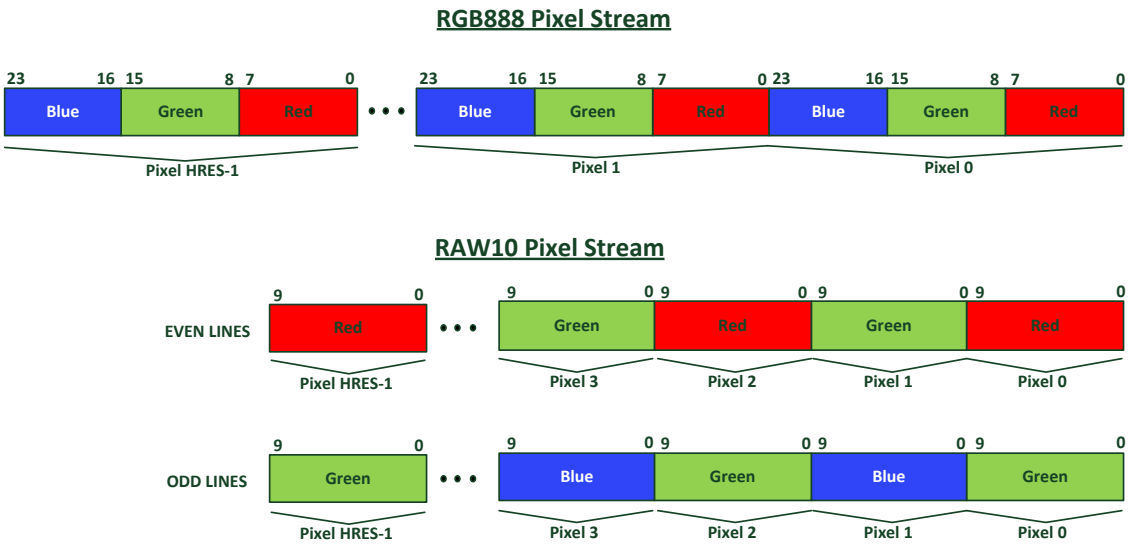
Table 108: Description of TPG Configuration Parameters

Configuration Variables for CSI_0 and CSI_1 Test Pattern Generators	TPG Frame Configuration	Image Height	Lines per frame
		Image Width	Pixels per line
		Vertical Blanking	Blank lines between frames
		Horizontal Blanking	Blank pixels between lines
		Initial Phase	Initial phase
		Mode	Direct or color patch
		Format	RGB888 or RAW10 support
	TPG Channel Configurations (R, G, and B)	Vertical Initial Frequency	Initial frequency
		Horizontal Initial Frequency	Initial frequency
		Vertical Frequency Rate	Rate of change for vertical frequency
		Horizontal Frequency Rate	Rate of change for horizontal frequency

26.12.1 TPG Frame Configuration Parameters

The TPG can be configured to provide the test images in either an RGB888 or Bayer RAW10 data format. The RGB888 data is delivered to the lane merging logic as a sequence of bytes representing the RGB triads for each pixel in an HRESxVRES image frame. For the Bayer RAW10 data, the color components of the RGB pixel are sampled in an alternating fashion, depending on whether the current row and pixel within the row is even or odd.

Figure 90: RGB888 and RAW10 TPG Pixel Streams



Note: Byte ordering for RGB888 and RAW10 on the CSI2VI interface follows the same convention as data received over the MIPI interface.

The data from the test pattern generator has the same format (with the packet header, CRC, ECC, etc.) as received on the output of lane-merging logic during normal operation.

26.12.2 Modes of Operation

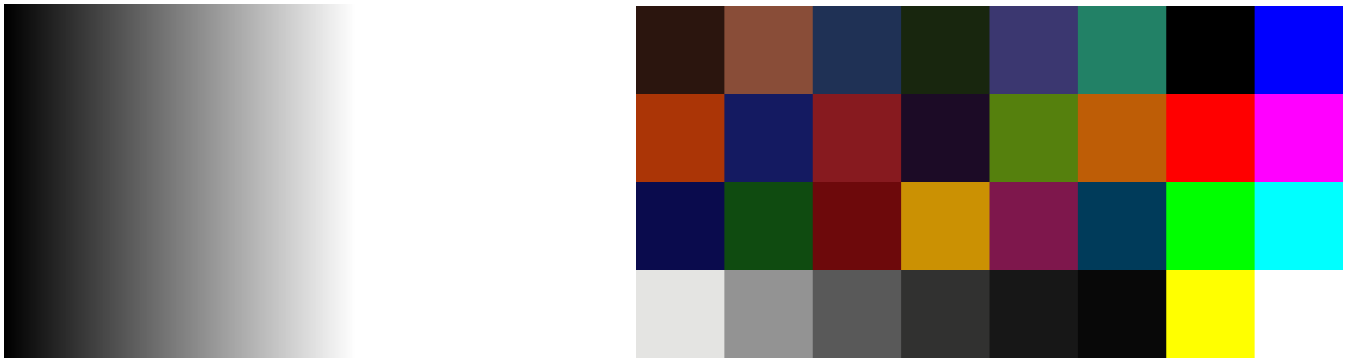
The test pattern generator operates in two modes:

- Direct The output of the difference engine computation will be viewed directly.
- Color Patch The difference engine output will be used to generate a patchwork of colors.

In Direct mode, the output comes directly from the value of the phase accumulator in the difference engine. An example of the kind of pattern that can be made is shown in Figure 91(a). In Color Patch mode, the output comes from indexing a 32-element LUT.

The various bits from both the horizontal and vertical phase accumulators are used as address bits into a LUT of standard color values, allowing a patchwork of color test patterns to be generated. The colors in the pattern consist of linear RGB space representations of the 24 “Macbeth” test chart colors, shown on the left side of Figure 91(b), and the 8 “100% saturation” colors of a TV test pattern, on the right side of Figure 91(a). This gives a total of 32 color patches.

Figure 91: Example of (a) Direct Mode (b) Color Patch Generator Output



(a) (b)

26.13 Differential Pulse Code Modulation Support

The use of Differential Pulse Code Modulation (DPCM) compression schemes to reduce the data bandwidth requirements have been approached in both the SMIA and MIPI camera serial interface standards. In the MIPI CSI2 rev 1.1 a new data type for compressed data was introduced. In this format, RAW-10 and RAW-12 data can be transmitted as 6/7/8 bits per pixel. The SMIA also introduces a compression for RAW14 data providing transmission as 8/10 bits per pixel. The DPCM support is an optional feature for the CSI-2 and the data compression is not mandated. However, if data compression is used, it must be implemented as described in annex E of the MIPI CSI-2 specification v01-01-00.

The MIPI and SMIA data compression schemes use an X–Y–Z naming convention, where:

- X is the number of bits per pixel in the original image
- Y is the encoded (compressed) bits per pixel
- Z is the decoded (uncompressed) bits per pixel.

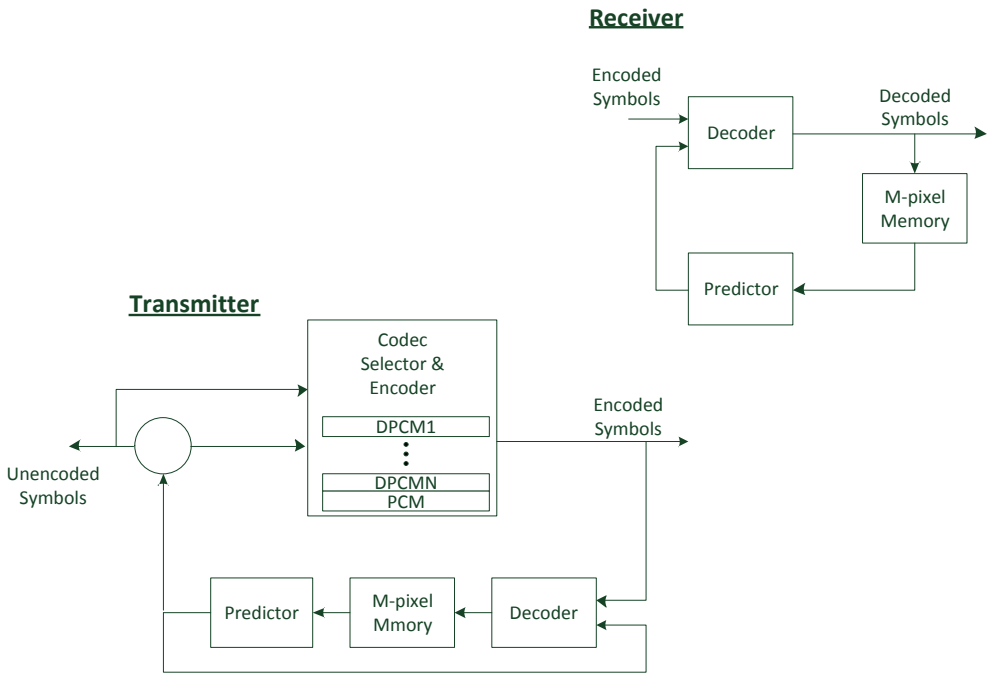
The following data compression schemes are defined for the Tegra K1 CSI unit:

- 14-bit RAW Compression Support (SMIA): 14-8-14; 14-10-14
- 12-bit RAW Compression Support (MIPI): 12–8–12; 12-7-12; 12-6-12
- 10-bit RAW Compression Support (MIPI): 10–8–10; 10-7-10; 10-6-10

To identify the type of data on the CSI-2 interface, packets with compressed data have a user-defined data type value. The encoder uses a simple algorithm to encode the pixel values. A fixed number of pixel values at the beginning of each line are

encoded without using prediction. These first few values are used to initialize the predictor block. The remaining pixel values on the line are encoded using prediction. The following figure illustrates the data compression system for the transmitter and receiver.

Figure 92: Data Compression System Block Diagram



26.14 Software Requirements

26.14.1 Error Counters

To help debug, three 32-bit error counters have been implemented. Software can program each counter to increment at the event of any one of many error conditions or status change. The error conditions are:

- Header errors corrected
- Header uncorrectable errors
- CRC errors
- Packets too short, actual length less than WC
- Overflow errors due to padding packets too short
- FIFO overflow errors
- Illegal word count
- SoT single-bit error
- SoT multi-bit error, packet discarded
- EoT sequence error
- LP-CTRL error
- The statistics that can be monitored include:
- Line packets processed
- Total packets processed

26.14.2 Programming Sequence

The following sequence is recommended for capturing a single frame:

1. Set up CSI registers for use case such as number of lanes, virtual channel, etc.
2. Initialize and power up CSI interface
3. Wait for initialization time or done signal from calibration logic
4. Power up camera through the I^2C interface
5. All CSI data and clock lanes are in stop state, LP11
6. Initiate frame capture through the I^2C
7. Frame done, CSI goes back to stop state, LP11

26.14.3 Escape Mode Handling

In the MIPI PHY specification, an escape mode is available for low speed command and data transfer. In our implementation, the escape mode entry is detected inside CSICIL. The command byte will be deposited in a register and interrupt generated from CSI. Software reads the register and decodes. CSI supports only one escape mode command which is Ultra-Low Power Mode (ULPM).

ULPM Command

Upon receiving the ULPM, software will synchronously power down the CSI interface and the camera as follows:

1. Software puts the camera in sleep mode through I^2C
2. The camera sends a ULPM command to CSI
3. CSI receives the ULPM command and raises an interrupt
4. Software powers down CSI, which goes to sleep in sync with the camera's CSI transmitter

26.15 DPHY Modes of Operation

The MIPI DPHY has 3 basic modes of operation. High speed mode employs differential signaling and achieves data rate of 1 Gbps. Both the driver and receiver are matched to 100 ohms differential. The driver is voltage mode for lower power consumption as opposed to current mode.

Low power control mode employs single-ended CMOS signaling for handshaking between camera and host. In this mode, there is no clock and no maximum symbol time defined in the specification. The receiver samples the input using both edges of the internal pixel clock, so the timing resolution is half the clock period of the pixel clock period.

Table 109: MIPI DPHY Mode of Operations

Modes	Description	Clock
High speed (HS)	High speed differential signaling. Up to 1.5 Gbps. Burst transmission for low power.	750 MHz differential
Low Power (LP) Control	Single-ended 1.2V CMOS level. Low speed signaling for handshaking. Supports ULPM sleep state.	No Clock

26.16 MIPI-CSI Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

26.16.1 CSI_INPUT_STREAM_A_CONTROL_0

CSI Input Stream A Control

Offset: 0x20e | Byte Offset: 0x838 | Read/Write: R/W | Reset: 0x00ff0004 (0bxxxxxxx011111111xxxxxxxxxx0x100)

Bit	Reset	Description
24:16	0xff	CSI_A_SKIP_PACKET_THRESHOLD: CSI-A Skip Packet Threshold. This value is compared against the internal FIFO that buffer the input streams. A packet will be skipped (discarded) if the pixel stream processor is busy (probably due to padding process of a short line) and the number of entries in the internal FIFO exceeds this threshold value. Note that each entry in the internal FIFO buffer is four bytes. To turn off this feature, set the value to its maximum value (all ones).
4	0x0	CSI_A_SKIP_PACKET_THRESHOLD_ENABLE: Enables skip packet threshold feature. Skip packet feature is enabled. 0 = DISABLE: Skip packet feature is disabled. 1 = ENABLE
2	0x1	CSI_A_BYPASS_ALIGN: Bypass aligning CSIA and CSIB lanes if the valids for the lanes are out of sync by one cycle
1:0	0x0	CSI_A_DATA_LANE: CSI-A Data Lane. 0= 1 data lane; 1= 2 data lanes; 2= 3 data lanes; 3= 4 data lanes Note: Three data lanes are not supported in Test Pattern Generation mode.

26.16.2 CSI_PIXEL_STREAM_A_CONTROL0_0

CSI Pixel Stream A Control 0

Offset: 0x20f | Byte Offset: 0x83c | Read/Write: R/W | Reset: 0xXXXX01X0 (0bxxxxxxxxxxxxxxxxxxxxxxxx1xxxxx000)

Bit	Reset	Description
29:28	X	CSI_PPA_PAD_FRAME: CSI Pixel Parser A Pad Frame. This specifies how to deal with frames that are shorter (fewer lines) than expected. Short frames are usually caused by line packets being dropped because of packet errors. Expected frame height is specified in PPA_EXP_FRAME_HEIGHT. To do padding the value in CSI_PPA_WORD_COUNT needs to be set to the number of input bytes in each line's payload. 0 = PAD0S: Lines of all zeros will be used to pad out frames that are shorter than expected height. PPA_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this field is set to PAD0S. 1 = PAD1S: Lines of all ones will be used to pad out frames that are shorter than expected height. PPA_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this fields is set to PAD1S. 2 = NOPAD: Short frames will not be padded out.
27	X	CSI_PPA_HEADER_EC_ENABLE: CSI Pixel Parser A Packet Header Error Correction Enable. This parameter specifies whether single bit errors in the packet header will be automatically corrected, or not. 0 = ENABLE: Single bit errors in the header will be automatically corrected. 1 = DISABLE: Single bit errors in the header will not be corrected. Header ECC check will still set header ECC status bits and the packet will be processed by Pixel Parser A. DISABLE should not be used when processing interleaved streams (Same stream going to both PPA and PPB).

Bit	Reset	Description
25:24	X	CSI_PPA_PAD_SHORT_LINE: CSI Pixel Parser A Pad Short Line. This specifies how to deal with shorter than expected line (the number of bytes received is less than the specified word count). 0 = PAD0S: short line is padded by pixel of zeros such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet may be discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 1 = PAD1S: short line is padded by pixel of ones such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet may be discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 2 = NOPAD: A short line is not padded (will output less pixels than expected). This option is not recommended and may cause other modules that receives CSI output stream to hang up.
21:20	X	CSI_PPA_EMBEDDED_DATA_OPTIONS: CSI Pixel Parser A Embedded Data Options. This specifies how to deal with embedded data within the specified input stream assuming that the CSI_PPA_DATA_TYPE is not embedded data and assuming that embedded data is not already processed by other CSI pixel stream processor. 0 = DISCARD: discard (throw away) embedded data 1 = EMBEDDED: Output embedded data as an 8-bpp arbitrary data stream.
19:16	X	CSI_PPA_OUTPUT_FORMAT_OPTIONS: CSI Pixel Parser A Output Format Options. This parameter specifies options for output data format. 0 = ARBITRARY: Output as 8-bit arbitrary data stream This may be used for compressed JPEG stream 1 = PIXEL: Output the normal 1 pixel/clock. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed. 2 = PIXEL_REP: Same as PIXEL except MS color bits, for RGB_666, RGB_565, RGB_555, and RGB_444, will be replicated to their undefined LS bits. 3 = STORE: Output for storing RAW data to memory through ISP. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444 will be zeroed.
8	0x1	CSI_PPA_WC_CHECK: CSI Pixel Parser A Data WC Check. This parameter specifies whether the word count is checked. 0 = DISABLE : Wordcount Check is disabled 1 = ENABLE: Wordcount Check is enabled.
7	X	CSI_PPA_CRC_CHECK: CSI Pixel Parser A Data CRC Check. This parameter specifies whether the last 2 bytes of packet should be treated as CRC checksum and used to perform CRC check on the payload data. Note that in case there are 2 bytes of data CRC at the end of the packet, the packet word count does not include the CRC bytes. 0 = DISABLE: Data CRC Check is disabled regardless of whether there are CRC checksum at the end of the packet. 1 = ENABLE: Data CRC Check is enabled.
6	X	CSI_PPA_WORD_COUNT_SELECT: CSI Pixel Parser A Word Count Select. This parameter is effective only if packet header is sent as part of the stream. 0 = REGISTER: Word Count in packet header is ignored and the number of bytes per line/packet is specified by CSI_PPA_WORD_COUNT. Payload CRC check will not be valid if the word count in CSI_PPA_WORD_COUNT is different than the count in the packet header. Interlaced support relies on frame number and will not work in REGISTER mode. 1 = HEADER: The number of bytes per line is to be extracted from Word Count field in the packet header. Note that if the serial link is not error free, programming this bit to HEADER may be dangerous because the word count information in the header may be corrupted. It is recommended to always program this bit to HEADER
5	X	CSI_PPA_DATA_IDENTIFIER: CSI Pixel Parser A Data Identifier (DI) byte processing. This parameter is effective only if packet header is sent as part of the stream. 0 = DISABLED: Disabled - Data Identifier byte in packet header should be ignored (not checked against CSI_PPA_DATA_TYPE and against CSI_PPA_VIRTUAL_CHANNEL_ID). In this case, CSI_PPA_DATA_TYPE specifies the stream data format. 1 = ENABLED: Enabled - Data Identifier byte in packet header should be compared against the CSI_PPA_DATA_TYPE and the CSI_PPA_VIRTUAL_CHANNEL_ID.
4	X	CSI_PPA_PACKET_HEADER: CSI Pixel Parser A Packet Header processing. This specifies whether packet header is sent in the beginning of packet or not. 0 = NOT_SENT: Packet header is not sent. This setting should not be used if the stream

Bit	Reset	Description
		source is CSI Interface A or B. Unless CSI-A, or CSI-B, is operating in a stream capture debug mode. In this case, CSI_PPA_DATA_TYPE specifies the stream data format and the number of bytes per line/packet is specified by CSI_PPA_WORD_COUNT. This implies that a packet footer is also not sent. In this case, no packet footer CRC check should be performed. 1 = SENT: Packet header is sent. This setting should be used if the stream source is CSI Interface A or B.
2:0	0x0	CSI_PPA_STREAM_SOURCE: CSI Pixel Parser A Stream Source 0 = CSI_A: CSI Interface A 1 = CSI_B: CSI Interface B

26.16.3 CSI_PIXEL_STREAM_A_CONTROL1_0

CSI Pixel Stream A Control 1

Offset: 0x210 | Byte Offset: 0x840 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)|

Bit	Reset	Description
7:4	0x0	CSI_PPA_TOP_FIELD_FRAME_MASK: CSI Pixel Parser A Top Field Frame Mask
3:0	0x0	CSI_PPA_TOP_FIELD_FRAME: CSI Pixel Parser A Top Field Frame. This parameter specifies the frame number for top field detection for interlaced input video stream. Top Field is indicated when each of the least significant four bits of the frame number that has a one in its mask bit matches the corresponding bit in this parameter. In other words, Top Field is detected when the bitwise OR of ~(CSI_PPA_TOP_FIELD_FRAME ^ <frame number>) & CSI_PPA_TOP_FIELD_FRAME_MASK is one. Frame Number is taken from the WC field of the Frame Start short packet. Due to the reliance on WC field in packet header, interlaced support will not work if WC is selected from REGISTER mode.

26.16.4 CSI_PIXEL_STREAM_A_GAP_0

CSI Pixel Stream A Gap

Offset: 0x211 | Byte Offset: 0x844 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	PPA_FRAME_MIN_GAP: Minimum number of viclk cycles from end of frame (Video_control = EF) to start of next frame (Video_control = SF). This parameter ensures that the minimum V-blank time requirement of VI/ISP is satisfied. This field takes effect only when the frame gap of the input stream is less than the specified value.
15:0	0x0	PPA_LINE_MIN_GAP: Minimum number of viclk cycles from end of previous line (Video_control = EL_DATA) to start of next line (Video_control = SL). This parameter ensures that the minimum H-blank time requirement of VI/ISP is satisfied. This field takes effect only when the line gap of the input stream is less than the specified value.

26.16.5 CSI_PIXEL_STREAM_PPA_COMMAND_0

CSI Pixel Parser A Command

Offset: 0x212 | Byte Offset: 0x848 | Read/Write: R/W | Reset: 0x0000XXX4 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx100)

Bit	Reset	Description
15:12	X	CSI_PPA_START_MARKER_FRAME_MAX: CSI Pixel Parser A Start Marker Maximum. Start Frame is indicated when the Minimum condition above is met and the least significant four bits of the frame number are less than or equal to this value.
11:8	X	CSI_PPA_START_MARKER_FRAME_MIN: CSI Pixel Parser A Start Marker Minimum. Start Frame is indicated when the Maximum condition below is met and the least significant four bits of the frame number are greater than or equal to this value.

Bit	Reset	Description
4	X	CSI_PPA_VSYNC_START_MARKER: CSI Pixel Parser A VSYNC Start Marker. The start of frame is indicated when the VSYNC signal is received. When the input stream is from the VIP path and the data mode is PACKET, then this field may be programmed to VSYNC. 0 = FSPKT: Start of frame is indicated when a Frame Start short packet is received with a frame number whose least significant four bits are greater than or equal to CSI_PPA_START_MARKER_FRAME_MIN and less than or equal to CSI_PPA_START_MARKER_FRAME_MAX. When the input stream is from a CSI port, or from the host path, or from the VIP path and the data mode is PAYLOAD_ONLY, then this field may be programmed to FSPKT. 1 = VSYNC
2	0x1	CSI_PPA_SINGLE_SHOT: CSI Pixel Parser A Single Shot Mode. Software should clear it along with disabling the CSI_PPA_ENABLE, once a frame is captured 0 = DISABLE 1 = ENABLE
1:0	0x0	CSI_PPA_ENABLE: CSI Pixel Parser A Enable. This parameter controls CSI Pixel Parser A to start or stop receiving data. Reset (disable immediately) Enabling the pixel parser does not enable the corresponding input source to receive data. If the pixel parser is enabled later than the corresponding input source, the CSI will keep on rejecting incoming stream, until it encounters a valid SF. 0 = NOP: no operation 1 = ENABLE: enable at the next frame start as specified by the CSI Start Marker 2 = DISABLE: disable after current frame end and before next frame start. 3 = RST

26.16.6 CSI_PIXEL_STREAM_A_EXPECTED_FRAME_0

CSI Pixel Stream A Expected Frame

Offset: 0x213 | Byte Offset: 0x84c | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:4	X	PPA_MAX_CLOCKS: Maximum Number of viclk clock cycles between line start requests. The value in this field is in terms of 256 viclk clock cycles.
0	X	PPA_ENABLE_LINE_TIMEOUT: When set to one enables checking of the time between start line requests from the Header Parser to CSI-PPA. A fake EF will be outputted by CSI-PPA if this time between line starts exceeds the value in MAX_CLOCKS_BETWEEN_LINES. Padding lines can be inserted before the fake EF, if the number of lines outputted, when the fake EF is generated is less than the expected frame height. The type of padding is specified using CSI_PPA_PAD_FRAME.

26.16.7 CSI_CSI_PIXEL_PARSER_A_INTERRUPT_MASK_0

CSI Pixel Parser A Interrupt Mask

Offset: 0x214 | Byte Offset: 0x850 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxx0xx000000000000)

Bit	Reset	Description
14	0x0	HPA_UNC_HDR_ERR_INT_MASK: Interrupt Mask for HPA_UNC_HDR_ERR. 0 = DISABLED : Do not generate an interrupt when HPA_UNC_HDR_ERR is set. 1 = ENABLED: Generate an interrupt when HPA_UNC_HDR_ERR is set.
10	0x0	PPA_SPARE_STATUS_1_INT_MASK: Interrupt Mask for PPA_SPARE_STATUS_1. 0 = DISABLED : Do not generate an interrupt when PPA_SPARE_STATUS_1 is set. 1 = ENABLED: Generate an interrupt when PPA_SPARE_STATUS_1 is set.
9	0x0	PPA_INTERFRAME_LINE_INT_MASK: Interrupt Mask for PPA_INTERFRAME_LINE. 0 = DISABLED : Do not generate an interrupt when PPA_INTERFRAME_LINE is set. 1 = ENABLED: Generate an interrupt when PPA_INTERFRAME_LINE is set.
8	0x0	PPA_EXTRA_SF_INT_MASK: Interrupt Mask for PPA_EXTRA_SF. 0 = DISABLED : Do not generate an interrupt when PPA_EXTRA_SF is set.

Bit	Reset	Description
		1 = ENABLED: Generate an interrupt when PPA_EXTRA_SF is set.
7	0x0	PPA_SHORT_FRAME_INT_MASK: Interrupt Mask for PPA_SHORT_FRAME. 0 = DISABLED : Do not generate an interrupt when PPA_SHORT_FRAME is set. 1 = ENABLED: Generate an interrupt when PPA_SHORT_FRAME is set.
6	0x0	PPA_STMERR_INT_MASK: Interrupt Mask for PPA_STMERR. 0 = DISABLED : Do not generate an interrupt when PPA_STMERR is set. 1 = ENABLED: Generate an interrupt when PPA_STMERR is set.
5	0x0	PPA_FIFO_OVRF_INT_MASK: Interrupt Mask for PPA_FIFO_OVRF. 0 = DISABLED : Do not generate an interrupt when PPA_FIFO_OVRF is set. 1 = ENABLED: Generate an interrupt when PPA_FIFO_OVRF is set.
4	0x0	PPA_PL_CRC_ERR_INT_MASK: Interrupt Mask for PPA_PL_CRC_ERR. 0 = DISABLED : Do not generate an interrupt when PPA_PL_CRC_ERR is set. 1 = ENABLED: Generate an interrupt when PPA_PL_CRC_ERR is set.
3	0x0	PPA_SL_PKT_DROPPED_INT_MASK: Interrupt Mask for PPA_SL_PKT_DROPPED. 0 = DISABLED : Do not generate an interrupt when PPA_SL_PKT_DROPPED is set. 1 = ENABLED: Generate an interrupt when PPA_SL_PKT_DROPPED is set.
2	0x0	PPA_SL_PROCESSED_INT_MASK: Interrupt Mask for PPA_SL_PROCESSED. 0 = DISABLED : Do not generate an interrupt when PPA_SL_PROCESSED is set. 1 = ENABLED: Generate an interrupt when PPA_SL_PROCESSED is set.
1	0x0	PPA_ILL_WD_CNT_INT_MASK: Interrupt Mask for PPA_ILL_WD_CNT. 0 = DISABLED : Do not generate an interrupt when PPA_ILL_WD_CNT is set. 1 = ENABLED: Generate an interrupt when PPA_ILL_WD_CNT is set.
0	0x0	PPA_HDR_ERR_COR_INT_MASK: Interrupt Mask for PPA_HDR_ERR_COR. 0 = DISABLED : Do not generate an interrupt when PPA_HDR_ERR_COR is set. 1 = ENABLED: Generate an interrupt when PPA_HDR_ERR_COR is set.

26.16.8 CSI_CSI_PIXEL_PARSER_A_STATUS_0

Pixel Parser A Status

These status bits are cleared to zero when its bit position is written with one. For example writing 0x2 to CSI_PIXEL_PARSER_STATUS will clear only PPA_ILL_WD_CNT.

Offset: 0x215 | Byte Offset: 0x854 | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
14	X	HPA_UNC_HDR_ERR: Uncorrectable Header Error, Set when header parser A parses a header with a multi bit error. This error will be detected by the headers ECC, but can't be corrected. The packet will be discarded.
10	X	PPA_SPARE_STATUS_1: PPA Spare Status bit. This bit will get set when Pixel Parser A has a line timeout. Line timeout needs to be enabled by setting PPA_ENABLE_LINE_TIMEOUT and programming PPA_MAX_CLOCKS for the MAX clocks between lines.
9	X	PPA_INTERFRAME_LINE: Set when CSI-PPA receives a request to output a line that is not in the active part of the frame output. That is after EF and before SF, or before start marker is found. The interframe line will not be outputted by the Pixel Parser.
8	X	PPA_EXTRA_SF: Set when CSI-PPA receives a SF when it is expecting an EF. This happens when EF of the frame gets corrupted before arriving CSI. CSI-PPA will insert a fake EF and the drop the current frame with Correct SF.
7	X	PPA_SHORT_FRAME: Set when CSI-PPA receives a short frame. This bit gets set even if CSI_PPA_PAD_FRAME specifies that short frames are to be padded to the correct line length.
6	X	PPA_STMERR: Stream Error, set when the control output of PPA does not follow the correct sequence. The correct sequence for CSI is: SF -> (SL_DATA or EF), SL_DATA -> (DATA or EL_DATA), DATA -> EL_DATA, EL_DATA -> (SL_DATA or EF), EF -> SF. Stream Errors can be caused by receiving a corrupted stream.

Bit	Reset	Description
5	X	PPA_FIFO_OVRF: FIFO Overflow, set when the FIFO that is feeding packets to PPA overflows.
4	X	PPA_PL_CRC_ERR: PayLoad CRC Error, Set when a packet that was processed by PPA had a payload CRC error.
3	X	PPA_SL_PKT_DROPPED: Short Line Packet Dropped, set when an incoming packet gets dropped because the input FIFO level reaches CSI_A_SKIP_PACKET_THRESHOLD when padding a short line.
2	X	PPA_SL_PROCESSED: Short Line Processed, Set when a line with a payload that is shorter than its packet header word count is processed by PPA.
1	X	PPA_ILL_WD_CNT: Illegal Word Count, set when a line with a word count that does not generate an integer number of pixels (Unused bytes at the end of payload) is processed by PPA.
0	X	PPA_HDR_ERR_COR: Header Error Corrected, Set when a packet that was processed by PPA has a single bit header error. This error will be detected by the headers ECC, and corrected by it if header error correction is enabled (CSI_A_HEADER_EC_ENABLE = 0). This flag will be set and the packet will be processed even if the error is not corrected.

26.16.9 CSI_CSI_SW_SENSOR_A_RESET_0

Offset: 0x216 | Byte Offset: 0x858 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CSI_SENSOR_A_RESET: Reset CSI sensor A

26.16.10 CSI_INPUT_STREAM_B_CONTROL_0

CSI Input Stream B Control

Offset: 0x21b | Byte Offset: 0x86c | Read/Write: R/W | Reset: 0x00ff0004 (0bxxxxxxx011111111xxxxxxxxxx0x100)

Bit	Reset	Description
24:16	0xff	CSI_B_SKIP_PACKET_THRESHOLD: CSI-B Skip Packet Threshold. This value is compared against the internal FIFO that buffers the input streams. A packet will be skipped (discarded) if the pixel stream processor is busy (probably due to padding process of a short line) and the number of entries in the internal FIFO exceeds this threshold value. Note that each entry in the internal FIFO buffer is four bytes. To turn off this feature, set the value to its maximum value (all ones).
4	0x0	CSI_B_SKIP_PACKET_THRESHOLD_ENABLE: Enables skip packet threshold feature. 0 = DISABLE : Skip packet feature is disabled. 1 = ENABLE: Skip packet feature is enabled.
2	0x1	CSI_B_BYPASS_ALIGN: Bypass aligning CSIB lanes if valids for the lanes are out of sync by a cycle
1:0	0x0	CSI_B_DATA_LANE: CSI-B Data Lane 0= 1 data lane, 1= 2 data lanes, 2= 3 data lanes (not supported), 3= 4 data lanes (not supported) Note: 3 data lanes is not supported in Test Pattern Generation mode.

26.16.11 CSI_PIXEL_STREAM_B_CONTROL0_0

CSI Pixel Stream A Control 0

Offset: 0x21c | Byte Offset: 0x870 | Read/Write: R/W | Reset: 0xXXXX01X0 (0bxxxxxxxxxxxxxxxxxxxxxxxx1xxxxx000)

Bit	Reset	Description
29:28	X	CSI_PPB_PAD_FRAME: CSI Pixel Parser B Pad Frame. This specifies how to deal with frames that are shorter (fewer lines) than expected. Short frames are usually caused by line packets being dropped because of packet errors. Expected frame height is specified in PPB_EXP_FRAME_HEIGHT. To do padding the value in CSI_PPB_WORD_COUNT needs to be set to the number of input bytes in each lines payload. 0 = PAD0S: Lines of all zeros will be used to pad out frames that are shorter than

Bit	Reset	Description
		expected height. PPB_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this field is set to PAD0S. 1 = PAD1S: Lines of all ones will be used to pad out frames that are shorter than expected height. PPB_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this field is set to PAD1S. 2 = NOPAD: Short frames will not be padded out.
27	X	CSI_PPB_HEADER_EC_ENABLE: CSI Pixel Parser B Packet Header Error Correction Enable. This parameter specifies whether single bit errors in the packet header will be automatically corrected or not. 0 = ENABLE: Single bit errors in the header will be automatically corrected. 1 = DISABLE: Single bit errors in the header will not be corrected. Header ECC check will still set header ECC status bits and the packet will be processed by Pixel Parser B. DISABLE should not be used when processing interleaved streams (Same stream going to both PPA and PPB).
25:24	X	CSI_PPB_PAD_SHORT_LINE: CSI Pixel Parser B Pad Short Line. This specifies how to deal with shorter than expected line (the number of bytes received is less than the specified word count) short line is not padded (will output less pixels than expected). 0 = PAD0S: short line is padded by pixel of zeros such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet may be discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 1 = PAD1S: short line is padded by pixel of ones such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet may be discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 2 = NOPAD: This option is not recommended and may cause other modules that receive CSI output stream to hang up.
21:20	X	CSI_PPB_EMBEDDED_DATA_OPTIONS: CSI Pixel Parser B Embedded Data Options. This specifies how to deal with embedded data within the specified input stream assuming that the CSI_PPB_DATA_TYPE is not embedded data and that embedded data is not already processed by another CSI pixel stream processor. 0 = DISCARD: discard (throw away) embedded data 1 = EMBEDDED: Output embedded data as 8-bpp arbitrary data stream.
19:16	X	CSI_PPB_OUTPUT_FORMAT_OPTIONS: CSI Pixel Parser B Output Format Options. This parameter specifies output data format. 0 = ARBITRARY: Output as 8-bit arbitrary data stream This may be used for compressed JPEG stream 1 = PIXEL: Output the normal 1 pixel/clock. Undefined LS. color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed. 2 = PIXEL_REP: Same as PIXEL except MS color bits, for RGB_666, RGB_565, RGB_555, and RGB_444, will be replicated to their undefined LS bits. 3 = STORE: Output for storing RAW data to memory through ISP. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed.
8	0x1	CSI_PPB_WC_CHECK: CSI Pixel Parser B Data WC Check. This parameter specifies whether the wordcount is checked. 0 = DISABLE : Wordcount Check is disabled 1 = ENABLE: Wordcount Check is enabled
7	X	CSI_PPB_CRC_CHECK: CSI Pixel Parser B Data CRC Check. This parameter specifies whether the last 2 bytes of packet should be treated as CRC checksum and used to perform CRC check on the payload data. Note that in case there are 2 bytes of data CRC at the end of the packet, the packet word count does not include the CRC bytes. 0 = DISABLE: Data CRC Check is disabled regardless of whether there are CRC checksum at the end of the packet. 1 = ENABLE: Data CRC Check is enabled.
6	X	CSI_PPB_WORD_COUNT_SELECT: CSI Pixel Parser B Word Count Select. This parameter is effective only if packet header is sent as part of the stream. 0 = REGISTER: Word Count in packet header is ignored and the number of bytes per line/packet is specified by CSI_PPB_WORD_COUNT. Payload CRC check will not be valid if the word count in CSI_PPB_WORD_COUNT is different than the count in the packet header. Interlaced support relies on frame number and will not work in REGISTER mode. 1 = HEADER: The number of bytes per line is to be extracted from Word Count field in the packet header. Note that if the serial link is not error free, programming this bit to

Bit	Reset	Description
		HEADER may be dangerous because the word count information in the header may be corrupted. It is recommended to always program this bit to HEADER.
5	X	CSI_PPB_DATA_IDENTIFIER: CSI Pixel Parser B Data Identifier (DI) byte processing. This parameter is effective only if packet header is sent as part of the stream. 0 = DISABLED: Disabled - Data Identifier byte in packet header should be ignored (not checked against CSI_PPB_DATA_TYPE and against CSI_PPB_VIRTUAL_CHANNEL_ID). In this case, CSI_PPB_DATA_TYPE specifies the stream data format. 1 = ENABLED: Enabled - Data Identifier byte in packet header should be compared against the CSI_PPB_DATA_TYPE and the CSI_PPB_VIRTUAL_CHANNEL_ID.
4	X	CSI_PPB_PACKET_HEADER: CSI Pixel Parser B Packet Header processing. This specifies whether packet header is sent in the beginning of packet or not. 0 = NOT_SENT: Packet header is not sent. This setting should not be used if the stream source is CSI Interface A or B. Unless CSI-A, or CSI-B, is operating in a stream capture debug mode. In this case, CSI_PPB_DATA_TYPE specifies the stream data format and the number of bytes per line/packet is specified by CSI_PPB_WORD_COUNT. This implies that a packet footer is also not sent. In this case, no packet footer CRC check should be performed. 1 = SENT: Packet header is sent. This setting should be used if the stream source is CSI Interface A or B.
2:0	0x0	CSI_PPB_STREAM_SOURCE: CSI Pixel Parser B Stream Source 0 = CSI_A: CSI Interface A 1 = CSI_B: CSI Interface B

26.16.12 CSI_PIXEL_STREAM_B_CONTROL1_0

CSI Pixel Stream B Control 1

Offset: 0x21d | Byte Offset: 0x874 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:4	0x0	CSI_PPB_TOP_FIELD_FRAME_MASK: CSI Pixel Parser B Top Field Frame Mask
3:0	0x0	CSI_PPB_TOP_FIELD_FRAME: CSI Pixel Parser B Top Field Frame. This parameter specifies the frame number for top field detection for interlaced input video stream. Top Field is indicated when each of the least significant four bits of the frame number that has a one in its mask bit matches the corresponding bit in this parameter. In other words, Top Field is detected when the bitwise OR of ~(CSI_PPB_TOP_FIELD_FRAME ^ <frame number>) & CSI_PPB_TOP_FIELD_FRAME_MASK is one. Frame Number is taken from the WC field of the Frame Start short packet. Due to the reliance on WC field in packet header, interlaced support will not work if WC is selected from REGISTER mode.

26.16.13 CSI_PIXEL_STREAM_B_GAP_0

CSI Pixel Stream B Gap

Offset: 0x21e | Byte Offset: 0x878 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	PPB_FRAME_MIN_GAP: Minimum number of viclk cycles from end of frame (Video_control = EF) to start of next frame (Video_control = SF). This parameter ensures that the minimum V-blank time requirement of VI/ISP is satisfied. This field takes effect only when the frame gap of the input stream is less than the specified value.
15:0	0x0	PPB_LINE_MIN_GAP: Minimum number of viclk cycles from end of previous line (Video_control = EL_DATA) to start of next line (Video_control = SL). This parameter ensures that the minimum H-blank time requirement of VI/ISP is satisfied. This field takes effect only when the line gap of the input stream is less than the specified value.

26.16.14 CSI_PIXEL_STREAM_PPB_COMMAND_0

CSI Pixel Parser B Command

Offset: 0x21f | Byte Offset: 0x87c | Read/Write: R/W | Reset: 0x0000XXX4 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx100)

Bit	Reset	Description
15:12	X	CSI_PPB_START_MARKER_FRAME_MAX: CSI Pixel Parser B Start Marker Maximum. Start Frame is indicated when the Minimum condition above is met and the least significant four bits of the frame number are less than, or equal to, this value.
11:8	X	CSI_PPB_START_MARKER_FRAME_MIN: CSI Pixel Parser B Start Marker Minimum. Start Frame is indicated when the Maximum condition below is met and the least significant four bits of the frame number are greater than, or equal to, this value.
4	X	CSI_PPB_VSYNC_START_MARKER: CSI Pixel Parser B VSYNC Start Marker. 0 = FSPKT: Start of frame is indicated when a Frame Start short packet is received with a frame number whose least significant four bits are greater than, or equal to, CSI_PPB_START_MARKER_FRAME_MIN and less than, or equal to, CSI_PPB_START_MARKER_FRAME_MAX. When the input stream is from a CSI port, or from the host path, or from the VIP path and the data mode is PAYLOAD_ONLY, then this field may be programmed to FSPKT. 1 = VSYNC: Start of frame is indicated when VSYNC signal is received. When the input stream is from the VIP path and the data mode is PACKET, then this field may be programmed to VSYNC.
2	0x1	CSI_PPB_SINGLE_SHOT: CSI Pixel Parser B Single Shot Mode. Software should clear it along with disabling CSI_PPB_ENABLE, once a frame is captured 0 = DISABLE 1 = ENABLE
1:0	0x0	CSI_PPB_ENABLE: CSI Pixel Parser B Enable. This parameter controls CSI Pixel Parser B to start or stop receiving data. 0 = NOP: no operation 1 = ENABLE: enable at the next frame start as specified by the CSI Start Marker 2 = DISABLE: disable after current frame end and before next frame start. 3 = RST: reset (disable immediately). Enabling the pixel parser does not enable the corresponding input source to receive data. If the pixel parser is enabled later than the corresponding input source, the CSI will keep rejecting the incoming stream, until it encounters a valid SF.

26.16.15 CSI_PIXEL_STREAM_B_EXPECTED_FRAME_0

CSI Pixel Stream B Expected Frame

Offset: 0x220 | Byte Offset: 0x880 | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:4	X	PPB_MAX_CLOCKS: Maximum Number of viclk clock cycles between line start requests. The value in this field is in terms of 256 viclk clock cycles.
0	X	PPB_ENABLE_LINE_TIMEOUT: When set to one, enables checking of the time between start line requests from the Header Parser to CSI-PPB. A fake EF will be output by CSI-PPB if this time between line starts exceeds the value in MAX_CLOCKS_BETWEEN_LINES. Padding lines can be inserted before the fake EF, if the number of lines output, when the fake EF is generated is less than the expected frame height. The type of padding is specified using CSI_PPB_PAD_FRAME.

26.16.16 CSI_CSI_PIXEL_PARSER_B_INTERRUPT_MASK_0

CSI Pixel Parser B Interrupt Mask

Offset: 0x221 | Byte Offset: 0x884 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxx0xx000000000000)

Bit	Reset	Description
14	0x0	HPB_UNC_HDR_ERR_INT_MASK: Interrupt Mask for HPB_UNC_HDR_ERR. 0 = DISABLED : Do not generate an interrupt when HPB_UNC_HDR_ERR is set. 1 = ENABLED: Generate an interrupt when HPB_UNC_HDR_ERR is set.
10	0x0	PPB_SPARE_STATUS_1_INT_MASK: Interrupt Mask for PPB_SPARE_STATUS_1. 0 = DISABLED : Do not generate an interrupt when PPB_SPARE_STATUS_1 is set. 1 = ENABLED: Generate an interrupt when PPB_SPARE_STATUS_1 is set.
9	0x0	PPB_INTERFRAME_LINE_INT_MASK: Interrupt Mask for PPB_INTERFRAME_LINE. 0 = DISABLED : Do not generate an interrupt when PPB_INTERFRAME_LINE is set. 1 = ENABLED: Generate an interrupt when PPB_INTERFRAME_LINE is set.
8	0x0	PPB_EXTRA_SF_INT_MASK: Interrupt Mask for PPB_EXTRA_SF. 0 = DISABLED : Do not generate an interrupt when PPB_EXTRA_SF is set. 1 = ENABLED: Generate an interrupt when PPB_EXTRA_SF is set.
7	0x0	PPB_SHORT_FRAME_INT_MASK: Interrupt Mask for PPB_SHORT_FRAME. 0 = DISABLED : Do not generate an interrupt when PPB_SHORT_FRAME is set. 1 = ENABLED: Generate an interrupt when PPB_SHORT_FRAME is set.
6	0x0	PPB_STMERR_INT_MASK: Interrupt Mask for PPB_STMERR. 0 = DISABLED : Do not generate an interrupt when PPB_STMERR is set. 1 = ENABLED: Generate an interrupt when PPB_STMERR is set.
5	0x0	PPB_FIFO_OVRF_INT_MASK: Interrupt Mask for PPB_FIFO_OVRF. 0 = DISABLED : Do not generate an interrupt when PPB_FIFO_OVRF is set. 1 = ENABLED: Generate an interrupt when PPB_FIFO_OVRF is set.
4	0x0	PPB_PL_CRC_ERR_INT_MASK: Interrupt Mask for PPB_PL_CRC_ERR. 0 = DISABLED : Do not generate an interrupt when PPB_PL_CRC_ERR is set. 1 = ENABLED: Generate an interrupt when PPB_PL_CRC_ERR is set.
3	0x0	PPB_SL_PKT_DROPPED_INT_MASK: Interrupt Mask for PPB_SL_PKT_DROPPED. 0 = DISABLED : Do not generate an interrupt when PPB_SL_PKT_DROPPED is set. 1 = ENABLED: Generate an interrupt when PPB_SL_PKT_DROPPED is set.
2	0x0	PPB_SL_PROCESSED_INT_MASK: Interrupt Mask for PPB_SL_PROCESSED. 0 = DISABLED : Do not generate an interrupt when PPB_SL_PROCESSED is set. 1 = ENABLED: Generate an interrupt when PPB_SL_PROCESSED is set.
1	0x0	PPB_ILL_WD_CNT_INT_MASK: Interrupt Mask for PPB_ILL_WD_CNT. 0 = DISABLED : Do not generate an interrupt when PPB_ILL_WD_CNT is set. 1 = ENABLED: Generate an interrupt when PPB_ILL_WD_CNT is set.
0	0x0	PPB_HDR_ERR_COR_INT_MASK: Interrupt Mask for PPB_HDR_ERR_COR. 0 = DISABLED : Do not generate an interrupt when PPB_HDR_ERR_COR is set. 1 = ENABLED: Generate an interrupt when PPB_HDR_ERR_COR is set.

26.16.17 CSI_CSI_PIXEL_PARSER_B_STATUS_0

Pixel Parser B Status

Offset: 0x222 | Byte Offset: 0x888 | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
14	X	HPB_UNC_HDR_ERR: Uncorrectable Header Error, Set when header parser B parses a header with a multi bit error. This error will be detected by the headers ECC, but can't be corrected.
10	X	PPB_SPARE_STATUS_1: PPB Spare Status bit. This bit will get set when Pixel Parser B has a line timeout. Line timeout needs to be enabled by setting PPB_ENABLE_LINE_TIMEOUT and programming PPB_MAX_CLOCKS for the MAX clocks between lines.

Bit	Reset	Description
9	X	PPB_INTERFRAME_LINE: Set when CSI-PPB receives a request to output a line that is not in the active part of the frame output. That is after EF and before SF, or before start marker is found. The interframe line will not be outputted by the Pixel Parser.
8	X	PPB_EXTRA_SF: Set when CSI-PPB receives a SF when it is expecting an EF. This happens when EF of the frame gets corrupted before arriving CSI. CSI-PPB will insert a fake EF and the drop the current frame with Correct SF.
7	X	PPB_SHORT_FRAME: Set when CSI-PPB receives a short frame. This bit gets set even if CSI_PPB_PAD_FRAME specifies that short frames are to be padded to the correct line length.
6	X	PPB_STMERR: Stream Error, set when the control output of PPB doesn't follow the correct sequence. The correct sequence for CSI is: SF -> (SL_DATA or EF), SL_DATA -> (DATA or EL_DATA), DATA -> EL_DATA, EL_DATA -> (SL_DATA or EF), EF -> SF. Stream Errors can be caused by receiving a corrupted stream.
5	X	PPB_FIFO_OVRF: FIFO Overflow, set when the FIFO that is feeding packets to PPB overflows.
4	X	PPB_PL_CRC_ERR: PayLoad CRC Error, Set when a packet that was processed by PPB had a payload CRC error.
3	X	PPB_SL_PKT_DROPPED: Short Line Packet Dropped, set when an incoming packet gets dropped because the input FIFO level reaches CSI_B_SKIP_PACKET_THRESHOLD when padding a short line.
2	X	PPB_SL_PROCESSED: Short Line Processed, Set when a line with a payload that is shorter than its packet header word count is processed by PPB.
1	X	PPB_ILL_WD_CNT: Illegal Word Count, set when a line with a word count that doesn't generate an integer number of pixels (Unused bytes at the end of payload) is processed by PPB.
0	X	PPB_HDR_ERR_COR: Header Error Corrected, set when a packet that was processed by PPB has a single bit header error. This error will be detected by the headers ECC, and corrected by it if header error correction is enabled (CSI_B_HEADER_EC_ENABLE = 0). This flag will be set and the packet will be processed even if the error is not corrected.

26.16.18 CSI_CSI_SW_SENSOR_B_RESET_0

Offset: 0x223 | Byte Offset: 0x88c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CSI_SENSOR_B_RESET: Reset CSI sensor B

26.16.19 CSI_PHY_CIL_COMMAND_0

CSI Phy and CIL Command

Offset: 0x242 | Byte Offset: 0x908 | Read/Write: R/W | Reset: 0x00000000 (0bxx00xx00xxxxxx00xxxxxx00xxxxxx00)

Bit	Reset	Description
29:28	0x0	CSI_E_PHY_CIL_ENABLE: CSI E PHY and CIL Enable. This parameter controls CSI C PHY and CIL receiver to start or stop receiving data. disable (reset) 0 = NOP : no operation 1 = ENABLE : enable 2 = DISABLE
25:24	0x0	CSI_D_PHY_CIL_ENABLE: CSI D PHY and CIL Enable. This parameter controls CSI A PHY and CIL receiver to start or stop receiving data. 0 = NOP : no operation 1 = ENABLE : enable 2 = DISABLE
17:16	0x0	CSI_C_PHY_CIL_ENABLE: CSI C PHY and CIL Enable. This parameter controls CSI A PHY and CIL receiver to start or stop receiving data. 0 = NOP : no operation 1 = ENABLE : enable 2 = DISABLE

Bit	Reset	Description
9:8	0x0	CSI_B_PHY_CIL_ENABLE: CSI B PHY and CIL Enable. This parameter controls CSI B PHY and CIL receiver to start or stop receiving data. disable (reset) 0 = NOP : no operation 1 = ENABLE : enable 2 = DISABLE
1:0	0x0	CSI_A_PHY_CIL_ENABLE: CSI A PHY and CIL Enable. This parameter controls CSI A PHY and CIL receiver to start or stop receiving data. disable (reset) 0 = NOP : no operation 1 = ENABLE : enable 2 = DISABLE

26.16.20 CSI_CIL_PAD_CONFIG0_0

CIL Pad Configuration 0

Offset: 0x243 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx00000000xxxxxxxx)

Bit	Reset	Description
15:8	0x0	PAD_CIL_SPARE: Spare bit for CIL BIAS Config. PAD_CIL_SPARE[7] is used is being used to flush VI's Y-FIFO when it is being use as a stream source for one of the Pixel Parsers. Setting PAD_CIL_SPARE[7] to 1 will hold vi2csi_host_stall low. This will force VI's Y-FIFO to be purged. PAD_CIL_SPARE[7] must be low for the pixel parser to receive source data from VI's Y-FIFO.

26.16.21 CSI_CILA_PAD_CONFIG0_0

CIL-A Pad Configuration 0

Offset: 0x24b | Byte Offset: 0x92c | Read/Write: R/W | Reset: 0x00000007 (0b0000x000000000000000x000x0000111)

Bit	Reset	Description
31	0x0	PAD_CILA_E_TXBW: 0 = default to enable VCLAMP regulator 1 = turn off regulator and short vclamp to VDDP. will cause stress and need waiver to use
30:28	0x0	PAD_CILA_SLEWDNADJ: Pull down slew rate adjust, default 000. From 000 -> 011, slew rate increases. 100 is the same as 000. From 100->111, skew rate decreases.
26:24	0x0	PAD_CILA_SLEWUPADJ: Pull up slew rate adjust, default 000. From 000 -> 011, slew rate increases. 100 is the same as 000. From 100->111, skew rate decreases.
23:21	0x0	PAD_CILA_LPDNADJ: Driver pull down impedance control. 00 -> 130ohm, default 01 -> 110ohm 10 -> 130ohm, same as 00 11 -> 150ohm
20:18	0x0	PAD_CILA_LPUPADJ: Driver pull up impedance control. 00 -> 130ohm, default 01 -> 110ohm 10 -> 130ohm, same as 00 11 -> 150ohm

1:0	0x3	PAD_CILA_PDIO: Power down for each data bit, including drivers, receivers and contention detectors

26.16.22 CSI_CILA_PAD_CONFIG1_0

CIL-A Pad Configuration 4

Offset: 0x24c | Byte Offset: 0x930 | Read/Write: R/W | Reset: 0xXXXX0000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	R/W	Reset	Description
31:16	RO	X	PAD_CILA_SPARE_RO: Spare Read only bits for CILA Config
15:8	RW	0x0	PAD_CILA_SPARE: Spare bits for CILA Config. PAD_CILA_SPARE[15] is being used to disable the CSI-A RTL code that blocks FIFO pushes that are past the end of the line packet. 0: disabled 1: push blocking enabled
7:6	RW	0x0	PAD_CILA_PEMPD_CLK: Enable data bit HS driver pull down pre-emphasis, 00=no pre-emphasis, 11=max
5:4	RW	0x0	PAD_CILA_PEMPU_CLK: Enable data bit HS driver pull up pre-emphasis, 00=no pre-emphasis, 11=max
3:2	RW	0x0	PAD_CILA_PEMPD: Enable data bit HS driver pull down pre-emphasis, 00=no pre-emphasis, 11=max
1:0	RW	0x0	PAD_CILA_PEMPU: Enable data bit HS driver pull up pre-emphasis, 00=no pre-emphasis, 11=max

26.16.23 CSI_PHY_CILA_CONTROL0_0

CSI-A PHY and CIL Control

Offset: 0x24d | Byte Offset: 0x934 | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxxxxxxx000000x0000010)

Bit	Reset	Description
13:8	0x0	CILA_CLK_SETTLE: Settle time for clock lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many CSICIL clock cycles (72 MHz LP clock cycles) to wait after LP00. Hardware uses an internal delay of ~15 csicil cycles for the default value. So the programming value (0 to 15) of this field works like this: 0 = 15 cilclk cycles (default internal delay) 1 = 15 - 7 (8 cilclk cycles) 2 = 15 - 6 (9 cilclk cycles) … 7 = 15 - 1 (14 cilclk cycles) 8 = 15 - 0 (default internal delay) 9 = 15 + 1 (16 cilclk cycles) … 57 = 15 + 49 (64 cilclk cycles)
6	0x0	CILA_BYPASS_LP_SEQ: The LP signals should sequence through LP11->LP01->LP00 state, to indicate to CLOCK CIL about the mode switching to HS Rx mode. In case the Camera is enabled earlier than CIL, it is highly likely that the camera sends this control sequence sooner than CIL can detect it. Enabling this bit allows the CLOCK CIL to overlook the LP control sequence and step in HS Rx mode directly looking at LP00 only.
5:0	0x2	CILA_THS_SETTLE: Settle time for data lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many CSICIL clock cycles (102 MHz LP clock cycles)

Bit	Reset	Description
		to wait, after LP00, before starting to look at the data. 0xF is an illegal value for this field. 85ns + 6 * UI < (Ths-settle-programmed + 5) * csicil_clk_period < 145ns + 10 * UI

26.16.24 CSI_CSI_CIL_A_INTERRUPT_MASK_0

CSI Control and Interface Logic A Interrupt Mask

Offset: 0x24e | Byte Offset: 0x938 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0x0000x000)

Bit	Reset	Description
9	0x0	CILA_CLK_LANE_CTRL_ERR_INT_MASK: Interrupt Mask for CILA_CLK_CTRL_ERR. 0 = DISABLED : Do not generate an interrupt when CILA_CLK_CTRL_ERR is set. 1 = ENABLED: Generate an interrupt when CILA_CLK_CTRL_ERR is set.
6	0x0	CILA_ESC_DATA_REC_INT_MASK: Interrupt Mask for CILA_ESC_DATA_REC. 0 = DISABLED : Do not generate an interrupt when CILA_ESC_DATA_REC is set. 1 = ENABLED: Generate an interrupt when CILA_ESC_DATA_REC is set.
5	0x0	CILA_ESC_CMD_REC_INT_MASK: Interrupt Mask for CILA_ESC_CMD_REC. 0 = DISABLED : Do not generate an interrupt when CILA_ESC_CMD_REC is set. 1 = ENABLED: Generate an interrupt when CILA_ESC_CMD_REC is set.
4	0x0	CILA_CTRL_ERR_INT_MASK: Interrupt Mask for CILA_CTRL_ERR. 0 = DISABLED : Do not generate an interrupt when CILA_CTRL_ERR is set. 1 = ENABLED: Generate an interrupt when CILA_CTRL_ERR is set.
2	0x0	CILA_SYNC_ESC_ERR_INT_MASK: Interrupt Mask for CILA_SYNC_ESC_ERR. 0 = DISABLED : Do not generate an interrupt when CILA_SYNC_ESC_ERR is set. 1 = ENABLED: Generate an interrupt when CILA_SYNC_ESC_ERR is set.
1	0x0	CILA_SOT_MB_ERR_INT_MASK: Interrupt Mask for CILA_SOT_MB_ERR. 0 = DISABLED : Do not generate an interrupt when CILA_SOT_MB_ERR is set. 1 = ENABLED: Generate an interrupt when CILA_SOT_MB_ERR is set.
0	0x0	CILA_SOT_SB_ERR_INT_MASK: Interrupt Mask for CILA_SOT_SB_ERR. 0 = DISABLED : Do not generate an interrupt when CILA_SOT_SB_ERR is set. 1 = ENABLED: Generate an interrupt when CILA_SOT_SB_ERR is set.

26.16.25 CSI_CSI_CIL_A_STATUS_0

CSI Control and Interface Logic A Status

These status bits are cleared to zero when its bit position is written with one. For example writing 0x2 to CSI_CIL_A_STATUS will clear only CILA_SOT_MB_ERR.

Offset: 0x24f | Byte Offset: 0x93c | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
6	X	CILA_ESC_DATA_REC: Escape Mode Data Received, set when CIL-A receives an Escape Mode Data byte. The Data Byte can be read from bits 7-0 of ESCAPE_MODE_DATA. This status bit will also be cleared when CILA_ESC_CMD_REC is set.
5	X	CILA_ESC_CMD_REC: Escape Mode Command Received, set when CIL-A receives an Escape Mode Command byte. The Command Byte can be read from bits 7-0 of ESCAPE_MODE_COMMAND.
4	X	CILA_CTRL_ERR: Control Error, set when CIL-A detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning into the Escape mode or Turn Around mode (LP00).
2	X	CILA_SYNC_ESC_ERR: Sync Escape Error, set when CIL-A detects that the wrong (non-multiple of 8) number of bits have been received for an Escape Command, or Data Byte.
1	X	CILA_SOT_MB_ERR: Start of Transmission Multi Bit Error, set when CIL-A detects a multi bit start of transmission byte error in one of the packet's SOT bytes. The packet will be discarded.

Bit	Reset	Description
0	X	CILA_SOT_SB_ERR: Start of Transmission Single Bit Error, set when CIL-A detects a single bit error in one of the packet's Start of Transmission bytes. The packet will be sent to the CSI-A for processing.

26.16.26 CSI_CSI_CILA_STATUS_0

CSI-CILA Control and Interface Logic Status

These status bits are cleared to zero when its bit position is written with one. For example writing 0x2 to CSI_CIL_STATUS will clear only SOT_MB_ERR.

Offset: 0x250 | Byte Offset: 0x940 | Read/Write: RO | Reset: 0x000X00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18	X	CILA_DATA_LANE1_CTRL_ERR: Control Error, set when CIL-A detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
17	X	CILA_DATA_LANE1_SOT_MB_ERR: Start of Transmission Multi Bit Error, set when CIL-A detects a multi bit start of transmission byte error in one of the packet's SOT bytes on data lane-1. The packet will be discarded.
16	X	CILA_DATA_LANE1_SOT_SB_ERR: Start of Transmission Single Bit Error, set when CIL-A detects a single bit error in one of the packet's Start of Transmission bytes on data lane-1. The packet will be sent to the CSI-A for processing.
6	X	CILA_DATA_LANE0_CTRL_ERR: Control Error, set when CIL-A detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
5	X	CILA_DATA_LANE0_SOT_MB_ERR: Start of Transmission Multi Bit Error, set when CIL-A detects a multi bit start of transmission byte error in one of the packet's SOT bytes on data lane-0. The packet will be discarded.
4	X	CILA_DATA_LANE0_SOT_SB_ERR: Start of Transmission Single Bit Error, set when CIL-A detects a single bit error in one of the packet's Start of Transmission bytes on data lane-0. The packet will be sent to the CSI-A for processing.
0	X	CILA_CLK_LANE_CTRL_ERR: Control Error, set when CIL-A detects incorrect line state sequence on clk lane

26.16.27 CSI_CIL_A_ESCAPE_MODE_COMMAND_0

Escape Mode Command

This register is used to receive escape mode command bytes from CIL-A.

Offset: 0x251 | Byte Offset: 0x944 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILA_ESC_CMD_BYTE: CIL-A Escape Mode Command Byte, this is the 8 bit entry command that was received, by CIL-A, during the last escape Mode sequence. CIL-A monitors Byte Lane 0, only, for escape mode sequences. This command byte can only be assumed to be valid when CILA_ESC_CMD_REC status bit is set.

26.16.28 CSI_CIL_A_ESCAPE_MODE_DATA_0

Escape Mode Data

This register is used to receive escape mode data bytes from CIL-A.

Offset: 0x252 | Byte Offset: 0x948 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILA_ESC_DATA_BYTE: CIL-A Escape Mode Data Byte, when read this field returns the last Escape Mode Data byte that was received by CIL-A. Escape Mode Data bytes are the bytes that are received in Escape Mode after receiving the Escape Mode Command. These bytes can be used to implement MIPI's CSI Specs Low Power Data Transmission. This field is only valid when the status bit, CILA_ESC_DATA_REC, is set, and will be overwritten by the next Escape Mode data byte if not read before the next byte come in.

26.16.29 CSI_CSICIL_SW_SENSOR_A_RESET_0

Offset: 0x253 | Byte Offset: 0x94c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CSICIL_SENSOR_A_RESET: Reset CSICIL sensor A

26.16.30 CSI_CILB_PAD_CONFIG0_0

CIL-B Pad Configuration 0

Offset: 0x258 | Byte Offset: 0x960 | Read/Write: R/W | Reset: 0x00000007 (0b0000x000000000xx0000x000x0000111)

Bit	Reset	Description

26.16.32 CSI_PHY_CILB_CONTROL0_0

CSI-B PHY and CIL Control

Offset: 0x25a | Byte Offset: 0x968 | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxxxxxxx000000x0000010)

Bit	Reset	Description
13:8	0x0	CILB_CLK_SETTLE: Settle time for clock lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many CSICIL clock cycles (72 MHz LP clock cycles) to wait after LP00. Hardware uses an internal delay of ~15 CSICIL cycles for default value. So the programming value (0 to 15) of this field works like this: 0 = 15 cilclk cycles (default internal delay) 1 = 15 - 7 (8 cilclk cycles) 2 = 15 - 6 (9 cilclk cycles) … 7 = 15 - 1 (14 cilclk cycles) 8 = 15 - 0 (default internal delay) 9 = 15 + 1 (16 cilclk cycles) … 57 = 15 + 49 (64 cilclk cycles)
6	0x0	CILB_BYPASS_LP_SEQ: see CILA_BYPASS_LP_SEQ above
5:0	0x2	CILB_THS_SETTLE: Settle time for data lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many CSICIL clock cycles (102 MHz LP clock cycles) to wait, after LP00, before starting to look at the data. 0xF is an illegal value for this field. 85ns + 6 * UI < (Ths-settle-programmed + 5) * csicil_clk_period < 145ns + 10 * UI

26.16.33 CSI_CSI_CIL_B_INTERRUPT_MASK_0

CSI Control and Interface Logic B Interrupt Mask

Offset: 0x25b | Byte Offset: 0x96c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxx0x0000x000)

Bit	Reset	Description
6	0x0	CILB_ESC_DATA_REC_INT_MASK: Interrupt Mask for CILB_ESC_DATA_REC.

Bit	Reset	Description
		0 = DISABLED : Do not generate an interrupt when CILB_ESC_DATA_REC is set. 1 = ENABLED: Generate an interrupt when CILB_ESC_DATA_REC is set.
5	0x0	CILB_ESC_CMD_REC_INT_MASK: Interrupt Mask for CILB_ESC_CMD_REC. 0 = DISABLED : Do not generate an interrupt when CILB_ESC_CMD_REC is set. 1 = ENABLED: Generate an interrupt when CILB_ESC_CMD_REC is set.
4	0x0	CILB_CTRL_ERR_INT_MASK: Interrupt Mask for CILB_CTRL_ERR. 0 = DISABLED : Do not generate an interrupt when CILB_CTRL_ERR is set. 1 = ENABLED: Generate an interrupt when CILB_CTRL_ERR is set.
2	0x0	CILB_SYNC_ESC_ERR_INT_MASK: Interrupt Mask for CILB_SYNC_ESC_ERR. 0 = DISABLED : Do not generate an interrupt when CILB_SYNC_ESC_ERR is set. 1 = ENABLED: Generate an interrupt when CILB_SYNC_ESC_ERR is set.
1	0x0	CILB_SOT_MB_ERR_INT_MASK: Interrupt Mask for CILB_SOT_MB_ERR. 0 = DISABLED : Do not generate an interrupt when CILB_SOT_MB_ERR is set. 1 = ENABLED: Generate an interrupt when CILB_SOT_MB_ERR is set.
0	0x0	CILB_SOT_SB_ERR_INT_MASK: Interrupt Mask for CILB_SOT_SB_ERR. 0 = DISABLED : Do not generate an interrupt when CILB_SOT_SB_ERR is set. 1 = ENABLED: Generate an interrupt when CILB_SOT_SB_ERR is set.

26.16.34 CSI_CSI_CIL_B_STATUS_0

CSI Control and Interface Logic B Status

Each status bit is cleared to zero when its bit position is written with one. For example writing 0x2 to CSI_CIL_B_STATUS will clear only CILB_SOT_MB_ERR.

Offset: 0x25c | Byte Offset: 0x970 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
6	X	CILB_ESC_DATA_REC: Escape Mode Data Received, set when CIL-B receives an Escape Mode Data byte. The Data Byte can be read from bits 23-16 of ESCAPE_MODE_DATA. This status bit will also be cleared when CILB_ESC_CMD_REC is set.
5	X	CILB_ESC_CMD_REC: Escape Mode Command Received, set when CIL-B receives an Escape Mode Command byte. The Command Byte can be read from bits 23-16 of ESCAPE_MODE_COMMAND.
4	X	CILB_CTRL_ERR: Control Error, set when CIL-B detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning into the Escape mode or Turn Around mode (LP00)..
2	X	CILB_SYNC_ESC_ERR: Sync Escape Error, set when CIL-B detects that the wrong (non-multiple of 8) number of bits have been received for an Escape Command, or Data Byte.
1	X	CILB_SOT_MB_ERR: Start of Transmission Multi Bit Error, set when CIL-B detects a multi bit start of transmission byte error in one of the packet's SOT bytes. The packet will be discarded.
0	X	CILB_SOT_SB_ERR: Start of Transmission Single Bit Error, set when CIL-B detects a single bit error in one of the packets start of transmission bytes. The packet will be sent to CSI-B for processing.

26.16.35 CSI_CSI_CILB_STATUS_0

CSI-CILB Control and Interface Logic Status

Each status bit is cleared to zero when its bit position is written with one. For example writing 0x2 to CSI_CIL_STATUS will clear only SOT_MB_ERR.

Offset: 0x25d | Byte Offset: 0x974 | Read/Write: RO | Reset: 0x000X00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18	X	CILB_DATA_LANE1_CTRL_ERR: Control Error, set when CIL-B detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning

Bit	Reset	Description
17	X	CILB_DATA_LANE1_SOT_MB_ERR: Start of Transmission Multi Bit Error, set when CIL-B detects a multi bit start of transmission byte error in one of the packet's SOT bytes on data lane-1. The packet will be discarded.
16	X	CILB_DATA_LANE1_SOT_SB_ERR: Start of Transmission Single Bit Error, set when CIL-A detects a single bit error in one of the packet's Start of Transmission bytes on data lane-1. The packet will be sent to the CSI-B for processing.
6	X	CILB_DATA_LANE0_CTRL_ERR: Control Error, set when CIL-B detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
5	X	CILB_DATA_LANE0_SOT_MB_ERR: Start of Transmission Multi Bit Error, set when CIL-B detects a multi bit start of transmission byte error in one of the packet's SOT bytes on data lane-0. The packet will be discarded.
4	X	CILB_DATA_LANE0_SOT_SB_ERR: Start of Transmission Single Bit Error, set when CIL-B detects a single bit error in one of the packet's Start of Transmission bytes on data lane-0. The packet will be sent to the CSI-B for processing.
0	X	CILB_CLK_LANE_CTRL_ERR: Control Error, set when CIL-B detects incorrect line state sequence on clk lane

26.16.36 CSI_CIL_B_ESCAPE_MODE_COMMAND_0

Escape Mode Command

This register is used to receive escape mode command bytes from CIL-B.

Offset: 0x25e | Byte Offset: 0x978 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILB_ESC_CMD_BYTE: CIL-B Escape Mode Command Byte, this is the 8-bit entry command that was received, by CIL-B, during the last escape Mode sequence. CIL-B monitors Byte Lane 0, only, for escape mode sequences. This command byte can only be assumed to be valid when CILB_ESC_CMD_REC status bit is set.

26.16.37 CSI_CIL_B_ESCAPE_MODE_DATA_0

Escape Mode Data

This register is used to receive escape mode data bytes from CIL-B.

Offset: 0x25f | Byte Offset: 0x97c | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILB_ESC_DATA_BYTE: CIL-A Escape Mode Data Byte, when read this field returns the last Escape Mode Data byte that was received by CIL-B. Escape Mode Data bytes are the bytes that are received in Escape Mode after receiving the Escape Mode Command. These bytes can be used to implement MIPI's CSI Specs Low Power Data Transmission. This field is only valid when the status bit, CILB_ESC_DATA_REC, is set, and will be overwritten by the next Escape Mode data byte if not read before the next byte come in.

26.16.38 CSI_CSICIL_SW_SENSOR_B_RESET_0

Offset: 0x260 | Byte Offset: 0x980 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CSICIL_SENSOR_B_RESET: Reset CSICIL sensor B

26.16.39 CSI_CILC_PAD_CONFIG0_0

CIL-C Pad Configuration 0

Offset: 0x265 | Byte Offset: 0x994 | Read/Write: R/W | Reset: 0x00000007 (0b0000x000000000000000x000x0000111)

Bit	Reset	Description
31	0x0	PAD_CILC_E_TXBW: Increase bandwidth of output driver
30:28	0x0	PAD_CILC_SLEWDNADJ: Pull down slew rate adjust, default 000. From 000 -> 011, slew rate increases. 100 is the same as 000. From 100->111, skew rate decreases.
26:24	0x0	PAD_CILC_SLEWUPADJ: Pull up slew rate adjust, default 000. From 000 -> 011, slew rate increases. 100 is the same as 000. From 100->111, skew rate decreases.
23:21	0x0	PAD_CILC_LPDNADJ: Driver pull down impedance control 00 -> 130ohm, default. 01 -> 110ohm. 10 -> 130ohm, same as 00. 11 -> 150ohm
20:18	0x0	PAD_CILC_LPUPADJ: Driver pull up impedance control 00 -> 130ohm, default. 01 -> 110ohm. 10 -> 130ohm, same as 00. 11 -> 150ohm
17:16	0x0	PAD_CD_BK_MODE: 00: two independent 2x bricks 01: one 4x brick, received clock from partition C is used. Clock from partition D is not used 10: one 4x brick, received clock from partition D is used. Clock from partition C is not used 11: illegal
15	0x0	PAD_CILC_BANDWD_IN: Increase bandwidth of differential receiver
14:12	0x0	PAD_CILC_INADJ1: bit 1 input delay trimmer, each tap delays 20ps
10:8	0x0	PAD_CILC_INADJ0: bit 0 input delay trimmer, each tap delays 20ps
6:4	0x0	PAD_CILC_INADJCLK: Clock bit input delay trimmer, each tap delays 20ps
3	0x0	PAD_CILC_PDVCLAMP: Power down regulator which supplies current to serializer/deserializer logic
2	0x1	PAD_CILC_PDIO_CLK: Power down for clock bit, including drivers, receivers and contention detectors
1:0	0x3	PAD_CILC_PDIO: Power down for each data bit, including drivers, receivers and contention detectors

26.16.40 CSI_CILC_PAD_CONFIG1_0

CIL-C Pad Configuration 1

Offset: 0x266 | Byte Offset: 0x998 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	PAD_CILC_SPARE: Spare bits for CILC Config
7:6	0x0	PAD_CILC_PEMPD_CLK: Enable data bit HS driver pull down pre-emphasis, 00=no pre-emphasis, 11=max
5:4	0x0	PAD_CILC_PEMPU_CLK: Enable data bit HS driver pull up pre-emphasis, 00=no pre-emphasis, 11=max
3:2	0x0	PAD_CILC_PEMPD: Enable data bit HS driver pull down pre-emphasis, 00=no pre-emphasis, 11=max
1:0	0x0	PAD_CILC_PEMPU: Enable data bit HS driver pull up pre-emphasis, 00=no pre-emphasis, 11=max

26.16.41 CSI_PHY_CILC_CONTROL0_0

CSI-C Phy and CIL Control

Offset: 0x267 | Byte Offset: 0x99c | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxxxxxxxx000000x0000010)

Bit	Reset	Description
13:8	0x0	CILC_CLK_SETTLE: settle time for clk lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many csicil clock cycles (72 MHz LP clock cycles) to wait after LP00. HW uses

26.16.43 CSI_CSI_CIL_C_STATUS_0

CSI Control and Interface Logic C Status

These status bits are cleared to zero when its bit position is written with one. For example write 0x2 to CSI_CIL_STATUS will clear only CILC_SOT_MB_ERR.

Offset: 0x269 | Byte Offset: 0x9a4 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
6	X	CILC_ESC_DATA_REC: Escape Mode Data Received, set when CIL-C receives an Escape Mode Data byte. The Data Byte can be read from bits 7-0 of ESCAPE_MODE_DATA. This status bit will also be cleared when CILC_ESC_CMD_REC is set.
5	X	CILC_ESC_CMD_REC: Escape Mode Command Received, set when CIL-C receives an Escape Mode Command byte. The Command Byte can be read from bits 7-0 of ESCAPE_MODE_COMMAND.

Bit	Reset	Description
4	X	CILC_CTRL_ERR: Control Error, set when CIL-C detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning into the Escape mode or Turn Around mode (LP00).
2	X	CILC_SYNC_ESC_ERR: Sync Escape Error, set when CIL-C detects that the wrong (non-multiple of 8) number of bits have been received for an Escape Command, or Data Byte.
1	X	CILC_SOT_MB_ERR: Start of Transmission Multi Bit Error, set when CIL-C detects a multi bit start of transmission byte error in one of the packet's SOT bytes. The packet will be discarded.
0	X	CILC_SOT_SB_ERR: Start of Transmission Single Bit Error, set when CIL-C detects a single bit error in one of the packet's Start of Transmission bytes. The packet will be sent to the CSI-C for processing.

26.16.44 CSI_CSI_CILC_STATUS_0

CSI-CILC Control and Interface Logic Status

Each status bit is cleared to zero when its bit position is written with one. For example writing 0x2 to CSI_CIL_STATUS will clear only SOT_MB_ERR.

Offset: 0x26a | Byte Offset: 0x9a8 | Read/Write: RO | Reset: 0x000X00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18	X	CILC_DATA_LANE1_CTRL_ERR: Control Error, set when CIL-C detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
17	X	CILC_DATA_LANE1_SOT_MB_ERR: Start of Transmission Multi Bit Error, set when CIL-C detects a multi bit start of transmission byte error in one of the packet's SOT bytes on data lane-1. The packet will be discarded.
16	X	CILC_DATA_LANE1_SOT_SB_ERR: Start of Transmission Single Bit Error, set when CIL-C detects a single bit error in one of the packet's Start of Transmission bytes on data lane-1. The packet will be sent to the CSI-C for processing.
6	X	CILC_DATA_LANE0_CTRL_ERR: Control Error, set when CIL-C detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
5	X	CILC_DATA_LANE0_SOT_MB_ERR: Start of Transmission Multi Bit Error, set when CIL-C detects a multi bit start of transmission byte error in one of the packet's SOT bytes on data lane-0. The packet will be discarded.
4	X	CILC_DATA_LANE0_SOT_SB_ERR: Start of Transmission Single Bit Error, set when CIL-C detects a single bit error in one of the packet's Start of Transmission bytes on data lane-0. The packet will be sent to the CSI-C for processing.
0	X	CILC_CLK_LANE_CTRL_ERR: Control Error, set when CIL-C detects incorrect line state sequence on clk lane

26.16.45 CSI_CIL_C_ESCAPE_MODE_COMMAND_0

Escape Mode Command

This register is used to receive escape mode command bytes from CIL-C.

Offset: 0x26b | Byte Offset: 0x9ac | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILC_ESC_CMD_BYTE: CIL-C Escape Mode Command Byte, this is the 8 bit entry command that was received by CIL-C, during the last escape Mode sequence. CIL-C monitors Byte Lane 0, only, for escape mode sequences. This command byte can only be assumed to be valid when CILC_ESC_CMD_REC status bit is set.

26.16.46 CSI_CIL_C_ESCAPE_MODE_DATA_0

Escape Mode Data

This register is used to receive escape mode data bytes from CIL-C.

Offset: 0x26c | Byte Offset: 0x9b0 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILC_ESC_DATA_BYTE: CIL-C Escape Mode Data Byte, when read this field returns the last Escape Mode Data byte that was received by CIL-C. Escape Mode Data bytes are the bytes that are received in Escape Mode after receiving the Escape Mode Command. These bytes can be used to implement MIPI's CSI Specs Low Power Data Transmission. This field is only valid when the status bit, CILC_ESC_DATA_REC, is set, and will be overwritten by the next Escape Mode data byte if not read before the next byte come in.

26.16.47 CSI_CSICIL_SW_SENSOR_C_RESET_0

2	0x0	CILD_SYNC_ESC_ERR_INT_MASK: Interrupt Mask for CILD_SYNC_ESC_ERR. 0 = DISABLED : Do not generate an interrupt when CILD_SYNC_ESC_ERR is set. 1 = ENABLED: Generate an interrupt when CILD_SYNC_ESC_ERR is set.
1	0x0	CILD_SOT_MB_ERR_INT_MASK: Interrupt Mask for CILD_SOT_MB_ERR. 0 = DISABLED : Do not generate an interrupt when CILD_SOT_MB_ERR is set. 1 = ENABLED: Generate an interrupt when CILD_SOT_MB_ERR is set.

Bit	Reset	Description
0	0x0	CILD_SOT_SB_ERR_INT_MASK: Interrupt Mask for CILD_SOT_SB_ERR. 0 = DISABLED : Do not generate an interrupt when CILD_SOT_SB_ERR is set. 1 = ENABLED: Generate an interrupt when CILD_SOT_SB_ERR is set.

26.16.52 CSI_CSI_CIL_D_STATUS_0

CSI Control and Interface Logic D Status

Offset: 0x276 | Byte Offset: 0x9d8 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
6	X	CILD_ESC_DATA_REC: Escape Mode Data Received, set when CIL-D receives an Escape Mode Data byte. The Data Byte can be read from bits 7-0 of ESCAPE_MODE_DATA. This status bit will also be cleared when CILD_ESC_CMD_REC is set.
5	X	CILD_ESC_CMD_REC: Escape Mode Command Received, set when CIL-D receives an Escape Mode Command byte. The Command Byte can be read from bits 7-0 of ESCAPE_MODE_COMMAND.
4	X	CILD_CTRL_ERR: Control Error, set when CIL-D detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning into the Escape mode or Turn Around mode (LP00).
2	X	CILD_SYNC_ESC_ERR: Sync Escape Error, set when CIL-D detects that the wrong (non-multiple of 8) number of bits have been received for an Escape Command, or Data Byte.
1	X	CILD_SOT_MB_ERR: Start of Transmission Multi Bit Error, set when CIL-D detects a multi bit start of transmission byte error in one of the packet's SOT bytes. The packet will be discarded.
0	X	CILD_SOT_SB_ERR: Start of Transmission Single Bit Error, set when CIL-D detects a single bit error in one of the packet's Start of Transmission bytes. The packet will be sent to the CSI-D for processing.

26.16.53 CSI_CSI_CILD_STATUS_0

CSI-CILD Control and Interface Logic Status

Each status bit is cleared to zero when its bit position is written with one. For example writing 0x2 to CSI_CIL_STATUS will clear only SOT_MB_ERR.

Offset: 0x277 | Read/Write: RO | Reset: 0x000X00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18	X	CILD_DATA_LANE1_CTRL_ERR: Control Error, set when CIL-D detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
17	X	CILD_DATA_LANE1_SOT_MB_ERR: Start of Transmission Multi Bit Error, set when CIL-D detects a multi bit start of transmission byte error in one of the packet's SOT bytes on data lane-1. The packet will be discarded.
16	X	CILD_DATA_LANE1_SOT_SB_ERR: Start of Transmission Single Bit Error, set when CIL-D detects a single bit error in one of the packet's Start of Transmission bytes on data lane-1. The packet will be sent to the CSI-D for processing.
6	X	CILD_DATA_LANE0_CTRL_ERR: Control Error, set when CIL-D detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
5	X	CILD_DATA_LANE0_SOT_MB_ERR: Start of Transmission Multi Bit Error, set when CIL-D detects a multi bit start of transmission byte error in one of the packet's SOT bytes on data lane-0. The packet will be discarded.
4	X	CILD_DATA_LANE0_SOT_SB_ERR: Start of Transmission Single Bit Error, set when CIL-D detects a single bit error in one of the packet's Start of Transmission bytes on data lane-0. The packet will be sent to the CSI-D for processing.
0	X	CILD_CLK_LANE_CTRL_ERR: Control Error, set when CIL-D detects incorrect line state sequence on clk lane

26.16.54 CSI_CIL_D_ESCAPE_MODE_COMMAND_0

Escape Mode Command

This register is used to receive escape mode command bytes from CIL-D.

Offset: 0x27b | Byte Offset: 0x9ec | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILD_ESC_CMD_BYTE: CIL-D Escape Mode Command Byte, this is the 8-bit entry command that was received, by CIL-D, during the last escape Mode sequence. CIL-D monitors Byte Lane 0, only, for escape mode sequences. This command byte can only be assumed to be valid when CILD_ESC_CMD_REC status bit is set.

26.16.55 CSI_CIL_D_ESCAPE_MODE_DATA_0

Escape Mode Data

This register is used to receive escape mode data bytes from CIL-D.

Offset: 0x27c | Byte Offset: 0x9f0 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILD_ESC_DATA_BYTE: CIL-D Escape Mode Data Byte, when read this field returns the last Escape Mode Data byte that was received by CIL-D. Escape Mode Data bytes are the bytes that are received in Escape Mode after receiving the Escape Mode Command. These bytes can be used to implement MIPI's CSI Specifications Low Power Data Transmission. This field is only valid when the status bit, CILD_ESC_DATA_REC, is set, and will be overwritten by the next Escape Mode data byte if not read before the next byte come in.

26.16.56 CSI_CSICIL_SW_SENSOR_D_RESET_0

Offset: 0x27d | Byte Offset: 0x9f4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CSICIL_SENSOR_D_RESET: Reset CSICIL sensor D

26.16.57 CSI_CILE_PAD_CONFIG0_0

CIL-E Pad Configuration 0

Offset: 0x282 | Byte Offset: 0xa08 | Read/Write: R/W | Reset: 0x00000005 (0b0000x000000000xx0xxxx000x00001x1)

Bit	Reset	Description
31	0x0	PAD_CILE_E_TXBW: Increase bandwidth of output driver
30:28	0x0	PAD_CILE_SLEWDNADJ: Pull down slew rate adjust, default 000. From 000 -> 011, slew rate increases. 100 is the same as 000. From 100->111, skew rate decreases.
26:24	0x0	PAD_CILE_SLEWUPADJ: Pull up slew rate adjust, default 000. From 000 -> 011, slew rate increases. 100 is the same as 000. From 100->111, skew rate decreases.
23:21	0x0	PAD_CILE_LPDNADJ: Driver pull down impedance control. 00 -> 130ohm, default. 01 -> 110ohm. 10 -> 130ohm, same as 00. 11 -> 150ohm
20:18	0x0	PAD_CILE_LPUPADJ: Driver pull up impedance control. 00 -> 130ohm, default. 01 -> 110ohm. 10 -> 130ohm, same as 00. 11 -> 150ohm
15	0x0	PAD_CILE_BANDWD_IN: Increase bandwidth of differential receiver
10:8	0x0	PAD_CILE_INADJ0: bit 0 input delay trimmer, each tap delays 20ps

Bit	Reset	Description
6:4	0x0	PAD_CILE_INADJCLK: Clock bit input delay trimmer, each tap delays 20ps
3	0x0	PAD_CILE_PDVCLAMP: Power down regulator which supplies current to serializer/deserializer logic
2	0x1	PAD_CILE_PDIO_CLK: Power down for clock bit, including drivers, receivers and contention detectors
0	0x1	PAD_CILE_PDIO: Power down for each data bit, including drivers, receivers and contention detectors

26.16.58 CSI_CILE_PAD_CONFIG1_0

CIL-B Pad Configuration 4

Offset: 0x283 | Byte Offset: 0xa0c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:6	0x0	PAD_CILE_PEMPD_CLK: Enable data bit HS driver pull down pre-emphasis, 00=no pre-emphasis, 11=max
5:4	0x0	PAD_CILE_PEMPU_CLK: Enable data bit HS driver pull up pre-emphasis, 00=no pre-emphasis, 11=max
3:2	0x0	PAD_CILE_PEMPD: Enable data bit HS driver pull down pre-emphasis, 00=no pre-emphasis, 11=max
1:0	0x0	PAD_CILE_PEMPU: Enable data bit HS driver pull up pre-emphasis, 00=no pre-emphasis, 11=max

26.16.59 CSI_PHY_CILE_CONTROL0_0

CSI-E PHY and CIL Control

Offset: 0x284 | Byte Offset: 0xa10 | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxxxxxxxx000000x0000010)

Bit	Reset	Description
13:8	0x0	CILE_CLK_SETTLE: settle time for clk lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many csicil clock cycles (72 MHz LP clock cycles) to wait after LP00. HW uses an internal delay of ~15 csicil cycles for default value. So the programming value (0 to 15) of this field works like this 0 = 15 cilclk cycles (default internal delay), 1 = 15 - 7 (8 cilclk cycles), 2 = 15 - 6 (9 cilclk cycles), . . 7 = 15 - 1 (14 cilclk cycles), 8 = 15 - 0 (default internal delay), 9 = 15 + 1 (16 cilclk cycles), . 57 = 15 + 49 (64 cilclk cycles)
6	0x0	CILE_BYPASS_LP_SEQ: The LP signals should sequence through LP11->LP01->LP00 state, to indicate to CLOCK CIL about the mode switching to HS Rx mode. In case Camera is enabled earlier than CIL , it is highly likely that camera sends this control sequence sooner than CIL can detect it. Enabling this bit allows the CLOCK CIL to overlook the LP control sequence and step in HS Rx mode directly looking at LP00 only.
5:0	0x2	CILE_THS_SETTLE: settle time for data lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many CSICIL clock cycles (102 MHz lp clock cycles) to wait, after LP00, before starting to look at the data. 0xF is an illegal value for this field 85ns + 6 * UI < (Ths-settle-programmed + 5) * csicil_clk_period < 145ns + 10 * UI

26.16.60 CSI_CSI_CIL_E_INTERRUPT_MASK_0

CSI Control and Interface Logic Interrupt Mask

Offset: 0x285 | Byte Offset: 0xa14 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0x0000x000)

Bit	Reset	Description
9	0x0	CILE_CLK_LANE_CTRL_ERR_INT_MASK: Interrupt Mask for CILE_CLK_CTRL_ERR. 0 = DISABLED : Do not generate an interrupt when CILE_CLK_CTRL_ERR is set. 1 = ENABLED: Generate an interrupt when CILE_CLK_CTRL_ERR is set.
7	0x0	CILE_SPARE_STATUS_1_INT_MASK: Interrupt Mask for CILE_SPARE_STATUS_1. 0 = DISABLED : Do not generate an interrupt when CILE_SPARE_STATUS_1 is set.

Bit	Reset	Description
		1 = ENABLED: Generate an interrupt when CILE_SPARE_STATUS_1 is set.
6	0x0	CILE_ESC_DATA_REC_INT_MASK: Interrupt Mask for CILE_ESC_DATA_REC. 0 = DISABLED : Do not generate an interrupt when CILE_ESC_DATA_REC is set. 1 = ENABLED: Generate an interrupt when CILE_ESC_DATA_REC is set.
5	0x0	CILE_ESC_CMD_REC_INT_MASK: Interrupt Mask for CILE_ESC_CMD_REC. 0 = DISABLED : Do not generate an interrupt when CILE_ESC_CMD_REC is set. 1 = ENABLED: Generate an interrupt when CILE_ESC_CMD_REC is set.

2	0x0	CILE_SYNC_ESC_ERR_INT_MASK: Interrupt Mask for CILE_SYNC_ESC_ERR. 0 = DISABLED : Do not generate an interrupt when CILE_SYNC_ESC_ERR is set. 1 = ENABLED: Generate an interrupt when CILE_SYNC_ESC_ERR is set.
1	0x0	CILE_SOT_MB_ERR_INT_MASK: Interrupt Mask for CILE_SOT_MB_ERR. 0 = DISABLED : Do not generate an interrupt when CILE_SOT_MB_ERR is set. 1 = ENABLED: Generate an interrupt when CILE_SOT_MB_ERR is set.
0	0x0	CILE_SOT_SB_ERR_INT_MASK: Interrupt Mask for CILE_SOT_SB_ERR. 0 = DISABLED : Do not generate an interrupt when CILE_SOT_SB_ERR is set. 1 = ENABLED: Generate an interrupt when CILE_SOT_SB_ERR is set.

26.16.61 CSI_CSI_CIL_E_STATUS_0

CSI Control and Interface Logic Status

These status bits are cleared to zero when its bit position is written with one. For example writing 0x1 to CSI_CIL_STATUS will clear only CILE_SOT_SB_ERR.

Offset: 0x286 | Byte Offset: 0xa18 | Read/Write: RO | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
8	X	CILE_CLK_LANE_CTRL_ERR: Control Error, set when CIL-E detects incorrect line state sequence on clk lane
6	X	CILE_ESC_DATA_REC: Escape Mode Data Received, set when CIL-E receives an Escape Mode Data byte. The Data Byte can be read from bits 7-0 of ESCAPE_MODE_DATA. This status bit will also be cleared when CILE_ESC_CMD_REC is set.
5	X	CILE_ESC_CMD_REC: Escape Mode Command Received, set when CIL-E receives an Escape Mode Command byte. The Command Byte can be read from bits 7-0 of ESCAPE_MODE_COMMAND.
4	X	CILE_CTRL_ERR: Control Error, set when CIL-E detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning into the Escape mode or Turn Around mode (LP00).
2	X	CILE_SYNC_ESC_ERR: Sync Escape Error, set when CIL-E detects that the wrong (non-multiple of 8) number of bits have been received for an Escape Command, or Data Byte.
1	X	CILE_SOT_MB_ERR: Start of Transmission Multi Bit Error, set when CIL-C detects a multi bit start of transmission byte error in one of the packet's SOT bytes. The packet will be discarded.
0	X	CILE_SOT_SB_ERR: Start of Transmission Single Bit Error, set when CIL-E detects a single bit error in one of the packet's Start of Transmission bytes. The packet will be sent to the CSI-C for processing.

26.16.62 CSI_CIL_E_ESCAPE_MODE_COMMAND_0

Escape Mode Command

This register is used to receive escape mode command bytes from CIL-E.

Offset: 0x287 | Byte Offset: 0xa1c | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILE_ESC_CMD_BYTE: CIL-E Escape Mode Command Byte, this is the 8 bit entry command that was received by CIL-E, during the last escape Mode sequence. CIL-E monitors Byte Lane 0, only, for escape mode sequences. This command byte can only be assumed to be valid when CILE_ESC_CMD_REC status bit is set.

26.16.63 CSI_CIL_E_ESCAPE_MODE_DATA_0

Escape Mode Data

This register is used to receive escape mode data bytes from CIL-E.

Offset: 0x288 | Byte Offset: 0xa20 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILE_ESC_DATA_BYTE: CIL-E Escape Mode Data Byte, when read this field returns the last Escape Mode Data byte that was received by CIL-E. Escape Mode Data bytes are the bytes that are received in Escape Mode after receiving the Escape Mode Command. These bytes can be used to implement MIPI's CSI Specs Low Power Data Transmission. This field is only valid when the status bit, CILE_ESC_DATA_REC, is set, and will be overwritten by the next Escape Mode data byte if not read before the next byte come in.

26.16.85 CSI_STALL_COUNTER_0

Offset: 0x2ba | Byte Offset: 0xae8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	STALL_SENSOR_B_COUNT
7:0	0x0	STALL_SENSOR_A_COUNT: Number of cycles to stall sensor A after every EOF

26.16.86 CSI_CSI_READONLY_STATUS_0

CSI Read Only Status

This register is used to return CSI read only status.

Offset: 0x2bb | Byte Offset: 0xaec | Read/Write: RO | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
1	X	CSI_PPB_ACTIVE: One only when Pixel Parser B is capturing frame data.
0	X	CSI_PPA_ACTIVE: One only when Pixel Parser A is capturing frame data.

26.16.87 CSI_CSI_SW_STATUS_RESET_0

Offset: 0x2bc | Byte Offset: 0xaf0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CSI_STATUS_RESET: Reset CSI status and dbgcnt registers

26.16.88 CSI_CLKEN_OVERRIDE_0

Second-level clock enable override register

This can override the 2nd level clock enables in case of malfunction. Only exposed to software when needed.

Offset: 0x2bd | Byte Offset: 0xaf4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxx00000xx00xxx00xxx00x00)

Bit	Reset	Description
21	CLK_GATED	CSI_CILE_CLKEN_OVR: 0 = CLK_GATED 1 = CLK_ALWAYS_ON
20	CLK_GATED	CSI_CILD_CLKEN_OVR: 0 = CLK_GATED 1 = CLK_ALWAYS_ON
19	CLK_GATED	CSI_CILC_CLKEN_OVR: 0 = CLK_GATED 1 = CLK_ALWAYS_ON
18	CLK_GATED	CSI_CILB_CLKEN_OVR: 0 = CLK_GATED 1 = CLK_ALWAYS_ON
17	CLK_GATED	CSI_CILA_CLKEN_OVR: 0 = CLK_GATED 1 = CLK_ALWAYS_ON
14	CLK_GATED	CSI_PPB_CLKEN_OVR: 0 = CLK_GATED 1 = CLK_ALWAYS_ON
13	CLK_GATED	CSI_PPA_CLKEN_OVR:

Bit	Reset	Description
		0 = CLK_GATED 1 = CLK_ALWAYS_ON
9	CLK_GATED	CSI_HPB_CLKEN_OVR: 0 = CLK_GATED 1 = CLK_ALWAYS_ON
8	CLK_GATED	CSI_HPA_CLKEN_OVR: 0 = CLK_GATED 1 = CLK_ALWAYS_ON
4	CLK_GATED	CSI_FB_CLKEN_OVR: 0 = CLK_GATED 1 = CLK_ALWAYS_ON
3	CLK_GATED	CSI_FA_CLKEN_OVR: 0 = CLK_GATED 1 = CLK_ALWAYS_ON
1	CLK_GATED	CSI_DBG_CLKEN_OVR: 0 = CLK_GATED 1 = CLK_ALWAYS_ON
0	CLK_GATED	CSI_CLKEN_OVR: 0 = CLK_GATED 1 = CLK_ALWAYS_ON

26.16.89 CSI_DEBUG_CONTROL_0

Debug Control

Offset: 0x2be | Byte Offset: 0xaf8 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	R/W	Reset	Description
31	RO	X	DBG_CNT_ROLLED_2: Set when dbg_cnt_2 is incremented past max count, cleared when clr_dbg_cnt_2 is written with a value of 1.
30:24	RW	X	DBG_CNT_SEL_2: Debug Count Select 2, this field selects what will be counted by debug counter 2. Encodings 00 to 31 select the set signal for one of the CSI_PIXEL_PARSER_STATUS register bits. In this case the select encoding of this field is the same as the bit position, in CSI_PIXEL_PARSER_STATUS, of the status bit whose set signal will be used to increment DBG_CNT_0. Encodings 32 to 63 select the set signal for one of the CSI_CIL_STATUS status bits. The least significant 5 bits of this select field give the bit position, in CSI_CIL_STATUS, of the status bit whose set signal pulses will be counted by dbg_cnt_0. Selections for encodings 64 to 127 are given below: 64 - PPA Line packets processed 65 - PPA short packets processed 66 - Total packets processed by PPA 67 - PPA Frame Starts Outputted 68 - PPA Frame Ends Outputted 69 - Reserved encoding 70 - PPB Line packets processed 71 - PPB short packets processed 72 - Total packets processed by PPB 73 - PPB Frame Starts Outputted 74 - PPB Frame Ends Outputted 75 - Reserved encoding 76 - HPA Headers Parsed 77 - HPA Headers Parsed with no ECC Errors 78 - HPB Headers Parsed 79 - HPB Headers Parsed with no ECC Errors 80 - HPV Headers Parsed 81 - HPV Headers Parsed with no ECC Errors 82 - HPH Headers Parsed 83 - HPH Headers Parsed with no ECC Errors 84 - 32 bit words read from vi2csi_host_data 85 to 127 - Reserved encodings
23	RO	X	DBG_CNT_ROLLED_1: Set when dbg_cnt_1 is incremented past max count, cleared when clr_dbg_cnt_1 is written with a value of 1.
22:16	RW	X	DBG_CNT_SEL_1: Debug Count Select 1, this field selects what will be counted by debug counter 1. Encodings 00 to 31 select the set signal for one of the CSI_PIXEL_PARSER_STATUS register bits. In this case the select encoding of this field is the same as the bit position, in CSI_PIXEL_PARSER_STATUS, of the status bit whose set signal will be used to increment DBG_CNT_0. Encodings 32 to 63 select the set signal for one of the CSI_CIL_STATUS status bits. The least significant 5 bits of this select field give the bit position, in CSI_CIL_STATUS, of the status bit whose set signal pulses will be counted by dbg_cnt_0. Selections for encodings 64 to 127 are given below: 64 - PPA Line packets processed 65 - PPA short packets processed 66 - Total packets processed by PPA 67 - PPA Frame Starts Outputted 68 - PPA Frame Ends Outputted 69 - Reserved encoding 70 - PPB Line packets processed 71 - PPB short packets processed 72 - Total packets processed by PPB 73 - PPB Frame Starts Outputted 74 - PPB

Bit	R/W	Reset	Description
			Frame Ends Outputted 75 - Reserved encoding 76 - HPA Headers Parsed 77 - HPA Headers Parsed with no ECC Errors 78 - HPB Headers Parsed 79 - HPB Headers Parsed with no ECC Errors 80 - HPV Headers Parsed 81 - HPV Headers Parsed with no ECC Errors 82 - HPH Headers Parsed 83 - HPH Headers Parsed with no ECC Errors 84 - 32 bit words read from vi2csi_host_data 85 to 127 - Reserved encodings
15	RO	X	DBG_CNT_ROLLED_0: Set when dbg_cnt_0 is incremented past max count, cleared when clr_dbg_cnt_0 is written with a value of 1.
14:8	RW	X	DBG_CNT_SEL_0: Debug Count Select 0, this field selects what will be counted by debug counter 0. Encodings 00 to 31 select the set signal for one of the CSI_PIXEL_PARSER_STATUS register bits. In this case the select encoding of this field is the same as the bit position, in CSI_PIXEL_PARSER_STATUS, of the status bit whose set signal will be used to increment DBG_CNT_0. Encodings 32 to 63 select the set signal for one of the CSI_CIL_STATUS status bits. The least significant 5 bits of this select field give the bit position, in CSI_CIL_STATUS, of the status bit whose set signal pulses will be counted by dbg_cnt_0. Selections for encodings 64 to 127 are given below: 64 - PPA Line packets processed 65 - PPA short packets processed 66 - Total packets processed by PPA 67 - PPA Frame Starts Outputted 68 - PPA Frame Ends Outputted 69 - Reserved encoding 70 - PPB Line packets processed 71 - PPB short packets processed 72 - Total packets processed by PPB 73 - PPB Frame Starts Outputted 74 - PPB Frame Ends Outputted 75 - Reserved encoding 76 - HPA Headers Parsed 77 - HPA Headers Parsed with no ECC Errors 78 - HPB Headers Parsed 79 - HPB Headers Parsed with no ECC Errors 80 - HPV Headers Parsed 81 - HPV Headers Parsed with no ECC Errors 82 - HPH Headers Parsed 83 - HPH Headers Parsed with no ECC Errors 84 - 32 bit words read from vi2csi_host_data 85 to 127 - Reserved encodings
7	RO	X	CLR_DBG_CNT_2: Clear Debug Counter 2, write a one to this bit to clear debug counter 2 and dbg_cnt_rolled_2.
6	RO	X	CLR_DBG_CNT_1: Clear Debug Counter 1, write a one to this bit to clear debug counter 1 and dbg_cnt_rolled_1.
5	RO	X	CLR_DBG_CNT_0: Clear Debug Counter 0, write a one to this bit to clear debug counter 0 and dbg_cnt_rolled_0.
2	RO	X	CSIB_DBG_SF: When CSI-B is operating in a "Header Not Sent mode", writing a 1 to this bit indicates start frame (SF) or end frame (EF) control code. After the pixel parser is enabled, writing a 1 to this bit will start frame capture and send start frame (SF) control code. Writing a 1 to this bit again will stop frame capture and send end frame (EF) control code. "Header Not Sent mode" can be used as a debug mode to capture what the sensor is sending without interpreting the packets. Writing a 1 to this bit continually will generate SF and EF control codes. Note that a wait for MISC_CSI_PPB_FRAME_END syncpt is needed between an EF trigger for the current frame and an SF trigger for the next frame.
1	RO	X	CSIA_DBG_SF: When CSI-A is operating in a "Header Not Sent mode", writing a 1 to this bit indicates start frame (SF) or end frame (EF) control code. After the pixel parser is enabled, writing a 1 to this bit will start frame capture and send start frame (SF) control code. Writing a 1 to this bit again will stop frame capture and send end frame (EF) control code. "Header Not Sent mode" can be used as a debug mode to capture what the sensor is sending without interpreting the packets. Writing a 1 to this bit continually will generate SF and EF control codes. Note that a wait for MISC_CSI_PPA_FRAME_END syncpt is needed between an EF trigger for the current frame and an SF trigger for the next frame.
0	RW	0x0	DEBUG_EN: Debug Enable Second level CSI Debug clock is enabled. Debug counters 2, 1 & 0 are powered up. 0 = DISABLED : Debug counters 2, 1 & 0 are powered down. Second level CSI Debug clock is disabled. 1 = ENABLED

26.16.90 CSI_DEBUG_COUNTER_0_0

Debug Counter 0

This register can be used to count error conditions or packets processed.

Offset: 0x2bf | Byte Offset: 0xafc | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DBG_CNT_0: When read returns the value of debug counter 0.

26.16.91 CSI_DEBUG_COUNTER_1_0

Debug Counter 1

This register can be used to count error conditions or packets processed.

Offset: 0x2c0 | Byte Offset: 0xb00 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DBG_CNT_1: When read returns the value of debug counter 1.

26.16.92 CSI_DEBUG_COUNTER_2_0

Debug Counter 2

This register can be used to count error conditions or packets processed.

Offset: 0x2c1 | Byte Offset: 0xb04 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DBG_CNT_2: When read returns the value of debug counter 2

[THIS PAGE INTENTIONALLY LEFT BLANK]

27.0 MIPI D-PHY CALIBRATION FOR CSI AND DSI

This section describes the MIPI D-PHY Calibration registers. This information is provided to aid in system debug and diagnostics. It is expected that NVIDIA® supplied drivers will normally be used to program these.

MIPI D-PHY blocks are used for both the DSI display interface and the CSI camera interface. Both interfaces are controlled by these registers.

27.1 MIPI-CAL Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

27.1.1 MIPI_CAL_MIPI_CAL_CTRL_0

Calibration Control Register

Offset: 0x0 | Read/Write: R/W | Reset: 0x2a000000 (0bxx101010xxxxxxxxxxxxxxxxxxxx0xx00)

Bit	R/W	Reset	Description
29:26	RW	0xa	MIPI_CAL_NOISE_FLT: The DRIVRY and TERMRY signals coming from MIPI pads are utilized by the Calibration state machine for pad calibration. The drivry/termry comes from a noisy analog source, which might have some glitches. The filter in calibsm is sensitive to these noises. If the calibration done status does not show up, the sensitivity of the filter can be changed through these bits. Ideally, this has to be programmed in a range from 10 to 15. When MIPI_CAL_PRESCALE = 2'b00, this needs to be programmed between 2 to 5.
25:24	RW	0x2	MIPI_CAL_PRESCALE: Auto-Cal calibration step prescale: 00: when calibration step is 0.1 µs 01: when calibration step is 0.5 µs 10: when calibration step is 1.0 µs (default) 11: when calibration step is 1.5 µs This keeps the MIPI bias calibration step between 0.1-1.5 µs.
4	RW	CLK_GATED	MIPI_CAL_CLKEN_OVR: 0 = CLK_GATED 1 = CLK_ALWAYS_ON
1	RW	0x0	MIPI_CAL_AUTOCAL_EN: When set, calibration is triggered periodically. The Period is set using MIPI_CAL_AUTOCAL_CTRL0 register
0	RO	0x0	MIPI_CAL_STARTCAL: Writing a one to this bit starts the Calibration State machine. This bit must be set even if both overrides are set in order to latch in the override value.

27.1.2 MIPI_CAL_MIPI_CAL_AUTOCAL_CTRL0_0

Offset: 0x4 | Read/Write: R/W | Reset: 0xffffffff (0b11111111111111111111111111111111)

Bit	Reset	Description
31:0	-1	MIPI_CAL_AUTOCAL_PERIOD: Auto-calibration period in number of APB sys clk cycles.

27.1.3 MIPI_CAL_CIL_MIPI_CAL_STATUS_0

CIL MIPI Calibrate Status

Offset: 0x8 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
29	X	MIPI_AUTO_CAL_DONE_DSIB: MIPI Auto Calibrate done for DSIB. Set when the auto calibrate sequence for DSI pad bricks is done. Write 1-to-clear.
28	X	MIPI_AUTO_CAL_DONE_DSIA: MIPI Auto Calibrate done for DSI. Set when the auto calibrate sequence for DSI pad bricks is done. Write 1-to-clear.
24	X	MIPI_AUTO_CAL_DONE_CSIE: MIPI Auto Calibrate done for CSI, set when the auto calibrate sequence for CSI pad bricks is done. Write 1-to-clear.
23	X	MIPI_AUTO_CAL_DONE_CSID: MIPI Auto Calibrate done for CSI. Set when the auto calibrate sequence for CSI pad bricks is done. Write 1-to-clear.
22	X	MIPI_AUTO_CAL_DONE_CSIC: Debug bit. MIPI Auto Calibrate done for CSI. Set when the auto calibrate sequence for CSI pad bricks is done. Write 1-to-clear.
21	X	MIPI_AUTO_CAL_DONE_CSIB: MIPI Auto Calibrate done for CSI. Set when the auto calibrate sequence for CSI pad bricks is done. Write 1-to-clear.
20	X	MIPI_AUTO_CAL_DONE_CSIA: MIPI Auto Calibrate done for CSI. Set when the auto calibrate sequence for CSI pad bricks is done. Write 1-to-clear.
16	X	MIPI_AUTO_CAL_DONE: MIPI Auto Calibrate done. Set when the auto-calibrate sequence for MIPI pad bricks is done. Write 1-to-clear.
15:12	X	MIPI_CAL_DRIV_DN_ADJ: Driver Pull-down calibration code generated by MIPI auto calibrate. Valid only after the auto-calibrate sequence has completed (MIPI_CAL_ACTIVE == 0).
11:8	X	MIPI_CAL_DRIV_UP_ADJ: Driver Pull up calibration code generated by MIPI auto calibrate. Valid only after auto calibrate sequence has completed (MIPI_CAL_ACTIVE == 0).
7:4	X	MIPI_CAL_TERMADJ: Termination code generated by MIPI auto calibrate. Valid only after the auto-calibrate sequence has completed (MIPI_CAL_ACTIVE == 0).
0	X	MIPI_CAL_ACTIVE: One when auto calibrate is active.

27.1.4 MIPI_CAL_CIL_MIPI_CAL_STATUS_2_0

MIPI CLK Calibration Status 2

Offset: 0xc | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
4	X	MIPI_CLK_AUTO_CAL_DONE_DSIB: MIPI CLK Auto Calibrate done for DSIB, set when the auto calibrate sequence for DSI pad bricks is done. Write 1-to-clear.
3	X	MIPI_CLK_AUTO_CAL_DONE_DSIA: MIPI CLK Auto Calibrate done for DSIA, set when the auto calibrate sequence for DSI pad bricks is done. Write 1-to-clear.
2	X	MIPI_CLK_AUTO_CAL_DONE_CSIE: MIPI CLK Auto Calibrate done for CSIE, set when the auto calibrate sequence for CSI pad bricks is done. Write 1-to-clear.
1	X	MIPI_CLK_AUTO_CAL_DONE_CSID: MIPI CLK Auto Calibrate done for CSID, set when the auto calibrate sequence for CSI pad bricks is done. Write 1-to-clear.
0	X	MIPI_CLK_AUTO_CAL_DONE_CSIC: MIPI CLK Auto Calibrate done for CSIC, set when the auto calibrate sequence for CSI pad bricks is done. Write 1-to-clear.

27.1.5 MIPI_CAL_CILA_MIPI_CAL_CONFIG_0

Calibration Settings for CIL-A MIPI Pads

Offset: 0x14 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxx100000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEA: When 0 (normal operation), use TERMOS/HSPUOS/HSPDOS as an offset to the Calibration State machine setting for channel A TERMADJ/HSPUADJ/HSPDADJ values to the MIPI pads. When 1, use the register values above as the actual value going to channel A TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads.
21	0x1	MIPI_CAL_SELA: Select the CSIA pads for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSA: 2's complement offset for HSPDADJ going to channel A (currently negative offsets are not supported)
12:8	0x0	MIPI_CAL_HSPUOSA: 2's complement offset for HSPUADJ going to channel A (currently negative offsets are not supported)
4:0	0x0	MIPI_CAL_TERMOSA: 2's complement offset for TERMADJ going to channel A (currently negative offsets are not supported)

27.1.6 MIPI_CAL_CILB_MIPI_CAL_CONFIG_0

Calibration Settings for CIL-B MIPI Pads

Offset: 0x18 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxx100000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEB: When 0 (normal operation), use TERMOS/HSPUOS/HSPDOS as an offset to the Calibration State machine setting for channel B TERMADJ/HSPUADJ/HSPDADJ values to the MIPI pads. When 1, use the register values above as the actual value going to channel B TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads. Writing a one to MIPI_CAL_STARTCAL starts the Calibration State machine.
21	0x1	MIPI_CAL_SELB: Select the CSIB pads for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSB: 2's complement offset for HSPDADJ going to channel B (currently negative offsets are not supported)
12:8	0x0	MIPI_CAL_HSPUOSB: 2's complement offset for HSPUADJ going to channel B (currently negative offsets are not supported)
4:0	0x0	MIPI_CAL_TERMOSB: 2's complement offset for TERMADJ going to channel B (currently negative offsets are not supported)

27.1.7 MIPI_CAL_CILC_MIPI_CAL_CONFIG_0

Calibration Settings for CIL-C MIPI Pads

Offset: 0x1c | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxx100000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEC: When 0 (normal operation), use TERMOS/HSPUOS/HSPDOS as an offset to the Calibration State machine setting for channel C TERMADJ/HSPUADJ/HSPDADJ values to the MIPI pads. When 1, use the register values above as the actual value going to channel C TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads. Writing a one to MIPI_CAL_STARTCAL starts the Calibration State machine.
21	0x1	MIPI_CAL_SELC: Select the CSIC pads for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSC: 2's complement offset for HSPDADJ going to channel C (currently negative offsets are not supported)

Bit	Reset	Description
12:8	0x0	MIPI_CAL_HSPUOSC: 2's complement offset for HSPUADJ going to channel C (currently negative offsets are not supported)
4:0	0x0	MIPI_CAL_TERMOSC: 2's complement offset for TERMADJ going to channel C (currently negative offsets are not supported)

27.1.8 MIPI_CAL_CILD_MIPI_CAL_CONFIG_0

Calibration Settings for CIL-D MIPI Pads

Offset: 0x20 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx100000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDED: When 0 (normal operation), use TERMOS/HSPUOS/HSPDOS as an offset to the Calibration State machine setting for channel D TERMADJ/HSPUADJ/HSPDADJ values to the MIPI pads. When 1, use the register values above as the actual value going to channel D TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads. Writing a one to MIPI_CAL_STARTCAL starts the Calibration State machine.
21	0x1	MIPI_CAL_SELD: Select the CSID PADS for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSD: 2's complement offset for HSPDADJ going to channel D (currently negative offsets are not supported)
12:8	0x0	MIPI_CAL_HSPUOSD: 2's complement offset for HSPUADJ going to channel D (currently negative offsets are not supported)
4:0	0x0	MIPI_CAL_TERMOSD: 2's complement offset for TERMADJ going to channel D (currently negative offsets are not supported)

27.1.9 MIPI_CAL_CILE_MIPI_CAL_CONFIG_0

Calibration Settings for CIL-E MIPI Pads

Offset: 0x24 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx100000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEE: When 0 (normal operation), use TERMOS/HSPUOS/HSPDOS as an offset to the Calibration State machine setting for channel E TERMADJ/HSPUADJ/HSPDADJ values to the MIPI pads. When 1, use the register values above as the actual value going to channel E TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads. Writing a one to MIPI_CAL_STARTCAL starts the Calibration State machine.
21	0x1	MIPI_CAL_SELE: Select the CSIE pads for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSE: 2's complement offset for HSPDADJ going to channel E (currently negative offsets are not supported)
12:8	0x0	MIPI_CAL_HSPUOSE: 2's complement offset for HSPUADJ going to channel E (currently negative offsets are not supported)
4:0	0x0	MIPI_CAL_TERMOSE: 2's complement offset for TERMADJ going to channel E (currently negative offsets are not supported)

27.1.10 MIPI_CAL_DSIA_MIPI_CAL_CONFIG_0

Calibration Settings for DSIA MIPI Pad

Offset: 0x38 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxx100000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEDSIA: When 0 (normal operation), use TERMOS/HSPUOS/HSPDOS as an offset to the Calibration State machine setting for TERMADJ/HSPUADJ/HSPDADJ values to the MIPI pads. When 1, use the register values above as the actual value going to TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads. Writing a one to MIPI_CAL_STARTCAL starts the Calibration State machine.
21	0x1	MIPI_CAL_SELDSIA: Select the DSI pads for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSDSIA: 2's complement offset for HSPDADJ (currently negative offsets are not supported)
12:8	0x0	MIPI_CAL_HSPUOSDSIA: 2's complement offset for HSPUADJ (currently negative offsets are not supported)
4:0	0x0	MIPI_CAL_TERMOSDSIA: 2's complement offset for TERMADJ (currently negative offsets are not supported)

27.1.11 MIPI_CAL_DSIB_MIPI_CAL_CONFIG_0

Calibration Settings for DSIB MIPI Pad

Offset: 0x3c | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxx100000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEDSIB: When 0 (normal operation), use TERMOS/HSPUOS/HSPDOS as an offset to the Calibration State machine setting for TERMADJ/HSPUADJ/HSPDADJ values to the MIPI pads. When 1, use the register values above as the actual value going to TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads. Writing a one to MIPI_CAL_STARTCAL starts the Calibration State machine.
21	0x1	MIPI_CAL_SELDSIB: Select the DSI pads for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSDSIB: 2's complement offset for HSPDADJ (currently negative offsets are not supported)
12:8	0x0	MIPI_CAL_HSPUOSDSIB: 2's complement offset for HSPUADJ (currently negative offsets are not supported)
4:0	0x0	MIPI_CAL_TERMOSDSIB: 2's complement offset for TERMADJ (currently negative offsets are not supported)

27.1.12 MIPI_CAL_MIPI_BIAS_PAD_CFG0_0

MIPI Bias Pad Configuration Register

Offset: 0x58 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	MIPI_BIAS_PAD_PDVCLAMP: 1=Power down regulator which supplies current to pre-driver logic.
0	0x0	MIPI_BIAS_PAD_E_VCLAMP_REF: 1=Enable VCLAMP reference voltage

27.1.13 MIPI_CAL_MIPI_BIAS_PAD_CFG1_0

MIPI Bias Pad Configuration Register

Offset: 0x5c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxx000xxxxx000xxxxx000xxxxx000)

Bit	Reset	Description
26:24	0x0	PAD_TEST_SEL: Controls which signal to be routed to TEST_OUT 000=VAUXP 001=RUP 010=RDN 011=VREG 1xx=TBD
18:16	0x0	PAD_DRIV_DN_REF: Adjust internal reference level for drive pull-down calibration
10:8	0x0	PAD_DRIV_UP_REF: Adjust internal reference level for drive pull-up calibration
2:0	0x0	PAD_TERM_REF: Adjust internal reference level for termination calibration

27.1.14 MIPI_CAL_MIPI_BIAS_PAD_CFG2_0

MIPI Bias Pad Configuration Register 2

Offset: 0x60 | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxxx00000000000x000x010)

Bit	Reset	Description
18:16	0x0	PAD_VCLAMP_LEVEL: VCLAMP level adjustment
15:8	0x0	PAD_SPARE: Spare bit for MIPI Bias Config
6:4	0x0	PAD_VAUXP_LEVEL: VAUXP level adjustment 00 = no adjustment, default 01 = 105% 10 = 110% 11 = 115% 100 = no adjustment 101 = 95% 110 = 90% 111 = 85%
2	0x0	PAD_E_TXBW: This bit should not be used. Set it to 0.
1	0x1	PAD_PDVREG: Power down voltage regulator, 1=power down
0	0x0	PAD_VBYPASS: Bypass bang gap voltage reference

27.1.15 MIPI_CAL_DSIA_MIPI_CAL_CONFIG_2_0

Calibration settings for DSIA pad Channel A

Offset: 0x64 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx1xxxxxxxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_CLKOVERIDEDSIA: When 0 (normal operation), use the above registers as an offset to the Calibration State machine setting for channel A HSCLKPUADJ/HSCLKPDADJ values to the MIPI Pads. When 1, use the register values above as the actual values going to channel A HSCLKPUADJ/HSCLKPDADJ on the MIPI Pads.
21	0x1	MIPI_CAL_CLKSELDSIA: Select the DSIA PAD Channel A for clock lane auto calibration.
12:8	0x0	MIPI_CAL_HSCLKPDOSDSIA: 2's complement offset for HSCLKPDADJ going to Channel B
4:0	0x0	MIPI_CAL_HSCLKPUOSDSIA: 2's complement offset for HSCLKPUADJ going to Channel A

27.1.16 MIPI_CAL_DSIB_MIPI_CAL_CONFIG_2_0

Calibration settings for DSIA pad Channel B

Offset: 0x68 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx1xxxxxxxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_CLKOVERIDEDSIB: When 0 (normal operation), use the above registers as an offset to the Calibration State machine setting for channel B HSCLKPUADJ/HSCLKPDADJ values to the MIPI Pads. When 1, use the register values above as the actual values going to channel B HSCLKPUADJ/HSCLKPDADJ on the MIPI Pads.
21	0x1	MIPI_CAL_CLKSELDSIB: Select the DSIA PAD Channel B for clock lane auto calibration.
12:8	0x0	MIPI_CAL_HSCLKPDOSDSIB: 2's complement offset for HSCLKPDADJ
4:0	0x0	MIPI_CAL_HSCLKPUOSDSIB: 2's complement offset for HSCLKPUADJ

27.1.17 MIPI_CAL_CILC_MIPI_CAL_CONFIG_2_0

Calibration settings for DSIB/CSICD pad

Offset: 0x6c | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx1xxxxxxxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_CLKOVERIDEC: When 0 (normal operation), use the above registers as an offset to the Calibration State machine setting for channel A HSCLKPUADJ/HSCLKPDADJ values to the MIPI Pads. When 1, use the register values above as the actual values going to channel A HSCLKPUADJ/HSCLKPDADJ on the MIPI Pads.
21	0x1	MIPI_CAL_CLKSELC: Select the DSIB PAD Channel A for clock lane auto calibration.
12:8	0x0	MIPI_CAL_HSCLKPDOSC: 2's complement offset for HSCLKPDADJ going to channel A
4:0	0x0	MIPI_CAL_HSCLKPUOSC: 2's complement offset for HSCLKPUADJ going to channel A

27.1.18 MIPI_CAL_CILD_MIPI_CAL_CONFIG_2_0

Calibration settings for DSIB/CSICD pad

Offset: 0x70 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx1xxxxxxxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_CLKOVERIDED: When 0 (normal operation), use the above registers as an offset to the Calibration State machine setting for channel B HSCLKPUADJ/HSCLKPDADJ values to the MIPI Pads. When 1, use the register values above as the actual values going to channel B HSCLKPUADJ/HSCLKPDADJ on the MIPI Pads.
21	0x1	MIPI_CAL_CLKSELD: Select the DSIB PAD Channel B for clock lane auto calibration.
12:8	0x0	MIPI_CAL_HSCLKPDOSD: 2's complement offset for HSCLKPDADJ going to channel B
4:0	0x0	MIPI_CAL_HSCLKPUOSD: 2's complement offset for HSCLKPUADJ going to channel B

27.1.19 MIPI_CAL_CSIE_MIPI_CAL_CONFIG_2_0

Calibration settings for CSIE MIPI pad

Offset: 0x74 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx1xxxxxxxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_CLKOVERIDEE: When 0 (normal operation), use the above registers as an offset to the

Bit	Reset	Description
		Calibration State machine setting for channel A HSCLKPUADJ/HSCLKPDADJ values to the MIPI Pads. When 1, use the register values above as the actual values going to channel A HSCLKPUADJ/HSCLKPDADJ on the MIPI Pads.
21	0x1	MIPI_CAL_CLKSELE: Select the CSIE PAD for clock lane auto calibration.
12:8	0x0	MIPI_CAL_HSCLKPDOSE: 2's complement offset for HSCLKPDADJ
4:0	0x0	MIPI_CAL_HSCLKPUOSE: 2's complement offset for HSCLKPUADJ

28.0 VIDEO INPUT (VI)

The Video Input 2 unit (VI2) receives data from the CSI unit and provides for its presentation to either system memory or the dedicated ISP execution resources. The VI2 provides for formatting RGB, YCbCr, and raw Bayer data in support of a number of user models. These models include single and multi-camera systems, which may use up to two image/video streams obtained from MIPI compliant CMOS sensor camera modules. In addition to packing of image data, several advanced use cases are supported with processing of the raw Bayer data. These user modes involve the capture of high-resolution still images while simultaneously maintaining a lower resolution preview or video capture through the ISP, and the capture of stereo video and still images.

This section also describes the VI registers; however, it is not intended to be a programming guide to VI, as it is expected that NVIDIA supplied drivers will always be used with it. However, the register interface is documented to aid with understanding those drivers.

28.1 Functionality

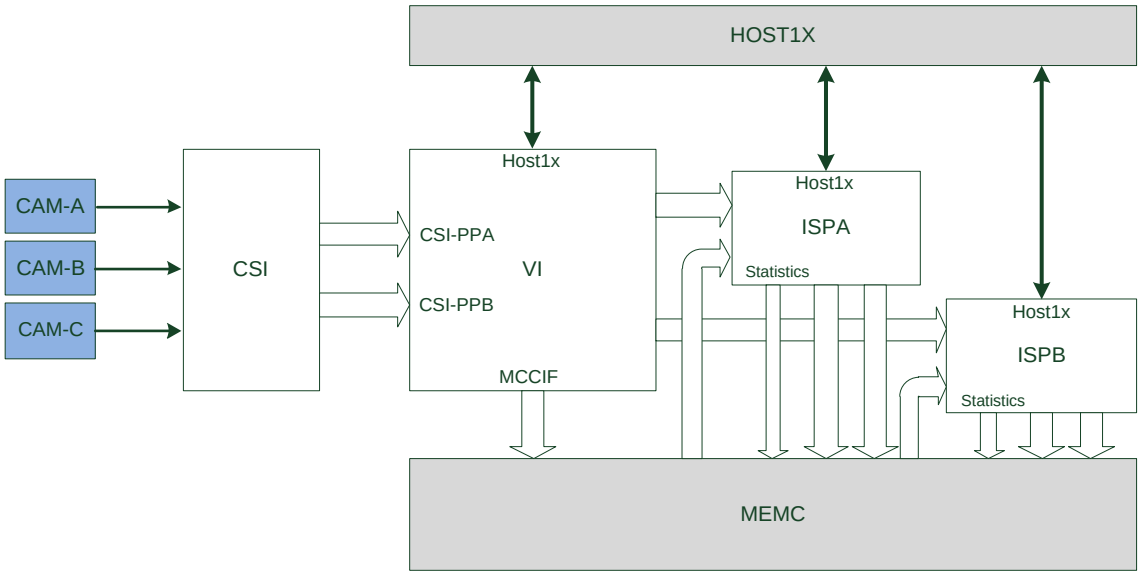
28.1.1 Camera Subsystem

The VI2 unit interfaces with four major functional units within the Tegra® K1 camera subsystem in addition to the Host1x, which is used for control programming:

- Camera Serial Interface (CSI) – Provides for the interface to MIPI compliant CMOS sensors and formats the pixel data for presentation to the VI2.
- Image Signal Processors A and B (ISPA and ISPB) – Execution resource providing image processing in support of various camera use cases and raw Bayer processing.
- Memory Controller (MC) – Interface between the VI2 and ISP and memory resources.

The main paths for the flow of image data for the VI2 are from the CSI → VI2 → ISPA/ISPB and from the CSI → VI2 → MC. There are also several additional paths for data flow within the camera's subsystem, which includes paths from the VI2 to MC and the MC to the ISP. The ability to present data to system memory allows customer-specific algorithms, such as blur reduction, chromatic aberration correction, and high ISO noise processing, to be inserted into the ISP pipeline. An added benefit is the ability to divide input data into more manageable widths when processing high-resolution still images. The high-level block diagram for the Tegra K1 camera subsystem is illustrated in the following figure.

Figure 93: Tegra K1 Camera Subsystem



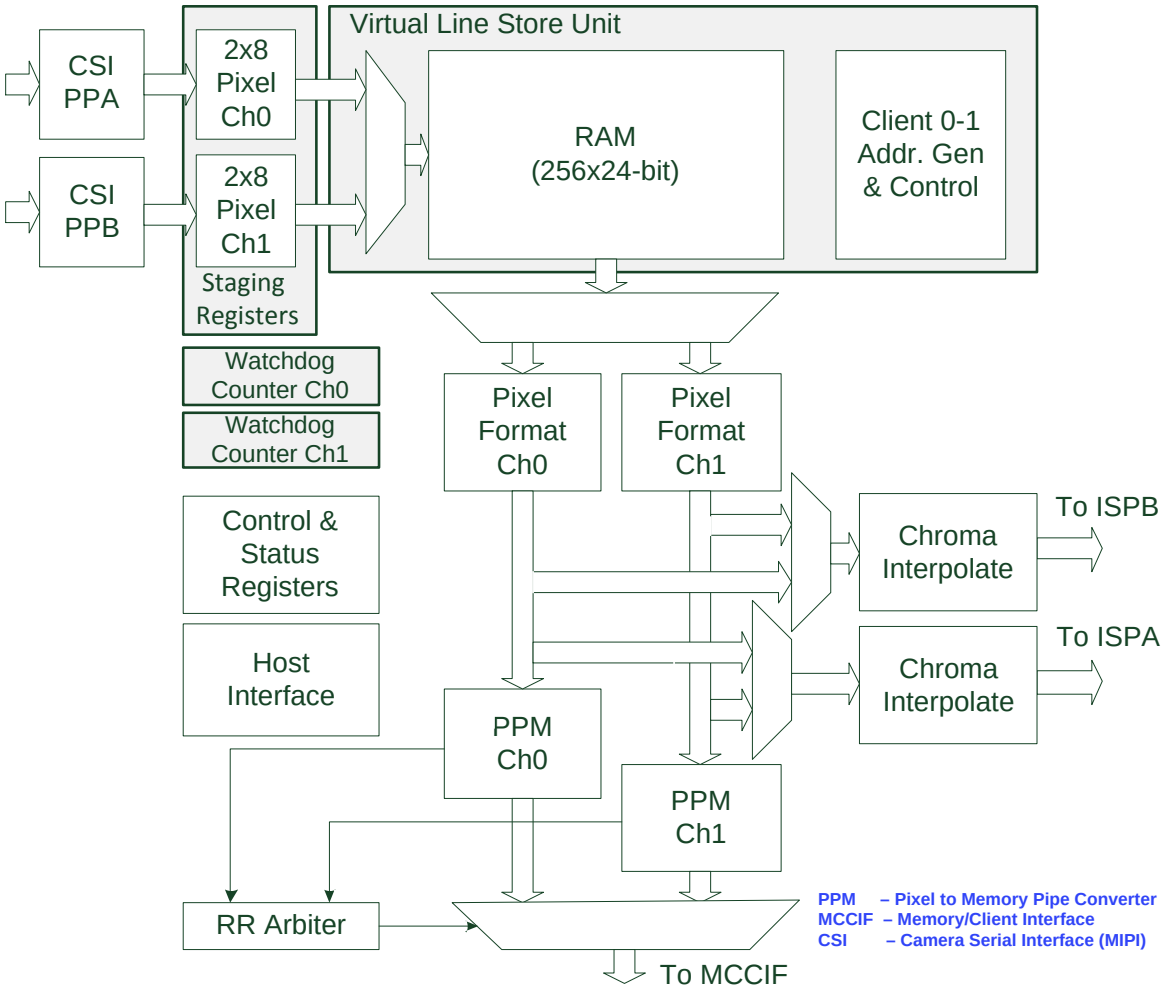
The support for multiple paths to and from memory within the camera subsystem is useful for very wide surfaces, such as still capture, where the alternative would be to have very large on-chip line stores. Because there are two ISP resources, two data streams from separate sensors or camera modules can be provided for immediate processing in support of dual and stereo camera capture models. In addition to the basic multi-camera user modes, the output path from the VI2 to memory allows the maintenance of a Zero Shutter Lag (ZSL) circular buffer for high-resolution capture while the ISP is processing the preview stream for display.

The Host1x interface handles the flow of the programmed control state. The CSI registers are in the VI2 unit and are accessed through the Host interface of the VI2. Refer to the CSI section in this document for more information.

28.1.2 Block Diagram

The VI2 unit accepts pixel data from an external source, packages the received data, and presents the data to either system memory or the ISP resources directly. The pixel data received can be in a variety of formats including Raw, RGB, and YCbCr. The high-level block diagram for the VI2 is shown in the following figure.

Figure 94: VI High-Level Block Diagram

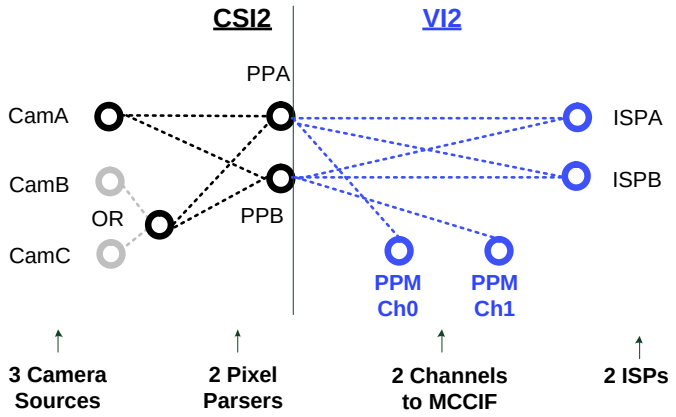


The VI2 provides a dual-stream capture mode in which two different resolution images are available to the system to support the various camera use cases. A high-resolution image can be captured and saved to memory while simultaneously presenting the image for processing through the ISP in support of scene preview and composition. The dual camera modes include support for stereo still and video capture, and the mixed format capture in support of video conference or scene annotation.

28.1.3 Single and Dual Stream Datapaths

The Tegra K1 camera subsystem provides considerable flexibility in the support of various single and dual camera user models. This flexibility is manifested as a number of programmable configurations that allow the image data to be directed to system memory and ISP execution resources. The datapaths for the camera subsystem are illustrated in the following figure.

Figure 95: Single and Dual Stream Datapaths through the CSI2 and VI2



The CSI2 unit provides for connection of up to three cameras in the system with the limitation that only two can be active simultaneously. The CSI2 can direct the data streams to either of the pixel parsers, PPA or PPB. In addition to supporting a dual stream capture from two sources, the CSI2 supports a broadcast mode in which a single camera data stream can be broadcast to both PPA and PPB simultaneously. In the broadcast mode the same data stream can be presented to the ISP or memory resources in a number of different ways. A summary of the various single camera configurations is provided in the following table.

Table 110: Datapath Options through VI2 for Single Camera User Models

Datapath Active for Single Camera Source	Comments
ISPA	Single stream capture through PPA or PPB
ISPB	Single stream capture through PPA or PPB
ISPA & ISPB	Single stream broadcast through both PPA and PPB
ISPA & ISPB & (PPM0 or PPM1)	Single stream broadcast through both PPA and PPB; single stream to MEM through PPM Channel 0 or PPM Channel 1.
ISPA & ISPB & PPM0 & PPM1	Single stream broadcast through both PPA and PPB; both ISPA and ISPB and both PPM Channel 0 and PPM Channel 1 active.
ISPA & (PPM0 or PPM1)	Single stream capture through PPA or PPB; single stream to MEM through PPM Ch0 or PPM Ch1.
ISPA & PPM0 & PPM1	Single stream broadcast through both PPA and PPB; PPM Ch0 and PPM Ch1 active.
ISPB & (PPM0 or PPM1)	Single stream capture through PPA or PPB; single stream to MEM through PPM Channel 0 or PPM Channel 1.
PPM0 or PPM1	Single stream capture through PPA or PPB; single stream to MEM through PPM Channel 0 or PPM Channel 1.
PPM0 & PPM1	Single stream broadcast through both PPA and PPB; both ISPA and ISPB and both PPM Channel 0 and PPM Channel 1 active.

The dual camera use cases have the limitation that CAMA is always active with either CAMB or CAMC. This limitation results because CAMB and CAMC share the same lane merging logic in the CSI allowing only one to be available at a time. The dual camera user models have a similar level of flexibility as the single camera except that variations due to a broadcast mode are not valid.

Table 111: Datapath Options through VI2 for Two Camera User Models

Datapaths Active for Dual Camera Sources		Comments
CAMA	CAMB or CAMC	
ISPA	ISPB	Dual Stream Capture through PPA and PPB
ISPB	ISPA	Dual Stream Capture through PPA and PPB
ISPA & (PPM0 or PPM1)	ISPB	Data streaming to memory through PPA is routed through PPM Channel 0 and if PPB it is routed thru PPM Channel 1.
ISPB & (PPM0 or PPM1)	ISPA	Data streaming to memory through PPA is routed through PPM Channel 0 and if PPB it is routed through PPM Channel 1.
ISPA	ISPB & (PPM0 or PPM1	Data streaming to memory through PPA is routed through PPM Channel 0 and if PPB it is routed through PPM Channel 1.
ISPB	ISPA & (PPM0 or PPM1)	Data streaming to memory through PPA is routed through PPM Channel 0 and if PPB it is routed through PPM Channel 1.
ISPA & (PPM0 or PPM1)	ISPB & (PPM0 or PPM1)	Data streaming to memory through PPA is routed through PPM Channel 0 and if PPB it is routed through PPM Channel 1.
ISPB & (PPM0 or PPM1)	ISPA & (PPM0 or PPM1)	Data streaming to memory through PPA is routed through PPM Channel 0 and if PPB it is routed through PPM Channel 1.

28.1.4 Host1x Interface

The Host1x interface is the primary method for communicating control state from the CPU to the VI2. It is responsible for the register write and read requests. The VI2 has total of two channels for Host1x interface. This provides flexibility to the software to simultaneously capture images from two cameras asynchronous to each other. A single channel is not bound to any camera and software can map any channel to any camera.

The Host1x interface of the VI2 is used to configure the registers for both VI2 and CSI units. The rest of the section also describes some of the CSI related logic.

The registers can be categorized in two categories: configuration registers and operational registers. The configuration registers should remain constant for the life of the camera operation (until the camera unit is re-enabled between application switching). The operational registers are required to process a given frame of image.

In order to process the images with minimum VBlank, the operational registers need to be double-buffered to speed up the transition between the operational parameters between the two frames.

28.1.4.1 State Updates

The operation registers are initially assembled in the assembly state. The registers are copied to the active state when the pipe is idle or immediately after startup. In all other cases, they are copied to the active state when the update command is received and when the next EOF is received. The following table describes the VI state update trigger.

Table 112: Single Shot Register Definition

Register	Field	Bits	Reset	Description
VI_CSI_[0..1]_SINGLE_SHOT	CAPTURE	0	0	Software sets this bit to request transition of the previously assembled assembly state to the active state and schedule single shot capture. The actual

Register	Field	Bits	Reset	Description
				update of the operational register is gated by the next EOF. Register read back returns the current capture status 0: No capture pending. 1: Capture pending
VI_CSI_[0..1]_SINGLE_SHOT_UPDATE	CAPTURE_GOOD_FRAME	0	1	This bit controls when the update command should be processed. 1'b0: Transition to update when the next EOF is received, irrespective of the state of previous frame. **Note1:** Useful for debugging and/or bring up when the sensor/VI configuration could be incorrect. 1'b1: Transition to next operational state when the next EOF is received AND the previous frame was the correct frame based on the current operational state. **Note2:** Any mismatch will result in the frame getting dropped and the CSI rearming with unchanged config. **Note3**: After exiting the reset state, the previous frame with the correct state should be set.

In the normal functional mode of operation, the EOF updates the pending assembly state to the active state only if the previous frame was successfully captured (or this is the first frame out of reset). If for any reason the previous frame was detected to be an errored frame, on the next SOF, the VI2 and CSI unit continue to work on the previous operational state configuration and do not update to the next set of operational parameters. An additional configuration register controls the behavior of VI2 unit.

28.1.4.2 Sync Points

Sync points (syncpts) are a means of synchronizing software programmed control state and hardware operations, without the need for register polling or interrupt service routines. Host1X contains a number of counters. These counters are referenced through an ***index***. Software can issue two kinds of syncpt-related methods:

- INCR_SYNCPT ***<condition> <index>***
- WAIT_SYNCPT ***<index> <threshold>***

INCR_SYNCPT tells the hardware that when ***<condition>*** is met, the hardware should send the value of ***<index>*** to the Host1X on the RtnIndx bus. On receiving the index return, Host1X will increment the counter pointed to by ***<index>***.

WAIT_SYNCPT is a Host1X method which tells Host1X to cease processing commands and register writes for that unit until the value of the counter pointed to by ***<index>*** reaches or exceeds the value of ***<threshold>***.

Since software can be made to wait for the counter to reach a certain value and hardware controls the incrementing of the counter, the two can be kept synchronized, ensuring that control state is metered out at the appropriate times by Host1X. In

order to support the single shot and shadow register behaviors, sync point conditions 0x03 thru 0x0F are buffered, allowing up to two sync points for each of these conditions to be programmed. The following table describes the VI2 sync point conditions.

Table 113: Sync Point Conditions

Condition	Value	FIFO Depth	Description
IMMEDIATE	0x00	1	Predefined Immediate condition. The VI2 returns this syncpt immediately.
OP_DONE	0x01	1	Predefined Operation Done Condition
RD_DONE	0x02	1	Predefined Read Done condition. The VI2 treats this as IMMEDIATE because CSI/VI do not have any read ports.
REG_WR_SAFE	0x03	2	Predefined Register Write Safe condition. Technically software should know when it is safe to write to the functional registers because it knows when CSI/VI is idle. The VI2 instead generates this syncpt when there are no pending captures and pending OP*_DONE syncpts have been sent to Host1x
VI_MWA_REQ_DONE	0x04	2	Predefined Operation Done for All Requests for a Frame condition. The VI2 generates this syncpt when all requests for a captured frame from the camera (PPA) to memory are completed.
VI_MWB_REQ_DONE	0x05	2	Predefined Operation Done for All Reqs for a Frame condition. The VI2 generates this syncpt when all requests for a captured frame from the camera (PPB) to memory are completed.
VI_MWA_ACK_DONE	0x06	2	Predefined Operation Done for all WrAcks for a Frame condition. The VI2 generates this syncpt when all WrAcks for a captured frame from the camera (PPA) to memory are received.
VI_MWB_ACK_DONE	0x07	2	Predefined Operation Done for all WrAcks for a Frame condition. The VI2 generates this syncpt when all WrAcks for a captured frame from the camera (PPB) to memory are received.
VI_ISPA_DONE	0x08	2	Predefined Operation Done condition. The VI2 generates this syncpt when it finishes sending a frame from the configured camera to ISPA
VI_CSI_PPA_FRAME_START	0x09	2	Valid SOF has been received by the camera (PPA) input. This SOF is detected at the VI2 input.
VI_CSI_PPB_FRAME_START	0x0A	2	Valid SOF has been received by the camera (PPB) input. This SOF is detected at the VI input.
VI_CSI_PPA_LINE_START	0x0B	2	Received an SOL indication on the camera (PPA) input stream. This SOL is detected at the VI2 input.
VI_CSI_PPB_LINE_START	0x0C	2	Received an SOL indication on the camera (PPB) input stream. This SOL is detected at the VI2 input.
VI_VGP0_RECD	0x0D	2	Rising edge detection on VGPx (VGPx being selected by a configuration register)
VI_VGP1_RECD	0x0E	2	Rising edge detection on VGPy (VGPy being selected by a configuration register)
VI_ISPB_DONE	0x0F	2	Predefined Operation Done condition.

Condition	Value	FIFO Depth	Description
			The VI2 generates this syncpt when it finishes sending a frame from the configured camera to ISPB
VI_PPA_TSC_MW_DONE	0x18	-	Reserved
VI_PPB_TSC_MW_DONE	0x19	-	Reserved
<reserved>	0x1A-0xFF	-	Reserved

28.1.4.3 Implementation Details of Configuration Registers

When the Host1x writes to any of the functional mode registers, the configuration value is immediately visible. So the software should write to such registers when the CSI/VI2 pipeline is idle. Software has visibility when the CSI/VI2 units are idle because it is not waiting for any syncpts.

When the VI2 unit receives the SOF from the CSI unit, it raises the syncpt corresponding to SOF_RECD on the appropriate syncpt index. This indicates to the software that the CSI and VI2 units are currently capturing a frame. At this time, software sends out the operational parameters for the next frame. These register writes are written to the shadow register. After the shadow register writes are complete, software indicates that the shadow registers update is done by writing to the VI_CSI_[0..1]_SINGLE_SHOT_CAPTURE register. After the single shot capture trigger is set, all shadow copies are now programmed and the VI2 will wait for the next EOF for transferring the active copy. When it receives the EOF and the previous frame is error free and correct, it updates the active registers from the shadow copy.

The VI2 marks all writes to memory as writes with ACK required. It also maintains a counter to keep track of number of writes outstanding. When the EOF is received from the CSI and there are no WrAcks pending, the VI2 generates the MWA_REQ_DONE or MWB_REQ_DONE syncpt to Host1x. Software uses this syncpt to pass this memory buffer to the next unit which will process the frame. In case the VI2 is configured to send the frame to ISP, it raises the syncpt ISPA_DONE when the EOF is sent. Depending on the configuration of HOST1X_UPDATE register configuration, these syncpts are either raised when the frame is known to be good or when any frame is sent to memory/ISP.

28.1.4.4 Error Status and Interrupts

This section discusses the reporting of various error conditions that can occur with the VI2 during the operation of the camera subsystem. The VI_CSI_[0..1]_ERROR_STATUS and VI_CSI_[0..1]_ERROR_INT_MASK functional registers are expected to be active for the camera use session. The remaining VI2 functional registers are described in the following table.

The VI_CSI_[0..1]_ERROR STATUS is a read-only register that indicates whether an error has occurred. All of the conditions defined in this register can be programmed to generate an interrupt using the VI_CSI_[0..1]_ERROR_INT_MASK as described in the following table.

Table 114: VI Error Status and Interrupt Mask Registers Functional Register Definitions

Register	Field	Bits	Reset Value	Description
VI_CSI_[0..1]_ERROR_STATUS	LINE_WIDTH_SHORT_ERROR:	0	X	Flagged if the frame line width is smaller than WIDTH. Write 1 to clear.
	LINE_WIDTH_LONG_ERROR:	1	X	Flagged if the frame line width is larger than WIDTH. Write 1 to clear
	FRAME_HEIGHT_SHORT_ERROR	2	X	Flagged if the frame height is smaller than HEIGHT. Write 1 to clear

Register	Field	Bits	Reset Value	Description
	FRAME_HEIGHT_LONG_ERROR	3	X	Flagged if the frame height is larger than HEIGHT. Write 1 to clear
	CSI_FRAME_ERROR	4	X	Flagged if the EOF field from the CSI has FRAME_ERROR bit set
	WATCHDOG_INT	5	X	This event occurs when Watchdog timer expires and the EOF is not received on the CSI2VI interface
VI_CSI_[0..1]_ERROR_INT_MASK	LINE_WIDTH_SHORT_INT_MASK	0	0x0	Line width short error interrupt mask
	LINE_WIDTH_LONG_INT_MASK	1	0x0	Line width long error interrupt mask
	FRAME_HEIGHT_SHORT_INT_MASK	2	0x0	Frame height short error interrupt mask
	FRAME_HEIGHT_LONG_INT_MASK	3	0x0	Frame height long error interrupt mask
	CSI_FRAME_ERROR_INT_MASK	4	0x0	CSI error interrupt mask
	WATCHDOG_INT_MASK:	5		Watchdog Timer 0 Interrupt Mask. This controls interrupts when a Watchdog trigger event occurs for the CSI stream. 0 = Disabled 1 = Enabled

28.1.4.5 Watchdog Counter

To detect catastrophic error conditions in which the CSI2 or VI2 has ceased operating, there are two Watchdog timers provided with the VI2 unit. The two WD timers are associated with the two image data streams being presented to the VI2 through the CSI PPA and PPB ports. Once the WD timer is configured for an image data stream, the timer must be prevented from expiring by the hardware. If the hardware does not disable the timer before the count expires, an interrupt is generated.

The WD timer counter is initialized to the value in the PERIOD register on the arrival of the SOF packet at the CSI to the VI interface for the active stream. The counter then proceeds to count down one count for every pixel clock. If the count reaches zero, with the WATCHDOG_INT_MASK bit set in the VI_CSI_[0..1]_ERROR_INT_MASK register, an interrupt is generated.

If an EOF packet is received at the CSI0 or CSI1 port, the countdown is stopped. In normal operation, this prevents the counter from reaching zero and generating an interrupt.

The ISP also provides a WD timer system.

28.1.5 Programming Sequences

The programming of the VI2 to initiate data capture involves setting up the image sensor, the CSI2 unit, the VI2 unit, and the ISP unit if the data is targeted for processing by the ISP. There are several different modes of image capture supported by the camera subsystem including progressive frame capture, interlaced frame capture, and interleaved frame capture. The capture modes may be set up as either single or dual stream to support the various user models, with the exception of the interleaved still capture. In the interleaved capture mode, both streams are assumed to be active.

28.1.5.1 Basic Progressive Frame Capture Sequence

The basic progressive frame capture programming sequence supports a number of user models involving both single and dual stream image captures. The basic sequence for the progressive capture is as follows:

1. Program the sensor or sensors in the dual stream use case.
2. Program the CSI and VI with parameters that do not change every frame.
3. Program Frame #1 specific parameters for the CSI and VI.
4. Enable CSI pixel parsers after completing PPA and/or PPB setup.
5. Arm the syncpt.
6. Trigger single shot by setting CAPTURE in the VI_CSI_[0..1]_SINGLE_SHOT register

   If (Outstanding capture requests == 1)

   Wait for SOF

   Else if (Outstanding capture requests > 1)

   Wait for MW_REQ_DONE
7. Program Frame #2 specific parameters for CSI and VI.
8. Repeat from step 5 for the next frames.

28.1.5.2 Basic Interlaced Frame Capture Sequence

The interlaced capture programming sequence is similar to the basic progressive capture sequence. However, since the interlaced capture results in the capture of a top and bottom field pair for each frame, there are some differences in how the hardware manages the syncpt generation and the single shot generation. Because the frame capture consists of a frame pair, both the syncpt and single shot are also managed based on frame pairs. The basic sequence for the interlaced capture is as follows:

1. Program the sensor or sensors in dual stream use case
2. Program the CSI and VI with parameters that do not change every frame.
3. Program Frame #1 Top/Bottom Field specific parameters for the CSI and VI.
4. Program the CSI TOP_FIELD_FRAME and TOP_FIELD_FRAME_MASK
5. Enable CSI Pixel Parser after completing the PPA and/or PPB setup
6. Arm syncpts for the field pair capture
7. Trigger single shot by setting CAPTURE in the VI_CSI_[0..1]_SINGLE_SHOT register

   If (Outstanding capture requests == 1)

   Wait for PP[A..B]_ FRAME_START

   Else if (Outstanding capture requests > 1)

   Wait for MW_REQ_DONE
8. Program Frame #2 specific parameters for CSI and VI.
9. Repeat from step 6 for next frames.

Step 4 is unique to the interlaced capture and is necessary for generating the top/bottom field signaling for the VI2. This signaling manages the data flow to memory and handling of field drop error conditions. The SOF syncpt is generated only when a top field is signaled on the CSI to VI interface, and the MW_REQ_DONE syncpt is generated only after a top and bottom field are paired and written to memory. The VI2 generates a single shot trigger for the top and bottom field when the

interlaced mode is enabled. In addition, the VI2 provides for a frame-dropping mechanism which automatically re-issues a single shot to capture another field if a frame is dropped.

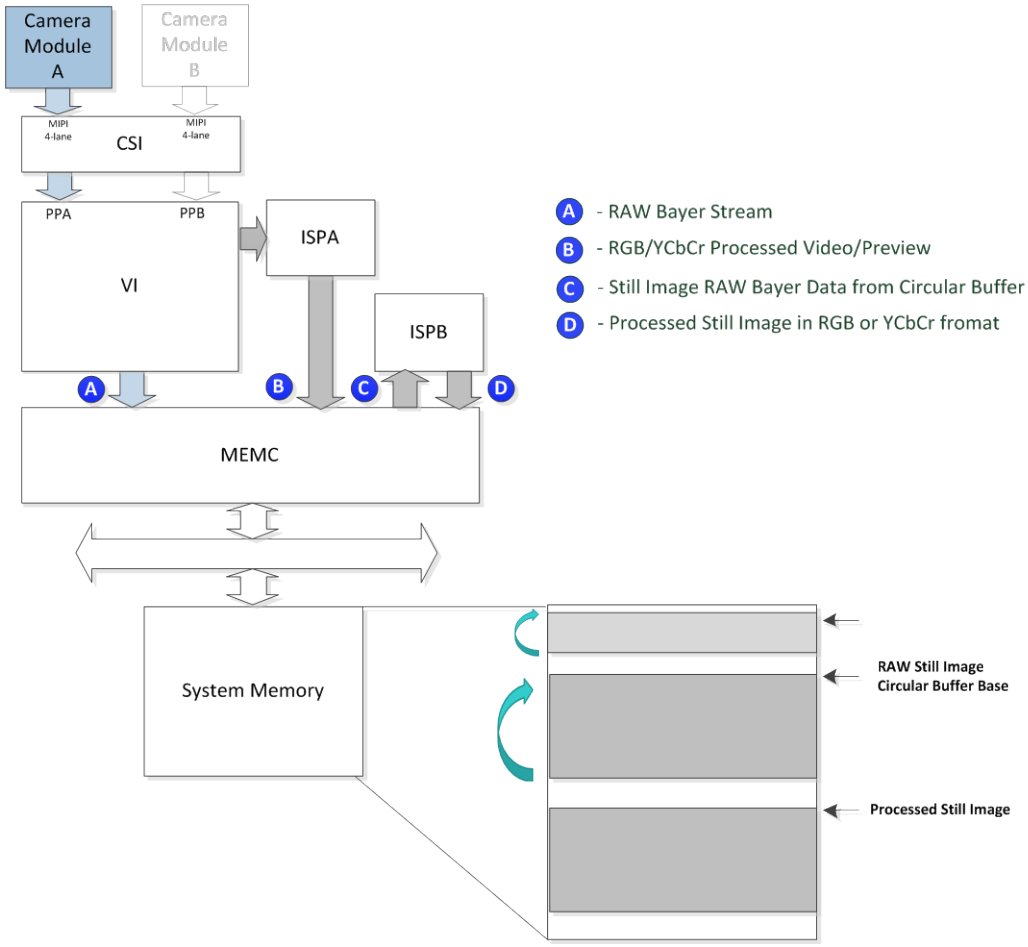
28.1.6 Frame Capture Modes

There are several frame capture scenarios available within the camera subsystem, which utilize various resources within the VI2. The modes include scene preview or simple progressive video capture, multi camera progressive or interlaced video capture, high-resolution still capture, high-resolution zero shutter lag still capture, and an 8-lane interleaved capture.

28.1.7 High Resolution and ZSL Still Image Capture

The high resolution and ZSL still capture models utilize the VI2 resources for providing a path to system memory for Raw Bayer image data while simultaneously maintaining an image data stream to the ISP(s) for preview. The following figure shows the active data paths during mono ZSL capture mode.

Figure 96: Zero Shutter Lag Mode

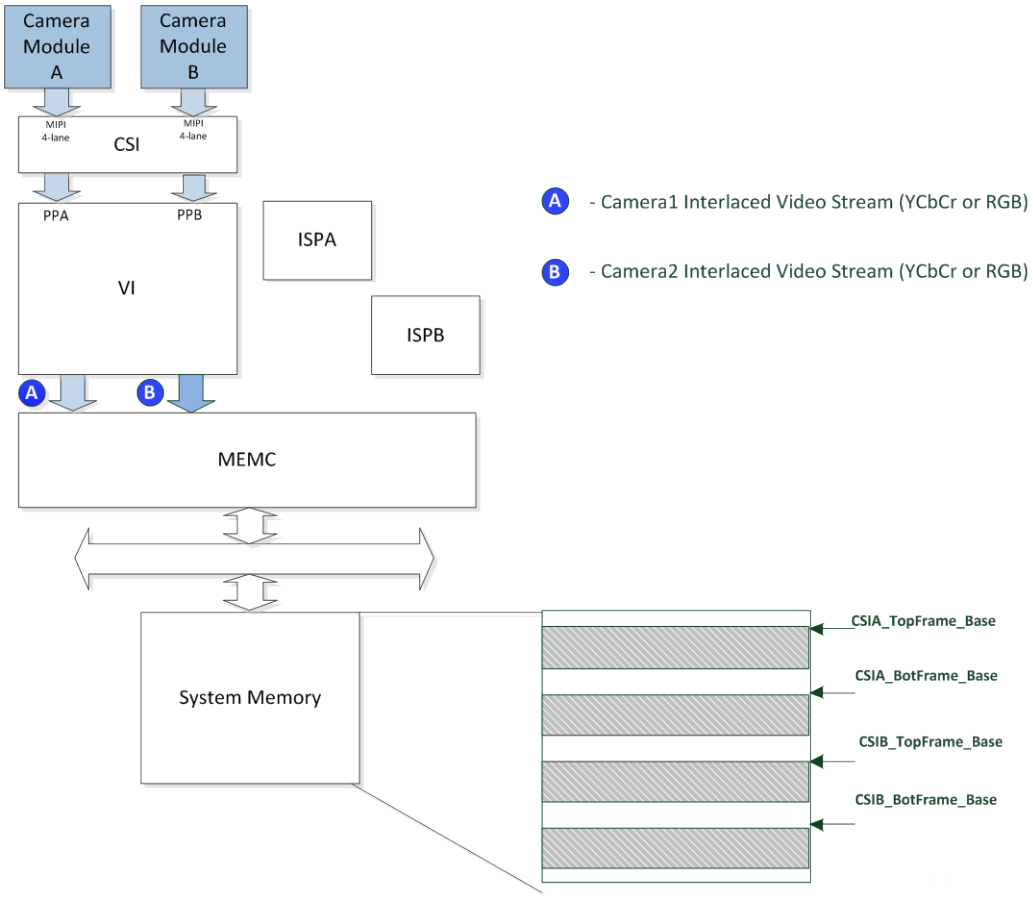


28.1.8 Interlaced Video Capture

The interlaced capture model provides for the management of interlaced video from an external camera module. The interleaved image data is presented to the CSI in a sequence of odd and even frames which represent the top and bottom fields in the interleaved composite frame. Since the interleaved image frames are not targeting raw Bayer processing by the ISP, the data formats are limited to either be RGB or YCbCr. The VI2 capture of interlaced video allows up to two camera

pixel streams and associated channel pointers frame pointers to be managed simultaneously. The interlaced video capture mode is shown in the following figure.

Figure 97: Interlaced Capture Mode



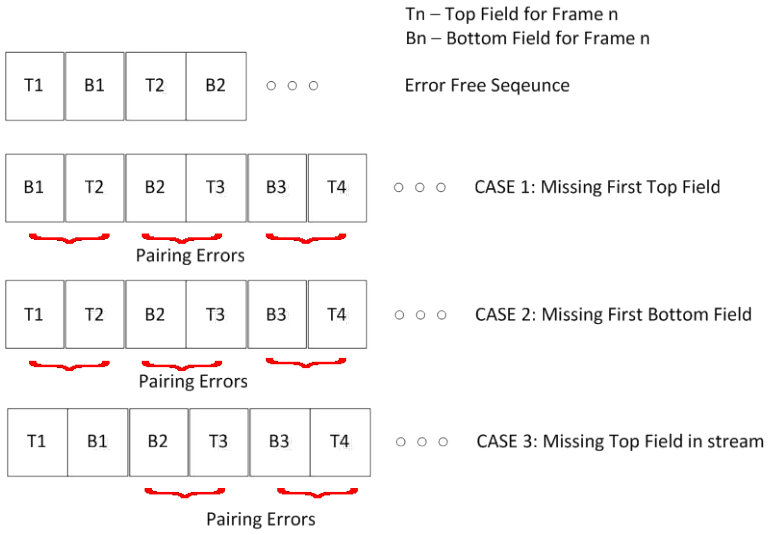
Twelve (12) pointers are available for managing the interleaved image streams. Three are available for the top field and three are available for the bottom fields for each of the two streams. All three pointers are used for each stream when the data is YCbCr422 and the target is planar, otherwise either two or only one are needed for semi-planar and non-planar formats, respectively.

The CSI unit signals the VI2 when a frame is either the top or bottom field by setting or clearing the LSB on the CSI[A,B]2VI_DATA bus when the SOF is being sent. The VI2 uses the signaling to provide for switching between the top and bottom field source and stride registers setting used for the address calculations. The signals are managed through the CSI by programming the CSI_PPA_TOP_FIELD_FRAME_MASK and CSI_PPA_TOP_FIELD_FRAME parameters. The actual frame number used in the associated calculation is taken from the WC field of the Frame Start short packet.

28.1.8.1 Interlaced Capture Error Handling

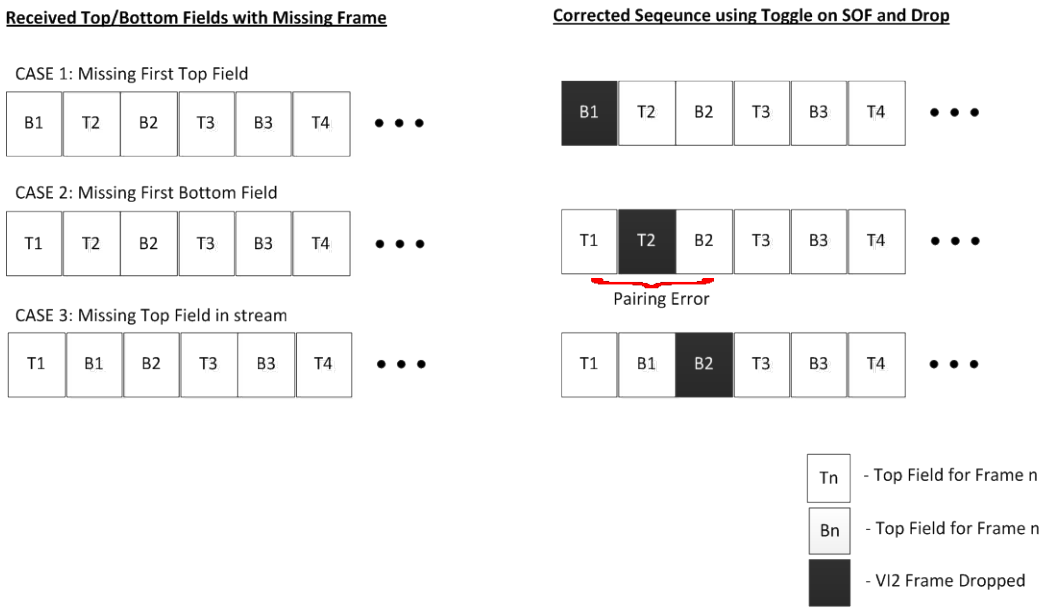
The interlaced capture generates two frames of data, one for the top field and one for the bottom field. It is important that the pairing of the frames in the top and bottom field buffers is accurate since any mismatch could result in artifacts that could propagate as errors in future frames captured in the video sequence. The issue is manifested with the occurrence of dropped frames either at the camera module or in the CSI2. If a frame is lost, several pairing errors are possible.

Figure 98: Interleaved Field Pairing Errors due to Dropped Frames



In order to manage the dropped frame event, a flag is maintained in hardware that toggles on every SOF received from the CSI while in interlaced video mode. This indicates whether the frame is even or odd. The VI2 also compares the state of the TOP field bit during the SOF. If the flag is odd and the top field bit is not set, the received field is then dropped. In a similar fashion, a missing bottom field results in a top field being dropped. The toggle and drop correction are illustrated in the following figure.

Figure 99: Error Correction for Interlaced Capture



The loss of a bottom field results in a single pairing error but is not propagated into the following field pair. It is considered to be an acceptable error tradeoff.

28.1.8.2 Interlaced Single Shot and Sync Points

The programming sequence for the interlaced capture is basically the same as for the progressive capture. The primary difference between the two modes is that the interlaced mode operates on the concept of top and field pairs. The VI2 manages the frame single shot trigger and EOF events based on the successful pairing of top and bottom fields.

The VI_CSI_[0..1]_SINGLE_SHOT is programmed once for each top and bottom field pair in the interlaced mode of frame capture and hardware manages the generation of a single shot trigger for both the top and bottom field capture. In the event that a top field is not signaled by the CSI following the issue of the single shot capture, the frame is dropped and the single shot is re-issued until a top field is indicated. Once a top field has been successfully captured and an EOF received, the VI2 then issues a single shot capture for the bottom field. In a similar fashion with a missing top field first, the single shot is re-issued if a bottom filed is not signaled after the top field was successfully captured.

Sync points are also managed in a field pair fashion making it necessary to arm a sync point once for the frame event. For example, the VI_CSI_PP[A..B]_FRAME_START sync points are only returned on a successful start of a top field capture and similarly the VI_MW[A..B]_REQ_DONE sync points are only returned after the successful completion of a bottom field capture in a top/bottom field pair.

28.1.9 Stereo Still and Video Capture

The stereo still and video capture modes can utilize ISPA and ISPB to process the left and right camera streams simultaneously in support of preview, video capture, and the combination of preview and high-resolution still processing. The stereo capture models should be managed carefully to achieve maximum throughput and minimize system loading. The stereo capture modes are listed in the following table.

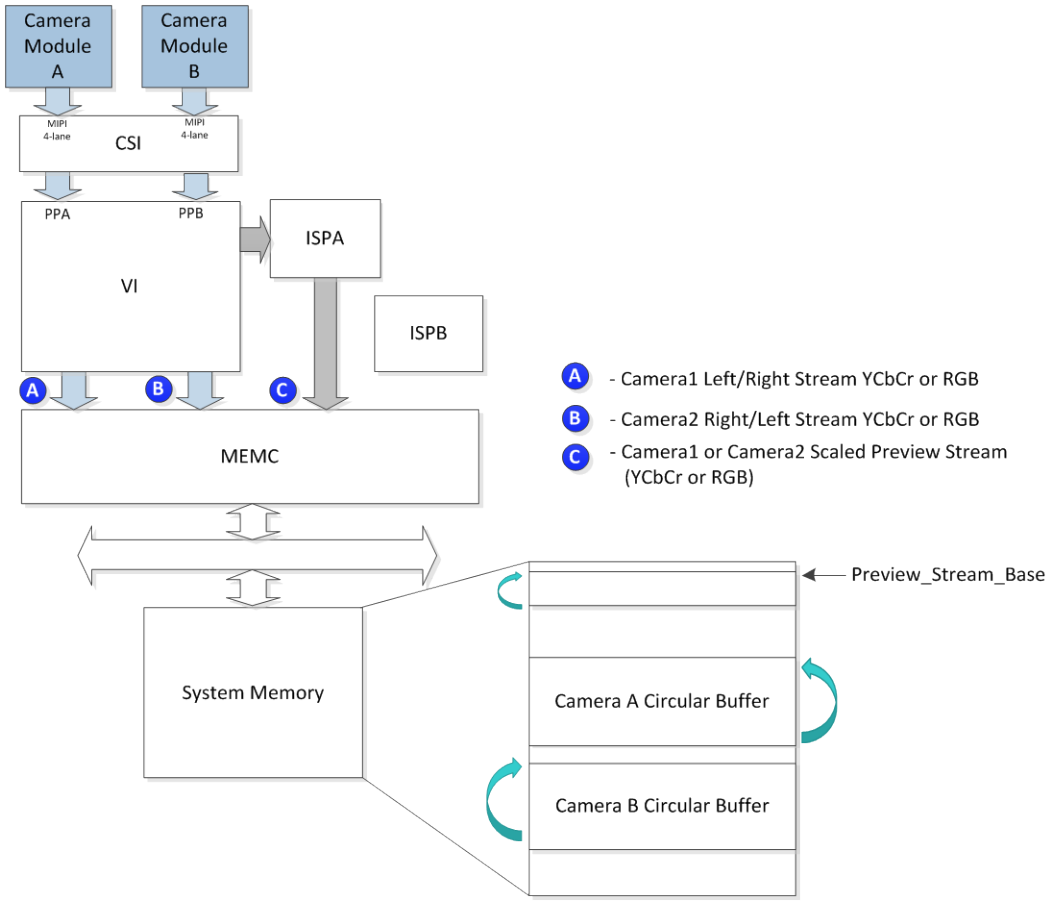
Table 115: Stereo Image/Video Capture Modes

Stereo Mode	Data Type	
Stereo Preview	YUV/RGB/RAW	Both Streams Active; ISPA or ISPB may be used for preview management; Should provide L/R preview switching; Raw data can be processed through the ISP or YUV. RGB data may be enhanced or delivered to memory through the MCCIF.
Stereo Preview for ZSL Still	YUV/RGB	Both Streams Active; ISPA or ISPB may be used for preview management; Should provide L/R preview switching; High resolution stills are delivered to the circular buffer in system memory through the MCCIF
	RAW	Both Streams Active; ISPA or ISPB used for Raw processing of one stream. Should provide L/R preview switching. High resolution Raw stills are delivered to the circular buffer in system memory through the MCCIF. During capture, the idle ISP may be used for processing so that preview can be continuous using the other ISP.
Stereo Preview + Video Capture	YUV/RGB/RAW	Both Streams Active; ISPA or ISPB may be used for preview management. Should provide L/R preview switching. Raw data may be processed through the ISP or YUV. RGB data may be enhanced or delivered to memory through the MCCIF.

There are three basic modes of operation when engaging the stereo capture user model: the preview of the image data for scene composition, the capture of a high resolution stereo pairs, and the capture of stereo video.

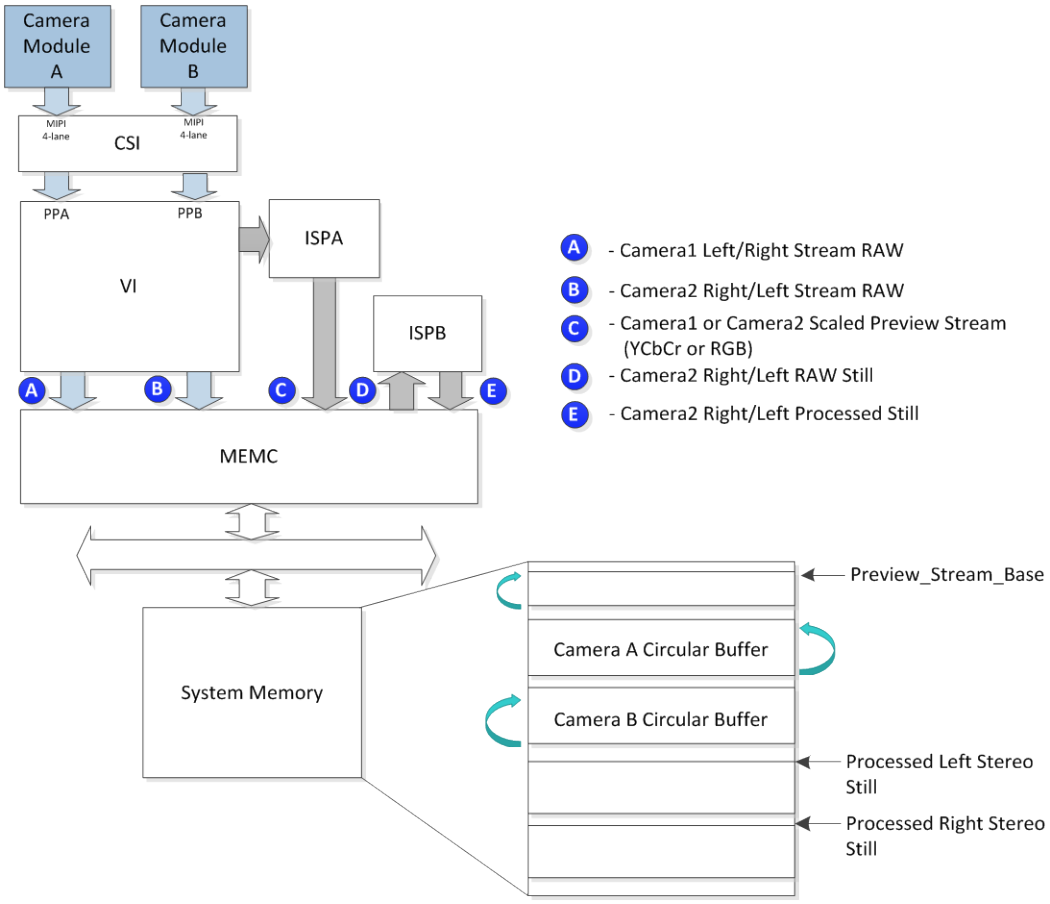
The still and video capture models for YUV or RGB processed data from the camera module may utilize the ISPA or ISPB resource as a scaling and image enhancement engine by providing the image data from either the left or right camera directly to the ISP. In most cases, the capture of processed data in a YUV or RGB format will be written directed to memory where it can be accessed by various resources in the system. The requirement for different resolutions for LCD display and the frame capture makes this option attractive since it can help to minimize memory traffic. A ZSL stereo capture sequence where both high-resolution streams are being stored in separate circular buffers for the left and right channels is illustrated in the following figure.

Figure 100: Zero Shutter Stereo Capture for YUV or RGB Image Data



The still and video capture models for Raw data utilize both ISPA and ISPB simultaneously under most conditions. During the stereo video capture, the image streams being captured by the left and right camera modules can each be assigned to either ISPA or ISPB, allowing a preview to be extracted from either processed stream with the stereo video being available to the compression resources. The ZSL stereo capture model also utilizes both ISPA and ISPB, however, only one ISP is used for managing the preview, and the second is idle until a still capture is initiated. Both high-resolution Raw streams are provided to system memory through the MCCIF to maintain the circular buffer for the left and right channels. Once the ZSL still capture is initiated, the idle ISP can be utilized to process the still images while the other is available to maintain a preview and allow a new ZSL sequence to be initiated with little delay. The basic sequence for the Raw stereo capture is shown in the following figure.

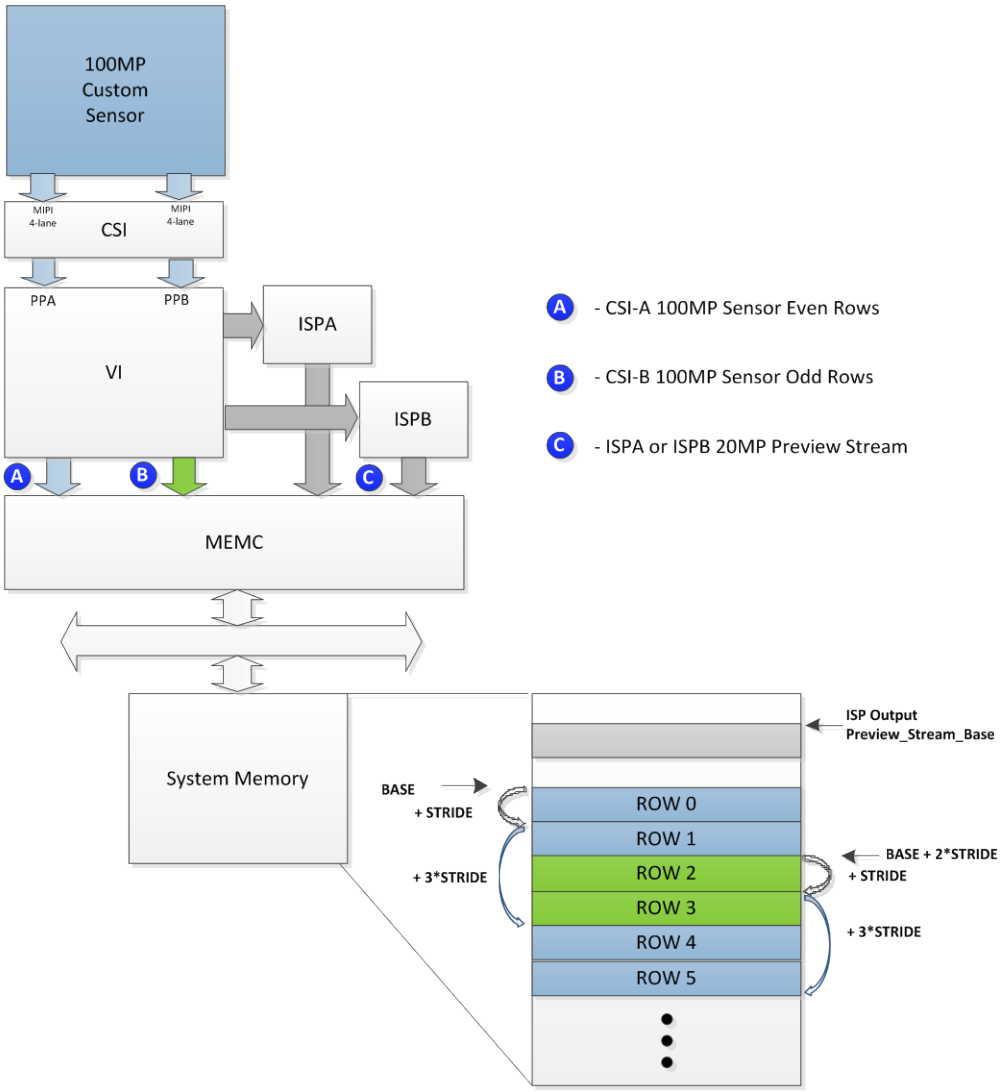
Figure 101: Zero Shutter Stereo Capture for Raw Image Data



28.1.10 Interleaved Capture

The interleaved capture mode supports management of pixel data delivered using all 8 available MIPI lanes. In this mode of operation, image data is delivered across all 8 lanes with two rows being provided simultaneously to the CSI-A and CSI-B MIPI ports. In this mode, the VI2 manages the interleaving of the even and odd rows when writing the data to system memory. The sensor interfaces to the CSI unit through the MIPI ports CSI-A and CSI-B using all four lanes for each interface. The following figure illustrates the interleaved capture model.

Figure 102: Interleaved Capture Model

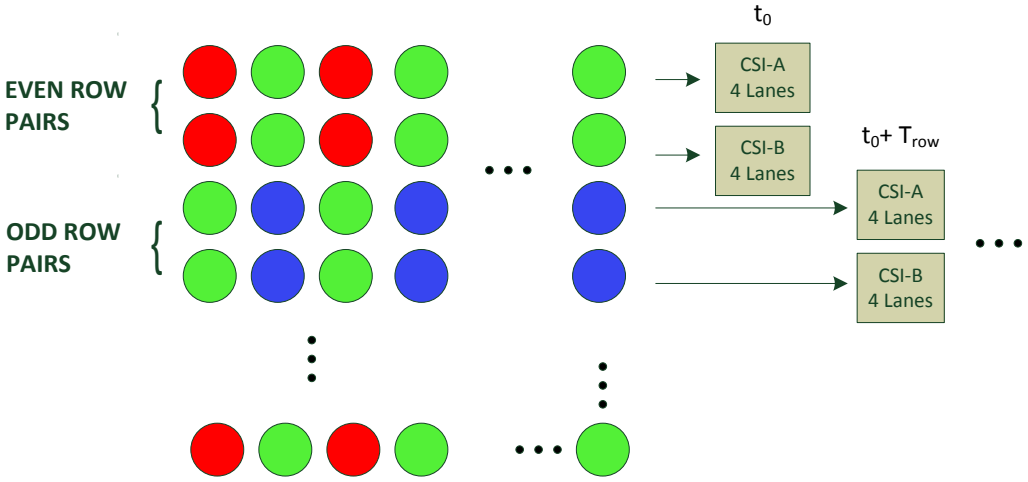


28.1.10.1 Interleaved Capture Model

The interleaved capture model supports image data that is presented as a standard RGGB Bayer pattern with either the even or odd rows available through CSI-A and the odd or even rows through CSI-B. The VI2 provides the RAW10 image data to system memory.

Utilizing both of the CSI 4-lane interfaces allows an effective still capture data rate to be doubled since all 8 MIPI lanes are active simultaneously. In this mode, the data is presented to the CSI interface in a unique fashion with even row pairs, both consisting of Red/Green pixels presented to CSI-A and CSI-B followed by the odd row pairs consisting of Green/Blue pixels.To provide a standard RGGB Bayer pattern in memory, an interleaving mechanism is provided as the data is written to memory. The following figure illustrates the even and odd row pair's presentation to the CSI.

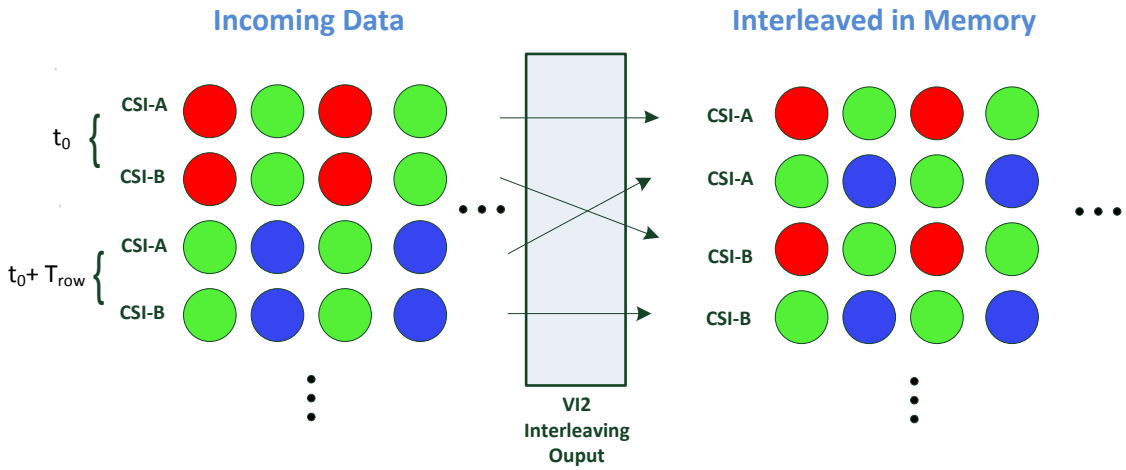
Figure 103: Interleaved Capture Data Presentation



28.1.10.2 Dual-Channel Interleaving

The interleaved still image is delivered in even and odd row pairs resulting in two Red/Green or two Blue/Green rows being presented to memory at the same time. The preparation of the data for processing involves interleaving the rows so that a Bayer pattern organization of the row data is available in system memory. To accomplish this, the VI2 provides a special interleaved mode in which the line counters for the two streams are incremented in a predetermined sequence. The following figure illustrates the interleaving of the incoming data stream in system memory.

Figure 104: Dual-Channel Interleaving During Write to Memory

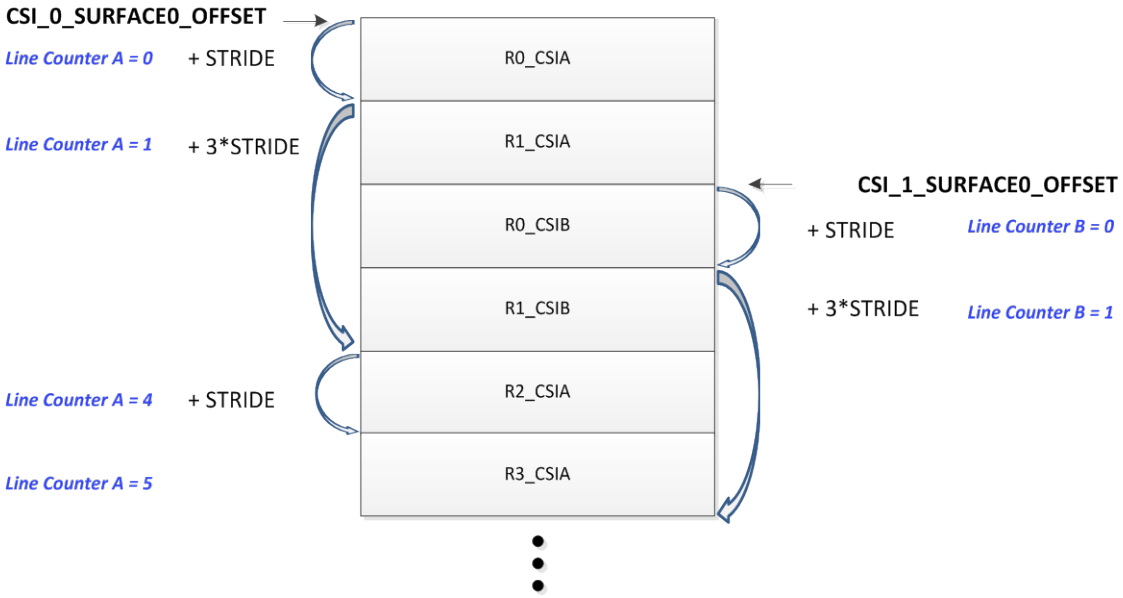


The interleaved mode is enabled by setting the INTERLEAVING_MODE bit in the VI_CSI_[0..1]_IMAGE_DEF registers. The mode setting changes the normal operation of the line counters used to calculate the memory address after a line is written to increment in a line pair skipping fashion as opposed to the normal mode of single increments.

Captured Row delivered by CSIA or CSIB	NORMAL MODE LINE COUNTER SEQUENCE	INTERLEAVED MODE LINE COUNTER SEQUENCE
Row 0	0	0
Row 1	1	1
Row 2	2	4
Row 3	3	5
Row 4	4	8
Row 5	5	9
.	.	.
.	.	.
.	.	.
Row (Height-1)	HEIGHT-1	HEIGHT-1

The base address and stride for each of the channels are programmed prior to initiating the image capture. Once the image capture is initiated, the line counters for the two channels will sequence in a row pair fashion as illustrated in the following figure.

Figure 105: Dual Channel Interleaving in Memory for T_R16_I



The RAW10 format is used for the interleaving capture and may be stored in either the T_R16_I or the T_L10_L10_L10_X2 formats. In addition to the INTERLEAVING_MODE selection, six registers must be programmed to manage the writing of the data to memory. Since the VI2 provide for memory writes on a 16 byte boundary, it is necessary to program the above registers accordingly

Table 116: Dual-Channel Interleaving Mode Address and Stride Programming

Register	Data Format	
VI_CSI_0_SURFACE0_OFFSET_LSB VI_CSI_0_SURFACE0_OFFSET_MSB	T_L16_I or T_L10_L10_L10_X2	Base Address for the first even row pair still image in system memory
VI_CSI_1_SURFACE0_OFFSET_LSB VI_CSI_1_SURFACE0_OFFSET_MSB	T_L16_I or	Base Address for the odd even row pair still image in system memory

Register	Data Format	
	T_L10_L10_L10_X2	VI_CSI_0_SURFACE0_OFFSET_LSB + 2 * STRIDE.
VI_CSI_0_SURFACE0_STRIDE0 VI_CSI_1_SURFACE0_STRIDE0	T_L16_I	STRIDE = 2 * IMAGE_WIDTH
	T_L10_L10_L10_X2	STRIDE = (4/3) * IMAGE_WIDTH

28.1.11 TrustZone Support

The VI2 allows management of several CSI registers associated with memory transactions and resets as either freely programmable in the system or only programmable by secure world functions. The registers supporting the secure programming feature include the reset and base, stride, and image definition registers for CSI0 and CSI1. These Trustzone support registers are listed below.

- VI_CSI_[0,1]_ SW_RESET
- VI_CSI_[0,1]_ IMAGE_DEF
- VI_CSI_[0,1]_SURFACE0_OFFSET_MSB
- VI_CSI_[0,1]_SURFACE0_OFFSET_LSB
- VI_CSI_[0,1]_SURFACE1_OFFSET_MSB
- VI_CSI_[0,1]_SURFACE1_OFFSET_LSB
- VI_CSI_[0,1]_SURFACE2_OFFSET_MSB
- VI_CSI_[0,1]_SURFACE2_OFFSET_LSB
- VI_CSI_[0,1]_SURFACE0_BF_OFFSET_MSB
- VI_CSI_[0,1]_SURFACE0_BF_OFFSET_LSB
- VI_CSI_[0,1]_SURFACE1_BF_OFFSET_MSB
- VI_CSI_[0,1]_SURFACE1_BF_OFFSET_LSB
- VI_CSI_[0,1]_SURFACE2_BF_OFFSET_MSB
- VI_CSI_[0,1]_SURFACE3_BF_OFFSET_LSB
- VI_CSI_[0,1]_SURFACE0_STRIDE
- VI_CSI_[0,1]_SURFACE1_STRIDE
- VI_CSI_[0,1]_SURFACE2_STRIDE
- VI_CSI_[0,1]_SURFACE_HEIGHT0

Programming control of the secure CSI registers is based on the programmed output security PMC's APBDEV_PMC_STICKY_BITS_0 field: CSI_SECURE_ENABLE and the Trustzone secure mode being active or inactive. Once the CPU is context switched from the normal operation “non-secure world” to the “secure world” (indicated to the rest of the system by the TrustZone _NS (non-secure bit) being deasserted, for example, there is a host1x trustzone_nonsecure signal), the VI allows for writes to the CSI registers when the sticky bit register is asserted. If the sticky bit is asserted, but the _NS signal is asserted (that is, the CPU is operating in the non-secure world), then the VI’s CSI registers are not writable. If the sticky bit is not asserted at all, then the VI’s CSI registers can be written to normally.

28.2 Data Formatting

The following sections describe the CSI Pixel formats, ISP pixel formatting, and the various formats and packing options for delivering data to system memory.

28.2.1 CSI Input Data Formats

The CSI provides data to the VI2 in one of several possible formats. The following table describes the different formats presented to the VI2 through the CSI interfaces.

Table 117: CSI to VI2 Pixel Formats

Format Name		23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

The formats include various flavors of RAW, RGB, and YCbCr in addition to 8-bit arbitrary or embedded data. The bits marked ‘0’ are actually don’t-care for VI2 and are ignored by the VI2 unit and the odd line in the above table refers to the first line from the CSI unit.

28.2.2 Raw Pixel Data Formatting

The Raw pixel data may be delivered to the ISP, system memory, or both the ISP and system memory simultaneously. In order to interface to the ISP efficiently, pixels are prepared for the ISP pipeline by converting to the unsigned offset binary representation of the form:

I.F

Where:

I is the number of integer bits.

F is the number of fractional bits.

The zero offset shall have a value of $2^{(F + I - 2)}$. For the ISP, it is suggested that the values of I and F should be:

I = 1, F = 13, offset = 4096_{10}

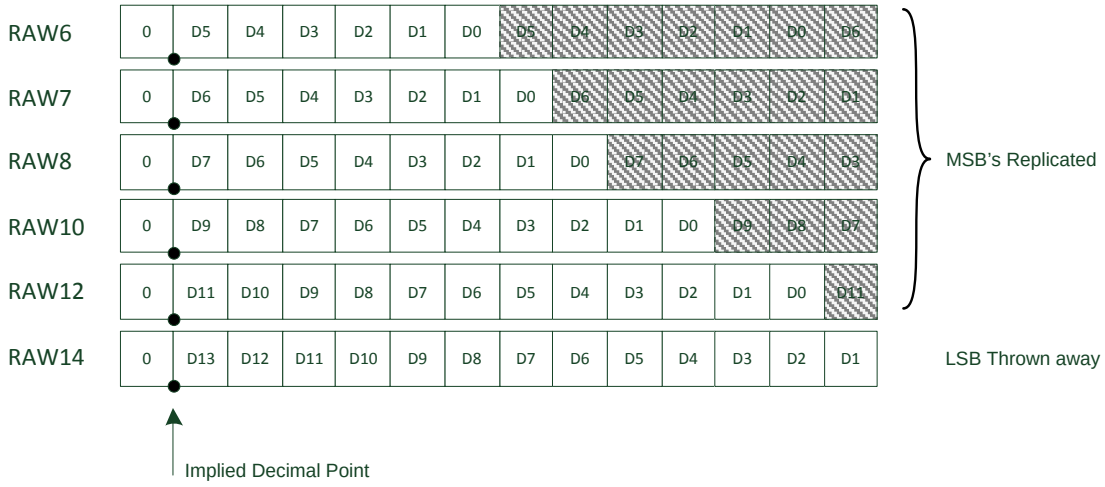
The formatting of the captured RAW data to the 14-bit I.F format requires several steps to be performed. Data may also be stored to memory either simultaneous with the ISP presentation or alone. When storing data to memory, either the formatted data or the original data may be stored to memory. Since the VI2 RAW data streams are all targeted for processing by the ISP, the storing of data which has formatting provided within the VI2 pipeline is the default behavior. Optionally the formatting may be bypassed by setting the BYPASS_PXL_TRANSFORM in the VI_CSI_[0..1]_IMAGE_DEF register.

The formatting steps for preparation of RAW pixel data for the ISP pipeline and/or memory are described in the following sections.

28.2.2.1 Raw Pixel Formatting to VI Pipeline

The Raw data received from the CSI unit is formatted as a 14-bit unsigned operand, U1.13. The data is scaled to provide align the MSB with the implied decimal point. When converting from a source data size that is smaller than the destination data size, the MSBs of the source are replicated to fill the missing LSBs in the destination. The bit replication is shown in the following figure.

Figure 106: VI2 Pipeline Formatting for U1.13 Raw Pixel Data

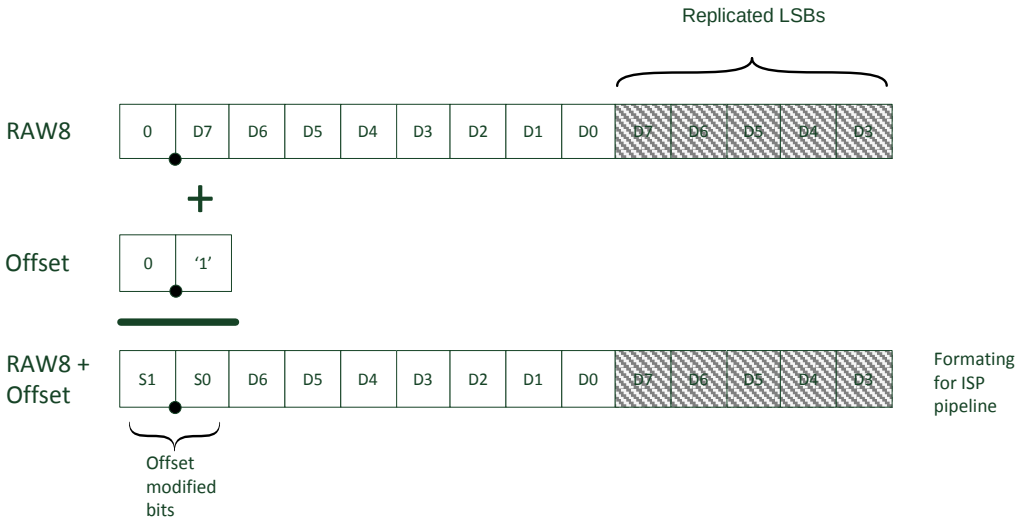


Since the RAW14 data would be wider than the ISP pipe when converting to the unsigned U1.13 format, the LSB is truncated.

28.2.2.2 RAW Pixel Formatting to ISP Pipeline

If the destination format is the pixel bus format, the data must be aligned with the implied decimal point position and the offset must be added. For example the formatting of RAW8 pixel data for the ISP pipeline is illustrated in the following figure.

Figure 107: RAW8 to ISP Pipeline Formatting Example



28.2.2.3 Raw Pixel Formatting to Memory

The raw pixel data may be presented to system memory in three possible formats specific to the input bit precision. The TL_8 formatting operation provides source to destination bit precision increase and decrease. All of the TL_8 formats are packed four per 32-bit word when stored to memory. The T_R16_I employs MSB replication based off of the RAW data previously formatted for the VI pipeline and a new format is introduced for packing three 10-bit raw pixels into a 32-bit word. The different options are summarized in the following table.

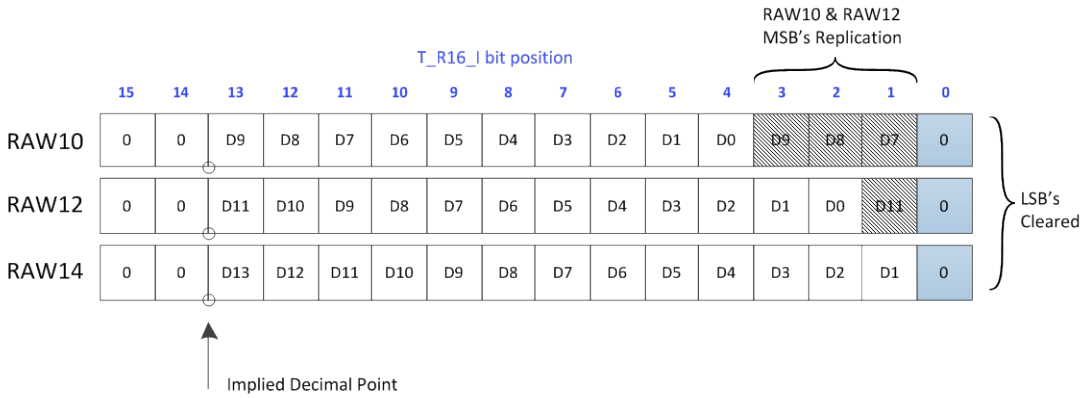
Table 118: Raw Supported Memory Formats

CSI Format Name	Pixel Format in Memory	bpp	Notes
RAW6	T_L8	8	
RAW7	T_L8	8	
RAW8	T_L8	8	
RAW10	T_L8	8	Drop 2 LSB
	T_R16_I	16	
	T_L10__L10__L10_X2	32	3 RAW10 Pixels Packed
RAW12	T_L8	8	Drop 4 LSB
	T_R16_I	16	
RAW14	T_L8	8	Drop 6 LSB
	T_R16_I	16	

T_R16_I Formatting for RAW10, RAW12, and RAW14

The formatting of the raw data from the VI2 pipeline for bit precisions above eight involves an additional MSB bit replicationI as illustrated in the following figure.

Figure 108: RAW10, RAW12, and RAW14 Formatting to Memory



T_L8_F Formatting for all Raw Pixel Precisions

The formatting for the 8-bit data is a straightforward mapping with either truncation or MSB replication being employed. The formatting for 8-bit data is illustrated in the following figure.

Figure 109: Raw Formatting to T_L8 Memory Format

T_L10__L10__L10_X2 Formatting for RAW10

The T_L10_L10_L10_X2 packed format is introduced to help reduce the burden on the system memory resources during high BW camera user models. In this format, three RAW10 pixels are packed per 32-bit word allowing an improvement in utilization to be realized. The memory efficiency is 93.75% compared to the T_R16_I format with 62.5%.

28.2.3 RGB Pixel Data Formatting

The VI2 receives RGB data from the CSI in one of several possible formats and provides for formatting and presentation to system memory. The RGB formats are represented through variation in the number of bits used to represent the red, green, and blue channels. The RGB memory formats and options for source to destination formatting are described in the following table.

Table 119: RGB Supported Memory Formats

CSI Format Name	Pixel Formats in Memory	bpp	Notes
RGB565	T_L8	8	(C1*R+C2*G+C3*B)/16
	T_A1B5G5R5; T_A1R5G5B5; T_B5G5R5A1; T_R5G5B5A1	16	
	T_B5G6R5; T_R5G6B5	16	
RGB555	T_L8	8	(C1*R+C2*G+C3*B)/16
	T_A1B5G5R5; T_A1R5G5B5; T_B5G5R5A1; T_R5G5B5A1	16	
	T_B5G6R5; T_R5G6B5	16	
RGB888	T_L8	8	(C1*R+C2*G+C3*B)/16
	T_A1B5G5R5; T_A1R5G5B5; T_B5G5R5A1; T_R5G5B5A1	16	
	T_A4B4G4R4; T_A4R4G4B4; T_B4G4R4A4; T_R4G4B4A4	16	
	T_B5G6R5; T_R5G6B5	16	
	T_A8B8G8R8; T_A8R8G8B8; T_B8G8R8A8; T_R8G8B8A8	32	
	T_A2B10G10R10; T_A2R10G10B10; T_B10G10R10A2; T_R10G10B10A2	32	
RGB444	T_L8	8	(C1*R+C2*G+C3*B)/16
	T_A1B5G5R5; T_A1R5G5B5; T_B5G5R5A1; T_R5G5B5A1;	16	
	T_A4B4G4R4; T_A4R4G4B4; T_B4G4R4A4; T_R4G4B4A4	16	
	T_B5G6R5; T_R5G6B5	16	
RGB666	T_L8	8	(C1*R+C2*G+C3*B)/16
	T_A1B5G5R5; T_A1R5G5B5; T_B5G5R5A1; T_R5G5B5A1	16	
	T_B5G6R5; T_R5G6B5	16	
	T_A8B8G8R8; T_A8R8G8B8; T_B8G8R8A8; T_R8G8B8A8	32	

Each of the capture RGB formats can be formatted by adjusting the precision of the channels, ordering the channels differently, or extracting a luminance approximation into a packed T_L8 format.

28.2.3.1 RGB Pixel Data Size Conversions

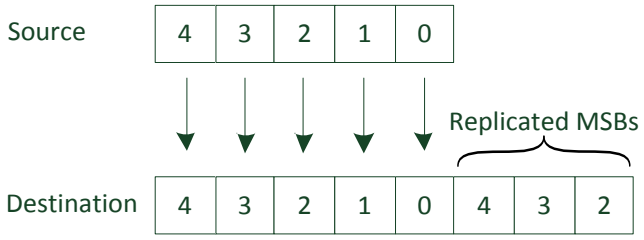
The VI2 supports the conversion of the received RGB data into other formats by either increasing or decreasing the precision of the data representing each of the channels. The following table describes the possible conversions.

Table 120: RGB Data Precision Adjustments Options

RGB Format Received	RGB Format Conversion (Precision Increase)	RGB Format Conversion (Precision Decrease)
RGB444	RGB555, RGB565	None
RGB555	RGB565	None
RGB565	None	RGB555
RGB666	RGB888	RGB555, RGB565
RGB888	RGB101010	RGB444,RGB555, RGB565, RGB666

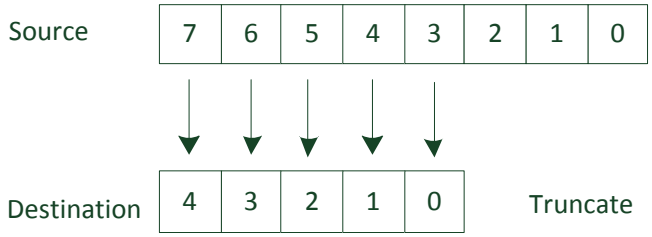
The RGB pixel data is converted to higher bit precision through replication of the MSBs in the source to fill in the missing LSBs in the destination in a similar fashion as the Raw data formatting for the ISP pipe. For example:

Figure 110: 5-bit to 8-bit Precision Increase



When converting from a source data size that is larger than the destination size, the destination is a truncated version of the source data. For example:

Figure 111: 8-bit to 5-bit Precision Decrease



28.2.3.2 RGB to Luma Data Formatting

In addition to providing format conversions, the RGB data may also be stored as luma data by approximating a luminance calculation. This is useful for applications that would otherwise have to compute the luminance channel from the RGB data in a separate step. The luma calculation is performed by multiplying each of the red, green, and blue channel components by a U0.6 coefficient as shown in the following pseudo code.

```
#define SHIFT      5
#define COEFF_BITS 6
```

```
 Y = ( (PIXEL.RED_CR * MW_R2Y_COEFF)
    + (PIXEL.GRN_Y  * MW_G2Y_COEFF)
   + (PIXEL.BLU_CB * MW_B2Y_COEFF) ) >> (SHIFT + COEFF_BITS);

if (Y < 0)   Y =   0;
```

```
    if (Y > 255) Y = 255;
```

28.2.3.3 RGB Pixel Formatting to ISP Pipeline

If the destination format is the pixel bus format, the data must be aligned with the implied decimal point position and the offset must be added. For example, the formatting of RGB565 pixel data for the ISP pipeline will involve formatting each of the color components into the 14-bit I.F format.

28.2.4 YUV Pixel Data Formatting

The VI2 provides for formatting and packing of YCbCr data received from the CSI and is responsible for its presentation to system memory or to the ISP for scaling or image enhancement. There are two formats captured: YUV422 and YUV420. The formatting provided for YUV capture data is shown in the following table.

Table 121: YUV Supported Memory Formats

CSI Format Name	Pixel Formats in Memory	bpp (per plane)	Notes
YUV422 8-bit	T_L8	8	Y component only
	T_Y8_U8__Y8_V8 [a] ; T_Y8_V8__Y8_U8 [a] ; T_U8_Y8__V8_Y8 [a] ; T_V8_Y8__U8_Y8 [a]	32	
	T_Y8___U8V8_N422	8	Semi-planar; Y+UV
	T_Y8___V8U8_N422	8	Semi-planar; Y+VU
	T_Y8___U8___V8_N422 [b]	8	Planar
YUV422 10-bit	T_L8	8	Y component only
	T_Y8_U8__Y8_V8 [a] ; T_Y8_V8__Y8_U8 [a] ; T_U8_Y8__V8_Y8 [a] ; T_V8_Y8__U8_Y8 [a]	32	
	T_Y8___U8V8_N422 [b]	8	Semi-planar; Y+UV
	T_Y8___V8U8_N422 [b]	8	Semi-planar; Y+VU
	T_Y8___U8___V8_N422 [b]	8	Planar
YUV420 8-bit legacy	T_L8	8	Y component only
YUV420 8-bit / 8-bit (CSPS)	T_L8	8	Y Component only.
YUV420 10-bit / 10-bit (CSPS)	T_L8	8	Y Component only.

The 8-bit YUV422 format is designated a primary format in the MIPI CSI specification and all others are considered as secondary formats. The supported pixel layout will be Pitch Linear or planar pitch-linear. YUV420 is always stored as T_L8 with even and odd lines stored to memory as they are received from the CSI interface.

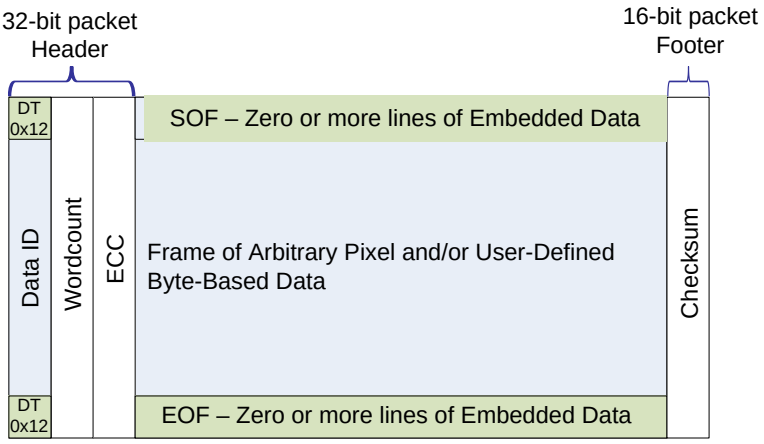
28.2.4.1 YUV Pixel Formatting to ISP Pipeline

The formatting of YUV422 data for presentation to the ISP follows a similar formatting as is done with the raw and RGB formats to convert the data to the unsigned offset binary representation with the exception that an offset of 8192 is used for the chroma channels and an offset of 4096 is used for the luma. The LSB replication follows the same approach as with the RGB and RAW formats. Following the conversion of the luma and chroma to the 14-bit representation for the ISP pipe, the data is then converted from 422 to 444 sampling through interpolation.

28.2.5 Embedded Data Formats

A number of sensor and camera modules utilize embedded data to communicate meta data or calibration data associated with an image capture to the host application. The inclusion of embedded data in the data stream is defined in the MIPI CSI2 specification and has a specific data type of 0x12 assigned. If the embedded data exists, it is identified by the embedded data type at the beginning of a long packet resulting in extra lines added to the beginning or end of a frame. An illustration of embedded and fare data is shown in the following figure.

Figure 112: CSI-2 Incoming Frame Structure with Embedded Data



The CSI2 and VI2 work together to manage the capture and handling of the embedded data during a frame capture. Three basic modes of operation associated with the embedded data capture model are supported. The embedded data capture modes are described in the following section.

28.2.5.1 Embedded Data Capture Modes

The CSI2 can discard embedded data in the CSI2, to pass embedded data through one pixel parser with the image data being presented to the other pixel parser, or to combine the embedded data with the frame data when presented to a single pixel parser.

Embedded data is discarded by setting CSI_PP[A..B]_EMBEDDED_DATA_OPTION to DISCARD in the CSI_PIXEL_STREAM_[A..B]_CONTROL_0 register. If it is desired to keep the embedded data, this field should be set. Depending on the mode of operation and the data format the embedded data, the frame data, or the combined embedded and frame data may be delivered to system memory or the ISP execution resources. The options for embedded data capture are described in the following table.

Table 122: Embedded Data Capture Modes

EMBEDDED	Pixel Format in Memory	Notes
DISCARD	Either PP will deliver frame data only.	MEM or ISPA/ISPB
Embedded Capture with One PP	Embedded Data and Frame Data using Same PP	MEM only
Embedded Capture with Two PPs	One PP used for streaming Embedded Data.	MEM only

EMBEDDED	Pixel Format in Memory	Notes
	One PP used for streaming Frame data.	MEM or ISPA/ISPB

If the mode is set to discard, the embedded data is discarded in the CSI2 and only image data is presented to the VI2 resulting in the normal data processing with the frame data formatting and presentation to memory and/or the ISP. If the mode is set to capture embedded data using one pixel parser, the embedded data is streamed with the image data using the same pixel parser. In this mode the embedded data is combined with the frame data and presented to system memory. The third mode uses both pixel parsers with one pixel parser managing the embedded data and the other managing the frame data.

The discard embedded capture is relatively straightforward and only requires the CSI_PP[A..B]_EMBEDDED_DATA_OPTION to be set to discard with all other programming settings the same as during non-embedded frame capture. The other two modes have some complexity associated with the programming and how the data is organized in memory. The following sections describe the single and dual Pixel Parser (PP) modes in more detail.

Embedded Capture using One PP

The embedded capture using one pixel parser will result in embedded data being stored with the frame data in system memory. Since the line width for the 8-bit embedded data may be longer or shorter than the line with for the pixel data, the line width short/long errors are ignored. In addition, the CSI2 will signal to the VI2 that an incoming line is embedded by setting the CSI[A,B]2VI_FRAME_ERROR during the start of a line. In this fashion, the VI2 will know that the line is embedded and provide for managing the capture and providing the specialized formatting depending on the VI2 memory format setting. The register programming is similar to non-embedded cases except that:

1. VI_CSI_[0..1]_CSI_IMAGE_SIZE register HEIGHT should be programmed with the SOF Embedded Lines+EOF Embedded lines +Normal Lines
2. The CSI_PP[A..B]_EMBEDDED_DATA_OPTION should be set to EMBEDDED in the CSI_PIXEL_STREAM_[A..B]_CONTROL_0 register

In the single PP embedded capture mode, the only destination supported is to MEM since the ISP does not support embedded data with the pixel stream. There are several additional constraints on the supported data formats when using this embedded capture option:

1. RGB Embedded Data capture is not supported.
2. Several Raw flavors with various output options are not supported.
3. YUV embedded capture will combine the embedded data with the Luma plane, and insert zeros into the Chroma planes for some formatting options.

Embedded Capture using Two PPs

The embedded capture using two pixel parsers results in one of the pixel parsers delivering only embedded data to the VI2 and the other delivering only image data. In order to accomplish this, one PP would be programed to parse pixel data and discard embedded data, and the other PP would be programmed to parse only embedded data. The embedded data would then be sent to memory for the VI2 and the pixel data could either be presented to system memory or the ISP.

For example, if an embedded image stream is being captured from CILA, the pixel path could be set up to be CILA → PPA →VI and the embedded data path could be set up to be CILA→PPB→VI→ MEM. The PPA stream programming is similar to normal cases and the stream B programming would be as follows:

1. Route CILA to PPB by setting the CSI_PPB_STREAM_SOURCE to CSI_A
2. Program VI_CSI_1_CSI_IMAGE_SIZE register HEIGHT to be the sum of SOF Embedded Lines+EOF Embedded lines.

3. Program VI_CSI_1_CSI_IMAGE_SIZE register WIDTH to be based on the pixel data line width/data format.
4. Set the DATA_TYPE to EMBED in the VI_CSI_1_CSI_IMAGE_DT register.
5. Set the CSI_PP[A..B]_EMBEDDED_DATA_OPTION to EMBEDDED in the CSI_PIXEL_STREAM_[A..B]_CONTROL_0 register

The programming of the image width in step three is sometimes different than the image width of the normal frame data since the embedded data lines have the same length in bytes as the image data. For example, for a RAW6 64x64 image, there are 48 bytes in each long packet payload resulting in a line width of 48 bytes for the embedded data. Embedded data is always stored as T_L8 in this mode.

28.2.5.2 Frame Data Type with Embedded Data Limitations

The embedded data when using the two pixel parser option is straightforward as long as the frame height and width are programmed appropriate to the data type and the number of embedded lines. The single PP mode of embedded capture is more complex and software will be required to parse the embedded data from the stored embedded data plus image data frame.

The Raw embedded data capture options supported with a single pixel parsers are summarized in the following table.

Table 123: Raw and DPCM Embedded Data Formatting

CSI Format	VI Pixel Format in Memory	1 PP Embed Mode Support	Embedded Data Layout in 32-bit DWORD
RAW6	T_L8	No	NA
RAW7	T_L8	No	NA
RAW8	T_L8	Yes	[emdat3, emdat2, emdat1, emdat0]
RAW10 or DPCM 10-8-10	T_L8	No	NA
	T_R16_I	Yes	*{4'h0,embed_data1,4'hX,4'h0,embed_data0,4'hX}*
	T_X2Lc10Lb10La10	Yes	*{2'b00,embed_data2,2'b00,embed_data1,2'b00,embed_data0}*
RAW12 or DPCM 12-8-12	T_L8	No	NA
	T_R16_I	Yes	*{6'h0,embed_data1,2'hX,6'h0,embed_data0,2'hX}*
RAW14 or DPCM 14-8-14	T_L8	No	NA
	T_R16_I	No	NA

The YUV420 format is very straightforward since only the Luma plane capture is supported. In this capture mode, embedded data is formatted to look like extra rows of equal length as the Luma data since both are packed T_L8. The YUV422 formatting is significantly more complex and some care is necessary to properly parse the data. The YUV embedded data formatting using a single PP is summarized in the following table.

Table 124: YUV Embedded Data Formatting

CSI Format	VI Pixel Format in Memory	1 PP Embed Mode Support	Embedded Data Layout in 32-bit DWORD
YUV420	T_L8	Yes	[emdat3, emdat2, emdat1, emdat0]

CSI Format	VI Pixel Format in Memory	1 PP Embed Mode Support	Embedded Data Layout in 32-bit DWORD
YUV422_8 or YUV422_10	T_L8	Yes	[emdat3, emdat2, emdat1, emdat0]
	T_Y8_U8__Y8_V8	Yes	{8'h0, embed_data1, 8'h0, embed_data0}
	T_U8_Y8__V8_Y8	Yes	{embed_data1, 8'h0, embed_data0, 8'h0}
	T_Y8_V8__Y8_U8	Yes	{8'h0, embed_data1, 8'h0, embed_data0}
	T_V8_Y8__U8_Y8	Yes	{embed_data1, 8'h0, embed_data0, 8'h0}
	T_Y8__U8V8_N422	Yes	*{embed_data3,embed_data2,embed_data1,embed_data0} in Y buffer, The Embedded lines in U/V buffer will be zeroes*
	T_Y8__U8V8_N422	Yes	*{embed_data3,embed_data2,embed_data1,embed_data0} in Y buffer, The Embedded lines in U/V buffer will be zeroes*
	T_Y8__U8__V8_N422	Yes	*{embed_data3,embed_data2,embed_data1,embed_data0} in Y buffer, The Embedded lines in U/V buffer will be zeroes*

28.2.6 Pixel Formats Memory Layout

28.2.6.1 Non-Planar Formats

The bit arrangement of the color components within a pixel for all the supported non-planar color formats are shown in the table below.

Table 125: Pixel Bit Assignments for Non-Planar Formats

Format	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

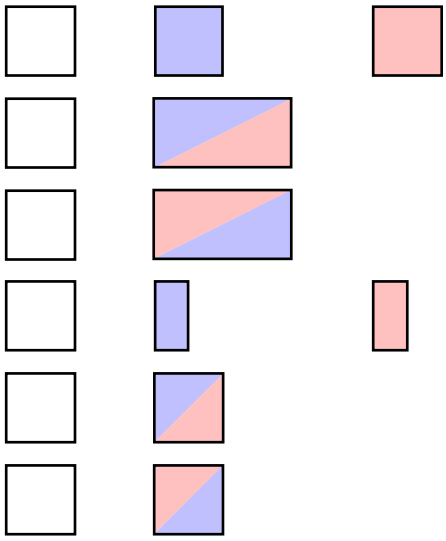
28.2.6.2 Pixel Formats (Planar and Semi-Planar)

Some pixel formats require that the individual color components are separated out into distinct buffers in memory. These formats are defined below:

Table 126: Planar and Semi-Planar Format Definitions

Name	FOURCC	Organization	Sample structure
T_Y8___U8___V8_N444		Planar	4:4:4
T_Y8___U8V8_N444		Semi-planar	4:4:4, U followed by V
T_Y8___V8U8_N444		Semi-planar	4:4:4, V followed by U
T_Y8___U8___V8_N422	YV16	Planar	4:2:2
T_Y8___U8V8_N422	NV16	Semi-planar	4:2:2, U followed by V
T_Y8___V8U8_N422	NV61	Semi-planar	4:2:2, V followed by U

Figure 113: Planar and Semi-Planar Buffer Layout Diagram



28.3 VGP (GPIO) Interface

The VI2 provides for six programmable GPIOs to control various aspects of the camera system. All may be configured as either I/O or PWM and two may also be configured for I2C camera control.

Table 127: VGP1-VGP6 Functions

GPIO	Functions		
	A	B	C
VGP1	I/O	PWM	I2C_SCK
VGP2	I/O	PWM	I2C_SDA
VGP3	I/O	PWM	-
VGP4	I/O	PWM	-
VGP5	I/O	PWM	-
VGP6	I/O	PWM	-

The Pulse Width Modulation (PWM) unit generates a series of 128 identical pulses. The unit can use any of the (VGP1-6) pins as an output, provided that the unit is enabled and the pin is configured to carry PWM data. A pulse's length (in clock cycles), duty cycle, and starting polarity are programmable. A single pulse can take between 2 and 32 clock cycles, where a high or low level is no more than 16 cycles long. A series' length is always 128 times the length of a single pulse. Once the unit is enabled, a series can be either generated once, a set number of times, or repeatedly until the unit is disabled.

28.4 Error Handling

The errors can be broadly classified in the categories provided in the following table.

Table 128: VI Error Categories

Error Categories	Description
CSI Error Indication	D-PHY Level Errors
	Packet Level Errors
	Protocol Decoding Errors
Bad Frame Size	Pixel Per Line Error
	Lines Per Frame Error
Overflow Conditions	Back pressure from ISP
	Backpressure from MCCIF
	Backpressure from ISP in ZSL and SZSL Modes
	Backpressure from MCCIF in ZSL and SZSL Modes
Control Flag Error from CSI	Error in control flag sequence

The rest of this section describes details of various errors and their handling by the VI.

28.4.1 SOF followed by EOF

This is not really an error condition. When the CSI is trying to capture a frame while in single shot mode, if it instead comes across a different frame (not matching the expected parameters of VC/DT/WC), it still sends the SOF indication for the 'bad' frame it dropped and then follows it up with the EOF. This results in the VI receiving an EOF marker without any pixel data or other control flags in between. On receiving this, the VI (depending on the HOSTIF_UPDATE.CAPTURE_GOOD_FRAME configuration) either updates the pending assembly state to active state or overwrites the SOF control flag in the input staging registers.

28.4.2 Missing Control Flags

The missing control flag error occurs when an SOF-SOL-EOL-SOL-EOL-..EOF-SOF sequence occurs. Since the VI does not check for SOL, any error in the sequence concerning SOL is ignored.

28.4.3 Pixels per Line Errors

Pixels Per Line Greater than Image Width

This error is for the case where the first line of the frame was correct and one or more intermediate lines were too long. The CSI will drop any line that does not have the matching WC in the header. This dropping of lines by the CSI might result in a frame-too-short scenario and should be handled as such. The CSI should indicate to the VI when it drops any line via the error flag along with the EOF for that frame. The VI checks for line width and, in case of any error, ignores the rest of the frame.

Pixels Per Line Greater than Image Width

This error is for the case where the first line of the frame was correct and one or more intermediate lines were shorter than expected. This dropping of lines by the CSI might result in a frame-too-short scenario and should be handled as such. The CSI should indicate to VI when it drops any line via the error flag along with the EOF for that frame. The VI checks for line width and, in case of any error, ignores the rest of the frame.

28.4.4 Lines per Frame Errors

Line per Frame Greater than Image Height

In this condition, the input logic should drop the lines beyond the expected frame height and indicate the error to the gatekeeper. On the output side, this error indication is used by output logic to mark the EOF with ‘frame too long’ error logic to ISP. When sending the frame to memory, the VI should drop the additional lines (beyond the expected height) and not corrupt the memory buffer.

Line per Frame Less than Image Height

In this condition, the input logic does not do any special handling. It may mark the EOF with the error flag (not necessarily required as the read logic can identify the frame too short condition too). The input logic still needs to indicate the error to the gatekeeper module for appropriate handling of next set of assembly registers based on CAPTURE_GOOD_FRAME configuration. On the output side of the line-store buffer, the EOF to ISP is marked with frame-too-short error flag.

28.4.5 CSI Error Indication

In this condition, the error flag is used by the gatekeeper module for appropriate handling (update from assembly state or not as defined by the CAPTURE_GOOD_FRAME configuration). The rest of the frame handling follows normal handling or as defined by other defined error-handling scenarios.

28.4.6 Line Buffer Overflow

In case the backpressure from ISP/MC causes the line buffer to overflow, the incoming pixel data from the CSI is dropped until the EOF. On the read side of line-store buffer, if a premature SOF is detected (since the rest of the frame was dropped at the input), the OP*_DONE syncpt is generated as programmed by the CAPTURE_GOOD_FRAME configuration.

28.5 VI Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

28.5.1 VI_CFG_VI_INCR_SYNCPT_0

Offset: 0x0 | Byte Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	VI_COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = VI_MWA_REQ_DONE 5 = VI_MWB_REQ_DONE 6 = VI_MWA_ACK_DONE 7 = VI_MWB_ACK_DONE 8 = VI_ISPA_DONE 9 = VI_CSI_PPA_FRAME_START 10 = VI_CSI_PPB_FRAME_START 11 = VI_CSI_PPA_LINE_START 12 = VI_CSI_PPB_LINE_START 13 = VI_VGP0_RCVD 14 = VI_VGP1_RCVD 15 = VI_ISPB_DONE 16 = COND_16 17 = COND_17 18 = COND_18 19 = COND_19

		20 = COND_20 21 = COND_21 22 = COND_22 23 = COND_23 24 = COND_24 25 = COND_25 26 = COND_26 27 = COND_27 28 = COND_28 29 = COND_29 30 = COND_30 31 = COND_31
7:0	0x0	VI_INDX: syncpt index value

28.5.2 VI_CFG_VI_INCR_SYNCPT_CNTRL_0

Offset: 0x1 | Byte Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxxx0)

Bit	Reset	Description
8	0x0	VI_INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	VI_INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do soft reset, first set SOFT_RESET of all host1x clients affected, then clear all SOFT_RESETs.

28.5.3 VI_CFG_VI_INCR_SYNCPT_ERROR_0

Offset: 0x2 | Byte Offset: 0x8 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VI_COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

28.5.4 VI_CFG_CTXSW_0

Context Switch Register

Should be common to all modules. Includes the current channel/class (which is writable by software) and the next channel/class (which the hardware sets when it receives a context switch).

The context switch works like this:

Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS. Software sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be preloaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module, and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts.

Another way to avoid context switch interrupts is to set the AUTO_ACK bit. This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 0x8 | Byte Offset: 0x20 | Read/Write: R/W | Reset: 0xXXXXf800 (0bxxxxxxxxxxxxxxxx11111x0000000000)

Bit	R/W	Reset	Description
31:28	RO	X	NEXT_CHANNEL: Next requested channel
25:16	RO	X	NEXT_CLASS: Next requested class
15:12	RW	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	RW	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests 0 = MANUAL 1 = AUTOACK
9:0	RW	0x0	CURR_CLASS: Current working class

28.5.5 VI_CFG_INTSTATUS_0

Offset: 0x9 | Byte Offset: 0x24 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CTXSW_INT: Context switch interrupt status (clear on write)

28.5.6 VI_PWM_CONTROL_0

VI Pulse Width Modulation Control

PWM signal generation logic can generate up to 128 pulses per line internally and the PWM pulse select registers determine which of the 128 pulses will be output. Any of the 128 internally generated pulse can be independently selected as output if they occur within one line time.

The PWM signal can be output on the VGP6 pin if VGP6 output is enabled and the output select is set to PWM.

The PWM is triggered by the first VSYNC after the PWM_ENABLE bit has been set.

Offset: 0xe | Byte Offset: 0x38 | Read/Write: R/W | Reset: 0x00000000 (0b00000000xx00xxxxxxxxxxxxxxx0xxx0)

Bit	Reset	Description
31:24	0x0	PWM_COUNTER: 8-bit PWM Counter value used when PWM_MODE is set to COUNTER to determine how many times the PWM will cycle through the 128 cycles before stopping.
21:20	0x0	PWM_MODE: PWM Mode Continuous: After the PWM is turned on, continue through the PWM's 128 cycles repeatedly until the PWM is turned off. Single: After the PWM is turned on, cycle once through the 128 cycles and stop. Counter: After the PWM is turned on, cycle through the 128 cycles PWM_COUNTER number of times then stop. 0 = CONTINUOUS 1 = SINGLE 2 = COUNTER
4	0x0	PWM_DIRECTION: PWM Direction 0= Incrementing 1= Decrementing 0 = INCR 1 = DECR
0	0x0	PWM_ENABLE: PWM Enable 0 = DISABLED 1 = ENABLED

28.5.7 VI_CFG_PWM_HIGH_PULSE_0

PWM High Pulse Period

Offset: 0xf | Byte Offset: 0x3c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description

PWM Pulse Select B

Offset: 0x12 | Byte Offset: 0x48 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	PWM_SELECT_B: PWM Select bits 63 to 32

28.5.11 VI_CFG_PWM_SELECT_PULSE_C_0

PWM Pulse Select C

Offset: 0x13 | Byte Offset: 0x4c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	PWM_SELECT_C: PWM Select bits 95 to 64

28.5.12 VI_CFG_PWM_SELECT_PULSE_D_0

PWM Pulse Select D

Offset: 0x14 | Byte Offset: 0x50 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	PWM_SELECT_D: PWM Select bits 127 to 96

28.5.13 VI_CFG_VGP*n*_0

VI VGP*n* Input/Output Config/Data

There are six VI VGP*n* Config registers, where *n* = 1 through 6.

Offset: 0x19 + (*n* – 1) | Byte Offset: 0x64 + (*n* – 1)*0x4 | Read/Write: R/W | Reset: 0x00000X0X (0b0xxxxxx00xxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
24	RW	0x0	VGP*n*_INPUT_ENABLE: VGP*n* pin Input Enable. This bit controls the VGP*n* pin input. 0 = DISABLED 1 = ENABLED
17	RW	0x0	PIN_OUTPUT_SELECT_VGP*n*: Pin Output Select VGP*n* 0 = VG*Pn*_OUTPUT_DATA 1 = 1'b0
16	RW	0x0	VGP*n*_OUTPUT_ENABLE: VGP*n* pin Output Enable. This bit controls the VGP*n* pin output. 0 = DISABLED 1 = ENABLED
8	RO	X	VGP*n*_INPUT_DATA: VGP*n* pin Input Data (effective if VGP*n*_INPUT_ENABLE is ENABLED) 0= VGP*n* input low 1= VGP*n* input high
0	RW	X	VGP*n*_OUTPUT_DATA: VGP*n* pin Output Data (effective if VGP*n*_OUTPUT_ENABLE is ENABLED and VGP*n*_OUTPUT_SELECT is DATA)

28.5.14 VI_CFG_INTERRUPT_MASK_0

Interrupt Mask

Offset: 0x23 | Byte Offset: 0x8c | Read/Write: R/W | Reset: 0x00000000 (0b000000)

Bit	Reset	Description
6	0x0	VGP6_INT_MASK: VGP6 pin Interrupt Mask. This bit controls interrupting when a VGP6 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
5	0x0	VGP5_INT_MASK: VGP5 pin Interrupt Mask. This bit controls interrupting when a VGP5 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
4	0x0	VGP4_INT_MASK: VGP4 pin Interrupt Mask. This bit controls interrupting when a VGP4 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
3	0x0	VGP3_INT_MASK: VGP3 pin Interrupt Mask. This bit controls interrupting when a VGP3 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
2	0x0	VGP2_INT_MASK: VGP2 pin Interrupt Mask. This bit controls interrupting when a VGP2 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
1	0x0	VGP1_INT_MASK: VGP1 pin Interrupt Mask. This bit controls interrupting when a VGP1 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED

28.5.15 VI_CFG_INTERRUPT_TYPE_SELECT_0

Interrupt Type Select

Offset: 0x24 | Byte Offset: 0x90 | Read/Write: R/W | Reset: 0x00000000 (0b000000)

Bit	Reset	Description
6	0x0	VGP6_INT_TYPE: VGP6 pin Interrupt Type. This bit controls interrupt VGP6 0= Edge type 1= Level type 0 = EDGE 1 = LEVEL
5	0x0	VGP5_INT_TYPE: VGP5 pin Interrupt Type. This bit controls interrupt VGP5 0= Edge type 1= Level type 0 = EDGE 1 = LEVEL
4	0x0	VGP4_INT_TYPE: VGP4 pin Interrupt Type. This bit controls interrupt VGP4 0= Edge type 1= Level type 0 = EDGE 1 = LEVEL
3	0x0	VGP3_INT_TYPE: VGP3 pin Interrupt Type. This bit controls interrupt VGP3 0= Edge type 1= Level type 0 = EDGE 1 = LEVEL
2	0x0	VGP2_INT_TYPE: VGP2 pin Interrupt Type. This bit controls interrupt VGP2 0= Edge type 1= Level type 0 = EDGE 1 = LEVEL
1	0x0	VGP1_INT_TYPE: VGP1 pin Interrupt Type. This bit controls interrupt VGP1 0= Edge type 1= Level type 0 = EDGE 1 = LEVEL

28.5.16 VI_CFG_INTERRUPT_POLARITY_SELECT_0

Interrupt Polarity Select

Offset: 0x25 | Byte Offset: 0x94 | Read/Write: R/W | Reset: 0x00000000 (0b000000)

Bit	Reset	Description
6	0x0	VGP6_INT_POLARITY: VGP6 pin Interrupt Type. This bit controls interrupt VGP6. 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
5	0x0	VGP5_INT_POLARITY: VGP5 pin Interrupt Type. This bit controls interrupt VGP5. 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
4	0x0	VGP4_INT_POLARITY: VGP4 pin Interrupt Type. This bit controls interrupt VGP4. 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
3	0x0	VGP3_INT_POLARITY: VGP3 pin Interrupt Type. This bit controls interrupt VGP3. 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH

Bit	Reset	Description
2	0x0	VGP2_INT_POLARITY: VGP2 pin Interrupt Type. This bit controls interrupt VGP2. 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
1	0x0	VGP1_INT_POLARITY: VGP1 pin Interrupt Type. This bit controls interrupt VGP1. 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH

28.5.17 VI_CFG_INTERRUPT_STATUS_0

Interrupt Enable

This register returns interrupt status when read. When this register is written, the interrupt status corresponding to the bits written with 1 is reset. Interrupt status corresponding to the bits written with 0 will be left unchanged.

Note that interrupt status bits can be set even when their corresponding interrupt enable bits, in the VI_CFG_INTERRUPT_MASK_0 register, are cleared. When these bits are set and their corresponding interrupt enable bits are set, an interrupt is generated. The interrupt can be cleared or left unchanged by writing 1 or 0, respectively, to the corresponding bits in this register.

Clearing the interrupt status bits does not affect the interrupt enable bits.

Offset: 0x26 | Byte Offset: 0x98 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxx)

Bit	Reset	Description
6	X	VGP6_INT_STATUS: VGP6 pin Interrupt Status. This bit controls interrupt when a VGP6 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
5	X	VGP5_INT_STATUS: VGP5 pin Interrupt Status. This bit controls interrupt when a VGP5 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
4	X	VGP4_INT_STATUS: VGP4 pin Interrupt Status. This bit controls interrupt when a VGP4 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR

2	X	VGP2_INT_STATUS: VGP2 pin Interrupt Status. This bit controls interrupt when a VGP2 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
1	X	VGP1_INT_STATUS: VGP1 pin Interrupt Status. This bit controls interrupt when a VGP1 rising/falling

Bit	Reset	Description
		edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR

28.5.18 VI_CFG_VGP_SYNCPT_CONFIG_0

Offset: 0x2b | Byte Offset: 0xac | Read/Write: R/W | Reset: 0x00000000 (0b000x000)

Bit	Reset	Description
6:4	0x0	SYNCPT_VGPY_SELECT: Selects the VGP (1-6) for SYNCPT condition VGP_1_RECD
2:0	0x0	SYNCPT_VGPX_SELECT: Selects the VGP (1-6) for SYNCPT condition VGP_0_RECD

28.5.19 VI_CFG_VI_SW_RESET_0

Offset: 0x2d | Byte Offset: 0xb4 | Read/Write: R/W | Reset: 0x00000000 (0b0)

Bit	Reset	Description
0	0x0	MCCIF_RESET: Resets the MCCIF interface

28.5.20 VI_CFG_CG_CTRL_0

Offset: 0x2e | Byte Offset: 0xb8 | Read/Write: R/W | Reset: 0x00000000 (0b0)

Bit	Reset	Description
0	0x0	CG_2ND_LEVEL_EN: Second-level clock gating control 0: Disables any second-level clock gating (MCCIF clocks should be controlled from CAR registers) 1: Enables second-level clock gating 0 = DISABLE 1 = ENABLE

28.5.21 VI_CFG_VI_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control Register (where applicable) and Clock Gating Control

> **Note:** The FIFO timing aspects of this register are not supported but are retained for software compatibility.

The clock override/ovr_mode fields of this register control the 2nd-level clock gating for the client and MC side of the MCCIF. All clock gating is enabled by default.

A '1' written to the rclk/wclk override field will result in one of the following:

- With wclk/rclk override mode = LEGACY, the clock reverts to the legacy mode of operation where the clock is on whenever the client clock is enabled.
- With wclk/rclk override mode = ON, the clock is always on inside the MCCIF and PC.

A '1' written to the cclk override field keeps the client's clock always on inside the MCCIF.

Offset: 0x39 | Byte Offset: 0xe4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxx00000xxxxxxxxxxxxxx00)

Bit	Reset	Description

28.6.6 VI_CSI_0_MEM_TILING_0

Offset: 0x45 | Byte Offset: 0x114 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	TILING_FORMAT: VI channel memory surface tiling format 254 = BLOCK_LINEAR 0 = PITCH_LINEAR

28.6.7 VI_CSI_0_CSI_IMAGE_SIZE_0

Offset: 0x46 | Byte Offset: 0x118 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	HEIGHT: Height of VI channel frame in Lines. This Register field is double buffered.
15:0	X	WIDTH: Width of VI channel frame in Pixels. This Register field is double buffered.

28.6.8 VI_CSI_0_CSI_IMAGE_SIZE_WC_0

Offset: 0x47 | Byte Offset: 0x11c | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	WORDCOUNT: VI channel word count for the Image to be captured This parameter specifies the number of bytes per line/packet. This is matched against the Word Count field in packet header if enabled. This count does not include the additional 2 bytes of CRC checksum if data CRC check is enabled. When the input stream comes from a CSI camera port, this parameter must be programmed when CSI_PPA_PAD_SHORT_LINE is set to either PAD0S or PAD1S, no matter whether CSI_PPA_WORD_COUNT_SELECT is set to REGISTER or HEADER. When the input stream comes from the host path or from the VIP path, and the data mode is PAYLOAD_ONLY, this count must be programmed. Given a line width of N pixels, the programming value of this parameters is as follows ---------- data format value ---------- YUV420_8 N bytes YUV420_10 N/4*5 bytes LEG_YUV420_8 N/2*3 bytes YUV422_8 N*2 bytes YUV422_10 N/2*5 bytes RGB888 N*3 bytes RGB666 N/4*9 bytes RGB565 N*2 bytes RGB555 N*2 bytes RGB444 N*2 bytes RAW6 N/4*3 bytes RAW7 N/8*7 bytes RAW8 N bytes RAW10 N/4*5 bytes RAW12 N/2*3 bytes RAW14 N/4*7 bytes ---------- This register is used in to set the wordcount in Test Pattern Generation mode. The wordcount size needed to be set in 16-pixel boundary depended on data type selection (RAW10 or RGB888) This Register field is double buffered.

28.6.9 VI_CSI_0_CSI_IMAGE_DT_0

Offset: 0x48 | Byte Offset: 0x120 | Read/Write: R/W | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxx0xxxxxxxxxxx)

Bit	Reset	Description
12	0x0	INTERLACED_VIDEO: VI channel interlaced video format enable

1	0x0	DEST_ISPA: 1= send VI channel data to ISPA
0	0x0	DEST_MEM: 1= send VI channel data to MEM

28.6.35 VI_CSI_1_RGB2Y_CTRL_0

Offset: 0x84 | Byte Offset: 0x210 | Read/Write: R/W | Reset: 0x00XXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:18	X	B2Y_COEFF: Blue coefficient used to convert RGB pixel data to Y for writing to Memory(in U0.6 format)
15:10	X	G2Y_COEFF: Green coefficient used to convert RGB pixel data to Y for writing to Memory(in U0.6 format)
7:2	X	R2Y_COEFF: Red coefficient used to convert RGB pixel data to Y for writing to Memory(in U0.6 format)

28.6.36 VI_CSI_1_MEM_TILING_0

Offset: 0x85 | Byte Offset: 0x214 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	TILING_FORMAT: VI channel memory surface tiling format 254 = BLOCK_LINEAR 0 = PITCH_LINEAR

28.6.37 VI_CSI_1_CSI_IMAGE_SIZE_0

Offset: 0x86 | Byte Offset: 0x218 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	HEIGHT: Height of VI channel frame in Lines. This Register field is double buffered.
15:0	X	WIDTH: Width of VI channel frame in Pixels. This Register field is double buffered.

28.6.38 VI_CSI_1_CSI_IMAGE_SIZE_WC_0

Offset: 0x87 | Byte Offset: 0x21c | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	WORDCOUNT: VI channel word count for the Image to be captured This parameter specifies the number of bytes per line/packet. This is matched against the Word Count field in packet header if enabled. This count does not include the additional 2 bytes of CRC checksum if data CRC check is enabled. When the input stream comes from a CSI camera port, this parameter must be programmed when CSI_PPA_PAD_SHORT_LINE is set to either PAD0S or PAD1S, no matter whether CSI_PPA_WORD_COUNT_SELECT is set to REGISTER or HEADER. When the input stream comes from the host path or from the VIP path, and the data mode is PAYLOAD_ONLY, this count must be programmed. Given a line width of N pixels, the programming value of this parameters is as follows ---------- data format value ---------- YUV420_8 N bytes YUV420_10 N/4*5 bytes LEG_YUV420_8 N/2*3 bytes YUV422_8 N*2 bytes YUV422_10 N/2*5 bytes RGB888 N*3 bytes RGB666 N/4*9 bytes RGB565 N*2 bytes RGB555 N*2 bytes RGB444 N*2 bytes RAW6 N/4*3 bytes RAW7 N/8*7 bytes RAW8 N bytes RAW10 N/4*5 bytes RAW12 N/2*3 bytes RAW14 N/4*7 bytes ---------- This register is used in to set the wordcount in Test Pattern Generation mode. The wordcount size needed to be set in 16-pixel boundary depended on data type selection (RAW10 or RGB888) This Register field is double buffered.

28.6.39 VI_CSI_1_CSI_IMAGE_DT_0

Offset: 0x88 | Byte Offset: 0x220 | Read/Write: R/W | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxx0xxxxxxxxxxx)

Bit	Reset	Description
12	0x0	INTERLACED_VIDEO: VI channel interlaced video format enable
9:8	X	VC: VI channel virtual channel ID. This Register field is double buffered.

28.6.58 VI_CSI_1_ERROR_INT_MASK_0

Offset: 0xa2 | Byte Offset: 0x288 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx000000)

Bit	Reset	Description
5	0x0	WATCHDOG_INT_MASK: Watchdog Timer 0 Interrupt Mask This controls interrupt when WATCHDOG trigger event occurs for the CSI stream 0 = Disabled, 1 = Enabled
4	0x0	CSI_FRAME_ERROR_INT_MASK: CSI error interrupt mask
3	0x0	FRAME_HEIGHT_LONG_INT_MASK: frame height long error interrupt mask
2	0x0	FRAME_HEIGHT_SHORT_INT_MASK: frame height short error interrupt mask
1	0x0	LINE_WIDTH_LONG_INT_MASK: line width long error interrupt mask
0	0x0	LINE_WIDTH_SHORT_INT_MASK: line width short error interrupt mask

28.6.59 VI_CSI_1_WD_CTRL_0

Watch Dog Timer Control Register

Offset: 0xa3 | Byte Offset: 0x28c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	WD_ENABLE: Watch Dog Timer Enable 0 = DISABLE 1 = ENABLE

28.6.60 VI_CSI_1_WD_PERIOD_0

Watch Dog Timer Control Register

Offset: 0xa4 | Byte Offset: 0x290 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	WD_PERIOD: Watch Dog Timer Period in pixel clocks

28.7 MIPI-CSI Registers

Refer to the CSI section in this document for descriptions of these registers.

[THIS PAGE INTENTIONALLY LEFT BLANK]

29.0 SD/MMC CONTROLLER

The SD/MMC Controller can interface with SD/eSD, SDIO, or eMMC devices. It supports both on-board devices and plug-in cards.

Each Tegra® K1 mobile processor contains four instances of this controller, each of which is identical in its internal function, but they vary in I/O capabilities:

Controller	UHS-I Signaling Supported	8-bit eMMC Supported	Signaling Voltages
SDMMC1	Yes	No	1.8, 2.8-3.3 V
SDMMC2	Yes	Yes	1.8, 2.8-3.3 V
SDMMC3	Yes	No	1.8, 2.8-3.3 V
SDMMC4	Yes	Yes	1.2, 1.8 V

29.1 Supported Specifications and Standards

The SD/MMC controller supports the specifications from the SD Card Association and JEDEC (MMC) at the versions listed in the following table.

Protocol	Version
SD	4.0 (UHS-I only)
SDIO	4.0 (UHS-I only)
eSD	2.1
eMMC	4.51
SDHOST	4.0 (UHS-I only)

The specifications are as follows:

- “SD Specifications, Part E1, SDIO Specification”, Technical Committee SD Card Association, Version 4.00, 20-February 2012
- “SD Specifications, Part 1, Physical Layer Specification”, Technical Committee SD Card Association, Version 4.00, 30-May 2011.
- “SD Specification, Part 1, eSD (Embedded SD) Addendum”, Technical Committee SD Card Association, Version 2.10, 25-November 2008.
- “SD Specifications, Part A2, SD Host Controller Standard Specification”, Technical Committee SD Card Association, Version 4.00, 20-February 2012.
- “JEDEC Standard, Embedded Multimedia Card (eMMC) Electrical Standard 4.51”, JEDEC Solid State Technology Association, June 2012.

29.2 Supported Speeds

These tables show the maximum data rates available over the physical interface. The speeds achievable in actual use will be less than these rates, depending on the performance of the device itself, protocol limitations, and the software driver.

For SD 3.0 data transfer modes, these are the maximum data transfer speeds:

Speed Mode	Signal Voltage	I/O Frequency (MHz)	Bus Width	Maximum Throughput (MBytes/s)	UHS Protocol
Default Speed	3.3	25	1,4	12.5	UHS-I, 50 (SD3.0) UHS-I, 104 (SD3.0)
High Speed	3.3	50	1,4	25	UHS-I, 50 (SD3.0) UHS-I, 104 (SD3.0)
SDR12	1.8	25	1,4	12.5	UHS-I, 50 (SD3.0) UHS-I, 104 (SD3.0)
SDR25	1.8	50	1,4	25	UHS-I, 50 (SD3.0) UHS-I, 104 (SD3.0)
SDR50	1.8	100	1,4	50	UHS-I, 50 (SD3.0) UHS-I, 104 (SD3.0)
SDR104 UHS-I	1.8	208	1,4	104	UHS-I, 104 (SD3.0)

For eSD 2.1 data transfer modes, these are the maximum data transfer speeds:

Speed Mode	Signal Voltage	I/O Frequency (MHz)	Bus Width	Maximum Throughput (MBytes/s)	eSD Protocol
Default Speed	3.3	25	1,4,8	12.5	eSD 2.1
High Speed	3.3	50	1,4,8	25	eSD 2.1

For SDIO data transfer modes, these are the maximum data transfer speeds:

Speed Mode	I/O Frequency (MHz)	Bus Width	Maximum Throughput (MBytes/s)	Protocol Version/UHS Version
Default Speed	25	1,4	12.5	SDIO2.0 /UHS-I, 50/ UHS-I, 104
High Speed	50	1,4	25	SDIO2.0 /UHS-I, 50/ UHS-I, 104
SDR12	25	1,4	12.5	UHS-I, 50 (SDIO3.0) UHS-I, 104 (SDIO3.0)
SDR25	50	1,4	25	UHS-I, 50 (SDIO3.0) UHS-I, 104 (SDIO3.0)
SDR50	100	1,4	50	UHS-I, 50 (SDIO3.0) UHS-I, 104 (SDIO3.0)
SDR104 UHS-I	208	1,4	104	UHS-I, 104 (SDIO3.0)

For eMMC data transfer modes, these are the maximum data transfer speeds:

Speed Mode	I/O Frequency (MHz)	Bus Width	Maximum Throughput (MBytes/s)	MMC Revision
Legacy Speed	26	1,4,8	26	MMC 4.3
High Speed SDR	52	1,4,8	52	MMC 4.3
High Speed DDR	52	4,8	104	MMC 4.4

Speed Mode	I/O Frequency (MHz)	Bus Width	Maximum Throughput (MBytes/s)	MMC Revision
HS200 (SDR)	200	4,8	200	MMC 4.5

29.3 Operation

29.3.1 Hardware / Software Partitioning

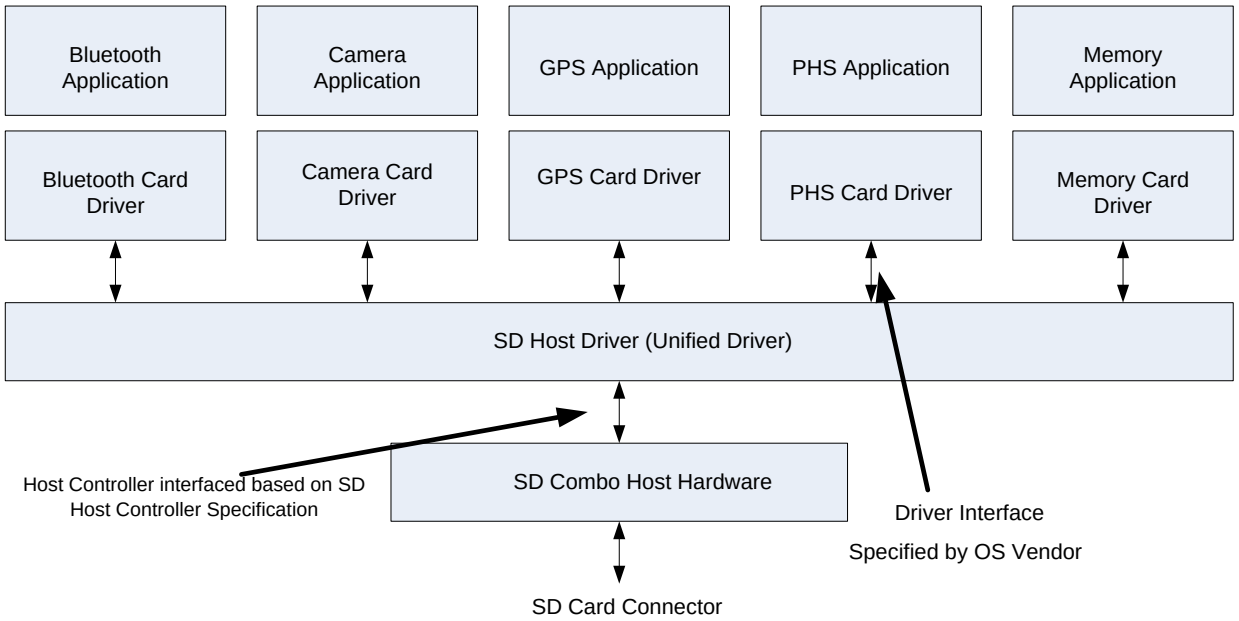
Hardware

The role of the hardware controller is to send out the programmed command, store the response, and make it visible to software. It updates the status registers and generates interrupts when attention is required. Software may also configure it for DMA operation.

Software

The software driver determines which type of card is inserted in the slot by sending the initialization commands and observing the responses received from the card. After identifying the card that is inserted, it should only program the corresponding set of commands that are applicable. It can enable interrupts for which notification is desired.

Figure 114: Host Hardware and Driver Architecture



29.4 Caveats and Assumptions

- A single SD/MMC controller handles only one device at a time.
- The software should configure SDMMC_VENDOR_CLOCK_CNTRL_0_SDMMC_CLK to _DISABLE before turning off the SD/MMC clock (and configure back to _ENABLE after turning on the SD/MMC clock). This is required in order to support asynchronous card interrupts when no clock is supplied to the card.
- PMC can be configured to wake the Tegra K1 device from the LP0 power state based on either:
  - Card Detection pin.

- Asynchronous interrupt on the DAT1 line

- Write protect and card detect logic is implemented in Tegra only for SDMMC1 and SDMMC3.
- Off-card ECC, described in the MMC specification, is not supported.

29.5 SD/MMC Interfaces

Controller	Number of Pinmuxings		Bus Width (Legacy)	Legacy Pads	Voltage (V)	Legacy I/O Clock (MHz)	eMMC4.51	Use Case	Maximum Bandwidth (MBps)
SDMMC1	1	SDMMC1	4	BDSDMEM	3.3/1.8	208		SD/SDIO	104
SDMMC2	2	GMI (SDMMC2A)	8	BDSDMEM	3.3/1.8	208		1st SDIO (with 2 SD), 2nd SDIO (with 1 SD),or 2nd (1.8V) eMMC	104
		PEMMC (SDMMC2B)	8	BDPGLP	3.3/1.8	40 DDR/ 80 SDR		1st SDIO when GMI used for NOR	40
SDMMC3	1	SDMMC3	4	BDSDMEM	3.3/1.8	208		SD/SDIO	104
SDMMC4	1	SDMMC4	8	BDSDMEMLV	1.2/1.8	200		Bootable eMMC	200

29.6.1 SD CD# and SDWP# Pins

The removable SD cards' Card Detect and Write protect pins apply to SDMMC1 and SDMMC3 only. Tegra K1 devices provide the below pinmux options for these pins.

Controller	Signal	Ball Name	PINGROUP	Alt
SDMMC1	SDMMC1_WP_N	SDMMC1_WP_N	sdmmc1_wp_n_pm	0
	SDMMC1_CD_N	UART3_CTS_N	uart3_cts_n_pm	1
	SDMMC1_CD_N	KB_COL5	kb_col5_pm	2
SDMMC3	SDMMC3_WP_N	KB_COL4	kb_col4_pm	2
	SDMMC3_WP_N	GPIO_PCC2	gpio_pcc5_pm	2
	SDMMC3_CD_N	KB_COL5	kb_col5_pm	2

29.7 Programming Guidelines

This section assumes a SD Host driver complying with the SD Specifications' Part A2, SD Host Control Standard Specification. The following subsections detail the necessary changes required for fully featured SD (and eMMC boot mode) operation.

29.7.1 Initialization

The following register writes should be done before the SD host driver is loaded. These register writes can be done in any order, and writes to different register fields within the same register should ideally be combined into a single write for efficiency:

29.7.1.1 General

These settings apply to all SD/MMC controllers in use:

- Enable tuning in SDR50 by setting SDMMC_VENDOR_CLOCK_CNTRL_0_SDR50_TUNING_OVERRIDE.
- Enable SDR104 (HS200 for eMMC application) support by setting UHS_MODE_SEL to SDR104 in HOST_CONTROL_2 (offset 03Eh) register.
- In DDR50 mode, SD clock divisor should always be 2. That means the host clock should be double that of the card clock for data to be sampled properly.
  - Register SDMMC_SW_RESET_TIMEOUT_CTRL_CLOCK_CONTROL_0_SDCLK_FREQUENCYSELECT value would be 0x1.

- Clamp clocks during resets by setting these two values:
  - SDMMC_VENDOR_CLOCK_CNTRL_0_PADPIPE_CLKEN_OVERRIDE_NORMAL
  - SDMMC_VENDOR_CLOCK_CNTRL_0_SPI_MODE_CLKEN_OVERRIDE_NORMAL

Loopback Clock Selection for SDMMC3 only:

For all modes that require tuning (SDR104, SDR50), disable external loopback on SDMMC3.

For all modes that are non-tunable (DS, HS, SDR12, SDR25, DDR50), enable external loopback on SDMMC3.

The following are the register settings to enable/disable external loopback on SDMMC3 for Tegra K1 devices:

reg SDMMC_VENDOR_MISC_CNTRL_0 SDMMC_SPARE1 0xFFFF// Enables external loopback on SDMMC3
reg SDMMC_VENDOR_MISC_CNTRL_0 SDMMC_SPARE1 0xFFFD// Disables external loopback and uses internal loopback on SDMMC3

29.7.1.2 SDMMC1

These settings are specific to the SDMMC1 controller:

Supply Voltage	33 Ohm		50 Ohm		66 Ohm		100 Ohm	
	UP	DN	UP	DN	UP	DN	UP	DN
1.8 V	6'h46	6'h36	6'h2A	6'h20	6'h22	6'h17	6'h13	6'hB
3.3 V	-		6'h24	6'h14	-		-	

UP - APB_MISC_GP_SDIO1CFGPADCTRL_0_CFG2TMC_SDIO1CFG_CAL_DRVUP

DN - APB_MISC_GP_SDIO1CFGPADCTRL_0_CFG2TMC_SDIO1CFG_CAL_DRVDN

- APB_MISC_GP_SDIO1CFGPADCTRL_0_CFG2TMC_SDIO1CFG_CAL_DRVDN_SLWR **= 2'h0**
- APB_MISC_GP_SDIO1CFGPADCTRL_0_CFG2TMC_SDIO1CFG_CAL_DRVUP_SLWF **= 2'h0**
  SDMMC_SDMEMCOMPPADCTRL_0_SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL **= 4'h7**
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_ENABLE_ENABLED
- The following pull-up and pull-down offsets should be used along with the auto-calibration results for both 3.3V and 1.8V modes. (Note: the offsets are required to eliminate the overshoot/undershoot seen when 33Ω calibration resistors are used. For a 50 Ω driver no offset is required for all modes.)
  - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = 8'h76
  - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = **8'h76**

- If using the SDMMC1 interface, correctly enable the integrated pullup/down resistors there:
  - PINMUX_AUX_SDMMC1_CLK_0_PULL_UP_NORMAL
  - If using eMMC (a stronger external 4.7 kΩ pull-up is used on the CMD line):
    - PINMUX_AUX_SDMMC1_CMD_0_PULL_UP_NORMAL
  - If using SD or SDIO:
    - PINMUX_AUX_SDMMC1_CMD_0_PULL_UP_PULL_UP
  - PINMUX_AUX_SDMMC1_DAT3_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC1_DAT2_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC1_DAT1_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC1_DAT0_0_PUPD_PULL_UP

29.7.1.3 SDMMC2A

These settings are specific to the SDMMC2A controller:

Supply Voltage	33 Ohm		50 Ohm		66 Ohm		100 Ohm	
	UP	DN	UP	DN	UP	DN	UP	DN
1.8 V	6'h46	6'h36	6'h2A	6'h20	6'h22	6'h17	6'h13	6'hB
3.3 V	-		6'h24	6'h14	-		-	

UP - APB_MISC_GP_ATCFG6PADCTRL_0_CFG2TMC_ATCFG6_CAL_DRVUP

DN - APB_MISC_GP_ATCFG6PADCTRL_0_CFG2TMC_ATCFG6_CAL_DRVDN

- APB_MISC_GP_ATCFG6PADCTRL_0_CFG2TMC_SDIO2CFG_CAL_DRVDN_SLWR **= 2'h0**
- APB_MISC_GP_ATCFG6PADCTRL_0_CFG2TMC_SDIO2CFG_CAL_DRVUP_SLWF **= 2'h0**
- SDMMC_SDMEMCOMPPADCTRL_0_SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL **= 4'h7**
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_ENABLE_ENABLED
- The following pull-up and pull-down offsets should be used along with the auto-calibration results for both 3.3V and 1.8V modes. (Note: the offsets are required to eliminate the overshoot/undershoot seen when 33Ω calibration resistors are used. For a 50Ω driver no offset is required for all modes.)
  - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = **8'h76**
  - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = **8'h76**

- If using the SDMMC2 controller's external interface shared with the GMI pins, correctly enable the integrated pullup/down resistors there:
  - PINMUX_AUX_ GMI_CLK_0 _PUPD_PUUL_DOWN
  - If using eMMC (a stronger external 4.7 kOhm pull-up is used on the CMD line):
    - PINMUX_AUX_GMI_AD15_0_PUPD_NORMAL
  - If using SD or SDIO:
    - PINMUX_AUX_GPIO_PH7_0_PUPD_PULL_UP
  - PINMUX_AUX_GPIO_PH4_0_PUPD_PULL_UP
  - PINMUX_AUX_GPIO_PH5_0_PUPD_PULL_UP
  - PINMUX_AUX_GPIO_PH6_0_PUPD_PULL_DOWN
  - PINMUX_AUX_GPIO_PI2_0_PUPD_PULL_UP
  - PINMUX_AUX_GPIO_PI6_0_PUPD_PULL_UP
  - PINMUX_AUX_GPIO_PI5_0_PUPD_PULL_UP
  - PINMUX_AUX_GPIO_PK3_0_PUPD_PULL_UP
  - PINMUX_AUX_GPIO_PK4_0_PUPD_PULL_UP

29.7.1.4 SDMMC2B

These settings are specific to the SDMMC2B controller:

Supply Voltage	50 Ohm	
	UP	DN
1.8 V	6'd14	6'd8
3.3 V	6'd5	6'd4

CLK, CMD, DAT0, DAT1, and DAT6:

- APB_MISC_GP_GMECFGPADCTRL_0_CFG2TMC_GMECFG_CAL_DRVUP

DAT7:

- APB_MISC_GP_GMHCFGPADCTRL_0_CFG2TMC_GMHCFG_CAL_DRVUP
- APB_MISC_GP_GMHCFGPADCTRL_0_CFG2TMC_GMHCFG_CAL_DRVDN
- APB_MISC_GP_GMHCFGPADCTRL_0_CFG2TMC_GMHCFG_CAL_DRVDN_SLWR **= 2'h0**
- APB_MISC_GP_GMHCFGPADCTRL_0_CFG2TMC_GMH2CFG_CAL_DRVUP_SLWF **= 2'h0**
    - SDMMC_SDMEMCOMPPADCTRL_0_SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL = **4'h7**
    - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_ENABLE_ENABLED
    - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = **8'h0**
    - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = **8'h0**

- If using the SDMMC2B controller's external interface shared with the CAM/PEMMC pins, correctly enable the integrated pullup/down resistors there:
    - PINMUX_AUX_ GPIO_PBB3_0 _PUPD_PUUL_DOWN
    - If using eMMC (a stronger external 4.7 kOhm pull-up is used on the CMD line):
        - PINMUX_AUX_CAM_I2C_SDA_0_PUPD_NORMAL
    - If using SD or SDIO:
        - PINMUX_AUX_CAM_I2C_SDA_0_PUPD_PULL_UP
    - PINMUX_AUX_GPIO_PBB0_0_PUPD_PULL_UP
    - PINMUX_AUX_CAM_I2C_SCL_0_PUPD_PULL_UP
    - PINMUX_AUX_GPIO_PBB5_0_PUPD_PULL_UP
    - PINMUX_AUX_CAM_MCLK_0_PUPD_PULL_DOWN
    - PINMUX_AUX_GPIO_PBB6_0_PUPD_PULL_UP
    - PINMUX_AUX_GPIO_PBB7_0_PUPD_PULL_UP
    - PINMUX_AUX_GPIO_PCC2_0_PUPD_PULL_UP
    - PINMUX_AUX_GPIO_PCC1_0_PUPD_PULL_UP

29.7.1.5 SDMMC3

These settings are specific to the SDMMC3 controller:

Supply Voltage	33 Ohm		50 Ohm		66 Ohm		100 Ohm	
	UP	DN	UP	DN	UP	DN	UP	DN
1.8 V	6'h46	6'h36	6'h2A	6'h20	6'h22	6'h17	6'h13	6'hB
3.3 V	-		6'h24	6'h14	-		-	

UP - APB_MISC_GP_SDIO3CFGPADCTRL_0_CFG2TMC_SDIO3CFG_CAL_DRVUP

DN - APB_MISC_GP_SDIO3CFGPADCTRL_0_CFG2TMC_SDIO3CFG_CAL_DRVDN

- APB_MISC_GP_SDIO3CFGPADCTRL_0_CFG2TMC_SDIO3CFG_CAL_DRVUP_SLWF = **2'h0**
- SDMMC_SDMEMCOMPPADCTRL_2_SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL = **4'h7**
  SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_ENABLE_ENABLED
- The following pull-up and pull-down offsets should be used along with the auto-calibration results for both 3.3V and 1.8V modes. (Note: the offsets are required to eliminate the overshoot/undershoot seen when 33Ω calibration resistors are used. For a 50Ω driver no offset is required for all modes.)
  - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = **8'h76**
  - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = **8'h76**

- If using the SDMMC3 interface, correctly enable the integrated pullup/down resistors there:
  - PINMUX_AUX_SDMMC3_CLK_0_PUPD_NORMAL
  - If using eMMC (a stronger external 4.7 kOhm pullup is used on the CMD line):
    - PINMUX_AUX_SDMMC3_CMD_0_PUPD_NORMAL
  - If using SD or SDIO:
    - PINMUX_AUX_SDMMC3_CMD_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC3_DAT3_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC3_DAT2_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC3_DAT1_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC3_DAT0_0_PUPD_PULL_UP

29.7.1.6 SDMMC4

These settings are specific to the SDMMC4 controller:

Supply Voltage	33 Ohms		50 Ohms	
	UP	DN	UP	DN
1.8 V	6'h07	6'h07	6'h02	6'h01
1.2 V	6'h0E	6'h0E	6'h05	6'h05

UP - APB_MISC_GP_GMACFGPADCTRL_0_CFG2TMC_GMACFG_CAL_DRVUP

DN - APB_MISC_GP_GMACFGPADCTRL_0_CFG2TMC_GMACFG_CAL_DRVDN

- APB_MISC_GP_GMACFGPADCTRL_0_CFG2TMC_GMACFG_CAL_DRVDN_SLWR **= 2'h0**
- APB_MISC_GP_GMACFGPADCTRL_0_CFG2TMC_GMACFG_CAL_DRVUP_SLWF **= 2'h0**
- SDMMC_SDMEMCOMPPADCTRL_0_SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL **= 4'h7**
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_ENABLE_ENABLED
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = **8'h2**
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = **8'h2**
- If using the SDMMC4 interface, correctly enable the integrated pullup/down resistors there:
- PINMUX_AUX_SDMMC4_CLK_0_PUPD_PULL_DOWN
- If using eMMC (a stronger external 4.7 kOhm pullup is used on the CMD line):
  - PINMUX_AUX_SDMMC4_CMD_0_PUPD_NORMAL
- If using SD or SDIO:
  - PINMUX_AUX_SDMMC4_CMD_0_PUPD_PULL_UP
- PINMUX_AUX_SDMMC4_DAT7_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_DAT6_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_DAT5_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_DAT4_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_DAT3_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_DAT2_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_DAT1_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_DAT0_0_PULL_UP_PULL_UP

29.7.2 Tap Values

Software should select the proper tap values for outbound (SDMMC_VENDOR_CLOCK_CNTRL_0_TRIM_VAL) and inbound (SDMMC_VENDOR_CLOCK_CNTRL_0_TAP_VAL) datapaths.

The value of the tap depends on speed modes.

29.7.2.1 Inbound Tap Values (SDMMC_VENDOR_CLOCK_CNTRL_0_TAP_VAL)

The below tap values can be used up to SDR25 speeds.

Controller	IB Tap Val
SDMMC1	0
SDMMC2A	0

Controller	IB Tap Val
SDMMC2B	0
SDMMC3	0
SDMMC4	0

29.7.2.2 DDR52 (eMMC) Tap Settings

Controller	IB Tap Val
SDMMC1	2
SDMMC2A	2
SDMMC2B	1
SDMMC3	0
SDMMC4	4

Note: Software should use tuning procedure to determine the tap value in SDR50 and SDR104/HS200 modes.

29.7.2.3 Outbound Tap Values (SDMMC_VENDOR_CLOCK_CNTRL_0_TRIM_VAL)

The below settings are valid in all speed modes for SDMMC1, SDMMC2A, SDMMC2B and SDMMC3 .

Controller	OB TRIM Val
SDMMC1	2
SDMMC2A	3
SDMMC2B	3
SDMMC3	3

The below settings are valid only for SDMMC4.

Controller	OB TRIM Val	Speed Mode
SDMMC4	4	SDR26, SDR52, HS-200
SDMMC4	0	HS-DDR (DDR52)

29.7.3 eMMC Boot Modes

The section of this document on the boot process describes the boot process in more detail, but note that only the SDMMC4 controller can be used as the eMMC boot device.

29.7.4 Boot Option1

1. The clock to the card needs to be configured to 26 MHz.
2. Program the number of blocks. Configuring block length has no effect; it is always fixed to 512 bytes.
3. Configuring the data transfer direction has no impact, since it taken as CARD to HOST for boot mode.
4. Select either SDMA or PIO mode.
5. Configure SDMMC_VENDOR_BOOT_ACK_TIMEOUT_0 – The maximum timeout value that needs to be programmed is 50ms.The value programmed should exclude the 74 cycles that are required to enter boot mode.
6. Configure SDMMC_VENDOR_BOOT_DAT_TIMEOUT_0 – The max timeout value that needs to be programmed is 1 second .The value programmed should exclude the 74 cycles that are required to enter boot mode.

7. Configure SDMMC_VENDOR_BOOT_CNTRL_0[1] to 1 to ask the engine to look for boot_ack.
8. Configure SDMMC_VENDOR_BOOT_CNTRL_0[0] to trigger the engine.
9. If SDMMC_INTERRUPT_STATUS_0[31] = 1, the BOOT_ACK is not equal to 00101.The engine just informs the software and continues to fetch data from the card
10. If SDMMC_INTERRUPT_STATUS_0[30] = 1, the BOOT_ACK timeout has occurred. The engine just informs the software and continues to fetch data from the card.
11. The software should look for transfer complete interrupt. If “data_time_out” error has occurred, then the data transfer is not successful.
12. After successful data transfer from card, the software should look for “sdma_engine_busy” bit of SDMMC_OBS_SDMMC_DBG0_0 [0]. Software shouldn’t program commands until this bit is zero.

29.7.5 Boot Option2

Boot option2 is treated like any normal read command. The BOOT_ACK should be enabled if the card supports boot acknowledgment. SDMMC_VENDOR_BOOT_ACK_TIMEOUT_0, SDMMC_VENDOR_BOOT_DAT_TIMEOUT_0 should be programmed based on the frequency of operation.

29.7.6 Card Detect and Write Protect

Only SDMMC1 and SDMMC3 support removable SD cards. The standard SD Host, SDCD# pin act as card detect pin and CDWP# pin act as Write protect pin. The SD Card State registers can be ignored for embedded on-board devices.

PIN MUX detail for CD and WP pins for SDMMC1 and SDMMC3.

PINMUX_AUX_SDMMC1_WP_N_0_PUPD_PULL_UP

PINMUX_AUX_KB_COL4_0_PUPD_PULL_UP - This is the Pinmux option for SDMMC1 CD

PINMUX_AUX_KB_COL4_0_PUPD_PULL_UP - This is the Pinmux option for SDMMC3 WP

PINMUX_AUX_SDMMC3_CD_N_0_PUPD_PULL_UP

Additionally, an abort command should be issued if a card is removed during an SD transfer.

29.7.7 Improving Non-DMA (PIO) Performance

When transferring more than a single 512 byte block size, PIO performance is reduced because the standard process waits for the buffer ready interrupt before beginning to move the next block of data.

Next block data movement can instead be pipelined on a four-byte word basis. To do this, software should waiting for SDMMC_PRESENT_STATE_0’s BUFFER_READ_EN or BUFFER_WRITE_EN fields to assert instead of the buffer ready interrupt. These status fields signify that the next four-byte word can be read from or written to the internal 512 byte buffer.

29.7.8 SD3.0 Signal Voltage Switching

Note:	This section is applicable only to the UHS-I SDMMC1 and SDMMC3 controllers. The SDMMC2 and SDMMC4 controllers do not require these settings.

Signal Voltage Switching happens after setting 1.8V signal enable in the host control 2 register. Switching the voltage from 3.3V to 1.8V, UHS-I signaling requires switching the external power supply.

After setting 1.8V Signal Enable in the *Host Control 2* register, the SD host driver communicates with the hardware platform to change the SDMMC1, SDMMC2 and SDMMC3 I/O voltage from 3.3 to 1.8V. This is typically via I2C control of an external “PMIC” (Power Management IC).

When resetting the controller (e.g., when an SD3.0 card in 1.8V mode has been removed), the SD host driver again communicates with the system software/platform to increase the SD I/O voltage back to 3.3V.

29.7.8.1 Initialization

Before the standard SD driver begins running:

1. Route the SDMMC controller's system interrupt to the appropriate driver.
2. Write 1 to SDMMC_VENDOR_SYS_SW_CNTRL_0_VOLT_SWITCH_INT_STATUS to clear any latent interrupts.
3. Set SDMMC_VENDOR_SYS_SW_CNTRL_0_VOLT_SWITCH_INT _ENABLE to enable the system interrupt on an SD3.0 UHS-I Voltage Switch event.

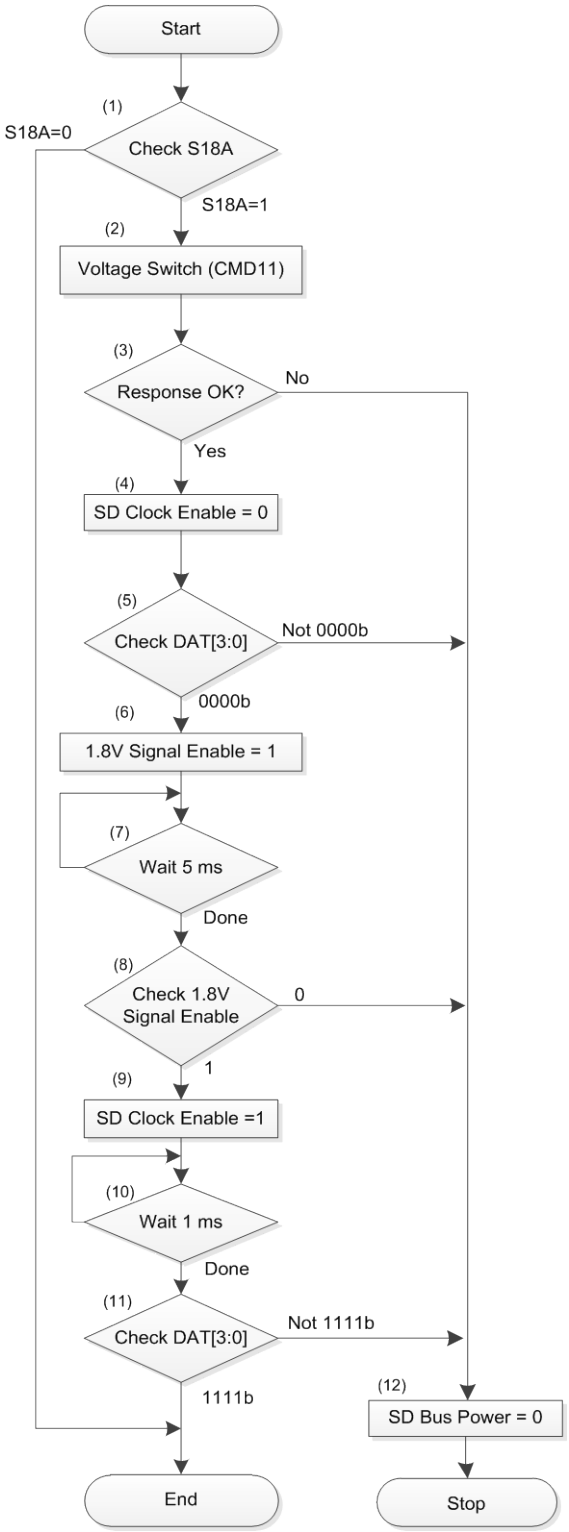
29.7.8.2 Entry

Once an SDMMC controller generates a system interrupt:

- Confirm the SDMMC System interrupt was from a voltage switch event by reading SDMMC_VENDOR_SYS_SW_CNTRL_0_VOLT_SWITCH_INT _STATUS.

29.7.8.3 Voltage Switch Procedure

The following figure shows the standard voltage switch procedure.



29.7.8.1 Exit

Write 1 to SDMMC_VENDOR_SYS_SW_CNTRL_0_VOLT_SWITCH_INT _STATUS to clear the interrupt condition.

29.7.9 Tuning

Tuning is required because SD/MMC controllers do not automatically vary the RX clock trim each time that Execute Tuning is set to 1; the SD Host driver must do this manually.

SD 3.0 cards can operate at frequencies up to 208 MHz. For the card to operate at high frequencies, the correct tap value must be programmed. The tap value in the vendor clock control register controls the track delay so that the input data is sampled correctly. The appropriate tap delay for the given platform is found using frequency tuning. The passing tap value range can be found by incrementing the tap value after each iteration and running frequency tuning.

In frequency tuning, CMD19 for SD and CMD21 for eMMC (emmc4.51) card is issued to the card and wait for the Buffer Read Ready interrupt. Once the interrupt is generated, in the HOST_CONTROL_2 register (offset 03Ch), check whether the EXECUTE_TUNING bit is cleared and the SAMPLING_CLK_SELECT bit is set. If both conditions are met, treat tuning as successful and consider the tap value as working. After finding the passing tap range, the ideal tap value is calculated, which is 75% between the highest passing tap and the lowest passing tap. Set this tap value and run frequency tuning again to confirm that the tap value works. If the passing tap range falls in between 0 and 10, discount it and try to find a higher passing tap range.

During testing, the tap range between 0 and 10 was found to be insufficient for operating frequencies up to 208MHz.

29.7.9.1 Initialization

Before the standard SD drive begins running:

1. Route the SD/MMC controller's system interrupt to the appropriate driver.
2. Write 1 to SDMMC_VENDOR_SYS_SW_CNTRL_0_TUNING_SYS_INT_STATUS to clear any latent interrupts.
3. Set SDMMC_VENDOR_SYS_SW_CNTRL_0_TUNING_SYS_INT_ENABLE to enable the system interrupt on an SD3.0 UHS-I tuning start event.

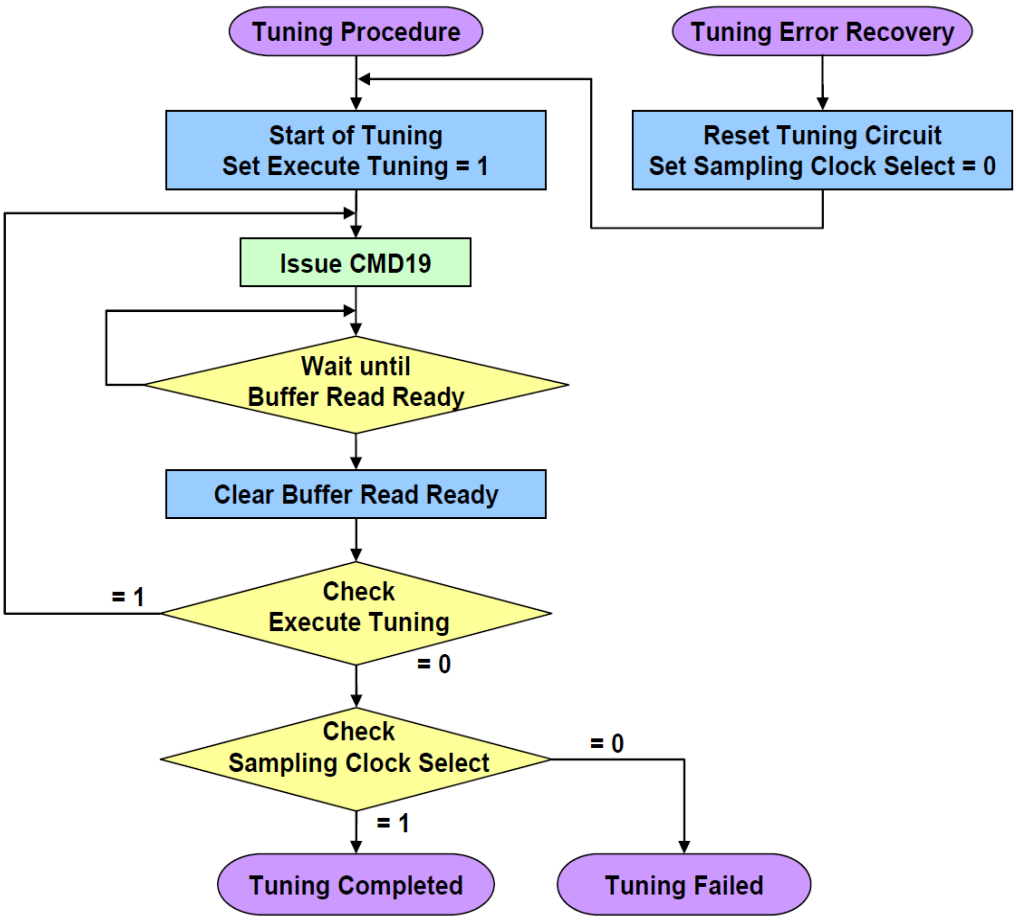
29.7.9.2 Entry

Once an SD/MMC system interrupt is received:

1. Confirm the SDMMC System interrupt was from a tuning event by reading SDMMC_VENDOR_SYS_SW__CNTRL_0_TUNING_SYS_INT_STATUS.
2. Disable the future tuning interrupts (to avoid interrupting yourself) by clearing SDMMC_VENDOR_SYS_SW_CNTRL_0_TUNING_SYS_INT_ENABLE.
3. Write 1 to SDMMC_VENDOR_SYS_SW_CNTRL_0_TUNING_SYS_INT_STATUS to clear the interrupt condition.
4. Disable the Buffer Read Ready interrupt to keep the standard SD Host Driver inactive until the tuning sequence is complete: Clear SDMMC_INTERRUPT_STATUS_ENABLE_0_ BUFFER_READ_READY.

29.7.9.3 Tuning Procedure

The figure below shows the standard tuning procedure.



29.7.9.4 Exit

1. Write 1 to SDMMC_VENDOR_SYS_SW_CNTRL_0_TUNING_SYS_INT_STATUS to clear any pending tuning interrupts.
2. Set SDMMC_VENDOR_SYS_SW_CNTRL_0_TUNING_SYS_INT_ENABLE to enable the system interrupt on any future SD3.0 UHS-I tuning start events.
3. Signal to the SD Host driver that tuning has completed by asserting SDMMC_VENDOR_SYS_SW_CNTRL_0_ASSERT_BUFF_RD_RDY_INT.

29.7.10 SD Bus Power

When the standard SD driver changes the Power Control Register's SD Bus Power field, the hardware needs assistance from platform software to implement the change via the PMIC.

29.7.10.1 Initialization

Before the standard SD drive begins running:

1. Route the SD/MMC controller's system interrupt to the appropriate driver.
2. Write 1 to SDMMC_VENDOR_SYS_SW_CNTRL_0_SD_BUS_POWER_ON_OFF_INT_STATUS to clear any latent interrupts.

3. Set SDMMC_VENDOR_SYS_SW_CNTRL_0_SD_BUS_POWER_ON_OFF_INT_ENABLE to enable the system interrupt on an SD3.0 UHS-I Bus Power change event.

29.7.10.2 Entry

Once an SD/MMC system interrupt is received:

1. Confirm the SDMMC System interrupt was from a Bus Power change event by reading SDMMC_VENDOR_SYS_SW_CNTRL_0_SD_BUS_POWER_ON_OFF_INT_STATUS.
2. Write 1 to SDMMC_VENDOR_SYS_SW_CNTRL_0_SD_BUS_POWER_ON_OFF_INT_STATUS to clear the interrupt condition.
3. Read SDMMC_POWER_CONTROL_HOST_0_SD_BUS_POWER to determine the power state change request.

   If Bus Power is cleared, power off the SD power supply via the PMIC. Otherwise, if Bus Power is set, power on the SD power supply via the PMIC.

29.7.10.3 Exit

No actions required.

29.8 SD/MMC Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

29.8.1 Standard Registers

Note: For standard registers’ usage, refer to the SD Host Controller Specification version 4.00.

There are a few vendor-specific register fields within the standard register offset range (0x00 through 0xff). (Future products will move these vendor-specific register fields out of the standard-defined register offset range.) These fields are described below:

29.8.1.1 Present State Register

Offset: 0x24 | Read/Write: R | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
28:25	X	DAT_7_4_LINE_LEVEL: This status reflects the DAT[7:4] lines’ state for debug.

29.8.1.2 Interrupt Status Register

Offset: 0x30 | Read/Write: R/W | Reset: 0x00000000 (0b0000000000000000xxxxxxxx00000000)

Bit	Reset	Description
31:30	0	VEND_SPEC_ERR Bit 1: BOOT_ACK_ERR: Occurs when Boot Ack Status is not equal to ‘010’ Bit 0: BOOT_ACK_TIMEOUT_ERR: Occurs when Boot Ack is not received within the programmed number of cycles.

29.8.1.3 Interrupt Status Enable Register

Offset: 0x34 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000xxx0xxx000000000)

Bit	Reset	Description
31:30	0	VENDOR_SPECIFIC_ERR 0 = Enable neither BOOT_ACK_ERR nor BOOT_ACK_TIMEOUT_ERR statuses. 1 = Enable only BOOT_ACK_TIMEOUT_ERR status. 2 = Enable only BOOT_ACK_ERR status. 3 = Enable both BOOT_ACK_ERR and BOOT_ACK_TIMEOUT_ERR statuses.

29.8.1.4 Interrupt Signal Enable Register

Offset: 0x38 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000xxx0xxx000000000)

Bit	Reset	Description
31:30	0	VENDOR_SPECIFIC_ERR 0 = Enable neither BOOT_ACK_ERR nor BOOT_ACK_TIMEOUT_ERR interrupts to CPU. 1 = Enable only BOOT_ACK_TIMEOUT_ERR interrupt to CPU. 2 = Enable only BOOT_ACK_ERR interrupt to CPU. 3 = Enable both BOOT_ACK_ERR and BOOT_ACK_TIMEOUT_ERR interrupts to CPU.

29.8.1.5 Force Event Register

Offset: 0x50 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000xxxxxxxx0x000000)

Bit	Reset	Description
31:30	0	VENDOR_SPECIFIC_ERR_STATUS 0 = No effect 1 = Force a BOOT_ACK_TIMEOUT_ERR event 2 = Force a BOOT_ACK_ERR event. 3 = Force both BOOT_ACK_ERR and BOOT_ACK_TIMEOUT_ERR events.

29.8.2 Vendor Registers

29.8.2.1 SDMMC_VENDOR_CLOCK_CNTRL_0

The following registers are Vendor Specific Registers and are mapped to Vendor Specific Address Space (0x100 - 0x1FF)

Vendor Clock Control Register

TAP_VAL - Tap Value for the input data path trimmer

This determines the tap value needed to sample the input data correctly. The delay per each tap can range from 70ps to 500ps. The following values are recommended on different SD/MMC interfaces for all modes up to SDR25:

- SDMMC1 - 2
- SDMMC2 - 2
- SDMMC3 - 3
- SDMMC4 - 5

For SDR50 and above modes, the tap value is determined by the tuning procedure.

BASE_CLK_FREQ: Software should program the actual clock frequency programmed in the CAR registers CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC*_0 for each SD/MMC controller. This should be done after every time

SDMMC is reset and after every soft reset. This is important because all SD/MMC controllers follow the same register map, but could be programmed with different frequencies depending on the use case.

SPI_MODE_CLKEN_OVERRIDE: Software should always program this to 0 (NORMAL).

PADPIPE_CLKEN_OVERRIDE: Software should always program this to 0 (NORMAL).

Offset: 0x100 │ Read/Write: R/W │ Reset: 0x0005d00d (0bxxx00000000010111010000x0001101)

Bit	Reset	SW Default	Description
28:24	0x0	NONE	TRIM_VAL: Reserved. Software should not change these bits.
23:16	0x5	NONE	TAP_VAL: Tap value for input data path trimmer.
15:8	0xd0	NONE	BASE_CLK_FREQ: System software programs the base SD/MMC clock frequency into this register before loading the SD/MMC driver. This value is readable in the standard, but not writeable, SDMMC_CAPABILITIES_0_BASE_CLOCK_FREQUENCY register field.
5	0x0	0x1	SDR50_TUNING_OVERRIDE: override the SDR50_TUNING capabilities bit. Software should only set this bit if it is required to use Tuning for SDR50. (only supported for SDMMC1 and SDMMC3) 0 = NORMAL : 0 -> No tuning support advertised for SDR50 mode. 1 = OVERRIDE: 1 -> Tuning support is enabled for SDR50 mode.
3	0x1	0x0	PADPIPE_CLKEN_OVERRIDE: Override for pad macro and pipe macro clken. 0 -> CLKEN is to pad macro and pipe macro can be deasserted along with internal CLKEN. 0 = NORMAL: 0 -> CLKEN is to pad macro and pipe macro can be deasserted along with internal CLKEN. 1 = OVERRIDE: 1 -> CLKEN is kept asserted to pad macro and pipe macro when internal CLKEN is deasserted.
2	0x1	NONE	SPI_MODE_CLKEN_OVERRIDE: Override for CLKEN during SPI_MODE during sw_reset. 0 = NORMAL: 0 -> CLKEN is deasserted while doing sw_reset. 1 = OVERRIDE: 1 -> CLKEN is kept asserted while doing sw_reset.
1	0x0	NONE	INPUT_IO_CLK: Feedback clock is selected by default. Software should not change this. Disabling the Feedback clock will select the Internal Clock that requires different tap value programming. 0 = FEEDBACK 1 = INTERNAL
0	0x1	NONE	SDMMC_CLK: This is set when sdmmc_clk is supplied by the CAR module. Prior to sdmmc_clk switch OFF. This bit should be written '0'. By writing zero, the asynchronous card interrupt is routed to the Interrupt controller. 0 = DISABLE 1 = ENABLE

29.8.2.2 SDMMC_VENDOR_SYS_SW_CNTRL_0

Vendor System SW Control Register

Offset: 0x104 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxx000xxxxx0000x00)

Bit	Reset	Description
14	0x0	SD_BUS_POWER_ON_OFF_INT_STATUS: SD_BUS_POWER was changed. System software can use this interrupt to implement power switch. 0 = NO_INT 1 = GEN_INT
13	0x0	VOLT_SWITCH_INT_STATUS: VOLT_18_EN was changed. System software can use this interrupt to implement a UHS-I voltage switch procedure for a standard SD Host driver 0 = NO_INT 1 = GEN_INT
12	0x0	TUNING_SYS_INT_STATUS: CMD19 was issued while EXECUTE_TUNING was set. System software can use this interrupt to implement a UHS-I tuning procedure for a standard SD Host driver. 0 = NO_INT 1 = GEN_INT
6	0x0	SD_BUS_POWER_ON_OFF_INT_ENABLE: Enables a separate system interrupt (i.e., not the standard SDHCI interrupt) when SD_BUS_POWER is changed.

Bit	Reset	Description
		0 = DISABLE 1 = ENABLE
5	0x0	VOLT_SWITCH_INT_ENABLE: Enables a separate system interrupt (i.e., not the standard SDHCI interrupt) when VOLT_18_EN is changed. 0 = DISABLE 1 = ENABLE
4	0x0	TUNING_SYS_INT_ENABLE: Enables a separate system interrupt (i.e., not the standard SDHCI interrupt) when CMD19 is issued while EXECUTE_TUNING is set. 0 = DISABLE 1 = ENABLE
3	0x0	ASSERT_BUFF_RD_RDY_INT: Write a 1 to this field to assert sdmmc_interrupt_status_0_buffer_read_ready. Used by the system software that implements the tuning procedure to signal to the standard SD driver that the tuning process has completed 0 = DISABLE 1 = ENABLE
1	0x0	INT_MASK_WHILE_TUNING: to avoid breaking software compatibility, interrupt generation behavior is changed when a this bit is set 0 = DISABLE 1 = ENABLE
0	0x0	SPI_MODE: This is a mirror bit. The SPI mode is set if this bit is set or CMD_XFER_MODE[7] is set. Writing 1 will drive the CS Low and writing zero will deassert the CS signal 0 = DISABLE : 0 -> SPI mode is disabled. 1 = ENABLE: 1 -> SPI mode is enabled.

29.8.2.3 SDMMC_VENDOR_CAP_OVERRIDES_0

Capabilities Override Bits

Offset: 0x10c │ Read/Write: R/W │ Reset: 0x00000007 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx111)

Bit	Reset	Description
2	0x1	VOLTAGE_3_3_V_SUPPORT_OVERRIDE: Voltage support 3_3_V override
1	0x1	VOLTAGE_3_0_V_SUPPORT_OVERRIDE: Voltage support 3_0_V override
0	0x1	VOLTAGE_1_8_V_SUPPORT_OVERRIDE: Voltage support 1_8_V override

29.8.2.4 SDMMC_VENDOR_BOOT_CNTRL_0

Vendor Boot Control Register

This register is used to configure Boot Mode to support MMC v4.3 cards.

Offset: 0x110 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	BOOT_ACK: This bit is used to support Boot Option in MMC 4.3 version cards. If set Boot acknowledgment is given by card else not given by card 0 = DISABLE 1 = ENABLE
0	0x0	BOOT: This bit enables/disable BootOption1.If set BootOption1 is enabled, hardware auto clears it when boot data is done. Writing 0 terminates the BootOption1 0 = DISABLE 1 = ENABLE

29.8.2.5 SDMMC_VENDOR_BOOT_ACK_TIMEOUT_0

Vendor Boot Acknowledgment Timeout Register

Offset: 0x114 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
19:0	0x0	VALUE: If Boot Acknowledgment is not received within the programmed number of cycles, aBoot Acknowledgement Timeout error occurs (VENDOR_SPECIFIC_ERR[0])

29.8.2.6 SDMMC_VENDOR_BOOT_DAT_TIMEOUT_0

Boot Data Timeout Register

Offset: 0x118 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

Bit	Reset	Description
24:0	0x0	VALUE: If Boot Data is not received within the programmed number of cycles, a Data Timeout error occurs.

29.8.2.7 SDMMC_VENDOR_DEBOUNCE_COUNT_0

Debounce Counter Value Register

The Debounce Counter runs on a 32 KHz clock. Keeping the default value to 100ms = (100 * 32 cycles/1ms) = 3200 cycles for 100ms = 0xC80

Offset: 0x11c | Read/Write: R/W | Reset: 0x00000c80 (0b00000000000000110010000000)

Bit	Reset	Description
23:0	0xc80	VALUE: The number of 32KHz clock cycles is programmed to meet the debounce period of the card slot.

29.8.2.8 SDMMC_VENDOR_MISC_CNTRL_0

Miscellaneous Vendor Control Register

- SDMMC_SPARE0: Spare register bits with reset value of 0
  - SDMMC_SPARE0[0]: SW_RESET_CLKEN_OVERRIDE, override the ‘sdmmc_clken’ when doing SW_RESET if set to 1.
  - SDMMC_SPARE0[1]: When set, allows SD clock to be stopped in the middle of a read data block while in SDR104 mode. Unsafe for at least some SD cards, but may improve SDR104 DMA read performance in some cases.
  - SDMMC_SPARE0[2]: When set, SDR104 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_SDR104
  - SDMMC_SPARE0[3]: When set, SDR50 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_SDR50
  - SDMMC_SPARE0[5]: When 0, masks the pad macro's "high speed" enable to 0, causing the pad macro to always launch data on the falling edge of the clock. This prevents the SD Host driver's setting of SDMMC_POWER_CONTROL_HOST_x_HIGH_SPEED_EN from undesirably affecting the output timing.
  - SDMMC_SPARE0[7:6]: Number of pipe stages.
  - SDMMC_SPARE0[8]: When set, DDR50 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_DDR50
  - SDMMC_SPARE1: Spare register bits with reset value of 1
  - SDMMC_SPARE1[0]: CMD_CONFLICT_DISABLE, disable command line conflict if set to 1.

Offset: 0x120 | Read/Write: R/W | Reset: 0xffff0098 (0b11111111111111110000000010011000)

Bit	Reset	Description
31:16	0xffff	SDMMC_SPARE1: Spare register bits with reset value of 1
15:1	0x4c	SDMMC_SPARE0: Spare register bits with reset value of 0x40
0	0x0	ERASE_TIMEOUT_LIMIT: Erase timeout value. 0 = FINITE: Finite. It is limited to the programmed value in the DATA_TIMEOUT_VALUE 1 = INFINITE: Infinite. Controller would be monitoring until the card is busy.

29.8.2.9 SDMMC_MAX_CURRENT_OVERRIDE_0

Offset: 0x124 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx000000000000000000000000)

Bit	Reset	Description
23:16	0x0	OVERRIDE_FOR_1_8V: Maximum override for 1.8V VDD1.
15:8	0x0	OVERRIDE_FOR_3_0V: Maximum override for 3.0V VDD1.
7:0	0x0	OVERRIDE_FOR_3_3V: Maximum override for 3.3V VDD1.

29.8.2.10 SDMMC_MAX_CURRENT_OVERRIDE_HI_0

Offset: 0x128 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description

Bit	Reset	Description
5:0	0xf	CLK_COUNT: Before gating second-level clocks, the controller waits for these many cycles. Recovery is possible if any idle windows are missed in the clken equation

29.8.2.12 SDMMC_VENDOR_PRESET_VAL0_0

Vendor Preset Value Registers

The SD host specification defines one preset value register for each bus speed mode which should be set by the host by some unique method. Preset values vary based on the base frequency used which is under software (Tegra system driver) control. The Tegra System driver configures the BASE_CLK_FREQ in VENDOR_CLOCK_CNTRL register before handling over control to the SD host standard driver.

In a similar way, the system driver should set the below vendor preset values based on the base clock frequency and the desired card clock frequency in each bus speed mode. This should be done after the SDMMC is reset and after every soft reset. This is important because all SDMMC controllers follow the same register map, but can be programmed with different frequencies depending on the use case.

The default values are set assuming base clock frequency = 208 MHz.

Offset: 0x1d4 | Read/Write: R/W | Reset: 0x00201000 (0bxx00000001000000001000000000000)

Bit	Reset	Description
29:20	0x2	SDCLK_FREQ_SEL_HIGH_SPEED: System software programs the 10-bit divider value to generate an SD clock in default speed mode (< 50 MHz,3.3V signaling). This value is readable in the standard via PRESET_SDR12_AND_HIGH_0_SDCLK_FREQ_VAL_LOW register field. The default value is 0x2 assuming a 208 MHz base clock.
19:10	0x4	SDCLK_FREQ_SEL_DEFAULT: System software programs the 10-bit divider value to generate an SD clock in default speed mode (<25 MHz,3.3V signaling). This value is readable in the standard via PRESET_DEFAULT_AND_INIT_0_SDCLK_FREQ_VAL_HIGH register field. The default value is 0x4 assuming a 208 MHz base clock.
9:0	0x0	SDCLK_FREQ_SEL_INIT: System software programs the 10-bit divider value to generate the desired SD clock frequency during initialization. This value is readable in the standard via PRESET_DEFAULT_AND_INIT_0_SDCLK_FREQ_VAL_LOW register field. For example, if a 400KHz SDCLK is desired @base clk freq=48 MHz, this register should be programmed with 0x3C.

29.8.2.13 SDMMC_VENDOR_PRESET_VAL1_0

Offset: 0x1d8 | Read/Write: R/W | Reset: 0x00100804 (0bxx00000000100000000100000000100)

Bit	Reset	Description
29:20	0x1	SDCLK_FREQ_SEL_SDR50: System software programs the 10-bit divider value to generate the SD clock in SDR50 mode (<100 MHz,1.8V signaling). This value is readable in the standard via PRESET_SDR50_AND_SDR25_0_SDCLK_FREQ_VAL_HIGH register field. The default value is 0x1 (gives 2N divider) assuming a 208 MHz base clock.
19:10	0x2	SDCLK_FREQ_SEL_SDR25: System software programs the 10-bit divider value to generate the SD clock in SDR25 mode (<50 MHz,1.8V signaling). This value is readable in the standard via PRESET_SDR50_AND_SDR25_0_SDCLK_FREQ_VAL_LOW register field. The default value is 0x2 assuming a 208 MHz base clock.
9:0	0x4	SDCLK_FREQ_SEL_SDR12: System software programs the 10-bit divider value to generate the SD clockk in SDR12 mode (<25 MHz,1.8V signaling). This value is readable in the standard via PRESET_SDR12_AND_HIGH_0_SDCLK_FREQ_VAL_HIGH register field.

29.8.2.14 SDMMC_VENDOR_PRESET_VAL2_0

Offset: 0x1dc | Read/Write: R/W | Reset: 0x00000800 (0bxxxxxxxxxxxxx00000000100000000000)

Bit	Reset	Description
19:10	0x2	SDCLK_FREQ_SEL_DDR50: System software programs the 10-bit divider value to generate the SD clock in DDR50 mode (<50 MHz,1.8V signaling). This value is readable in the standard via PRESET_DDR50_AND_SDR104_0_SDCLK_FREQ_VAL_HIGH register field. The default value is 0x2 assuming 208 MHz base clock.
9:0	0x0	SDCLK_FREQ_SEL_SDR104: System software programs the 10-bit divider value to generate the SD clock in SDR104 mode (<208 MHz,1.8V signaling). This value is readable in the standard via PRESET_DDR50_AND_SDR104_0_SDCLK_FREQ_VAL_LOW register field.

29.8.2.15 SDMMC_SDMEMCOMPPADCTRL_0

SDMEMCOMP Pad Control Register

If AUTO_CAL_ENABLE is disabled (0), the values in this register are used to drive the DRVUP/DRVDN controls to the SDMMC comp pads.

30:24	X	AUTO_CAL_PULLDOWN_ADJ: Pull-down code sent to pads
22:16	X	AUTO_CAL_PULLUP_ADJ: Pull-up code sent to pads
14:8	X	AUTO_CAL_PULLDOWN: Pull-down code generated by auto-calibration
6:0	X	AUTO_CAL_PULLUP: Pull-up code generated by auto-calibration

29.8.2.19 SDMMC_SDMMC_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control (where applicable) and Clock Gating Control Register

Note: The FIFO timing aspects of this register are no longer supported, but retained for software compatibility.

The clock override/ovr_mode fields of this register control the second-level clock gating for the client and MC side of the MCCIF. All clock gating is enabled by default.

A '1' written to the rclk/wclk override field will result in one of the following:

- With wclk/rclk override mode = LEGACY, the clock reverts to the legacy mode of operation where the clock is on whenever the client clock is enabled.
- With wclk/rclk override mode = ON, the clock is always on inside the MCCIF and PC.

A '1' written to the cclk override field keeps the client's clock always on inside the MCCIF.

Offset: 0x1f4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxx00000xxxxxxxxxxxxxxx)

30.0 SNOR (GMI) CONTROLLER

The GMI Controller, also known as the Sync-NOR (SNOR) Controller, supports a number of NOR flash memory types, including synchronous NOR and asynchronous NOR. It enables:

- Data transfer between internal and external memory.
- Interface with Synchronous/Asynchronous Flash Memories.

The GMI/SNOR Controller is on the AHB bus, it provides a way to access external NOR Flash through Master as well as Slave modes. The GMI/SNOR controller supports DMA transfer between Flash Memory and System Memory.

The GMI/SNOR controller can operate in 2 modes:

- Programmed I/O (PIO) mode – In this case the CPU operates as master and issues the read/write commands, and the SNOR controller operates as the slave. The SNOR controller handles the transfer of data between the flash memory and CPU registers.
- DMA mode – In this case the SNOR controller operates as the master; the SNOR controller handles the transfer of data between the flash memory and system memory.

30.1 Functional Description

The GMI/SNOR Controller supports the following operation:

- Synchronous and Asynchronous Flash Memories support
- AHB Master and Slave mode support.
- Booting Option.
- Address-Data Mux / Non-Mux Configuration.
- Fast Access Modes – Burst (Reads/Writes) and Page Mode (Reads).
- Programmable WAIT states for Asynchronous access.
- Programmable Data RDY Configuration (same cycle or next cycle).
- Support 16/32 bits wide Data Bus.
- Support for 8 chip selects: Any combination of 8-SNOR chip selects.

30.1.1 Functional Waveforms

Table 129 GMI (SNOR) Signal Descriptions

Pin Function	Description	Type
Non-Muxed		
GMI_A[27:0]	Address bus: Up to 28 bits of address, depending on type/size of device	Out
GMI_D[31:28] GMI_AD[27:0]	Data bus: 32- or 16-bit data bus	Bidir
Muxed AD		
GMI_D[31:28] GMI_AD[27:0]	Multiplexed Address/Data bus: For 16-bit, muxed A/D memory, the lower 16 bits of address are muxed with the data bus. The upper address lines, GMI_AD[27:16], are non-multiplexed.	Bidir
GMI_A[27:16]	Upper Address bus	Out
General		
GMI_CLK	Clock: Used to synchronize the Tegra® K1 and SNOR devices during Synchronous operations. Rising Edge active.	Out
GMI_ADV_N	Address Valid: Programmable polarity output. For synchronous read operations, the address is typically latched either on the inactive edge of ADV_N or on the first rising edge of CLK after ADV_N goes active (slower devices <= 108MHz) or on the last rising edge of CLK after ADV_N goes active (faster devices >= 108MHz) For Asynchronous reads, the address is latched on the inactive of ADV_N. For writes, ADV_N is held active and the address is valid throughout the cycle for non-muxed operation. In the non-muxed case the address will be valid for the duration of the entire access. Only in the muxed mode is it valid during the ADV_N (ADV_WIDTH) + MUXED_WIDTH (the minimum in this case is 1 + 1 = 2 cycles)	Out
GMI_CE[7:0]_N	Chip Enable: Programmable polarity output. When active, CEx_N selects the device and when inactive, de-selects the device which is typically put in low power mode.	Out
GMI_OE_N	Output Enable: Programmable polarity output. When active, OE_N enables the output drivers of the selected (CEx_N active) devices. When inactive, OE_N disables the output drivers of selected devices (CEx_N active) and places them in High-Z.	Out
GMI_WR_N	Write Enable: Programmable polarity output. When active, WR_N enables write operations for the enabled (CEx_N active) devices. The address and write data is latched by the enabled devices on the inactive (trailing) edge of WR_N.	Out
GMI_RST_N	Reset: Active low output. When low, RST_N resets the connected devices and inhibits writes. When high, RST_N enables normal operation.	Out
GMI_WAIT	Wait (or Ready): Level configurable input. When asserted, WAIT (RDY) indicates the read data is invalid (Wait) or Valid (Ready). WAIT (RDY) is driven by the devices when CEx_N and OE_N are low and High-Z when when CEx_N or OE_N are high.	In
GMI_WP_N	Write Protect: Active low output. When low, WP_N enables the device lock down mechanism, or inhibits write cycles.	Out
GMI_DPD	Deep Power Down: Active high output. When high, Device will enter Deep Power Down mode. When low, device will be in or return to normal operating mode.	Out

30.2 Programming Guidelines

During power-on reset the GMI/SNOR Controller has the Slave Interface active. This means any processor can send a request to the GMI Controller/Device. The default setting for the controller as well as external device is in 16-bit MUX mode. Depending on the internal fuses burned, the boot ROM can configure the GMI interface to match that of the external nonvolatile memory, either multiplexed or non-multiplexed. SNOR DMA can be programmed in Burst, Page and Asynchronous modes for NON-MUX devices whereas only Burst and Asynchronous modes are present in case of MUX devices. The GMI Controller supports Burst Writes/Reads, Asynchronous Writes/Reads and Page Reads (only for NON-MUX Devices).

SNOR Register Base address is 0x7000_9000.

SNOR Clock Source Register address is 0x6000_61D0.

The following should be considered while accessing the GMI:

- Using the Slave Interface, Asynchronous Writes/Reads are permitted.
- To work in Master Mode, program the “MST_ENB” bit of the Configuration Register.
- Provide the DMA starting NOR Address (0xD000_0000) as well as AHB Address (iRAM 0x4000_0000 or DRAM 0x0000_0000) first, before enabling the “GO_NOR” and “DMA_GO” bits.
- Use the device configuration command cycles to enable the different features of the device including Burst Mode.
- Enable the “GO_NOR” bit followed by “DMA_GO” bit for DMA operation.
- DMA status can be seen by polling the DMA Status Busy Signal or using the transfer done interrupt.
- SNOR timing registers should be programmed per the device specifications.
- In Interrupt polling mode, DMA operation is completed when DMA_GO/GO_NOR are deasserted (disabled).

30.3 GMI/SNOR Registers

30.3.1 SNOR_CONFIG_0

SNOR Configuration Register

Offset: 0x0 | Read/Write: R/W | Reset: 0b00010000010000xxx00xxx00000000000

Bit	Reset	Description
31	0x0	GO_NOR: When set a NOR operation commences. 0 = DISABLE 1 = ENABLE
30	0x0	WORDWIDE_GMI: NOR Device Data Bus width Configuration Bit. 0 = NOR16BIT 1 = NOR32BIT
29	0x0	NOR_DEVICE_TYPE: External NOR Memory Type. 0 = SNOR
28	0x1	MUXMODE_GMI: NOR Device Address-Data Configuration Bit. 0 = AD_NONMUX 1 = AD_MUX
27:26	0x0	BURST_LENGTH: Burst Length Types 00=Continuous Burst, 01=8 Words, 10=16 Words, 11=32 Words. 0 = CNTBRST 1 = BL8WORD 2 = BL16WORD 3 = BL32WORD
25	0x0	Reserved
24	0x0	RDY_ACTIVE: Device RDY Active Status 0=With Data, 1=One Cycle Before Data. 0 = WITHDATA 1 = BEFOREDATA
23	0x1	RDY_POLARITY: Ready signal polarity 0=Active low, 1=Active high. 0 = RESV 1 = HIGH
22	0x0	ADV_POLARITY: ADV pulse polarity 0=Active low, 1=Active high. 0 = LOW 1 = RESV
21	0x0	OE_WE_POLARITY: OE/WE polarity 0=Active low, 1=Active high. 0 = LOW 1 = RESV
20	0x0	CS_POLARITY: Chip Select polarity 0=Active low, 1=Active high. 0 = LOW 1 = RESV
19	0x0	NOR_DPD: Indicates the Power Down Mode enable bit. 0 = DISABLE 1 = ENABLE
15	0x0	NOR_WP: Sets the NOR Write protect enable bit. 0 = DISABLE 1 = ENABLE
14	0x0	NMUX_ASYNC_IO: Sets the non-mux async IO mode . 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
10:8	0x0	PAGE_SIZE: Sets the number of words in a page if page mode is selected. Note: Programming this field to 0 is not used. 1 = PG4WORD 2 = PG8WORD 3 = PG16WORD 4 = RESV4 5 = RESV5 6 = RESV6 7 = RESV7
7	0x0	MST_ENB: Selection bit between Master DMA and Slave Interface. 0 = DISABLE 1 = ENABLE
6:4	0x0	SNOR_SEL: SNOR 8 chip selects combinations. 0 = CS0 1 = CS1 2 = CS2 3 = CS3 4 = CS4 5 = CS5 6 = CS6 7 = CS7
3	0x0	CE_LAST: Indicates if the ADV gets asserted before CE. 0 = DISABLE 1 = RESV
2	0x0	CE_FIRST: Indicates if the CE gets asserted before ADV. 0 = DISABLE 1 = RESV
1:0	0x0	DEVICE_MODE: This field specifies the Mode of Operation for SYNC Memories. 0 = ASYNC 1 = PAGE 2 = BURST 3 = RESV

30.3.2 SNOR_STA_0

This status register has bits that provide the controller status, along with the external interrupts from the SNOR devices. The FIFO status is also provided along with the status on the count of the words transferred through DMA

SNOR Status Register

Offset: 0x4 | Read/Write: R/W | Reset: 0xX0X0XXXX (0bx0x00000xxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
31	RO	X	DEVICE_BSY: Indicates that the device status.
30	RW	0x0	SLAVE_DONE: Indicates that the slave access is completed
28	RW	0x0	CONT_OVERFLOW: Overflow during continuous mode
27	RW	0x0	Reserved
26	RW	0x0	Reserved
25	RW	0x0	DEVICE_INTR_2_ENB: Device Interrupt-2 Enable Bit.

Bit	R/W	Reset	Description
24	RW	0x0	DEVICE_INTR_1_ENB: Device Interrupt-1 Enable Bit.
23	RO	X	SLV_FIFO_FULL: SLV FIFO full status.
22	RO	X	SLV_FIFO_EMPTY: SLV FIFO empty status.
21	RO	X	MST_FIFO_FULL: MST FIFO full status.
20	RO	X	MST_FIFO_EMPTY: MST FIFO empty status.
15:0	RO	X	DMA_DATA_CNT: Indicates the number of Data to be transferred; current dma_data_count.

30.3.3 SNOR_NOR_ADDR_PTR_0

Contains the starting address of the NOR access.

SNOR Address Register

Offset: 0x8 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	SNOR_NOR_ADDR_PTR: Indicates that the NOR controller Address.

30.3.4 SNOR_AHB_ADDR_PTR_0

Contains the starting address of the AHB access.

SNOR AHB Address Register

Offset: 0xc | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	SNOR_AHB_ADDR_PTR: Indicates that the AHB side Address.

30.3.5 SNOR_TIMING0_0

This register contains the timing parameters used for the page access, along with the timing parameters for the widths of ADV pulse, CE hold, etc.

SNOR Timing0 Register

Offset: 0x10 | Read/Write: R/W | Reset: 0b0011xxxx0001xxxx0001000100010100

Bit	Reset	Description
31:28	0x3	PAGE_RDY_WIDTH: This represents the number of wait clock cycles from address to 1st data ready. This field must be programmed with a minimum value of 3.
23:20	0x1	PAGE_SEQ_WIDTH: Page Sequential width indicates the delay cycle between the intra page Read access. This field must be programmed with a minimum value of 2.
15:12	0x1	MUXED_WIDTH: Indicates in number of cycles MUX address/data asserted on the bus.

Bit	Reset	Description
11:8	0x1	HOLD_WIDTH: Indicates in number of cycles CE stays asserted after the de-assertion of WR_N (in case of SLAVE/MASTER Request) or OE_N (in case of MASTER Request).
7:4	0x1	ADV_WIDTH: Indicates the number of cycles during which ADV stays asserted.
3:0	0x4	CE_WIDTH: Indicates the number of cycles before CE is asserted.

30.3.6 SNOR_TIMING1_0

This register contains the timing parameters of the WE and OE widths along with the WAIT width.

SNOR Timing1 Register.

Offset: 0x14 | Read/Write: R/W | Reset: 0x10010103 (0b000100x00000000100000001000000011)

Bit	Reset	Description
31:26	0x4	SNOR_TAP_DELAY: Tap delay
24	0x0	SNOR_CE: Clock Override
23:16	0x1	WE_WIDTH: Write access time
15:8	0x1	OE_WIDTH: Read access time.
7:0	0x3	WAIT_WIDTH: Indicates in cycles the number of wait states before when READY is issued. This field needs to be programmed to 0x4 when the RDY_ACTIVE bit in the SNOR_CONFIG register is set.

30.3.7 SNOR_DMA_CFG_0

SNOR DMA Configuration Register

Offset: 0x20 | Read/Write: R/W | Reset: 0x04000000 (0b000001000xxxxxxx00000000000000xx)

Bit	Reset	Description
31	0x0	DMA_GO: This represents the number of DMA is enabled. 0 = DISABLE 1 = ENABLE
30	0x0	BSY: Indicates the status of DMA.
29	0x0	DIR: This represents the direction of DMA data transfer. 0 = NOR2AHB 1 = AHB2NOR
28	0x0	IE_DMA_DONE: Interrupt Enable on DMA transfer completion. 0 = DISABLE 1 = ENABLE
27	0x0	IS_DMA_DONE: Interrupt Status (Write 1 to clear). 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
26:24	0x4	BURST_SIZE: DMA burst size. 0 = RESV0 1 = RESV1 2 = RESV2 3 = RESV3 4 = BS1WORD 5 = BS4WORD 6 = BS8WORD 7 = RESV7
23	0x0	CONTINUOUS: 0 = Once DMA transfer 0 = DISABLE 1 = ENABLE
15:2	0x0	WORD_COUNT: Specifies the number of words that need to be transferred.

30.3.8 SNOR_TIMING2_0

Tap Delay programming for the Trimmer on the Input path.

Offset: 0x28 | Read/Write: R/W | Reset: 0x00000004 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx000100)

Bit	Reset	Description
5:0	0x4	SNOR_IN_TAP_DELAY: Tap delay for the trimmer on the input path.

31.0 SATA CONTROLLER

31.1 Overview

The Serial Advance Technology Attachment (SATA) controller enables a control path from a Tegra® K1 device to an external SATA device. A SSD/HDD/ODD/e-SATA drive can be connected. This is a one port configuration.

The SATA controller is compliant with SATA specification rev. 3.1 and AHCI specification rev. 1.3.1.

31.2 Device ID

The device ID for the SATA controller in Tegra K1 is 0x0E1E. The AHCI driver needs to make sure the class code is set to 0x0106 and the program interface code is set to 0x01 before it starts operating the controller in AHCI mode.

31.3 Device Sleep

The SATA device sleep feature allows the host to put the SATA device into the low-power state by asserting the DEVSLP sideband signal in the following conditions:

- Software initiating DEVSLP only when the link is in slumber state
- Software initiating DEVSLP from any link state when the link is idle
- Hardware initiating DEVSLP only when the link is in slumber state and HW's idle timer times out
- Hardware initiating DEVSLP from any link state when the link is idle and HW's idle timer times out

The SATA design implements the control/status registers, timers, and revised port state machine with the additional PM.DevSleep state to support all four DEVSLP conditions as described in the TP001 to AHCI rev. 1.3.1 specification. The SATA controller implements the override bits in the Miscellaneous Register to allow software programming of the capability declarations.

31.3.1.1 Device Sleep and Unit Low Power State

After the link enters the DEVSLP state, the PAD should be put to IDDQ state, the PLL should be powered down, and the SATA controller itself can be put to either controller clock gating or ELPG.

Exiting from DEVSLP state can only be initialized by software; thus software should ensure the PAD, PLL, and SATA logic are restored to the operational state before triggering DEVSLP exit.

Since SATA can power gated when the link is in DEVSLP state, an override should be added to the Misc Register unit to override the DEVSLP sideband signal. The override should be set to keep the DEVSLP sideband asserted when SATA is power gated and the link is in DEVSLP state. The override should be cleared after SATA exited power gated.

The following figure illustrates the programming sequence of the DEVSLP with SATA entering and exiting power gating.

T1: SATA asserts DEVSLP; SATA_AUX asserts interrupt as a result of SATA asserting DEVSLP.

T2: SW clears SATA_AUX interrupt and starts programming sequence to put SATA to power gating, including save the context of SATA registers.

T3: SW sets SATA_AUX DEVSLP override.

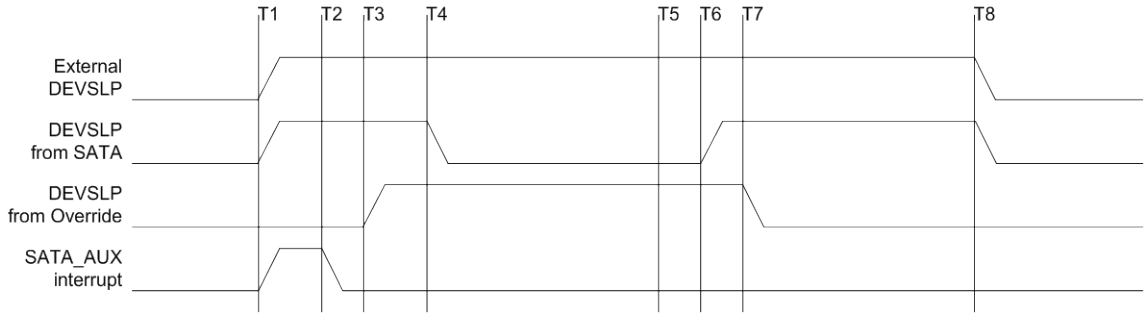
T4: SW removes power from SATA's power rail. Consequently, DEVSLP from SATA deasserts.

T5: SW restores power to SATA's power rail and starts programming sequence to restore context to SATA registers.

T6: SATA asserts its DEVSLP as a result of context restore.

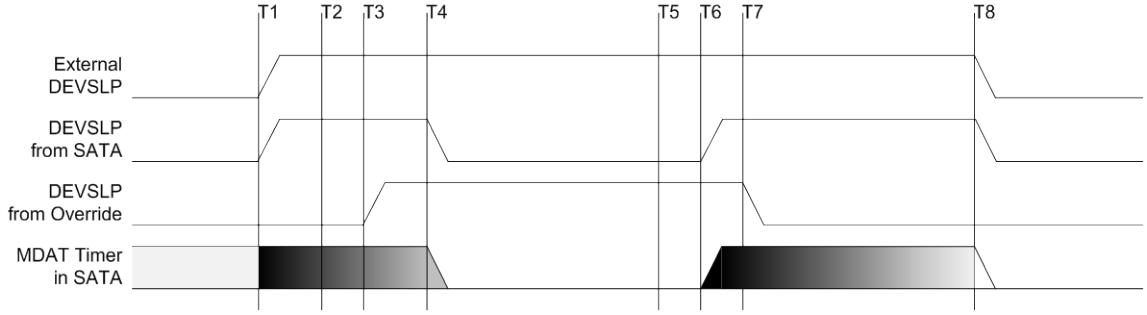
T7: SW clears SATA_AUX DEVSLP override.

T8: SATA deasserts DEVSLP.

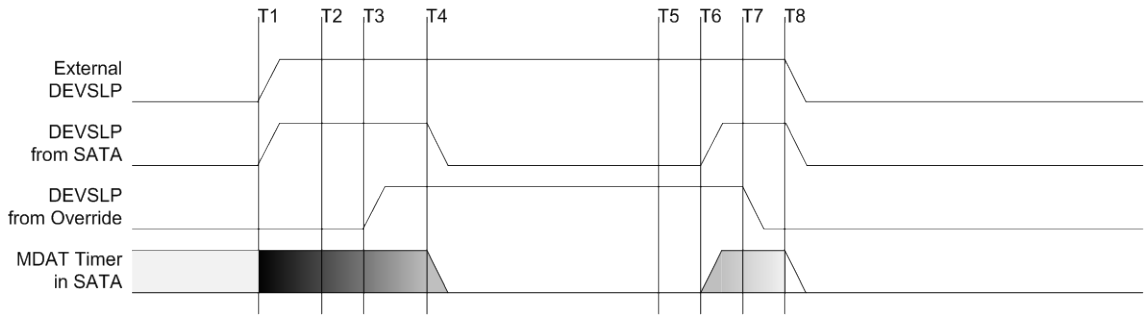


Update/Restore MDAT during ELPG

The MDAT timer in SATA is used to ensure DEVSLP is asserted for MDAT before it can be deasserted. As the following figure illustrates, after context is restored, the MDAT timer would be reloaded with the value programmed in PxDEVSLP.MDAT and counting down from there. This means DEVSLP would not be deasserted until MDAT time after context restore.



But to the SATA device, DEVSLP is kept asserted due to the override in SATA_AUX. Thus, it is possible to reduce the time SATA asserts DEVSLP after exited power gating by modify the value restored to MDAT timer, as the following figure illustrates.



The MDAT timer value should be updated/restored through MDAT_TIMER_AFTER_PG_VALID and MDAT_TIMER_AFTER_PG. It is the responsibility of software to track the time SATA is power gated and subtract it from the saved MDAT timer value before updating the value via the override.

31.3.1.2 Device Sleep with Port Multiplier

According to SATA I/O, device sleep feature is not used when the host controller is connecting to port multipliers:

31.3.2 AUX Version of PAD Idle Detection

In Tegra K1, the PAD supports VAUX bus idle detection. The Miscellaneous Register unit has been modified to support both the VCORE and VAUX version of bus idle detection for detecting the OOB signaling, while adding the control to put either or both the VCORE portion or the VAUX portion of the PAD in IDDQ mode when the SATA controller is power gated under the following conditions:

Link State	VCORE	VAUX	Note
Partial	ON	ON	VCORE portion is powered to maintain the common mode voltage. OOB detection using VCORE version with VAUX OOB detection disabled.
Slumber	OFF	ON	VAUX portion is used for OOB detection.
DEVSLP	OFF	OFF	OOB detection is not required during DEVSLP.

During LP0, the MUX between XUSB and SATA would keep the VAUX portion of the PAD in IDDQ, while the VCORE portion enters IDDQ when the system VCORE power rail is removed.

31.4 Power Gating Sequence

This section describes all the steps needed to achieve power gating.

- Wake events from the drives are supported
- Wake events can only happen in non LP0 mode
- No wake support in LP0 state
- The entire partition including the FPCI wrapper is power gated
- If there can be no wake event, the pads can be put in IDDQ mode. This is decided on the type of drive connected
- The wakeup of the partition (SAX) that hosts the SATA controller and the IPFS shall be initiated by software

31.4.1 Power Gating Overview

Power gating and ungating can be initiated by software. Power gating should be done when the SATA link is in slumber mode, with no outstanding commands. The software should keep a backup of a set of registers in system memory as they lose value once the power is removed. This involves all the configuration space, extended configuration space registers and the MMIO space registers. Since the software is expected to know the state of registers inside the controller, it need not read the registers every time a power gating sequence is performed.

If hardware wake up is to be supported (for example, hot plug detection), the pads should be left in slumber. If hardware wake up is not needed, then the pads should be placed in the IDDQ mode. This is the preferred mode of operation. The bits pad_iddq_override_en and pad_iddq_override_value could be used to control the state of the pads.

31.4.2 Hardware Initiated Wake up

For a hardware-initiated wake up, the pads detect activity on the SATA link. Once the OOB sequence is detected, the bit oob_wake_detected unit is written. Note that the controller itself is not involved in this signal as it is power gated.

The signal from the pads that is of concern here is the rx_stat_idle. This signal must be monitored for any activity. This is an active low signal. There should be two bits that the software needs to read for the interrupt.

1. To log the status and send an interrupt to software (software controlled PG) or signal to the PMC (hardware controlled PG). There are three bits associated with this.
    a. A status bit SATA_L0_RX_STAT_IDLE in the register SATA_AUX_RX_STAT_INT_0. This bit shows the current status of rx_stat_idle. It is set to 1 whenever there is activity on the RX path, else it is set to 0.

b. A sticky interrupt status bit SATA_RX_STAT_INT_STATUS in the register SATA_AUX_RX_STAT_INT_0. This is set whenever rx_stat_idle is set to 1 and will stay 1 until the interrupt is cleared by software.

c. There are bits to set/clear the bits above. Writing a 1 to SATA_RX_STAT_INT_SET bit in SATA_AUX_RX_STAT_SET_0 register will set the status. Writing a 1 to SATA_RX_STAT_INT_CLR will clear this status.

2. To have a mask to enable / disable interrupts. This is done via central interrupt controller with the interrupt SATA_RX_STAT in PRI_ICTLR_* registers. Follow the same guidelines as any other units to enable/disable the SATA_RX_STAT interrupt.

The software clears the interrupt and the mask during normal operation.

31.4.3 Bits Required in Power Gating Sequences

The following bits are required in power gating sequences. Some of them are needed in both hardware and software sequencing methods. Some of them are required only in one of the modes of power gating. The bits could be named differently. The bits are –

- Oob_wake_en – this bit is to be placed in a non-power gated region. Its role is to enable wake events from the drive. This is enabled by writing a 1 to SATA_RX_STAT in PRI_ICTLR_* registers
- Oob_wake_detected – this bit shall be written when “oob_wake_en” is asserted and a wake is detected on the SATA link. The “rx_stat_idle” toggling shall assert this bit. In software mode of power gating, an interrupt needs to be sent to the SATA driver. This is the SATA_RX_STAT_INT_STATUS bit in register SATA_AUX_RX_STAT_INT_0.
- Pmc2sata_pg_info – this bit shall drive the signal pmc2sata_pg_info.

31.4.4 Software Initiated Power Gating / Ungating Sequence

Steps involved in Power Gating

#	Description	Register Programming	Comments
1.	Driver decides to enter power gating, based on the fact that links are in slumber state and no commands are outstanding.		
2.	Driver programs a register in the PMC to indicate to SATA that it is entering power gating. This shall drive the pmc2sata_pg_info signal.	APBDEV_PMC_SATA_PWRGT_0.PG_INFO = 1	If driver detects a hardware wake from the drive before setting PG_INFO bit, it should bail out and should not begin the PG sequence.
3.	Driver would read out the registers in the SATA controller and save it in system memory.	Register list is in appendix.	The time taken for this would depend on the time taken for the software to read a register. Ideally, this should be done only once.
4.	Driver needs to read and set the rx_idle_t registers in the APBMISC block so idle threshold can be continuously driven while SAX is power-gated	Read SATA_AUX_MISC_CNTL_1_0 register L0_RX_IDLE_T_SAX field and write that value into same register L0_RX_IDLE_T_NPG field and write ‘1’ to L0_RX_IDLE_T_MUX field.	
5.	Driver should read the error and interrupt registers before entering power gating.	Read PxSERR and PxIS, and IS registers. Also read PxCI register to make sure that there are no outstanding commands. If (PxCI !=0) or any unexpected error, driver should bail out of PG sequence by setting APBDEV_PMC_SATA_PWRGT_0.PG_INFO = 0 Sets the bit rx_stat_idle_bypass to enable detection of a comwake.	If there is something unexpected or an error is detected or if HW wake is detected from the drive, then the software should bail out of PG sequence (clear PMC bit) Once PG_INFO=1 and/or rx_stat_idle bypass is enabled, HW wake could be detected via rx_stat_idle interrupt only. In that case, driver needs to wait until HBA is in active state (PxSSTS.DET=0x3 and PxSSTS.IPM=0x1) before issuing any new commands.

#	Description	Register Programming	Comments
6.	The driver should gate SATA clocks and assert reset to SATA.	CLK_RST_CONTROLLER_CLK_OUT_ENB_V_0 .SATA_CLKEN= '0' CLK_RST_CONTROLLER_RST_DEVICES_V_0. SATA_RESET=1 CLK_RST_CONTROLLER_RST_DEVICES_W_0 .SATACOLD_RST=1	
7.	*If HW wake up (example hot-plug or async notification) is needed:* The driver shall write a bit in the Interrupt Controller in non-power gated region to enable the rx_stat interrupt generation on detection of rx_stat (OOB) wake.	Clear sata_rx_stat interrupt status and enable sata_rx_stat interrupt to start detecting rx_stat_idle changes from SATA pad when detecting OOB wake sequence : Write apb_misc sata_aux register RX_STAT_CLR bit[0] "SATA_RX_STAT_INT_CLR" field to '1' Write interrupt controller register PRI_ICTLR_CPU_IER_SET_0 bit[13] "SATA_RX_STAT" field to '1' The mapped status bit for sata_rx_stat interrupt in interrupt controller is at register PRI_ICTLR_ISR_0 bit[13] "SATA_RX_STAT"	At this point, sideband (PHY logic + interrupt controller) takes over interrupt generation.
8.	*If HW wake up (example hot-plug or async notification) is needed:* The driver shall place the SATA PADPLL in reset. *If Hw wake up is not needed:* Driver shall place the SATA PHY and SATA PADPLL in IDDQ.	a) SATA_PADPLL_RESET_SWCTL =1 SATA_PADPLL_RESET_OVERRIDE_VALUE=1 b) SATA_PADPLL_RESET_SWCTL =1 SATA_PADPLL_RESET_OVERRIDE_VALUE=1 SATA_PADPHY_IDDQ_SWCTL=1 SATA_PADPHY_IDDQ_OVERRIDE_VALUE=1 Wait for time specified in SATA_LANE_IDDQ2_PADPLL_IDDQ SATA_PADPLL_IDDQ_SWCTL=1 SATA_PADPLL_IDDQ_OVERRIDE_VALUE=1	The driver controls SATA PLL at run time (no HW low power sequencing)..
9.	The driver reports that SATA is being powered down. If PCIE is not being used, the driver can set the PLLE to either reset or IDDQ. *If HW wake up is needed and exit latency cannot be met with PLLE IDDQ mode, then* PLLE can be set to reset. *If HW wake up is not needed or PLLE IDDQ mode exit latency is sufficient:* PLLE can be set to IDDQ.	a) PLLE_ENABLE_SWCTL=1 CLK_RST_CONTROLLER_PLLE_BASE_0.PLLE _ENABLE=0 b) PLLE_ENABLE_SWCTL=1 CLK_RST_CONTROLLER_PLLE_BASE_0.PLLE _ENABLE=0 PLLE_IDDQ_SWCTL=1 PLLE_IDDQ_OVERRIDE_VALUE=1	Wait Time= 1 µs
10.	The driver now shall power gate the controller. This shall also involve the setting of the clamps, and assertion of the resets.	APBDEV_PMC_PWRGATE_TOGGLE_0.SAX=1 << reset overrides exist in the CAR block.	The clamp value of the hardware is such that it shall place the SATA PAD PLL in IDDQ mode but it is overridden by software value as swctl on iddq/reset is enabled above.
11.	The driver indicates to the AHCI software, that power gating is complete.		This is more of an implicit step; returning of the PG API function indicates that power-gating is done.

Steps involved in Power Ungating

#	Description	Register Programming	Comments
1	If hardware wake up is allowed and an OOB sequence is detected, an rx_stat interrupt will be sent by the interrupt controller Or, driver decides to wake up the controller.	When sata_rx_stat interrupt is detected and serviced, interrupt routine should disable this interrupt and clear the status by doing : Write interrupt controller register PRI_ICTLR_CPU_IER_CLR_0 bit[13] "SATA_RX_STAT" field to '1' Write apb_misc sata_aux register RX_STAT_CLR	

#	Description	Register Programming	Comments
		bit[0] “SATA_RX_STAT_INT_CLR” field to ‘1’	
2	If SATA PHY and SATA PADPLL are in IDDQ mode, driver brings them out of IDDQ mode.	Get SATA PHY and PLL out of IDDQ as below: SATA_PADPLL_IDDQ_OVERRIDE_VALUE=0 Wait for programmable delay of SATA_PADPLL_IDDQ2LANE_SLUMBER_DLY. Suggested value of this delay is 3 microseconds. SATAPAD_IDDQ_OVERRIDE_VALUE=0	
3	The driver checks if PLLE is already turned on or not. Part (a) : If PLLE is already turned on, it waits for 1 ms before moving on to next step. Part (b): If PLLE is off, it brings it up.	If PCIE is running, PLLE could be already running. Check that it is running by checking its PLLE_ENABLE and PLLE_LOCK bits. Part (a): If both bits are set, then the PLLE is already turned on. Wait for 1 ms . Part (b) If neither bit is set, then do PLLE training and init sequence. If using spread spectrum, set the following bits: CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCBYP=1 CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_BYPASS_SS=1 CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_INTERP_RESET=1 Set PLLE_LOCK_ENABLE bit in CLK_RST_CONTROLLER_PLLE_MISC register to DISABLE (0). Set the PLLE_ENABLE and PLLE_ENABLE_CML bits to DISABLE (0) in CLK_RST_CONTROLLER_PLLE_BASE register. Also set PLLE_SETUP=0 and PLLE_EXT_SETUP_17_16=0 in CLK_RST_CONTROLLER_PLLE_MISC register. Check that PLLE_IDDQ_SWCTL=1 and PLLE_IDDQ_OVERRIDE_VALUE=1. If they are not set to 1, set them to 1. Then set PLLE_IDDQ_OVERRIDE_VALUE=0 to begin the training sequence. Wait for PLLE training sequence to finish by waiting until PLLE_PLL_READY bit is set to 1 in CLK_RST_CONTROLLER_PLLE_MISC register program PLLE parameters (most are the default Reset values) – set the following values: CLK_RST_CONTROLLER_PLLE_BASE register: PLLE_PLDIV_CML = 0xd PLLE_PLDIV = 0x18 PLLE_MDIV = 0x1 PLLE_NDIV = 0xc8 CLK_RST_CONTROLLER_PLLE_MISC register PLLE_SETUP = 0x7 (This is not the default) PLLE_LOCK_ENABLE = ENABLE (1) (This isn’t default) If using spread spectrum, set the following bits: CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCBYP=1 CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_BYPASS_SS=1 CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_INTERP_RESET=1 Enable the PLLE now by setting PLLE_ENABLE and PLLE_ENABLE_CML to ENABLE (1) in CLK_RST_CONTROLLER_PLLE_BASE register.	

#	Description	Register Programming	Comments
		Wait for PLLE to lock by waiting until PLLE_LOCK bit is set to 1 in CLK_RST_CONTROLLER_PLLE_MISC register. After PLLE_LOCK is detected, wait for an additional programmable delay of PLLE_LOCK_DLY. This will help in case the PLLE_LOCK gets asserted earlier. The suggested value of this additional delay is 25 microseconds. Do the following steps if you intend to use spread spectrum: program spread spectrum coefficients- CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCMAX = 0x25, CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCINCINTRV = 0x20, CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCINC = 0x1. CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_BYPASS_SS=0 CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCBYP=0 CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_INTERP_RESET=0 Enable CML clock for SATA by setting PLLE_CML1_OEN bit to 1 in CLK_RST_CONTROLLER_PLLE_AUX_0 register. If PLLE is already turned on, check that the SATA CML clock output is turned on. Otherwise, turn it on by setting PLLE_CML1_OEN bit to 1 in CLK_RST_CONTROLLER_PLLE_AUX_0 register.	
4	The driver deasserts reset to SATA PADPLL and waits until it locks.	SATA_PADPLL_RESET_OVERRIDE_VALUE=0 Wait for Satapll_lockdet =’1’	Expected maximum time for SATA PADPLL to lock = 15 microseconds.
5	The driver toggles the power-gate SAX bit in the PMC to power-ungate SAX partition.	Toggle the SAX partition register bits in the PMC APBDEV_PMC_PWRGATE_TOGGLE_0.SAX=0 APBDEV_PMC_REMOVE_CLAMPING_CMD_0.SAX=1	
6	The power ungating is complete.		This is an implicit step. No action here.
7	Driver turns on the clocks to SATA and deasserts resets.	Software to ungate txclk and all SATA clocks, reset CLK_RST_CONTROLLER_CLK_OUT_ENB_V_0.SATA_CLKEN= ‘1’ , CLK_RST_CONTROLLER_RST_DEVICES_W_0.SATACOLD_RST= ‘0’ , CLK_RST_CONTROLLER_RST_DEVICES_V_0.SATA_RESET =0	
8	Driver restores the registers of the controller.	Driver should restore the registers in the following order: IPFS, CFG, Ext CFG, BAR5. Make sure that any registers that change values based on customer design are restored to their proper values. During the restoration of the registers, the driver would now need to restore the register T_SATA0_CFG_POWER_GATE_SSTS_RESTORED after the ssts_det, ssts_spd are restored. This register is used to tell the controller whether a drive existed earlier or not and move the PHY state machines into either HR_slumber	Expected to take ~10 µs.

#	Description	Register Programming	Comments
		or not.	
9	Driver needs to switch the rx_idle_t driven source back to from Sata controller after SAX is power-ungated	Write SATA_AUX_MISC_CNTL_1_0 register L0_RX_IDLE_T_MUX field to '0'.	
10	Driver can start to use main SATA interrupt instead of the rx_stat_t interrupt.	After SATA logic power-ungated we can start to use main interrupt from SATA controller and interrupt status mapped to interrupt controller register PRI_ICTLR_ISR_0 bit[23] "SATA_CTL"	
11	Set the bits in the CAR to allow hardware based low power sequencing.	SATAPAD_PLL_PLLE_IDDQ_RESET_SWCTL =0	
12	Driver indicates to the controller that the power ungating process is complete.	Clear bit in PMC . APBDEV_PMC_SATA_PWRGT_0.Pmc2sata_pg _info = 0 Clears the bit rx_stat_idle_bypass to enable detection of a comwake.	

Note: Wakeup behavior when CPU is off

Wake up might include waking the CPU itself

If the CPU is powered down, the rx_stat interrupt causes flow controller/PMC to power up CPU, the CPU goes to reset vector handler code in OS kernel patch which will restore the CPU state, reinitialize the CPU, un-powergate SATA, restore the SATA state, and give control to AHCI software.

If the CPU is powered up, the rx_stat interrupt signal generates a CPU interrupt, interrupt handler in driver shall un-powergate SATA and restore SATA state.

31.4.5 Software Changes

In software initiated power gating and ungating, software controls the entry and exit of the power gating controller. In the hardware initiated wake up mode, the software needs to read the bit oob_wake_detected to determine if the controller needs to be power ungated. The software needs to keep a backup of all the registers in system memory and needs to reprogram them once in the power ungating process. The software needs to program the registers in the correct sequence as mentioned above.

The PxCMD.CR bit does not have the right value after register restoration following power-ungating. The software should not read that bit.

A software workaround is needed when software initiating power-gating. To prevent accidental COMRESET from being sent on the SATA link, software needs to set an override for hardware not to look at SATA PLL lockdet when shutting down the SATA PLL. This can be done by writing SATA ext. config space register T_SATA<0>_CFG_MISC (0x550): write bit [10] to '1' and bit [8] to '0' (field T_SATA<0>_CFG__PHY_RESET_USAGE_MODE).

31.5 Address Translation

The BAR spaces and PCI Config space from the PCI bus environment are mapped as-is to an address space carved out of ARM (ordering of the registers is not changed). Tegra K1 devices do not follow the PCI specifications. They do not have any concept of the PCI configuration space, BAR space, and the extended configuration space. The system addressing is of 32 bits, unlike 40 bits in the PCI bus environment. The address can map up to 4 GB.

There is an address translation mechanism in the IPFS. With this address translation, a certain address range is mapped to the configuration space registers, and likewise for the BAR 5 and the extended configuration space registers.

The address mapping that is being done is explained in the “Address Translation Table” subsection. Even though, BAR 0 to Bar 4 are not applicable to Tegra K1 devices, they too have been allocated address ranges.

31.5.1 Address Translation Table

The next table shows how all of the SATA register spaces and SATA-IPFS registers are mapped to the Tegra K1 memory map. In Tegra K1 devices, 64KB APB space is allocated for all these registers and 512B APB space is allocated for SATA IOBIST registers.

Register Section		DFPCI address [39:0]	APB adr[31:0] for DFPCI mapping	PRI address [31:0]	APB adr[31:0] for PRI mapping
			*APB address 0x7002_0000 - 0x7002_0FFF is reserved for IPFS local registers		
1. SATA Configuration Space		Address starting with 0xFD_FE or 0xFE_0			
SATA configuration space 0x0 - 0x255	Start address	0xFD_FE00_5000	0x7002_1000	0x5010_0000	0x7002_9000
	End address	0xFD_FE00_50FF	0x7002_10FF	0x5010_00FF	0x7002_90FF
SATA extended configuration space 0x100 - 0xFFF	Start address	0xFE_0100_5000	0x7002_1100	0x5010_0100	0x7002_9100
	End address	0xFE_0F00_50FF	0x7002_1FFF	0x5010_0FFF	0x7002_9FFF
		Format : 0xFE_0X00_50YZ			
		XYZ from 0x100 to 0xFFF			
I/O space		Address starting with 0xFD_FC			
2. SATA BAR0					
Register MCP_SATA_PRI_COMMAND_0	Address in SATA Compatible mode	0xFD_FC00_01F0	0x7002_21F0	0x5020_0200	0x7002_A200
	Address in SATA Native mode	SATA BAR0 with offset 0x0	0x7002_2000	0x5000_0200	0x7002_A200
	Address in SATA AHCI mode	Not used but address can be same as native mode	0x7002_2000	Not used but address can be same as native mode	0x7000_A200
Register MCP_SATA_PRI_COMMAND_1	Address in SATA Compatible mode	0xFD_FC00_01F4	0x7002_21F4	0x5020_0204	0x7002_A204
	Address in SATA Native mode	SATA BAR0 with offset 0x4	0x7002_2004	0x5000_0204	0x7002_A204
	Address in SATA AHCI mode	Not used but address can be same as native mode	0x7002_2004	Not used but address can be same as native mode	0x7000_A204
3. SATA BAR1					
Register MCP_SATA_PRI_CONTROL	Address in SATA Compatible mode	0xFD_FC00_03F4	0x7002_33F4	0x5020_0300	0x7002_A300
	Address in SATA Native mode	SATA BAR1 with offset 0x0	0x7002_3000	0x5020_0300	0x7002_A300

Register Section		DFPCI address [39:0]	APB adr[31:0] for DFPCI mapping	PRI address [31:0]	APB adr[31:0] for PRI mapping
	Address in SATA AHCI mode	Not used but address can be same as native mode	0x7002_3000	Not used but address can be same as native mode	0x7002_A300
4. SATA BAR2					
Register MCP_SATA_SEC_ COMMAND_0	Address in SATA Compatible mode	0xFD_FC00_0170	0x7002_4170	0x5020_0400	0x7002_A400
	Address in SATA Native mode	SATA BAR2 with offset 0x0	0x7002_4000	0x5020_0400	0x7002_A400
	Address in SATA AHCI mode	Not used but address can be same as native mode	0x7002_4000	Not used but address can be same as native mode	0x7002_A400
Register MCP_SATA_SEC_ COMMAND_1	Address in SATA Compatible mode	0xFD_FC00_0174	0x7002_4174	0x5020_0404	0x7002_A404
	Address in SATA Native mode	SATA BAR2 with offset 0x4	0x7002_4004	0x5020_0404	0x7002_A404
	Address in SATA AHCI mode	Not used but address can be same as native mode	0x7002_4004	Not used but address can be same as native mode	0x7002_A404
5. SATA BAR3					
Register MCP_SATA_SEC_ CONTROL	Address in SATA Compatible mode	0xFD_FC00_0374	0x7002_5374	0x5020_0500	0x7002_A500
	Address in SATA Native mode	SATA BAR3 with offset 0x0	0x7002_5000	0x5020_0500	0x7002_A500
	Address in SATA AHCI mode	Not used but address can be same as native mode	0x7002_5000	Not used but address can be same as native mode	0x7002_A500
6. SATA BAR4					
Bus Master Registers 0x0 - 0xF	Address in SATA Compatible mode	SATA BAR4 with offset 0x0 - 0xF	0x7002_6000 - 0x7002_600F	0x5020_0600 - 0x5020_060F	0x7002_A600 - 0x7002_A60F
	Address in SATA Native mode	SATA BAR4 with offset 0x0 - 0xF	0x7002_6000 - 0x7002_600F	0x5020_0600 - 0x5020_060F	0x7002_A600 - 0x7002_A60F
	Address in SATA AHCI mode	Not used but address can be same as native mode	0x7002_6000 - 0x7002_600F	Not used but address can be same as native mode	0x7002_A600 - 0x7002_A60F
Memory space		Address[39:32] = 0x0			
7. SATA BAR5 (claim 8KB)					
AHCI Registers 0x0 - 0x1FFF	Start address	SATA BAR5 with offset 0x0	0x7002_7000	0x5030_0000	0x7002_B000
	End address	SATA BAR5 with offset 0x1FFF	0x7002_8FFF	0x5030_1FFF	0x7002_CFFF
8. SATA IOBIST registers	Start address	Non accessible	N.A.	0x5050_0000	0x7002_D000
	End address	Non accessible	N.A.	0x5050_01F7	0x7002_D1F7
Note : In Tegra K1 devices, there is a standalone APB client created for SATA IOBIST register access, the PRI interface mapping from the SATA APB client is no longer valid					
The SATA IOBIST registers are mapped to 0x7000_6C00 - 0x7000_6DFF					

31.6 Programming Guidelines

31.6.1 Cold Boot

The IOPHY of SATA is shared with XUSB. Refer to the USB Complex section in this TRM for the IOPHY PLL initialization sequence.

The IOPHY lane ownership assignment is located in XUSB PADCTL, where the PAD parameter programming registers have also been moved to XUSB PADCTL. Refer to the USB Complex section in this TRM for the IOPHY PAD initialization sequence.

The PAD driver assigns the GPIO pins to the controllers:

- Set the following PINMUX register bits to initialize the GPIO pins for DEVSLP:
  - PINMUX_AUX_DAP_MCLK1_REQ_0[PM] to ‘SATA’
  - PINMUX_AUX_DAP_MCLK1_REQ_0[PUPD] to ‘NORMAL’
- Set the following PINMUX register bits to initialize the GPIO pins for DA:
  - PINMUX_AUX_GPIO_PFF2_0[PM] to ‘SATA’
  - PINMUX_AUX_GPIO_PFF2_0[PUPD] to ‘NORMAL’

The PAD driver programs the clocks and deasserts the resets to the controllers:

- Set the following CAR register bits to ‘1’ to enable the clocks to SATA:
  - CLK_RST_CONTROLLER_CLK_ENB_V_SET_0[SET_CLK_ENB_SATA]
  - CLK_RST_CONTROLLER_CLK_ENB_V_SET_0[SET_CLK_ENB_SATA_OOB]
- Program the following CAR register bits to set the source of the SATA clocks, where PLLP_OUT0 runs at 408 MHz:
  - CLK_RST_CONTROLLER_CLK_SOURCE_SATA_0[SATA_CLK_SRC] to ‘PLLP_OUT0’
  - CLK_RST_CONTROLLER_CLK_SOURCE_SATA_0[SATA_CLK_DIVISOR] to ‘0x6’
  - CLK_RST_CONTROLLER_CLK_SOURCE_SATA_OOB_0[SATA_OOB_CLK_SRC] to ‘PLLP_OUT0’
  - CLK_RST_CONTROLLER_CLK_SOURCE_SATA_OOB_0[SATA_OOB_CLK_DIVISOR] to ‘0x2’
- Set the following CAR register bits to ‘0’ to deassert reset to SATA:
  - CLK_RST_CONTROLLER_RST_DEVICES_V_0[SWR_SATA_RST]
  - CLK_RST_CONTROLLER_RST_DEVICES_V_0[SWR_SATA_OOB_RST]

The PAD driver brings the IOPHY out of IDDQ:

- Program the following XUSB PADCTL registers to ‘1’ to bring SATA IOPHY out of IDDQ.
  - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_SATA_PAD_IDDQ_DISABLE_MASK0]

The SATA PEP driver initializes the IPFS registers:

- Program the following SATA IPFS registers to allow software accesses to the SATA’s MMIO registers:
  - SATA_AXI_BAR5_START_0[AXI_BAR0_START] to ‘0x70020’
  - SATA_AXI_BAR5_SZ_0[AXI_BAR0_SIZE] to ‘0x00008’
  - SATA_FPCI_BAR5_0[FPCI_BAR0_START] to ‘0x0010000’
  - SATA_FPCI_BAR5_0[FPCI_BAR0_ACCESS_TYPE] to ‘0’
- Program the following SATA IPFS register to enable the SATA:
  - SATA_CONFIGURATION_0[EN_FPCI] to ‘1’

The SATA PEP driver initializes SATA’s configuration registers.

- Program the following SATA configuration registers to initialize SATA:
  - T_SATA<0>_CFG_1_BUS_MASTER to '1'
  - T_SATA<0>_CFG_1_MEMORY_SPACE to '1'
  - T_SATA<0>_CFG_9_BASE_ADDRESS to '0x08000'

The SATA PEP driver initializes SATA's AUX registers.

- Program the following SATA AUX registers to set the RX idle detection source and disable RX idle detection interrupt:
  - SATA_AUX_MISC_CTRL_1_0[AUX_OR_CORE_IDLE_STATUS_SEL] to 'CORE'
  - SATA_AUX_RX_STAT_INT_0[SATA_RX_STAT_INT_DISABLE] to '1'

31.6.2 ELPG Entry

The SATA PEP driver performs context saves for SATA registers specified in Section 31.7.1 .

The SATA PEP driver switches PAD control to SATA's AUX registers:

- Program the following SATA AUX registers to set the RX idle detection source and enable RX idle detection interrupt:
  - SATA_AUX_MISC_CTRL_1_0[AUX_OR_CORE_IDLE_STATUS_SEL] to 'AUX'
  - SATA_AUX_RX_STAT_INT_0[SATA_RX_STAT_INT_DISABLE] to '1'
- Program the following XUSB PADCTL registers to put the Vcore side of the IOPHY to IDDQ:
  - XUSB_PADCTL_IOPHY_MISC_PAD_S0_CTL_1_0[IDDQ_OVRD] to '1'
  - XUSB_PADCTL_IOPHY_MISC_PAD_S0_CTL_1_0[IDDQ] to '1'
- Check the assertion status of DEVSLP and set the DEVSLP override with the following SATA_AUX registers accordingly.
  - Read SATA_AUX_RX_STAT_INT_0[SATA_DEVLSP] as '$DEVSLP'
  - Set SATA_AUX_MISC_CTRL_1_0[DEVSLP_OVERRIDE] to '$DEVSLP'
- If DEVSLP# is asserted, read and store the MDAT timer value via the following *SATA* AUX register:
  - Read SATA_AUX_SPARE_CFG0_0[MDAT_TIMER_BEFORE_PG] as '$MDAT'

The System Power Management driver asserts reset to SATA then disables its clocks:

- Set the following CAR register bits to '1' to assert reset to SATA:
  - CLK_RST_CONTROLLER_RST_DEVICES_V_0[SWR_SATA_RST]
  - CLK_RST_CONTROLLER_RST_DEVICES_V_0[SWR_SATA_OOB_RST]
- Set the following CAR register bits to '1' to disable the clocks to individual SATA partitions:
  - CLK_RST_CONTROLLER_CLK_ENB_V_CLR_0[CLR_CLK_ENB_SATA]
  - CLK_RST_CONTROLLER_CLK_ENB_V_CLR_0[CLR_CLK_ENB_SATA_OOB]

The System Power Management driver uses software overrides to power down the IOPHY/UPHY PLL.

- Set the following CAR register bits to '1' to power down the PLL:
  - CLK_RST_CONTROLLER_SATA_PLL_CFG0_0[SATA_SEQ_PADPLL_PD_INPUT_VALUE]
  - CLK_RST_CONTROLLER_SATA_PLL_CFG0_0[SATA_SEQ_LANE_PD_INPUT_VALUE]
  - CLK_RST_CONTROLLER_SATA_PLL_CFG0_0[SATA_SEQ_RESET_PD_INPUT_VALUE]

The System Power Management driver disables the SATA power rails:

- Program the following PMC register bits in a single write to disable the power rail to SATA:

- APBDEV_PMC_PWRGATE_TOGGLE_0[START] to ‘enable’
- APBDEV_PMC_PWRGATE_TOGGLE_0[PARTID] to ‘SAX’

- Read the following *PMC* register bits to confirm the power gating status of *SATA*:
  - APBDEV_PMC_PWRGATE_STATUS_0[SAX] equals ‘OFF’

31.6.3 ELPG Exit

The System Power Management driver uses software overrides to enable the IOPHY/UPHY PLL.

- Set the following *CAR* register bits to ‘0’ to enable the PLL
  - CLK_RST_CONTROLLER_SATA_PLL_CFG0_0[SATA_SEQ_PADPLL_PD_INPUT_VALUE]
  - CLK_RST_CONTROLLER_SATA_PLL_CFG0_0[SATA_SEQ_LANE_PD_INPUT_VALUE]
  - CLK_RST_CONTROLLER_SATA_PLL_CFG0_0[SATA_SEQ_RESET_PD_INPUT_VALUE]

The System Power Management driver enables the SATA power rails:

- Program the following PMC register bits in a single write to disable the power rail to SATA:
  - APBDEV_PMC_PWRGATE_TOGGLE_0[START] to ‘enable’
  - APBDEV_PMC_PWRGATE_TOGGLE_0[PARTID] to ‘SAX’
- Read the following PMC register bits to confirm the power gating status of SATA:
  - APBDEV_PMC_PWRGATE_STATUS_0[SAX] equals ‘ON’

The System Power Management driver enables the SATA clocks:

- Set the following CAR register bits to ‘1’ to enable the clocks to the SATA partition:
  - CLK_RST_CONTROLLER_CLK_ENB_V_SET_0[SET_CLK_ENB_SATA]
  - CLK_RST_CONTROLLER_CLK_ENB_V_SET_0[SET_CLK_ENB_SATA_OOB]

The System Power Management driver removes power clamps to XUSB partitions:

- Set the following PMC register bits to ‘1’ to remove the power clamps to the SATA partitions:
  - APBDEV_PMC_REMOVE_CLAMPING_CMD_0 [SAX]
- Read the following PMC register bits to confirm the power clamps to the SATA partition are removed:
  - APBDEV_PMC_REMOVE_CLAMPING_CMD_0 [SAX] equals ‘0’

The System Power Management driver deasserts reset to SATA.

- Set the following CAR register bits to ‘0’ to assert reset to SATA:
  - CLK_RST_CONTROLLER_RST_DEVICES_V_0[SWR_SATA_RST]
  - CLK_RST_CONTROLLER_RST_DEVICES_V_0[SWR_SATA_OOB_RST]

The SATA PEP driver performs context restores for SATA registers specified in Section 31.7.1 ; starting from the IPFS registers followed by the SATA configuration registers and finally the SATA MMIO registers.

The SATA PEP driver switches PAD control to SATA:

- If DEVSLP is asserted, restore the MDAT timer value then deassert DEVSLP via the following *SATA* AUX registers:
  - Set SATA_AUX_SPARE_CFG0_0[MDAT_TIMER_AFTER_PG] to ‘$MDAT’
  - Set SATA_AUX_SPARE_CFG0_0[MDAT_TIMER_AFTER_PG_VALID] to ‘1’
  - Set SATA_AUX_MISC_CTRL_1_0[DEVSLP_OVERRIDE] to ‘0’
- Program the following XUSB_PADCTL registers to bring the Vcore side of the IOPHY out of IDDQ:

- XUSB_PADCTL_IOPHY_MISC_PAD_S0_CTL_1_0[IDDQ_OVRD] to ‘0’
- XUSB_PADCTL_IOPHY_MISC_PAD_S0_CTL_1_0[IDDQ] to ‘0’

- Program the following SATA_AUX registers to set the RX idle detection source, disable RX idle detection interrupt, and clear RX idle interrupt:
  - SATA_AUX_MISC_CTRL_1_0[AUX_OR_CORE_IDLE_STATUS_SEL] to ‘CORE’
  - SATA_AUX_RX_STAT_INT_0[SATA_RX_STAT_INT_DISABLE] to ‘0’
  - SATA_AUX_RX_STAT_CLR_0[SATA_RX_STAT_INT_CLR] to ‘1’

31.6.4 LP0

SATA AUX power is also removed during LP0, thus the assertion status of DEVSLP# through LP0 should be maintained by using the pull-down resistor of the GPIO pad via the PINMUX_AUX_DAP_MCLK1_REQ_0[PUPD] register:

If DEVSLP is asserted, the PAD driver should enable the pull-up of the GPIO pin by programming the following register before entering LP0.

- PINMUX_AUX_DAP_MCLK1_REQ_0[PUPD] to ‘PU’

If DEVSLP is asserted, the PAD driver should disable the pull-up of the GPIO pin by programming the following register after exiting LP0 and the DEVSLP override in SATA AUX register has been set:

- PINMUX_AUX_DAP_MCLK1_REQ_0[PUPD] to ‘NORMAL’

As part of the LP0 entry sequence, after setting the SATA controller to ELPG, the PAD driver should put the IOPHY to IDDQ:

- Program the following XUSB PADCTL registers to ‘0’ to bring SATA IOPHY to IDDQ.
  - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_SATA_PAD_IDDQ_DISABLE_MASK0]

As part of the LP0 exit sequence, after restoring power to SATA, the PAD driver brings the IOPHY out of IDDQ:

- Program the following XUSB PADCTL registers to ‘1’ to bring SATA IOPHY out of IDDQ:
  - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_SATA_PAD_IDDQ_DISABLE_MASK0]

31.7 Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

31.7.1 Registers for Save and Restore

The registers needed to be saved and restored are:

IPFS registers

Save and restore	Offset (hex)	Save and restore	Offset (hex)
SATA_FPCI_BAR5_0	94	SATA_MSI_EN_VEC6_0	158
SATA_MSI_BAR_SZ_0	C0	SATA_MSI_EN_VEC7_0	15C
SATA_MSI_AXI_BAR_ST_0	C4	SATA_CONFIGURATION_0	180
SATA_MSI_FPCI_BAR_ST_0	C8	SATA_FPCI_ERROR_MASKS_0	184
SATA_MSI_EN_VEC0_0	140	SATA_INTR_MASK_0	188
SATA_MSI_EN_VEC1_0	144	SATA_IPFS_INTR_ENABLE_0	198
SATA_MSI_EN_VEC2_0	148	SATA_CFG_REVID_0	1A0
SATA_MSI_EN_VEC3_0	14C	SATA_CLKGATE_HYSTERSIS_0	1BC

Save and restore	Offset (hex)	Save and restore	Offset (hex)
SATA_MSI_EN_VEC4_0	150	SATA_SATA_MCCIF_FIFOCTRL_0	1DC
SATA_MSI_EN_VEC5_0	154		

Configuration Space and Extended Configuration Space Registers

Note: Registers present in both the SATA and SATA0 address spaces are listed as SATA<0>.

Save and restore	Offset (hex)	Save and restore	Offset (hex)
T_SATA<0>_CFG_1	4	T_SATA<0>_CFG_LINK_0	174
T_SATA<0>_CFG_3	C	T_SATA<0>_CFG_LINK_1	178
T_SATA<0>_CFG_9	24	T_SATA<0>_CFG_LINK_2	17c
T_SATA<0>_CFG_10	28	MCP_SATA<0>_CFG_TRANS_0	1D0
T_SATA<0>_CFG_12	30	T_SATA0_ALPM_CTRL	238
T_SATA<0>_CFG_13	34	T_SATA0_AHCI_HBA_CTL_0	30C
T_SATA<0>_CFG_14	38	T_SATA0_AHCI_HBA_BIST_OVERRIDE_CTL	318
T_SATA<0>_CFG_15	3C	T_SATA0_AHCI_HBA_SPARE_1	320
T_SATA<0>_CFG_16	40	T_SATA0_AHCI_HBA_SPARE_2	324
T_SATA<0>_CFG_17	44	T_SATA0_AHCI_HBA_DYN_CLK_CLAMP	328
T_SATA<0>_CFG_18	48	T_SATA0_AHCI_CFG_ERR_CTRL	32C
T_SATA<0>_MSI_CTRL	B0	T_SATA0_AHCI_HBA_CTL_1	338
T_SATA<0>_MSI_ADDR1	B4	T_SATA0_AHCI_HBA_PRE_STAGING_CONTROL	340
T_SATA<0>_MSI_ADDR2	B8	T_SATA0_CFG_FPCI_0	430
T_SATA<0>_MSI_DATA	BC	T_SATA0_CFG_ESATA_CTRL	494
T_SATA<0>_MSI_QUEUE	C0	T_SATA<0>_CTL1	4A0
T_SATA<0>_MSI_MAP	EC	T_SATA<0>_CFG_CTL_GLUE	4B0
T_SATA0_CFG_PHY_POWER	124	T_SATA<0>_PHY_CTRL	534
T_SATA0_CFG_PHY_POWER_1	128	T_SATA<0>_CTRL	540
T_SATA<0>_CFG_PHY_1	12C	T_SATA<0>_LOW_POWER_COUNT	554

Save and Restore Following Protocol

(Program T_SATA<0>_INDEX to select port 0)

Save and restore	Offset (hex)	Save and restore	Offset (hex)
T_SATA<0>_CHXCFG1	530	T_SATA<0>_CHX_PHY_CTRL_3	6B0
T_SATA<0>_CHX_MISC	684	T_SATA<0>_CHX_PHY_CTRL_4	6B4
T_SATA<0>_CHXCFG3	700	T_SATA<0>_CHX_PHY_CTRL_5	6B8
T_SATA<0>_CHXCFG4_CHX	704	T_SATA<0>_CHX_PHY_CTRL_6	6BC
T_SATA<0>_CHX_PHY_CTRL1_GEN1	690	T_SATA<0>_PRBS_CHX – OP	714
T_SATA<0>_CHX_PHY_CTRL1_GEN2	694	T_SATA<0>_CHX_LINK0	750
T_SATA<0>_CHX_PHY_CTRL1_GEN3	698	T_SATA<0>_CHX_GLUE	7F0

Save and restore	Offset (hex)	Save and restore	Offset (hex)
T_SATA<0>_CHX_PHY_CTRL_2	69C		

BAR 5 Space Registers

Save and restore	Offset (hex)	Save and restore	Offset (hex)
T_AHCI_HBA_CCC_PORTS	18	T_AHCI_PORT_PXCLBU	104
T_AHCI_HBA_GHC	4	T_AHCI_PORT_PXFB	108
T_AHCI_HBA_CCC_CTL - OP (optional)	14	T_AHCI_PORT_PXFBU	10C
T_AHCI_HBA_EM_LOC	1C	T_AHCI_PORT_PXIE	114
T_AHCI_HBA_EM_CTL - OP	20	T_AHCI_PORT_PXCMD	118
T_AHCI_PORT_PXCLB	100	T_AHCI_PORT_PXSCTL	12C

Power-Gating Registers

These registers require save and restore across the power-gating sequence. Apart from this, the software is expected to save and restore the configuration space registers.

Save and restore	Offset (hex)	Save and restore	Offset (hex)
T_AHCI_HBA_SPARE_0	a4	T_AHCI_HBA_CCC_PORTS	18
T_AHCI_HBA_GHC	4	T_AHCI_HBA_CCC_CTL - OP (optional)	14

31.7.2 Registers Used in Power Gating/Ungating Sequence

Refer to the PMC and Clock and Reset Controller sections for the details of these registers:

- APBDEV_PMC_SATA_PWRGT_0

- CLK_RST_CONTROLLER_SATA_PLL_CFG0_0
- CLK_RST_CONTROLLER_PLLE_AUX_0

31.7.3 SATA Register Descriptions

31.7.3.1 SATA_AXI_BARi_SZ_0 Registers

There are eight SATA_AXI_BARi_SZ_0 registers (I = 0 through 7). The size of the address range associated with BARi is in 4K increments. A value of 0 signifies BARi is not used.

SATA_AXI_BAR0_START_0 through SATA_AXI_BAR4_START_0

- For BAR0 through BAR4 (i = 0 through 4):

Offset: 0x0 + (i * 0x4) | Read/Write: R/W | Reset: 0x00000001 (0b00000000000000000001)

Bit	Reset	Description
19:0	0x1	AXI_BARi_SIZE

SATA_AXI_BAR5_START_0

Offset: 0x14 | Read/Write: R/W | Reset: 0x00000002 (0b00000000000000000010)

Bit	Reset	Description
19:0	0x2	AXI_BAR5_SIZE

SATA_AXI_BAR6_START_0 through SATA_AXI_BAR7_START_0

- For BAR6 through BAR7 (i = 6 through 7)

Offset: 0x18 + (i * 0x4) | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000)

Bit	Reset	Description
19:0	0x0	AXI_BARi_SIZE

31.7.3.2 SATA_AXI_BARi_START_0 Registers

There are eight SATA_AXI_BARi_START registers. The AXI target address is compared to the start/size for each BAR to determine if the access is to that BAR.

SATA_AXI_BAR0_START_0

Offset: 0x40 | Read/Write: R/W | Reset: 0x70022000 (0b01110000000000100010)

Bit	Reset	Description
31:12	0x70022	AXI_BAR0_START:The start of AXI address space for BAR0.

SATA_AXI_BAR1_START_0

Offset: 0x44 | Read/Write: R/W | Reset: 0x70023000 (0b01110000000000100011)

Bit	Reset	Description
31:12	0x70023	AXI_BAR1_START:The start of AXI address space for BAR1.

SATA_AXI_BAR2_START_0

Offset: 0x48 | Read/Write: R/W | Reset: 0x70024000 (0b01110000000000100100)

Bit	Reset	Description
31:12	0x70024	AXI_BAR2_START:The start of AXI address space for BAR2.

SATA_AXI_BAR3_START_0

Offset: 0x4c | Read/Write: R/W | Reset: 0x70025000 (0b01110000000000100101)

Bit	Reset	Description
31:12	0x70025	AXI_BAR3_START:The start of AXI address space for BAR3.

SATA_AXI_BAR4_START_0

Offset: 0x50 | Read/Write: R/W | Reset: 0x70026000 (0b01110000000000100110)

Bit	Reset	Description
31:12	0x70026	AXI_BAR4_START: The start of AXI address space for BAR4.

SATA_AXI_BAR5_START_0

Offset: 0x54 | Read/Write: R/W | Reset: 0x70027000 (0b01110000000000100111)

Bit	Reset	Description
31:12	0x70027	AXI_BAR5_START: The start of AXI address space for BAR5.

SATA_AXI_BAR6_START_0

Offset: 0x58 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000)

Bit	Reset	Description
31:12	0x0	AXI_BAR6_START: The start of AXI address space for BAR6.

SATA_AXI_BAR7_START_0

Offset: 0x5c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000)

Bit	Reset	Description
31:12	0x0	AXI_BAR7_START: The start of AXI address space for BAR7.

31.7.3.3 SATA_FPCI_BARi_0 Registers

There are eight SATA_FPCI_BARi_0 registers. All registers have these two fields:

- Bits [31:4]: FPCI_BARi_START: This field contains the start of FPCI address space mapped into the BARi range of PCI memory space. The 40-bit FPCI address is determined by a shift left 12 of the value of this field.
- Bit 0: FPCI_BARi_ACCESS_TYPE: This field indicates if the address region is memory mapped versus configuration or I/ O space.
  0 = Memory-mapped access (PW only)
  1 = I/O / config access (NPW only)

SATA_FPCI_BAR0_0 through SATA_FPCI_BAR5_0

For BAR0 through BAR5 (i = 0 through 5)

Offset: 0x80 + (i * 0x4) | Read/Write: R/W | Reset: 0xfdfc0001 (0b11111101111111100000000000000xxx1)

Bit	Reset	Description
31:4	0xfdfc000	FPCI_BARi_START
0	0x1	FPCI_BARi_ACCESS_TYPE

SATA_FPCI_BAR6_0 through SATA_FPCI_BAR7_0

Offset: 0x98 + (i* 0x4) | Read/Write: R/W | Reset: 0x00000001 (0b00000000000000000000000000000xxx1)

Bit	Reset	Description
31:4	0x0	FPCI_BARi_START
0	0x1	FPCI_BARi_ACCESS_TYPE

31.7.3.4 SATA_MSI_BAR_SZ_0

MSI BAR Size

Offset: 0xc0 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000)

Bit	Reset	Description
19:0	0x0	MSI_BAR_SIZE: The size of the address range associated with MSI BAR is in 4K increments. A value of 0 signifies MSI BAR is not used.

31.7.3.5 SATA_MSI_AXI_BAR_ST_0

MSI AXI BAR Start

Offset: 0xc4 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000)

Bit	Reset	Description
31:12	0x0	MSI_AXI_BAR_START: The start of upstream AXI address space for MSI BAR. The upstream FPCI address is compared to start/1KB range for MSI BAR to determine if the access is MSI. Bits 31:12 of MSI BAR start correspond to AXI address bits 31:12.

31.7.3.6 SATA_MSI_FPCI_BAR_ST_0

MSI FPCI BAR Start

Offset: 0xc8 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:4	0x0	MSI_FPCI_BAR_START: The start of upstream FPCI address space for MSI BAR. The upstream FPCI address is compared to start/1KB range for MSI BAR to determine if the access is MSI. Bits 31:4 of MSI BAR start correspond to UFPCI address bits 39:12.

31.7.3.7 SATA_MSI_VECi_0 Registers

There are eight SATA_MSI_VECi_0 vector registers (i = 0 through 7). Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0.Vector7 corresponds to MSI vectors 255-223. When an

upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

Offset: 0x100 + (i * 0x4) | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTORi

31.7.3.8 SATA_MSI_EN_VEC0_0

There are eight SATA_MSI_EN_VECi_0 vector registers (i = 0 through 7). Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223. When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

Offset: 0x140 + (i * 0x4) | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTORi

31.7.3.9 SATA_CONFIGURATION_0

Configuration

Offset: 0x180 | Read/Write: R/W | Reset: 0x800X8X40 (0b1xxxxxxxxxxx1xxx10xxxxxx01000000)

Bit	R/W	Reset	Description
31	RW	0x1	CLKEN_OVERRIDE: This can override the clock enable in case of malfunction.
19	RW	0x1	PW_NO_DEVSEL_ERR_CYA: Setting this bit will disable detection of DECERR due to no DEVSEL for DS PWs only.
18	RO	X	INITIATOR_READ_IDLE: This read-only bit provides status reads on the AFI upstream. A value of 1b indicates there are no outstanding reads to the initiator.
17	RO	X	INITIATOR_WRITE_IDLE: This read-only bit provides status writes on the AFI upstream. A value of 1b indicates there are no outstanding writes to the initiator.
15	RW	0x1	WDATA_LEAD_CYA: Used to enable/disable the handling of write data ahead of requests on the IPFS AXI target.
14	RW	0x0	WR_INTRLV_CYA: Used to enable/disable the handling of interleaved write requests on the IPFS AXI target
11	RO	X	TARGET_READ_IDLE: This read-only bit provides status reads to the IPFS target. A value of 1b indicates there are no outstanding reads to the downstream FPCI.
10	RO	X	TARGET_WRITE_IDLE: This read-only bit provides status writes to IPFS target. A value of 1b indicates there are no outstanding writes to the downstream FPCI.
9	RO	X	MSI_VEC_EMPTY: This read-only bit provides status on whether MSI Vector registers have any active bits valid or not.
7	RW	0x0	UFPCI_MSIAW: MSI After Write ordering rule. 1 = whenever MSI is ready assert the interrupt 0 = default behavior, apply MSIAW ordering rule
6	RW	0x1	UFPCI_PWPASSPW: Input to upstream FPCI 1 = whenever a write is ready, send it 0 = write goes only when outstanding PWs outside of new write's region are retired (default).
5	RW	0x0	UFPCI_PASSPW: Input to the upstream FPCI. Allow the upstream FPCI reads to pass writes.
4	RW	0x0	UFPCI_PWPASSNPW: Used for upstream FPCI. Allow upstream FPCI PWs to pass NPWs.

Bit	R/W	Reset	Description
3	RW	0x0	DFPCI_PWPASSNPW: Used for the downstream FPCI. Allow downstream FPCI PWs to pass NPWs.
2	RW	0x0	DFPCI_RSPPASSPW: Input to the downstream FPCI. Allow downstream FPCI responses to pass writes.
1	RW	0x0	DFPCI_PASSPW: Input to the downstream FPCI. Allow downstream FPCI reads to pass writes.
0	RW	0x0	EN_FPCI: When the IPFS device block is disabled, it is completely invisible on the IPFS bus; that is, it does not even process IPFS configuration accesses.

31.7.3.10 SATA_FPCI_ERROR_MASKS_0

FPCI Error Masks

Offset: 0x184 | Read/Write: R/W | Reset: 0x00000000 (0b000)

Bit	Reset	Description
2	0x0	MASK_FPCI_MASTER_ABORT: This bit allows an FPCI error to be forwarded to the AXI response when the FPCI error response indicates Master Abort. 1 = forward error 0 = return AXI OKAY response (2'b0)
1	0x0	MASK_FPCI_DATA_ERROR: This bit allows an FPCI error to be forwarded to the AXI response when the FPCI error response indicates Data Error. 1 = forward error 0 = return AXI OKAY response (2'b0)
0	0x0	MASK_FPCI_TARGET_ABORT: This bit allows an FPCI error to be forwarded to the AXI response when the FPCI error response indicates Target Abort. This bit also covers decode errors generated when there is no DEVSEL received. 1 = forward error 0 = return AXI OKAY response (2'b0)

31.7.3.11 SATA_INTR_MASK_0

Interrupt Masks

Offset: 0x188 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxx0xxxxxxx0)

Bit	Reset	Description
16	0x0	IP_INT_MASK: IP (SATA/AZA) interrupt to the CPU gated by a mask.
8	0x0	MSI_MASK: MSI to the CPU gated by a mask.
0	0x0	INT_MASK: Interrupt to the CPU gated by a mask.

31.7.3.12 SATA_INTR_CODE_0

Interrupt Control

Offset: 0x18c | Read/Write: R/W | Reset: 0x00000000 (0b00000)

Bit	Reset	Description
4:0	0x0	INT_CODE: Interrupt codes. If the code is 0, logging of the next interrupt is enabled 0 = INT_CODE_CLEAR : Clear interrupt code 1 = INT_CODE_INI_SLVERR : Interrupt code for CPU AXI SLVERR response to IPFS 2 = INT_CODE_INI_DECERR : Interrupt code for CPU AXI DECERR response to IPFS 3 = INT_CODE_TGT_SLVERR : Interrupt code for PCIe endpoint FPCI target abort or data error response to IPFS 4 = INT_CODE_TGT_DECERR : Interrupt code for PCIe2 FPCI master abort response to IPFS 5 = INT_CODE_TGT_WRERR : Interrupt code for bufferable write to non-posted write address region

Bit	Reset	Description
		6 = RSVD1 : Reserved 7 = INT_CODE_DFPCI_DECERR : Interrupt code for PCIe2 response to downstream request when downstream FPCI address does not fall in a claimable downstream region 8 = INT_CODE_AXI_DECERR : Interrupt code for IPFS response to downstream request when AXI target address does not fall in any of IPFS downstream BARs 9 = INT_CODE_FPCI_TIMEOUT : Interrupt code for FPCI Timeout 10 = RSVD2 : Reserved for future expansion 11 = RSVD3 12 = RSVD4 13 = RSVD5 14 = RSVD6 15 = INT_CODE_SM_FATAL_ERROR : Interrupt code for SM fatal error 16 = INT_CODE_SM_NON_FATAL_ERROR : Interrupt code for SM non-fatal error

31.7.3.13 SATA_INTR_SIGNATURE_0

Interrupt Signature

Offset: 0x190 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000x0)

Bit	Reset	Description
31:2	0x0	INT_INFO: For interrupt codes 1-5/7-8, this field contains address bits [31:2], either in FPCI memory space or AXI space. For FPCI generated errors, this field contains the FPCI address. For AXI/IPFS generated errors, this field contains the AXI address.
0	0x0	DIR: Indicates the direction of the AXI/FPCI transaction. If the signature type is 6 (sideband message), this field is 1. 1=rd 0=wr 0 = WRITE : Interrupt due to a write transaction 1 = READ : Interrupt due to a read transaction

31.7.3.14 SATA_UPPER_FPCI_ADDR_0

Upper FPCI Address

Offset: 0x194 | Read/Write: R/W | Reset: 0x00000000 (0b00000000)

Bit	Reset	Description
7:0	0x0	INT_INFO_UPPER: These 8 bits are the upper byte of the captured FPCI address (bits [39:32])when the interrupt code is 3, 4, or 7.

31.7.3.15 SATA_IPFS_INTR_ENABLE_0

IPFS Interrupt Enable

Offset: 0x198 | Read/Write: R/W | Reset: 0x00000000 (0b00xxxx00000000)

Bit	Reset	Description
13	0x0	EN_SM_NON_FATAL_ERROR: Enable bit for interrupt code 15
12	0x0	EN_SM_FATAL_ERROR: Enable bit for interrupt code 14
7	0x0	EN_FPCI_TIMEOUT: Enable bit for interrupt code 9
6	0x0	EN_AXI_DECERR: Enable bit for interrupt code 8
5	0x0	EN_DFPCI_DECERR: Enable bit for interrupt code 7
4	0x0	EN_TGT_WRERR: Enable bit for interrupt code 5

Bit	Reset	Description
3	0x0	EN_TGT_DECERR: Enable bit for interrupt code 4
2	0x0	EN_TGT_SLVERR: Enable bit for interrupt code 3
1	0x0	EN_INI_DECERR: Enable bit for interrupt code 2
0	0x0	EN_INI_SLVERR: Enable bit for interrupt code 1

31.7.3.16 SATA_UFPCI_CONFIG_0

Upstream FPCI Configuration

Offset: 0x19c | Read/Write: R/W | Reset: 0x00000002 (0b00010)

Bit	Reset	Description
4:0	0x2	UNITID_T0C0: Upstream FPCI Unit ID for controller 0. HyperTransport, upstream FPCI request

31.7.3.17 SATA_CFG_REVID_0

CFG_REVID register

Offset: 0x1a0 | Read/Write: R/W | Reset: 0x000X10XX (0bxxxxxx0100xxxxxxx1)

Bit	R/W	Reset	Description
19	RO	X	DEV2SM_NONISO_REQUEST_PEND: Indicates if a non ISO request is pending. 0 = NO 1 = YES
18	RO	X	DEV2SM_ISO_REQUEST_PEND: Indicates if an ISO request is pending. 0 = NO 1 = YES
13:12	RW	0x1	STRAP_CPU_MODE: MCP : Mode to send MSI. Can be programmable 0 = NB_INTEL 1 = NB_AMD 2 = AMD 3 = TMTA
11	RW	0x0	CFG_REVID_WRITE_ENABLE: MCP : Enable to override the rev ID. Can be programmable 0 = CLEAR 1 = SET
10	RW	0x0	CFG_REVID_OVERRIDE: MCP : Can override the current revision ID. Can be programmable 0 = DISABLE 1 = ENABLE
4	RO	X	DEV2LEG_NONCOH_REQUEST_PEND: MCP : Tells the leg block that a non-coherent request is pending. 0 = NO 1 = YES
3	RO	X	DEV2LEG_COH_REQUEST_PEND: MCP comment : Tells the leg block that a coherent request is pending 0 = NO 1 = YES
2	RW	0x1	SM2DEV_FPCI_TIMEOUT_EN: FPCI timeout enable bit for Controller 0 = DISABLE 1 = ENABLE

31.7.3.18 SATA_FPCI_TIMEOUT_0

FPCI_TIMEOUT register

Offset: 0x1a4 | Read/Write: R/W | Reset: 0x000f0000 (0b11110000000000000000)

Bit	Reset	Description
19:0	0xf0000	SM2ALL_FPCI_TIMEOUT_THRESH: This sets the timeout threshold value for the FPCI bus. The counter starts counting when each queue (iso/niso- rd/wr) has a pending request in the FPCI wrapper. The count resets when the requests are popped.

31.7.3.19 SATA_TOM_0

Top of Memory Limit

Offset: 0x1a8 | Read/Write: R/W | Reset: 0x3fff0fff (0b11111111111111xxxx111111111111)

Bit	Reset	Description
29:16	0x3fff	LEG2ALL_TOM2: Top of Memory Limit 2.
11:0	0xfff	LEG2ALL_TOM1: Top of Memory Limit 1.

31.7.3.20 SATA_INITIATOR_ISO_PW_RESP_PENDING_0

Initiator ISO PW Response Pending

Offset: 0x1ac | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxx)

Bit	Reset	Description
7:0	X	NUM_INITIATOR_ISO_PW_RESP_PEND: Number of pending initiator ISO PW responses

31.7.3.21 SATA_INITIATOR_NISO_PW_RESP_PENDING_0

Initiator Non-ISO PW Response Pending

Offset: 0x1b0 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxx)

Bit	Reset	Description
7:0	X	NUM_INITIATOR_NISO_PW_RESP_PEND: Number of pending initiator NISO PW responses

31.7.3.22 SATA_INTR_STATUS_0

IPFS Interrupt Status

Offset: 0x1b4 | Read/Write: RO | Reset: 0x0000000X (0bxxx)

Bit	Reset	Description
2	X	IP_INTR_STATUS: Status of IP (SATA/AZA) interrupt
1	X	MSI_INTR_STATUS: Status of MSI interrupt
0	X	IPFS_INTR_STATUS: Status of IPFS interrupt

31.7.3.23 SATA_DFPCI_BEN_0

Downstream FPCI Byte Enables

Offset: 0x1b8 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
31	0x0	EN_DFPCI_BEN: Enable bit for BEN; when set, programmed BE is sent on the DFPCI bus
3:0	0x0	DFPCI_BYTE_ENABLE_N: Active low byte enables

31.7.3.24 SATA_CLKGATE_HYSTERESIS_0

Offset: 0x1bc | Read/Write: R/W | Reset: 0x00000014 (0b00010100)

Bit	Reset	Description
7:0	0x14	CLK_DISABLE_CNT: Number of IPFS clock cycles to wait after clock gating criteria is met to disable IPFS/FPCI clocks

31.7.3.25 SATA_SATA_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control (where applicable) and Clock Gating Control Register.

Note: The FIFO timing aspects of this register are no longer supported, but retained for software compatibility

The clock override/ovr_mode fields of this register control the second-level clock gating for the client and the MC side of the MCCIF. All clock gating is enabled by default.

A '1' written to the rclk/wclk override field will result in one of the following:

- With wclk/rclk override mode = LEGACY, the clock reverts to legacy mode of operation where the clock is on whenever the client clock is enabled.
- With wclk/rclk override mode = ON, the clock is always on inside the MCCIF and PC. A '1' written to the cclk override field keeps the client's clock always on inside the MCCIF.

Offset: 0x1dc | Read/Write: R/W | Reset: 0x00000000 (0b00000xxxxxxxxxxxx0000)

Bit	Reset	Description
20	LEGACY	SATA_RCLK_OVR_MODE: 0 = LEGACY 1 = ON
19	LEGACY	SATA_WCLK_OVR_MODE: 0 = LEGACY 1 = ON
18	0x0	SATA_CCLK_OVERRIDE
17	0x0	SATA_RCLK_OVERRIDE
16	0x0	SATA_WCLK_OVERRIDE
3	DISABLE	SATA_MCCIF_RDCL_RDFAST: 0 = DISABLE 1 = ENABLE
2	DISABLE	SATA_MCCIF_WRMC_CLLE2X: 0 = DISABLE 1 = ENABLE
1	DISABLE	SATA_MCCIF_RDMC_RDFAST: 0 = DISABLE

Bit	Reset	Description
		1 = ENABLE
0	DISABLE	SATA_MCCIF_WRCL_MCLE2X: 0 = DISABLE 1 = ENABLE

31.7.3.26 SATA_ORDERING_RULES_0

Offset: 0x1e0 | Read/Write: R/W | Reset: 0x00000000 (0b000)

Bit	Reset	Description
3	0x0	UPSTREAM_MSIAW: Modified upstream MSIAW ordering. 0 = Tegra K1 MSIAW behavior 1 = Tegra 3 MSIAW behavior
2	0x0	UPSTREAM_RESPAW: Modified RespAW ordering. 0 = Tegra K1 RespAW behavior 1 = Tegra 3 RespAW behavior
1	0x0	UPSTREAM_RAW: Modified RAW ordering. 0 = Tegra K1 RAW behavior 1 = Tegra 3 RAW behavior

31.7.3.27 SATA_A2F_UFPCI_CFG0_0

Offset: 0x1e4 | Read/Write: R/W | Reset: 0x00000050 (0b00000000xxxxx0000000000001010000)

Bit	Reset	Description
31:24	0x0	STATIC_WAIT_IDLE_CNTR
18:16	0x0	STATIC_UFPCI_UFA_STARVE_CNTR_PRI1
15:12	0x0	STATIC_UFPCI_UFA_STARVE_CNTR_PRI0
11:10	0x0	STATIC_UFPCI_RR_BURST_SZ_PRI1
9:8	0x0	STATIC_UFPCI_RR_BURST_SZ_PRI0
7	0x0	STATIC_WAIT_CLAMP_EN
6	0x1	STATIC_UFPCI_UFA_DYN_BLOCK_EN
5	0x0	STATIC_UFPCI_UFA_BLK_COHERENT
4:2	0x4	STATIC_UFPCI_BLOCK_CMD_THRESHOLD
1	0x0	STATIC_CYA_UFA_ARB
0	0x0	STATIC_CYA_BACK2BACK_UPSTREAM_BLOCK

31.7.3.28 SATA_A2F_UFPCI_CFG1_0

Offset: 0x1e8 | Read/Write: R/W | Reset: 0x00000000 (0b00000000)

Bit	Reset	Description
7:0	0x0	STATIC_WAIT_UNCLAMP_CNTR

31.7.4 SATA AHCI Register Descriptions

31.7.4.1 Generic Host Control Registers

T_AHCI_HBA_CAP_0

HBA_CAP (Host Bus Adaptor) Capabilities

This register indicates basic capabilities to software.

Offset: 0x00 | Read/Write: RO | Reset: 0xE620FF00

Bit	R/W	Reset	Description
31	R	1	T_AHCI_HBA_CAP_S64A: 1h: S64A_TRUE (default) 0h: S64A_FALSE
30	R	1	T_AHCI_HBA_CAP_SNCQ: 1h: SNCQ_TRUE (default) 0h: SNCQ_FALSE
29	R	1	T_AHCI_HBA_CAP_SSNTF: 1h: SSNTF_TRUE (default) 0h: SSNTF_FALSE
28	R	0	T_AHCI_HBA_CAP_SMPS: Supports Mechanical Presence Switch. 1h: SMPS_TRUE 0h: SMPS_FALSE (default)
27	R	0	T_AHCI_HBA_CAP_SSS: Supports Staggered Spin-up. When set to '1' the HBA supports staggered spin-up on its ports, for use in balancing power spikes. This needs to be set by BIOS. 1h: SSS_TRUE 0h: SSS_FALSE (default)
26	R	1	T_AHCI_HBA_CAP_SALP: Supports Aggressive Link Power Management. When set to '1' the HBA can support auto-generating link requests to the Partial or Slumber states when there are no commands to process. 1h: SALP_TRUE (default) 0h: SALP_FALSE
25	R	1	T_AHCI_HBA_CAP_SAL: Supports Activity LED. When set to '1' the HBA supports a single activity indication output pin. 1h: SAL_TRUE (default) 0h: SAL_FALSE
24	R	0	T_AHCI_HBA_CAP_SCLO: Supports Command List Override. When set to '1' HBA supports the T_AHCI_PORT_PXCMD_CLO nit and its associated functionality. When cleared to '0' the HBA is not capable of clearing the BSY and DRQ bits in the status register in order to issue a software reset if these bits are still set from a previous operation. 1h: SCLO_TRUE 0h: SCLO_FALSE (default)
23:20	R	2h	T_AHCI_HBA_CAP_ISS: Interface Speed Supported. Indicates the maximum interface speed supported by the ports. 0h: ISS_RSVD 1h: ISS_GEN1 2h: ISS_GEN1_2 (default)
19	R	0	T_AHCI_HBA_CAP_SNZO: Supports Non-Zero DMA Offsets. When set to '1' indicates that the HBA can support non-zero DMA offsets for DMA setup FISes. 1h: SNZO_TRUE 0h: SNZO_FALSE (default)
18	R	0	T_AHCI_HBA_CAP_SAM: Supports AHCI mode only. When set to '1' indicates that the SATA controller doesnot implement a legacy, task-file based register interface. When cleared indicates that controller supports legacy mechanism in addition to AHCI mode. 1h: SAM_TRUE 0h: SAM_FALSE (default)

Bit	R/W	Reset	Description
17	R	0	T_AHCI_HBA_CAP_SPM: Supports Port Multiplier. When set to '1' indicates that a port multiplier with command based switching is supported. 1h: SPM_TRUE 0h: SPM_FALSE (default)
16	R	0	T_AHCI_HBA_CAP_FBSS: FIS Based Switching Supported. When set to '1' indicates that the HBA supports Port Multiplier FIS-Based switching. 1h: FBSS_TRUE 0h: FBSS_FALSE (default)
15	R	1	T_AHCI_HBA_CAP_PMD: PIO Multiple DRQ Block. If set to '1' the HBA supports multiple DRQ block data transfers for the PIO command protocol. 1h: PMD_SUPPORTED (default) 0h: PMD_NOT_SUPPORTED
14	R	1	T_AHCI_HBA_CAP_SSC: Supports Slumber State. This field indicates HBA supports transitions to the slumber state to manage power. When set to 1 HBA and device initiated Slumber requests can be supported. 1h: SSC_TRUE (default) 0h: SSC_FALSE
13	R	1	T_AHCI_HBA_CAP_PSC: Supports Partial State. This field indicates HBA supports transitions to the partial state to manage power. When set to 1 HBA and device initiated. Partial requests can be supported. 1h: PSC_TRUE (default) 0h: PSC_FALSE
12:8	R	1Fh	T_AHCI_HBA_CAP_NCS: Number of Command Slots. This is a zero based value indicating the number of commands that can be cached in each of the ports implemented. Minimum number of command slots is 1 and maximum being 32. 0h: NCS_1 7h: NCS_8 Fh: NCS_16 1Fh: NCS_32 (default)
7	R	0	T_AHCI_HBA_CAP_CCCS: Command Completion Coalescing Support. If set to 1 it indicates that the controller supports command completion coalescing feature. If it is not set then T_AHCI_HBA_CCC_CTL and T_AHCI_HBA_CCC_PORTS are not implemented by the device. 1h: CCCS_TRUE 0h: CCCS_FALSE (default)
6	R	0	T_AHCI_HBA_CAP_EMS: Enclosure Management Support. If set to 1 it indicates the capability of the controller to support enclosure management. If it is not set then T_AHCI_HBA_EM_LOC and T_AHCI_HBA_EM_CTL are not implemented by the device. 1h: EMS_TRUE 0h: EMS_FALSE (default)
5	R	0	T_AHCI_HBA_CAP_SXS: Supports External SATA. This field indicates presence of 1 or many ports with the controller which support signal only connector for Serial ATA ports. The software should check the T_AHCI_PORT_PXCMD_ESP bit to find which port actually supports signal only connector. 1h: SXS_TRUE 0h: SXS_FALSE (default)
4:0	R	0	T_AHCI_HBA_CAP_NP: Number of ports. This is zero based value indicating maximum number of ports that is supported by the Host Bus Adapter. 1 port is the minimum requirement and a max of 32 (if not supporting command completion coalescing feature). 0h: NP_1 1h: NP_2 2h: NP_3 3h: NP_4 0h: NP_DEFAULT (default)

T_AHCI_HBA_GHC

HBA_GHC (Host Bus Adaptor) Global Host Control

This register indicates basic capabilities to Software.

Offset: 0x04 | Read/Write: R/W | Reset: 0xXXXXXXXX

Bit	R/W	Reset	Description
31	R/W	0h	T_AHCI_HBA_GHC_AE: When set, indicates that communication to the HBA shall be via AHCI mechanisms. This can be used by an HBA that supports both legacy mechanisms (such as SFF-8038i) and AHCI to know when the HBA is running under an AHCI driver. When set, software shall only communicate with the HBA using AHCI. When cleared, software shall only communicate with the HBA using legacy mechanisms. When cleared FISes are not posted to memory and no commands are sent via AHCI mechanisms. Software shall set this bit to 1 before accessing other AHCI registers. The implementation of this bit is dependent upon the value of the CAP.SAM bit. If CAP.SAM is '0', then GHC.AE shall be read-write and shall have a reset value of '0'. If CAP.SAM is '1', then AE shall be read-only and shall have a reset value of '1'. 1h: AE_YES 0h: AE_NO (default)
30:3	R	0h	T_AHCI_HBA_GHC_RSVD: 0h: RSVD_VAL
2	R	0h	T_AHCI_HBA_GHC_MRSM: When set to 1 by hardware, indicates that the HBA requested more than one MSI vector but has reverted to using the first vector only. When this bit is cleared to 0, the HBA has not reverted to single MSI mode (i.e. hardware is already in single MSI mode, software has allocated the number of messages requested, or hardware is sharing interrupt vectors if MC.MME < MC.MMC). The HBA may revert to single MSI mode when the number of vectors allocated by the host is less than the number requested. This bit shall only be set to 1 when the following conditions hold: MC.MSIE = 1 (MSI is enabled) MC.MMC > 0 (multiple messages requested) MC.MME > 0 (more than one message allocated) MC.MME != MC.MMC (messages allocated not equal to number requested) When this bit is set to 1, single MSI mode operation is in use and software is responsible for clearing bits in the IS register to clear interrupts. This bit shall be cleared to 0 by hardware when any of the four conditions stated is false. This bit is also cleared to 0 when MC.MSIE = 1 and MC.MME = 0h. In this case, the hardware has been programmed to use single MSI mode, and is not reverting to that mode. 1h: MRSM_YES 0h: MRSM_NO (default)
1	R/W	0h	T_AHCI_HBA_GHC_IE: This global bit enables interrupts from the HBA. When cleared (reset default), all interrupt sources from all ports are disabled. When set, interrupts are enabled. 1h: IE_TRUE 0h: IE_FALSE (default)
0	R/W	0h	T_AHCI_HBA_GHC_HR: When set by SW, this bit causes an internal reset of the HBA. All state machines that relate to data transfers and queuing shall return to an idle condition, and all ports shall be re-initialized via COMRESET (if staggered spin-up is not supported). If staggered spin-up is supported, then it is the responsibility of software to spin-up each port after the reset has completed. When the HBA has performed the reset action, it shall reset this bit to 0. A software write of 0 shall have no effect. 0h: HR_NOT (default) 1h: HR_TRUE 1h: HR_SET

T_AHCI_HBA_IS

HBA_IS (Host Bus Adaptor) Interrupt Status

This register indicates basic capabilities to Software.

Offset: 0x08 | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:4	R	0h	Reserved
3	RW1C	0h	T_AHCI_HBA_IS_PORT3_INTR: 0h: PORT3_INTR_ZERO (default) 1h: PORT3_INTR_SET 1h: PORT3_INTR_CLEAR
2	RW1C	0h	T_AHCI_HBA_IS_PORT2_INTR:

Bit	R/W	Reset	Description
			0h: PORT2_INTR_ZERO (default) 1h: PORT2_INTR_SET 1h: PORT2_INTR_CLEAR
1	RW1C	0h	T_AHCI_HBA_IS_PORT1_INTR: 0h: PORT1_INTR_ZERO (default) 1h: PORT1_INTR_SET 1h: PORT1_INTR_CLEAR
0	RW1C	0h	T_AHCI_HBA_IS_PORT0_INTR: 0h: PORT0_INTR_ZERO (default) 1h: PORT0_INTR_SET 1h: PORT0_INTR_CLEAR

T_AHCI_HBA_PI

HBA_PI (Host Bus Adaptor) Ports Implemented

This register indicates the ports exposed by the HBA. It is loaded by the BIOS.

Offset: 0x0c | Read/Write: R | Reset: 0x00000001

Bit	R/W	Reset	Description
31:0	R	1	T_AHCI_HBA_PI_PI: This register is bit significant. If a bit is set to 1, the corresponding port is available for software to use. If a bit is cleared to 0, the port is not available for software to use. The maximum number of bits set to 1 shall not exceed CAP.NP + 1, although the number of bits set in this register may be fewer than CAP.NP + 1. At least one bit shall be set to 1. 0h: PI_ZERO 1h: PI_FIRST 2h: PI_SECOND 4h: PI_THIRD 8h: PI_FOURTH 3Fh: PI_2PORTS_DIS Fh: PI_4PORTS_DIS 1h: PI_INIT (default)

T_AHCI_HBA_VS

HBA_VS AHCI Revision

This register indicates basic capabilities to software.

Offset: 0x10 | Read/Write: R | Reset: 0xXXXX0301

Bit	R/W	Reset	Description
31:16	R	1h	T_AHCI_HBA_VS_MAJOR_REV: Indicates the major version 1h: MAJOR_REV_1_3_1 1h: MAJOR_REV_1_3 1h: MAJOR_REV_1_2 1h: MAJOR_REV_1_0 0h: MAJOR_REV_0_95
15:0	R	0301h	T_AHCI_HBA_VS_MINOR_REV: Indicates the minor version NOTE: this field is reset by Cold Reset 301h: MINOR_REV_1_3_1 (default) 300h: MINOR_REV_1_3 200h: MINOR_REV_1_2 0h: MINOR_REV_1_0 905h: MINOR_REV_0_95

T_AHCI_HBA_CCC_CTL

HBA_CCC_CTL Command Completion Coalescing Control

This register indicates basic capabilities to Software.

Offset: 0x14 | Read/Write: R/W | Reset: 0xFFFFFFFx

Bit	R/W	Reset	Description
31:16	R/W	FFFFh	T_AHCI_HBA_CCC_CTL_TIMEOUT_VAL: The timeout value is specified in 1 millisecond intervals. The timer accuracy shall be within 5%. hCccTimer is loaded with this timeout value. hCccTimer is only decremented when commands are outstanding on selected ports. The HBA will signal a CCC interrupt when hCccTimer has decremented to 0. hCccTimer is reset to the timeout value on the assertion of each CCC interrupt. A timeout value of 0 is reserved. FFFFh: TIMEOUT_VAL_INIT (default)
15:8	R/W	FFh	T_AHCI_HBA_CCC_CTL_CC: Specifies the number of command completions that are necessary to cause a CCC interrupt. The HBA has an internal command completion counter, hCccComplete. hCccComplete is incremented by one each time a selected port has a command completion. When hCccComplete is equal to the command completions value, a CCC interrupt is signaled. The internal command completion counter is reset to 0 on the assertion of each CCC interrupt. A value of 0 for this field shall disable CCC interrupts being generated based on the number of commands completed, i.e. CCC interrupts are only generated based on the timer in this case. FFh: CC_INIT_VAL (default)
7:3	R	1Fh	T_AHCI_HBA_CCC_CTL_INT: Specifies the interrupt used by the CCC feature. This interrupt must be marked as unused in the Ports Implemented (PI) register by the corresponding bit being set to 0. Thus, the CCC interrupt corresponds to the interrupt for an unimplemented port on the controller. When a CCC interrupt occurs, the IS.IPS[INT] bit shall be asserted to 1. This field also specifies the interrupt vector used for MSI. 0h: INT_ZERO 4h: INT_FIVE 6h: INT_SEVEN 1Fh: INT_INIT (default)
2:1	R	0h	T_AHCI_HBA_CCC_CTL_RSVD: 0h: RSVD_ZEROS
0	R/W	0	T_AHCI_HBA_CCC_CTL_EN: When cleared to 0, the command completion coalescing feature is disabled and no CCC interrupts are generated. When set to 1, the command completion coalescing feature is enabled and CCC interrupts may be generated based on timeout or command completion conditions. Software shall only change the contents of the TV and CC fields when EN is cleared to 0. On transition of this bit from 0 to 1, any updated values for the TV and CC fields shall take effect. 1h: EN_SET 0h: EN_CLEAR (default)

T_AHCI_HBA_CCC_PORTS

HBA_CCC_PORTS Command Completion Coalescing Ports

This register indicates basic capabilities to Software.

Offset: 0x18 | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:0	R/W	0	T_AHCI_HBA_CCC_PORTS_PRT: When cleared to 0, the command completion coalescing feature is disabled and no CCC interrupts are generated. When set to 1, the command completion coalescing feature is enabled and CCC interrupts may be generated based on timeout or command completion conditions. Software shall only change the contents of the TV and CC fields when EN is cleared to 0. On transition of this bit from 0 to 1, any updated values for the TV and CC fields shall take effect. 0h: PRT_RESET_VAL (default)

T_AHCI_HBA_EM_LOC

HBA_EM_LOC Enclosure Management Location

This register indicates basic capabilities to Software.

Offset: 0x1c | Read/Write: R | Reset: 0xXXXXXXXX

Bit	R/W	Reset	Description
31:16	R	0h	T_AHCI_HBA_EM_LOC_OFST: The offset of the message buffer in Dwords from the beginning of the ABAR. 0h: OFST_VAL
15:0	R	0h	T_AHCI_HBA_EM_LOC_SZ: Specifies the size of the transmit message buffer area in Dwords. If both transmit and receive buffers are supported, then the transmit buffer begins at ABAR[EM_LOC.OFST*4] and the receive buffer directly follows it. If both transmit and receive buffers are supported, both buffers are of the size indicated in the Buffer Size field. A value of 0 is invalid. 0h: SZ_VAL

T_AHCI_HBA_EM_CTL

HBA_EM_CTL Enclosure Management Control

This register indicates basic capabilities to Software.

Offset: 0x20 | Read/Write: R/W | Reset: 0xXXXXXXXX

Bit	R/W	Reset	Description
31:28	R	0h	T_AHCI_HBA_EM_CTL_RSVD3: 0h: RSVD3_VAL
27	R	0h	T_AHCI_HBA_EM_CTL_ATTR_PM: If set to 1, the HBA supports enclosure management messages for devices attached via a Port Multiplier. If cleared to 0, the HBA does not support enclosure management messages for devices attached via a Port Multiplier. When cleared to 0, software should use the Serial ATA enclosure management bridge that is built into many Port Multipliers for enclosure services with these devices. For more information on Serial ATA enclosure management bridges, refer to the Serial ATA Revision 2.6 specification. 0h: ATTR_PM_FALSE 1h: ATTR_PM_TRUE
26	R	0h	T_AHCI_HBA_EM_CTL_ATTR_ALHD: If set to 1, the HBA drives the activity LED for the LED message type in hardware and does not utilize software settings for this LED. The HBA does not begin transmitting the hardware based activity signal until after software has written CTL.TM=1 after a reset condition. 0h: ATTR_ALHD_FALSE 1h: ATTR_ALHD_TRUE
25	R	0h	T_AHCI_HBA_EM_CTL_ATTR_XMT: If set to 1, the HBA only supports transmitting messages and does not support receiving messages. If cleared to 0, the HBA supports transmitting and receiving messages. 0h: ATTR_XMT_FALSE 1h: ATTR_XMT_TRUE
24	R	0h	T_AHCI_HBA_EM_CTL_ATTR_SMB: If set to 1, the HBA has one message buffer that is shared for messages to transmit and messages received. In this case, unsolicited receive messages are not supported and it is softwares responsibility to manage access to this buffer. If cleared to 0, there are separate receive and transmit buffers such that unsolicited messages could be supported. 0h: ATTR_SMB_FALSE 1h: ATTR_SMB_TRUE
23:20	R	0h	T_AHCI_HBA_EM_CTL_RSVD2: 0h: RSVD2_VAL
19	R	0h	T_AHCI_HBA_EM_CTL_SUPP_SGPIO: If set to 1, the HBA supports the SGPIO register interface message type. 0h: SUPP_SGPIO_FALSE 1h: SUPP_SGPIO_TRUE
18	R	0h	T_AHCI_HBA_EM_CTL_SUPP_SES2: If set to 1, the HBA supports the SES-2 message type. 0h: SUPP_SES2_FALSE 1h: SUPP_SES2_TRUE
17	R	0h	T_AHCI_HBA_EM_CTL_SUPP_SAFTE: If set to 1, the HBA supports the SAF-TE message type.

Bit	R/W	Reset	Description
			0h: SUPP_SAFTE_FALSE 1h: SUPP_SAFTE_TRUE
16	R	0h	T_AHCI_HBA_EM_CTL_SUPP_LED: If set to 1, the HBA supports the LED message 0h: SUPP_LED_FALSE 1h: SUPP_LED_TRUE
15:10	R	0h	T_AHCI_HBA_EM_CTL_RSVD1: 0h: RSVD1_VAL
9	RW1C	0h	T_AHCI_HBA_EM_CTL_RST: When set to 1 by software, the HBA shall reset all enclosure management message logic and the attached enclosure processor (if applicable) and take all appropriate reset actions to ensure messages can be transmitted/received after the reset. After the HBA completes the reset operation, the HBA shall set the value to 0. A write of 0 by software to this field shall have no effect. 1h: RST_SET 0h: RST_CLEAR (default)
8	RW1C	0h	T_AHCI_HBA_EM_CTL_TM: When set to 1 by software, the HBA shall transmit the message contained in the message buffer. When the message is completely sent, the HBA shall clear this bit to 0. A write of 0 to this bit by software shall have no effect. Software shall not change the contents of the message buffer while CTL.TM is set to 1. 0h: TM_CLEAR (default) 1h: TM_SET
7:1	R	0h	T_AHCI_HBA_EM_CTL_RSVD0: 0h: RSVD0_VAL
0	RW1C	0h	T_AHCI_HBA_EM_CTL_STS_MR: The HBA sets this bit to a 1 when a message is completely received into the message buffer. When software detects this bit is a 1, software should read the message and perform any actions necessary. When software is finished reading the message in the buffer, software writes a 1 to this bit in order to clear it. A write of 0 to this bit by software shall have no effect. 1h: STS_MR_TRUE 0h: STS_MR_FALSE (default) 1h: STS_MR_CLEAR

T_AHCI_HBA_CAP2

CAP2 - HBA Capabilities Extended

This register indicates basic capabilities to Software.

Offset: 0x24 | Read/Write: R | Reset: 0xXXXXXXXX

Bit	R/W	Reset	Description
31:6	R	0h	T_AHCI_HBA_CAP2_RSVD_1: 0h: RSVD_1_VAL
5	R	1	T_AHCI_HBA_CAP2_DESO: This field specifies that the HBA shall only assert the DEVSLP signal if the interface is in Slumber. When this bit is set to 1, the HBA shall ignore software directed entrance to DevSleep via PxCMD.ICC unless PxSSTS.IPM = 6h. When this bit is cleared to 0, the HBA may enter DevSleep from any link state (active, Partial, or Slumber). NOTE: this field is reset by Cold Reset 1h: DESO_TRUE (default) 0h: DESO_FALSE
4	R	1	T_AHCI_HBA_CAP2_SADM: When set to 1, the HBA supports hardware assertion of the DEVSLP signal after the idle timeout expires. When cleared to 0, this function is not supported and software shall treat the PxDEVSLP.ADSE field as reserved. NOTE: this field is reset by Cold Reset 1h: SADM_TRUE (default) 0h: SADM_FALSE
3	R	1	T_AHCI_HBA_CAP2_SDS: When set to 1, the HBA supports the Device Sleep feature. When cleared to 0, DEVSLP is not supported and software shall not set PxCMD.ICC to '8h' NOTE: this field is reset by Cold Reset 1h: SDS_TRUE (default)

Bit	R/W	Reset	Description
			0h: SDS_FALSE
2	R	1	T_AHCI_HBA_CAP2_APST: When set to 1, the HBA supports Automatic Partial to Slumber Transitions. When cleared to 0, Automatic Partial to Slumber Transitions are not supported. NOTE: this field is reset by Cold Reset 1h: APST_TRUE (default) 0h: APST_FALSE
1	R	0h	T_AHCI_HBA_CAP2_RSVD_0: 0h: RSVD_0_VAL
0	R	0h	T_AHCI_HBA_CAP2_BOH: When set to 1, the HBA supports the BIOS/OS handoff mechanism. When cleared to 0, the HBA does not support the BIOS/OS handoff mechanism. When BIOS/OS handoff is supported, the HBA has implemented the BOHC global HBA register. When cleared to 0, it indicates that the HBA does not support BIOS/OS handoff and the BOHC global HBA register is not implemented. NOTE: this field is reset by Cold Reset 1h: BOH_TRUE 0h: BOH_FALSE (default)

T_AHCI_HBA_BOHC

BOHC - BIOS/OS Handoff Control and Status

This register controls various global actions of the HBA

Offset: 0x28 | Read/Write: R | Reset: 0xXXXXXXX0

Bit	R/W	Reset	Description
31:5	R	0h	T_AHCI_HBA_BOHC_RSVD: 0h: RSVD_VAL
4	R/W	0h	T_AHCI_HBA_BOHC_BB: BIOS Busy (BB) 1h: BB_TRUE 0h: BB_FALSE (default)
3	RW1C	0h	T_AHCI_HBA_BOHC_OOC: OS Ownership Change (OOC) 1h: OOC_TRUE 0h: OOC_FALSE (default) 1h: OOC_CLEAR
2	R/W	0h	T_AHCI_HBA_BOHC_SOOE: SMI on OS Ownership Change Enable (SOOE) 1h: SOOE_TRUE 0h: SOOE_FALSE (default)
1	R/W	0h	T_AHCI_HBA_BOHC_OOS: OS Owned Semaphore (OOS) 1h: OOS_TRUE 0h: OOS_FALSE (default)
0	R/W	0h	T_AHCI_HBA_BOHC_BOS: BIOS Owned Semaphore (BOS) 1h: BOS_TRUE 0h: BOS_FALSE (default)

T_AHCI_HBA_CAP_BKDR

Offset: 0xa0 | Read/Write: R/W | Reset: 0xE620FF01

Bit	Reset	R/W	Description
31	1	R/W	T_AHCI_HBA_CAP_BKDR_S64A: 1h: S64A_TRUE (default) 0h: S64A_FALSE
30	1	R/W	T_AHCI_HBA_CAP_BKDR_SNCQ: 1h: SNCQ_TRUE (default) 0h: SNCQ_FALSE

Bit	Reset	R/W	Description
29	1	R/W	T_AHCI_HBA_CAP_BKDR_SSNTF: 1h: SSNTF_TRUE (default) 0h: SSNTF_FALSE
28	0	R/W	T_AHCI_HBA_CAP_BKDR_SMPS: 1h: SMPS_TRUE 0h: SMPS_FALSE (default)
27	0	R/W	T_AHCI_HBA_CAP_BKDR_SUPP_STG_SPUP: Backdoor field to advertise staggered spin up. BIOS has to write this we are going to support staggered spin up. 1h: SUPP_STG_SPUP_SET 0h: SUPP_STG_SPUP_CLEAR (default)
26	1	R/W	T_AHCI_HBA_CAP_BKDR_SALP: 1h: SALP_TRUE (default) 0h: SALP_FALSE
25	1	R/W	T_AHCI_HBA_CAP_BKDR_SAL: 1h: SAL_TRUE (default) 0h: SAL_FALSE
24	0	R/W	T_AHCI_HBA_CAP_BKDR_SUPP_CLO: 1h: SUPP_CLO_TRUE 0h: SUPP_CLO_FALSE (default)
23:20	2h	R/W	T_AHCI_HBA_CAP_BKDR_INTF_SPD_SUPP: CAP.ISS can be written using this 0h: INTF_SPD_SUPP_RSVD 1h: INTF_SPD_SUPP_GEN1 2h: INTF_SPD_SUPP_GEN1_2 (default)
19	0	R/W	T_AHCI_HBA_CAP_BKDR_SUPP_NONZERO_OFFSET: 1h: SUPP_NONZERO_OFFSET_TRUE 0h: SUPP_NONZERO_OFFSET_FALSE (default)
18	0	R/W	T_AHCI_HBA_CAP_BKDR_SUPP_AHCI_ONLY: 1h: SUPP_AHCI_ONLY_TRUE 0h: SUPP_AHCI_ONLY_FALSE (default)

31.7.4.2 Port Registers

T_AHCI_PORT_PXCLB

Port Command List Base Address

Offset: 0x100 | Read/Write: R/W | Reset: 0x00000XXX

Bit	R/W	Reset	Description

Bit	R/W	Reset	Description
31:10	R/W	0h	T_AHCI_PORT_PXCLB_CLB: Indicates the 32-bit base physical address for the command list for this port. This base is used when fetching commands to execute. The structure pointed to by this address range is 1K-bytes in length. This address must be 1K-byte aligned as indicated by bits 09:00 being read only. 0h: CLB_00 (default)
9:0	R	0h	T_AHCI_PORT_PXCLB_RSVD: 0h: RSVD_00

T_AHCI_PORT_PXCLBU

Port Command List Base Address Upper

Offset: 0x104 | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:0	R/W	0	T_AHCI_PORT_PXCLBU_CLB: Indicates the upper 32 bits for the command list base physical address for this port. This base is used when fetching commands to execute. This register shall be read only 0 for HBAs that do not support 64-bit addressing 0h: CLB_00 (default)

T_AHCI_PORT_PXFB

Port FIS Base Address

Offset: 0x108 | Read/Write: R/W | Reset: 0x000000XX

Bit	R/W	Reset	Description
31:8	R/W	0h	T_AHCI_PORT_PXFB_FB: Indicates the 32-bit base physical address for received FISes. The structure pointed to by this address range is 256 bytes in length. This address must be 256-byte aligned as indicated by bits 07:00 being read only. When FIS-based switching is in use, this structure is 4KB in length and the address shall be 4KB aligned 0h: FB_00 (default)
7:0	R	0h	T_AHCI_PORT_PXFB_RSVD: 0h: RSVD_00

T_AHCI_PORT_PXFBU

Port FIS Base Address Upper

Offset: 0x10c | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:0	R/W	0	T_AHCI_PORT_PXFBU_FB: Indicates the upper 32 bits for the received FIS base physical address for this port. This register shall be read only 0 for HBAs that do not support 64-bit addressing. 0h: FB_00 (default)

31.7.5 SATA and SATA0 FPCI Register Descriptions

This subsection describes the SATA and SATA0 FPCI registers. The SATA and SATA0 register sets are very similar. The register names and fields are shown as SATA<0> when both register sets are applicable.

For example, T_SATA<0>_CFG_0 defines two registers: T_SATA_CFG_0 and TSATA0_CFG_0. The register named T_SATA0_CFG_PHY_POWER is present only in the SATA0 register set.

See the Address Map section in this TRM for the mapping of both register sets.

31.7.5.1 PCI Configuration Registers

T_SATA<0>_CFG_0

PCI Vendor and Device ID Register

Offset: 0x00 | Read/Write: R | Reset: 0x0F70XXXX

Bit	R/W	Reset	Description
31:16	R	0F70h	T_SATA<0>_CFG_0_DEVICE_ID_UNIT: The DEVICE_ID bits identify the particular device. This identifier is allocated by the vendor. DEVICE_ID_FUNC bits contain the function number from the Configuration Address bits 10-8. DEVICE_ID_UNIT bits contain the Unit number within the chip. The Unit and Function are defined by parameters per block. D84h: DEVICE_ID_UNIT_MCP89 D84h: DEVICE_ID_UNIT_MCP89_PATA_DT D85h: DEVICE_ID_UNIT_MCP89_PATA_NB D88h: DEVICE_ID_UNIT_MCP89_AHCI_DT D89h: DEVICE_ID_UNIT_MCP89_AHCI_NB 580h: DEVICE_ID_UNIT_MCP89_AHCI_LINUX D8Ch: DEVICE_ID_UNIT_MCP89_RAID_DT D8Dh: DEVICE_ID_UNIT_MCP89_RAID_NB F70h: DEVICE_ID_UNIT_SATA (default)
15:0	R	10DEh	T_SATA<0>_CFG_0_VENDOR_ID: The VENDOR_ID bits identify the manufacturer of the device. Valid vendor identifiers are allocated by the PCI SIG to ensure uniqueness. VENDOR_ID is the joint SGS/NVIDIA PCI vendor ID. 10DEh: VENDOR_ID_NVIDIA

T_SATA<0>_CFG_1

PCI Device Control Register

The Device Control Command register provides coarse control over a device's ability to generate and respond to PCI cycles.

Offset: 0x04 | Read/Write: R/W | Reset: 0xXXXX0XXX

Bit	R/W	Reset	Description
31	R	0h	T_SATA<0>_CFG_1_DETECTED_PERR: The DETECTED_PERR bit indicates that the device has detected a parity error, even if parity error handing is disabled. (Bit 6 - T_SATA<0>_FPCI_PERR_DISABLED) 0h: DETECTED_PERR_NOT_ACTIVE
30	RW1C	0	T_SATA<0>_CFG_1_SIGNALED_SERR: The SIGNALED_SERR bit indicates that the device has asserted SERR#. NOTE: this field is reset by Cold Reset 0h: SIGNALED_SERR_NOT_ACTIVE (default) 1h: SIGNALED_SERR_ACTIVE 1h: SIGNALED_SERR_CLEAR
29	RW1C	0	T_SATA<0>_CFG_1_RECEIVED_MASTER: The RECEIVED_MASTER bit indicates that a master device's transaction (except for Special Cycle) was terminated with a master-abort. This means that no device on the PCI bus responded to the address of the mastered transaction. All master devices must implement this bit. When this bit is set, an interrupt is signaled in the PBUS_INTR_0 register. NOTE: this field is reset by Cold Reset 0h: RECEIVED_MASTER_NO_ABORT (default) 1h: RECEIVED_MASTER_ABORT 1h: RECEIVED_MASTER_CLEAR
28	RW1C	0	T_SATA<0>_CFG_1_RECEIVED_TARGET: The RECEIVED_TARGET bit indicates that a master device's transaction was terminated with a target-abort. All master devices must implement this bit. When this bit is set, an interrupt is signaled in the PBUS_INTR_0 register.

Bit	R/W	Reset	Description
			NOTE: this field is reset by Cold Reset 0h: RECEIVED_TARGET_NO_ABORT (default) 1h: RECEIVED_TARGET_ABORT 1h: RECEIVED_TARGET_CLEAR
27	R	0h	T_SATA<0>_CFG_1_SIGNALED_TARGET: The SIGNALED_TARGET bit indicates that the device has terminated a transaction with target-abort. Devices that will never signal target-abort do not need to implement this bit. When this bit is set, an interrupt is signaled in the PBUS_INTR_0 register. 0h: SIGNALED_TARGET_NO_ABORT
26:25	R	0h	T_SATA<0>_CFG_1_DEVSEL_TIMING: The DEVSEL_TIMING bits contain the timing of DEVSEL#. There are three allowable timings for assertion of DEVSEL#. These are encoded as 00b for fast, 01b for medium, and 10b for slow (11b is reserved). These bits are read only and must indicate the slowest time that a device asserts DEVSEL# for any bus command except Configuration Read and Configuration Write. Positive decode devices are required to respond with fast DEVSEL# (0-cycle). Only the subtractive function will respond with medium DEVSEL# to accept the cycle for the subtractive bus. 0h: DEVSEL_TIMING_FAST 1h: DEVSEL_TIMING_MEDIUM 2h: DEVSEL_TIMING_SLOW
24	R	0h	T_SATA<0>_CFG_1_MASTER_DATA_PERR: 0h: MASTER_DATA_PERR_NOT_ACTIVE
23	R	1h	T_SATA<0>_CFG_1_FAST_BACK2BACK: The FAST_BACK2BACK bit indicates that the device is capable of handling back-to-back transfers when the transactions are not to the same agent. This bit can be set to 1 if the device can accept these transactions, and must be set to 0 otherwise. 1h: FAST_BACK2BACK_CAPABLE 0h: FAST_BACK2BACK_INCAPABLE
22	R	0	Reserved
21	R	1h	T_SATA<0>_CFG_1_66MHZ: The 66MHZ bit indicates that the device is capable of 66 MHz PCI Bus operation. This value is initialized by a strapping bit. 1h: 66MHZ_CAPABLE 0h: 66MHZ_INCAPABLE
20	R	1h	T_SATA<0>_CFG_1_CAPLIST: The CAPLIST bit indicates that the device configuration space includes a capabilities list starting at the offset indicated by T_SATA<0>_CFG_13. 1h: CAPLIST_PRESENT 0h: CAPLIST_NOT_PRESENT
19	R	None	T_SATA<0>_CFG_1_INTR_STATUS: The INTR_STATUS bit is read-only and reflects the state of the interrupt in the device/function. Only when the INTR_DISABLE bit in the command register is a 0 and this INTR_STATUS bit is a 1, will the device's/function's INTx# singal be asserted. Setting the INTR_DISABLE bit to 1 has no effect on the state of this bit. 0h: INTR_STATUS_0 1h: INTR_STATUS_1
18:11	R	0	Reserved
10	R/W	0	T_SATA<0>_CFG_1_INTR_DISABLE: The INTR_DISABLE bit indicates that it could disable the device/function from asserting INTx#. A value of 0 enables the assertion of INTx#, and a value of 1 disables the assertion of INTx# signal. The Device Status register is used to record status information for PCI bus related events. 0h: INTR_DISABLE_ON (default) 1h: INTR_DISABLE_OFF
9	R	0h	T_SATA<0>_CFG_1_BACK2BACK: 0h: BACK2BACK_DISABLED 1h: BACK2BACK_ENABLED
8	R/W	0	T_SATA<0>_CFG_1_SERR: 0h: SERR_DISABLED (default)

Bit	R/W	Reset	Description
			1h: SERR_ENABLED
7	R	0h	T_SATA<0>_CFG_1_STEP: 0h: STEP_DISABLED 1h: STEP_ENABLED
6	R	0h	T_SATA<0>_CFG_1_PERR: 0h: PERR_DISABLED 1h: PERR_ENABLED
5	R	0h	T_SATA<0>_CFG_1_PALETTE_SNOOP: The PALETTE_SNOOP bit indicates that VGA compatible devices should snoop their palette registers. When this bit is set, special palette snooping behavior is enabled (ie, device must not respond). When the bit is reset, the device should treat palette accesses like all other accesses. VGA compatible devices should implement this bit. PALETTE_SNOOP is writable. 0h: PALETTE_SNOOP_DISABLED 1h: PALETTE_SNOOP_ENABLED
4	R	0h	T_SATA<0>_CFG_1_WRITE_AND_INVAL: The WRITE_AND_INVAL bit indicates that the device can use the Memory Write and Invalidate command when the transfer is aligned and 16 bytes and the contents of the Cache Line Size Register is 4 DWORDS. When this bit is 1, masters may generate the command. When it is 0, Memory Write must be used instead. State after RST# is 0. This bit must be implemented by master devices that can generate the Memory Write and Invalidate command. 0h: WRITE_AND_INVAL_DISABLED 1h: WRITE_AND_INVAL_ENABLED
3	R	0h	T_SATA<0>_CFG_1_SPECIAL_CYCLE: 0h: SPECIAL_CYCLE_DISABLED 1h: SPECIAL_CYCLE_ENABLED
2	R/W	0	T_SATA<0>_CFG_1_BUS_MASTER: The BUS_MASTER bit indicates that the device can act as a master on the PCI bus. A value of 0 disables the device from generating PCI accesses. A value of 1 allows the device to behave as a bus master. BUS_MASTER is writable. 0h: BUS_MASTER_DISABLED (default) 1h: BUS_MASTER_ENABLED
1	R/W	0	T_SATA<0>_CFG_1_MEMORY_SPACE: The MEMORY_SPACE bit indicates that the device will respond to memory space accesses. A value of 0 disables the device response. A value of 1 allows the device to respond to Memory space accesses. MEMORY_SPACE is writable. 0h: MEMORY_SPACE_DISABLED (default) 1h: MEMORY_SPACE_ENABLED
0	R/W	0	T_SATA<0>_CFG_1_IO_SPACE: The IO_SPACE bit indicates that the device will respond to I/O space accesses. A value of 0 disables the device response. A value of 1 allows the device to respond to I/O space accesses. IO_SPACE is writable. 0h: IO_SPACE_DISABLED (default) 1h: IO_SPACE_ENABLED

T_SATA<0>_CFG_2

PCI Revision ID and Class Code Register

This register provides a way to configure the SATA channel to operate in either compatibility or native PCI mode.

Offset: 0x08 | Read/Write: R | Reset: 0xXXXXxxA1

Bit	R/W	Reset	Description
31:16	R	101h	T_SATA<0>_CFG_2_CLASS_CODE: The CLASS_CODE bits identify the generic function of the device and (in some cases) a specific register-level programming interface. The register is broken into three byte-size fields. The upper byte (at offset 0BH) is a base class code which broadly classifies the type of function the device performs. The middle-byte (at offset 0AH)is a sub-class code which identifies more specificly the function of the device. The lower byte (at offset 09H) identifies a

Bit	R/W	Reset	Description
			specific register-level programming interface (if any) so that device independent software can interact with the device. 101h: CLASS_CODE_0101
15	R	1h	T_SATA<0>_CFG_2_SATA_BUS_MASTER: This bit defines the Bus mastering capability of SATA controller. SATA implements a back door register which can be used to change the class code. This register is T_SATA<0>_CFG_38_BKDOOR_CLASS_CODE. This provides BIOS a way to change the class code. 1h: SATA_BUS_MASTER_YES
14:12	R	0	Reserved
11	R	None (SATA) 0h (SATA0)	T_SATA<0>_CFG_2_SEC_PROG_IND: Secondary Programmable Indicator. Set to indicate it is programmable and can operate in both compatibility or native PCI mode. 0h: SEC_PROG_IND_NO (SATA0 only)
10	R	1 (SATA0)	T_SATA0_CFG_2_SEC_OP_MODE: Secondary Operating Mode 0 = Compatibility Mode (Use Legacy Addresses) 1 = Native Mode (Use Addresses Define in PCI I/O BARs) 1h: SEC_OP_MODE_INIT (default) (SATA0 only) 0h: SEC_OP_MODE_COMP 1h: SEC_OP_MODE_NTV
9	R	None (SATA) 0h (SATA0)	T_SATA<0>_CFG_2_PRI_PROG_IND: Primary Programmable Indicator. Set to indicate it is programmable and can operate in both compatibility or native PCI mode. 0h: PRI_PROG_IND_NO
8	R	1 (SATA0)	T_SATA0_CFG_2_PRI_OP_MODE: Primary Operating Mode 0 = Compatibility Mode (Use Legacy Addresses) 1 = Native Mode (Use Addresses Define in PCI I/O BARs) 1h: PRI_OP_MODE_INIT (default): (SATA0 only) 0h: PRI_OP_MODE_COMP 1h: PRI_OP_MODE_NTV
7:0	R	A1h	T_SATA<0>_CFG_2_REVISION_ID: The REVISION_ID bits specify a device specific revision identifier. The value is chosen by the vendor. Zero is an acceptable value. T_SATA<0>_CFG_3

PCI Configuration Register

Offset: 0x0c | Read/Write: R/W | Reset: 0x00XXXXXX

Bit	R/W	Reset	Description
31:24	R	0	Reserved
23	R	0h	T_SATA<0>_CFG_3_HEADER_TYPE_FUNC: 0h: HEADER_TYPE_FUNC_SINGLE 1h: HEADER_TYPE_FUNC_MULTI
22:16	R	0h	T_SATA<0>_CFG_3_HEADER_TYPE_DEVICE: The HEADER_TYPE bits identify the layout of the bytes 10h: through 3FH in configuration space and also whether or not the device contains multiple functions. Bit 7 in this register is used to identify a multi-function device. If the bit is 0, then the device is single function. If the bit is 1, then the device has multiple functions. Bits 6 through 0 specify the layout of bytes 10h: through 3Fh. The LATENCY_TIMER and HEADER_TYPE are defined by parameters per block. 0h: HEADER_TYPE_DEVICE_NON_BRIDGE 1h: HEADER_TYPE_DEVICE_P2P_BRIDGE

Bit	R/W	Reset	Description
15:11	R	0h	T_SATA<0>_CFG_3_LATENCY_TIMER: The LATENCY_TIMER bits contain, in units of PCI bus clocks, the value of the Latency Timer for this PCI bus master. This register must be implemented as writable by any master that can burst more than two data phases. This register may be implemented as read-only for devices that burst two or fewer data phases, but the hardwired value must be limited to 16 or less. A typical implementation would be to build the five high-order bits (leaving the bottom three as read-only), resulting in a timer granularity of eight clocks. At reset, the register should be set to 0 (if programmable). LATENCY_TIMER bits are writable. 0h: LATENCY_TIMER_0_CLOCKS 1h: LATENCY_TIMER_8_CLOCKS 1Eh: LATENCY_TIMER_240_CLOCKS 1Fh: LATENCY_TIMER_248_CLOCKS
10:8	R	0	Reserved
7:0	R	0h	T_SATA<0>_CFG_3_CACHE_LINE_SIZE: 0h: CACHE_LINE_SIZE_0 20h: CACHE_LINE_SIZE_32 40h: CACHE_LINE_SIZE_64

T_SATA<0>_CFG_4

PCI Configuration Register

Offset: 0x10 | Read/Write: R/W | Reset: 0x0000000X (SATA) / 0x00000001 (SATA0)

Bit	R/W	Reset	Description
31:3	R/W	0	T_SATA<0>_CFG_4_BASE_ADDRESS: The BASE_ADDRESS bits contain the base address of the device. The number of upper bits that a device actually implements depends on how much of the address space the device will respond to. A device that wants a 1 MB memory address space (using a 32-bit base address register) would build the top 12 bits of the address register, hardwiring the other bits to 0. Power-up software can determine how much address space the device requires by writing a value of all 1's to the register and then reading the value back. The device will return 0's in all address bits which are not required, effectively specifying the address space required. When T_SATA<0>_CFG_2_PRI_OP_MODE is cleared, T_SATA_CFG_4 and T_SATA_CFG_5 will always read 32'h00000000. And when T_SATA<0>_CFG_2_SEC_OP_MODE is cleared, T_SATA<0>_CFG_6 and T_SATA_CFG_7 will always read 32'h00000000. 0h: BASE_ADDRESS_00 (default) 0h: BASE_ADDRESS_NTV_PCA
2:1	R	0	Reserved

Bit	R/W	Reset	Description
31:0	R	0h	T_SATA<0>_CFG_12_RESERVED: 0h: RESERVED_0

T_SATA<0>_CFG_13

PCI Capability Pointer Register

Offset: 0x34 | Read/Write: R/W | Reset: 0x000000XX

Bit	R/W	Reset	Description
31:8	R	0	Reserved
7:0	R	44h	T_SATA<0>_CFG_13_CAP_PTR: The CAP_PTR bits indicate the offset into configuration space where the capabilities list begins. This always points to 0x44 where at least the PCI-PM registers are expected to reside. 44h: CAP_PTR_PCIPM

T_SATA<0>_CFG_14

PCI Configuration Register

Offset: 0x38 | Read/Write: R | Reset: 0xXXXXXXXX

Bit	R/W	Reset	Description
31:0	R	0h	T_SATA<0>_CFG_14_RESERVED: The RESERVED bits are reserved for future use. 0h: RESERVED_0

T_SATA<0>_CFG_15

PCI Configuration Register

Offset: 0x3c | Read/Write: R/W | Reset: 0xXXXXXX00 (SATA) / 0xXXXX0100 (SATA0)

Bit	R/W	Reset	Description
31:24	R	1h	T_SATA<0>_CFG_15_MAX_LAT: The MAX_LAT bits contain the maximum time the device requires to gain access to the PCI bus. This read-only register is used to specify the device's desired settings for Latency Timer values. The value specifies a period of time in units of 1/4 microsecond. Values of 0 indicate that the device has no major requirements for the settings of Latency Timers. MAX_LAT is nonzero.

Bit	R/W	Reset	Description
			The INTR_PIN, MIN_GNT, and MAX_LAT are configurable per block. 0h: MAX_LAT_NO_REQUIREMENTS 1h: MAX_LAT_250NS
23:16	R	3h	T_SATA<0>_CFG_15_MIN_GNT: The MIN_GNT bits contain the length of the burst period a device needs assuming a clock rate of 33 MHz. This read-only register is used to specify the device's desired settings for Latency Timer values. The value specifies a period of time in units of 1/4 microsecond. Values of 0 indicate that the device has no major requirements for the settings of Latency Timers. MIN_GNT is nonzero. 0h: MIN_GNT_NO_REQUIREMENTS 3h: MIN_GNT_750NS
15:8	R	1 (SATA0)	T_SATA0_CFG_15_INTR_PIN: The INTR_PIN bits contain the interrupt pin the device (or device function) uses. A value of 1 corresponds to INTA#. A value of 2 corresponds to INTB#. A value of 3 corresponds to INTC#. A value of 4 corresponds to INTD#. Devices (or device functions) that don't use an interrupt pin must put a 0 in this register. 0h: INTR_PIN_NONE (SATA0 only) 1h: INTR_PIN_INTA (default) (SATA0 only) 2h: INTR_PIN_INTB 3h: INTR_PIN_INTC 4h: INTR_PIN_INTD
7:0	R/W	0	T_SATA<0>_CFG_15_INTR_LINE: The INTR_LINE bits contain the interrupt routing information. The register is read/write and must be implemented by any device (or device function) that uses an interrupt pin. POST software will write the routing information into this register as it initializes and configures the system. The value in this register tells which input of the system interrupt controller(s) the device's interrupt pin is connected to. Device drivers and operating systems can use this information to determine priority and vector information. INTR_LINE is initialized to 0xff (no connection) at reset. Some PCI BIOS' can't handle aliased INTR_LINEs. If T_SATA<0>_CFG_2_PRI_OP_MODE or T_SATA<0>_CFG_2_SEC_OP_MODE are set, this register will read whatever value written by software. If both the bits are cleared the register will always return 00h: 0h: INTR_LINE_IRQ0 (default) 1h: INTR_LINE_IRQ1 Fh: INTR_LINE_IRQ15 FFh: INTR_LINE_UNKNOWN

31.7.5.2 Device Specific Configuration Registers

The CFG_16 through CFG_63 registers are Device Specific PCI configuration registers.

T_SATA<0>_CFG_16

Write Subsystem Vendor ID and Subsystem ID Register

Offset: 0x40 | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description

T_SATA<0>_MSI_CTRL

MSI Message Control and Capability Register

Following are registers required to support MSI interrupt modes.

int0 is either non-ADMA primary channel interrupt or primary channel ADMA interrupt if the command completes without any error. int1 is similarly non-ADMA secondary channel interrupt or secondary channel ADMA interrupt if the command completes without any error. int2 is used to signal primary channel erroneous command completion. int3 is used to signal secondary channel erroneous command completion.

MSI_CTRL is the main control register for MSI support.

Offset: 0xb0 | Read/Write: R/W | Reset: 0x008600XX

Bit	R/W	Reset	Description
31:25	R	0	Reserved
24	R	0h	T_SATA<0>_MSI_CTRL_VECTOR_MASK_CAP: The VECTOR_MASK_CAP field indicates whether or not the controller supports MSI-per-vector masking. 0h: VECTOR_MASK_CAP_DIS 1h: VECTOR_MASK_CAP_EN 0h: VECTOR_MASK_CAP_DEFAULT (default)
23	R	1h	T_SATA<0>_MSI_CTRL_64_ADDR_CAP: The 64_ADDR_CAP field indicates whether or not the controller is capable of generating a 64-bit message address. A value of 1 means the controller is capable of generating a 64-bit message address. 0h: 64_ADDR_CAP_DIS 1h: 64_ADDR_CAP_EN 1h: 64_ADDR_CAP_DEFAULT (default)
22:20	R/W	0	T_SATA<0>_MSI_CTRL_MULT_MSG_ENABLE: System software writes to this field to indicate the number of allocated vectors (less than or equal to the number of vectors requested). The number of vectors is aligned as a power of two. When MSI is enabled, the controller will be allocated at least one vector. 0h: MULT_MSG_ENABLE_1 1h: MULT_MSG_ENABLE_2 2h: MULT_MSG_ENABLE_4 3h: MULT_MSG_ENABLE_8 4h: MULT_MSG_ENABLE_16 5h: MULT_MSG_ENABLE_32 0h: MULT_MSG_ENABLE_DEFAULT (default)
19:17	R	3h	T_SATA<0>_MSI_CTRL_MULT_MSG_CAP: System software reads this field to determine the number of requested vectors. The number of requested vectors must be aligned to a power of two. Values of 6 and 7 in this field are reserved. 0h: MULT_MSG_CAP_1 1h: MULT_MSG_CAP_2 2h: MULT_MSG_CAP_4 3h: MULT_MSG_CAP_8 4h: MULT_MSG_CAP_16 5h: MULT_MSG_CAP_32 3h: MULT_MSG_CAP_DEFAULT (default)
16	R/W	0	T_SATA<0>_MSI_CTRL_MSI_ENABLE: The MSI_ENABLE field enables the MSI capability. If MSI_ENABLE is written to a 1, the controller is permitted to use MSI to request service and is prohibited from using the legacy interrupt. System configuration software sets this bit to enable MSI. A device driver is prohibited from writing this bit to mask the controller's service request. If this bit is written to a 0, the controller is prohibited from using MSI to request service. 0h: MSI_ENABLE_OFF 1h: MSI_ENABLE_ON 0h: MSI_ENABLE_DEFAULT (default)
15:8	R	0h	T_SATA<0>_MSI_CTRL_NEXT_PTR: The NEXT_PTR field identifies the next item in the capabilities list. It is a read-only field. 0h: NEXT_PTR_NULL ECh NEXT_PTR_MMAP 0h: NEXT_PTR_DEFAULT (default)
7:0	R	5h	T_SATA<0>_MSI_CTRL_CAP_ID: The CAP_ID field identifies this capability block as the MSI capability block. This is read-only as 0x5.

Bit	R/W	Reset	Description
			5h: CAP_ID_MSI

T_SATA<0>_MSI_ADDR1

MSI Message Address Register

MSI_ADDR1 specifies the lower 32 bits to which an MSI memory write transaction should occur.

Offset: 0xb4 | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:2	R/W	0	T_SATA<0>_MSI_ADDR1_MSG_ADDR: System-specified message address. When MSI is enabled, this field specifies the dword-aligned address for the MSI memory write transaction. 0h: MSG_ADDR_DEFAULT (default)
1:0	R	0	Reserved

T_SATA<0>_MSI_ADDR2

MSI Message Upper Address Register

MSI_ADDR2 specifies the upper 32 bits to which an MSI memory write transaction should occur.

Offset: 0xb8 | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:0	R/W	0	T_SATA<0>_MSI_ADDR2_MSG_ADDR: System-specified message address. When MSI is enabled, this field specifies the upper 32-bits of the address for the MSI memory write transaction. The contents of this register only apply when T_SATA<0>_MSI_CTRL_64_ADDR_CAP bit is set. 0h: MSG_ADDR_DEFAULT (default)

T_SATA<0>_MSI_DATA

MSI Message Data Register

The MSI_DATA register contains the system-specified message.

Offset: 0xbc | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:16	R	0	Reserved
15:0	R/W	0	T_SATA<0>_MSI_DATA_MSG_DATA: System-specified message. When MSI is enabled, the message data is driven onto the lower 16 bits of the MSI memory write. The MULT_MSG_ENABLE field in configuration register B0h specifies the number of low order message data bits that the SATA is permitted to modify to generate its system software allocated vectors. 0h: MSG_DATA_DEFAULT (default)

T_SATA<0>_MSI_QUEUE

MSI Message Queue Configuration Register

The MSI_QUEUE register is a private register. It specifies to which virtual channel queue (ISO or NON-ISO) that the MSI message will be sent to before being sent out on FPCI bus.

Offset: 0xc0 | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:4	R	0	Reserved
3:0	R/W	0	T_SATA<0>_MSI_QUEUE_Bit: This field specifies to which VC queue a particular MSI message will be sent. bit 0 corresponds to MSI vector 0 bit 1 corresponds to MSI vector 1 bit 2 corresponds to MSI vector 2 bit 3 corresponds to MSI vector 3 0h: Bit_DEFAULT (default)

T_SATA<0>_MSI_MAP

MSI Mapping Capability Register

The MSI_MAP register is used to tell the OS that MSIs are supported in K8 mode.

This is the per-device HT MSI Capability Block.

Offset: 0xec | Read/Write: R/W | Reset: 0xA80X00XX

Bit	R/W	Reset	Description
31:27	R	15h	T_SATA<0>_MSI_MAP_CAP_TYPE: The CAP_TYPE field is read only at 0x15 to indicate that this is an MSI Mapping Capability block. 15h: CAP_TYPE_DEFAULT (default)
26:18	R	0	Reserved
17	R	1h	T_SATA<0>_MSI_MAP_FIXD: The FIXD bit is a read-only bit indicating if the next 2 dwords for programmable address are present in the capability. If set, the address for mapping MSIs is fixed at 0x0000_0000_FEEx_xxxx and that this capability block is 1 dword long. 1h: FIXD_ON
16	R/W	0	T_SATA<0>_MSI_MAP_EN: The EN bit indicates if the mapping is active. It is cleared upon warm reset. 0h: EN_OFF 1h: EN_ON 0h: EN_DEFAULT (default)
15:8	R	0h	T_SATA<0>_MSI_MAP_NEXT_PTR: The NEXT_PTR field points to the next item in the capabilities list. It is a read-only field. 0h: NEXT_PTR_NULL 0h: NEXT_PTR_DEFAULT (default)
7:0	R	8h	T_SATA<0>_MSI_MAP_CAP_ID: The CAP_ID field identifies that this is an HT capability list item. (Read-only as 0x8). 8h: CAP_ID_MSI

T_SATA<0>_INDIRECT_IDP0

IDP pair to access 257-4K address space - Address register

Offset: 0xf0 | Read/Write: R/W | Reset: 0xXXXXX00X

Bit	R/W	Reset	Description

23:0	R	0	Reserved

T_SATA<0>_CROSS_BAR

SATA CROSS BAR

Offset: 0x118 | Read/Write: R/W | Reset: 0x00543210

Bit	R/W	Reset	Description
31:0	R/W	00543210h	T_SATA<0>_CROSS_BAR_PHY_SEL: This register contains the phy_select - indicates how a Lane(brick) is connected to the port. NOTE: this field is reset by Cold Reset 543210h: PHY_SEL_DEFAULT (default)

T_SATA<0>_PMUCTL

SATA PHY Control Register

This register contains various bits to control the PHY.

FORCE_CORE_CLAMP -- is used to enable core clock clamp. Software can only set this bit when the controller is idle. Any downstream cycle, including a read to this register, will wake up core clock automatically, and core_act_sts will change to 0x0. Software needs no future action to un-clamp the clock. But software needs to write 1 to this bit to re-clamp the clock when the controller is idle.

Note: Wake from core clock clamp can be done by a downstream cycle which will trigger the core_wake signal to PMU; or by hotplug event which will trigger the dev_wake signal.

DEV_STS_HOLD -- # of txclk cycles to hold the dev_act_tog and dev_act_sts. CORE_STS -- current core_act_sts. DEV_STS -- current dev_act_sts.

Offset: 0x11c | Read/Write: R/W | Reset: 0xX03F00XX

Miscellaneous CTL1

Offset: 0x4a0 | Read/Write: R/W | Reset: 0xXXXXXX01

Bit	R/W	Reset	Description
31	R	0	Reserved
30:10	R	0h	T_SATA<0>_CTL1_RSVD_30_10: 0h: RSVD_30_10_VAL
9	R/W	1	T_SATA<0>_CTL1_BLK_NONPIO_IDP: BLK_NONPIO_IDP is used to suppress the nonpio read in the case of idp read. At default 1 value the second read will be blocked. At 0 both reads will occur. 1h: BLK_NONPIO_IDP_DEFAULT (default)
8:1	R	0	Reserved
0	R/W	1	T_SATA<0>_CTL1_SATA_ADNVCD_SPD_NEGO: ADNVCD_SPD_NEGO turns on an advanced way of detecting sata speeds. SATA will mix detecting the two supported speeds. Otherwise it detects gen2 first and then gen1. NOTE: this field is reset by Cold Reset 1h: SATA_ADNVCD_SPD_NEGO_YES (default) 0h: SATA_ADNVCD_SPD_NEGO_NO

T_SATA<0>_BKDOOR_CC

This register is used to backdoor update the programming interface field and class code of the register at address 0x8 (T_SATA<0>_CFG_2[15:8]). Note that the default value of the programming interface field is 0x85 for SATA<0> and 0x8A for SATA1.

To update the programming interface field, the BIOS needs to do the following:

1. Read T_SATA<0>_CFG_SATA_BACKDOOR_PROG_IF_EN - Address 54C

2. Write 1 to T_SATA<0>_CFG_SATA_BACKDOOR_PROG_IF_EN

3. Write the desired programming interface value to T_SATA<0>_BKDOOR_CC[15:8]

4. Restore T_SATA<0>_CFG_SATA_BACKDOOR_PROG_IF_EN to the value read in step#1

Offset: 0x4a4 | Read/Write: R/W | Reset: 0x01018AXX (SATA) / 0x010185XX (SATA0)

Bit	R/W	Reset	Description
31:16	R/W	0101h	T_SATA<0>_BKDOOR_CC_CLASS_CODE: NOTE: this field is reset by Cold Reset 101h: CLASS_CODE_INIT (default)

T_SATA<0>_PERF0

Offset: 0x4f0 | Read/Write: R/W | Reset: 0x00000800

Bit	R/W	Reset	Description
31:29	R	0	Reserved
28	R/W	0	T_SATA<0>_PERF0_DONT_DELAY_ROK: Setting DONT_DELAY_ROK turns on an optimization feature that should help performance on DMA reads. Transport layer then completes the current transfer even when busmaster has not yet drained all of the Receive FIFO. Setting this bit to _TRUE should result in better performance and therefore it is the preferred mode of operation. This is not the default Reset value and it is expected that the BIOS or Driver will enable this feature. NOTE: this field is reset by Cold Reset 0h DONT_DELAY_ROK_FALSE (default) 1h: DONT_DELAY_ROK_TRUE
27	R	0	Reserved
26:25	R/W	0	T_SATA<0>_PERF0_SATA_PLL_POWERDOWN: NOTE: this field is reset by Cold Reset 1h: SATA_PLL_POWERDOWN_YES 0h SATA_PLL_POWERDOWN_NO (default)
24:12	R	0	Reserved
11:7	R/W	10h	T_SATA<0>_PERF0_MIN_FPCI_CLK_FREQ: This field set the minimum frequency at which the fpci_clk should run in increments of 1/16th. It provides SW to override value set by frequency adjuster unit. Note that the actual frequency level is maximum of all the controllers. NOTE: this field is reset by Cold Reset 10h MIN_FPCI_CLK_FREQ_16 (default)
6:0	R	0	Reserved

T_SATA<0>_PERF1

This register is used to configure some of the SATA implementation options.

Offset: 0x4f4 | Read/Write: R/W | Reset: 0x00005A6E

Bit	R/W	Reset	Description
31:24	R/W	0	T_SATA<0>_PERF1_MAX_WATER_MARK:

Bit	R/W	Reset	Description
			The MAX_WATER_MARK field tracks the maximum occupancy of the two i2f_fifos. The purpose of this field is to give us guidance on the setting of HIGH_WATER_MARK field. Ideally, the HIGH_WATER_MARK field should be set so that the MAX_WATER_MARK field almost hit full. Note that MAX_WATER_MARK field is only 8 bits wide, so it can only track the lower 8 bits of the fifo level. The MSB value can be inferred from the MSB value of the 9 bit HIGH_WATER_MARK field. T_SATA<0>_CFG_39_RXDATA_IB_DELAY[0] enables resetting SSTATUS_DET and SSTATUS_SPD fields to 0 when channels enter into partial or slumber low power modes. By default this bit is 0 and these fields are not reset. NOTE: this field is reset by Cold Reset 0h MAX_WATER_MARK_0 (default)
23:16	R	0	Reserved
15:8	R/W	5Ah	T_SATA<0>_PERF1_HIGH_WATER_MARK_PIO: Bit 13:8 of the register is used for PIO reads high water mark. For PIO reads, fifo depth is 48. But each entry is 32bit, that is it contains only one dword. So, if mark is set at Y, there is headroom for (48-Y) dwords for drive to react to us sending HOLD. 5Ah HIGH_WATER_MARK_PIO_INIT (default)
7:0	R/W	6Eh	T_SATA<0>_PERF1_HIGH_WATER_MARK: This field configures the read fifo limit at which point the host starts sending HOLD primitives to back-off the data transfer from device. This field is only relevant during READs and should typically be set to as high a value without running the risk of overflowing the Fifo. Bit5:0 of the register is used for DMA read high water mark. For DMA reads, fifo depth is 48. And, each entry is 64bit, that is it contains two dwords. So, if the watermark is set at X then there is headroom for (48-X)*2 dwords for drive to react to controller sending HOLD. 6Eh HIGH_WATER_MARK_INIT (default)

T_SATA0_SPARE_0

Spare register on cold reset with zero as the default value.

This register applies to SATA0 register space only.

Offset: 0x520 | Read/Write: R/W | Reset: 0x00000000

6	R/W	0	T_SATA<0>_CFG_SATA_MSI_CAP_DISABLE: Normally, the T_SATA<0>_CFG_17_NEXT_PTR field points to T_SATA<0>_MSI_CTRL (0xB0). However, if SATA_MSI_CAP_DISABLE is set to _YES, then the T_SATA<0>_CFG_17_NEXT_PTR field would point to _NULL. If future capabilities are added beyond the MSI pointer, then care should be taken to ensure that CFG_17_NEXT_PTR bypasses the T_SATA<0>_MSI_CTRL address and points to the next capabilities pointer instead of _NULL.

Bit	R/W	Reset	Description
			NOTE: this field is reset by Cold Reset 0h MSI_CAP_DISABLE_NO (default) 1h MSI_CAP_DISABLE_YES
5	R/W	1	T_SATA<0>_CFG_SATA_MSIX_CAP_DISABLE: 0h MSIX_CAP_DISABLE_NO 1h MSIX_CAP_DISABLE_YES (default)
4	R/W	0	T_SATA<0>_CFG_SATA_USE_40B_ADDR: If this bit is set then SATA uses NVIDIA style 40b addressing while DMAing data. It gets upper 8 bits from the 23:16 bits of the prd count associated with the prd address. NOTE: this field is reset by Cold Reset 0h USE_40B_ADDR_NO (default) 1h USE_40B_ADDR_YES
3	R/W	0	T_SATA<0>_CFG_SATA_ERROR_HANDLING: NOTE: this field is reset by Cold Reset 0h ERROR_HANDLING_NO (default) 1h ERROR_HANDLING_YES
2	R/W	0	T_SATA<0>_CFG_SATA_CTRL_RAID_MODE_CTRL: CTRL_RAID_MODE was originally intended to allow customers to downgrade their RAID capability in the SBIOS. Setting this bit to 0 would allow only RAID 0 and RAID 1 support in the driver while setting to 1 would allow all RAID support. Setting this bit to 1 modifies the DeviceID of the SATA controller which would be a key to the driver. NOTE: this field is reset by Cold Reset 0h CTRL_RAID_MODE_CTRL_OEM (default) 1h CTRL_RAID_MODE_CTRL_CHANNEL
1	R	Unknown	T_SATA<0>_CFG_SATA_CTRL_STORAGE_FEATURE: STORAGE_FEATURE goes to both SATA and IDE config spaces. This is a general purpose bit that SW can use to distinguish between Advanced and Basic storage controller modes. This bit will be interpreted to either allow or not allow RAID 0+1 or 5 mode. ADVANCED mode will allow all RAID modes and BASIC will allow only RAID 0 and RAID 1 modes. It is strongly encouraged to keep the meaning of this STORAGE_FEATURE bit the same for future chips and to create new bits if necessary. This will allow SW compatibility. 1h CTRL_STORAGE_FEATURE_BASIC 0h CTRL_STORAGE_FEATURE_ADVANCED
0	R	0h	T_SATA<0>_CFG_SATA_RSVD_0: 0h RSVD_0_VAL

T_SATA<0>_CFG_MISC

Offset: 0x550 | Read/Write: R/W | Reset: 0x00000163

Bit	R/W	Reset	Description
31:12	R	0	Reserved
11:8	R/W	1	T_SATA<0>_CFG_MISC_PHY_RESET_USAGE_MODE: Bit 0 controls use of lockdet as phy reset. Bit 1 when high lets us update ata status reg quickly during pio-writes. By default its high. Bit 2 controls pi_reset, it controls whether to use lockdet or a cfg bit to use as reset 1h INIT (default)
7:4	R/W	6h	T_SATA<0>_CFG_MISC_LINK_SM_MODE: Bit 0 enables holda bypass. Bits 3 and 2 control l_idle features. 6h INIT (default)
3:0	R/W	3h	T_SATA<0>_CFG_MISC_PHY_OOB_SEQ_MODE: bit 0 controls whether we need to back off sending comwake when we receive comwake from drive Bit 1 is used to control our comreset behavior. If this bit is set to 1 then we send only one COMRESET to drive when scontrol_det[0] bit is written. If this bit is 0 then we keep sending COMRESET sequences as long as scontrol_det bit is active. 3h INIT (default)

T_SATA<0>_INDEX

Index Mask Register

This register implements mask to select writes to channel specific registers. A write to any CHX field in this manual will affect corresponding register for channel n if the nth bit is set in this mask register. If mask register has no bits set then the write will not change any register.

A read from a CHX field will return data corresponding to the channel which has its mask set. If more than one bits are set in mask, then the returned data will be logical OR of register values corresponding to the channels which have mask bits set. If no mask bit is set then the returned value will be 0x00.

The following comment is no longer valid, separate registers are implemented for GEN[1,2,3] Further PEAK and AMP fields can be set differently for gen1 and gen2. A write to these fields will affect the setting for Genx if the bit corresponding to Genx is set in this register.

T_SATA<0>_CHXCFG3

Serial ATA Control Register

This register is used to send the SATA bist activate command to the SATA device. The bist code (byte) is loaded then a '1' is written to bit zero.

Offset: 0x700 | Read/Write: R/W | Reset: 0xXXXX0000

Bit	R/W	Reset	Description
31:16	R	None	T_SATA<0>_CHXCFG3_CHX_PRBS_ERROR_CNT: 0h CHX_PRBS_ERROR_CNT_0
15:8	R/W	0	T_SATA<0>_CHXCFG3_CHX_BIST_CODE: NOTE: this field is reset by Cold Reset 0h CHX_BIST_CODE_DEFAULT (default)
7:2	R	0	Reserved
1	R	0	T_SATA<0>_CHXCFG3_CHX_BIST_STAT: NOTE: this field is reset by Cold Reset 1h CHX_BIST_STAT_BUSY 0h CHX_BIST_STAT_NOT_BUSY (default)
0	RW1C	0	T_SATA<0>_CHXCFG3_CHX_BIST_SEND: NOTE: this field is reset by Cold Reset 1h CHX_BIST_SEND_NOW 0h CHX_BIST_SEND_INIT (default)

T_SATA<0>_CHXCFG4_CHX

Offset: 0x704 | Read/Write: R/W | Reset: 0x0000000a

Bit	R/W	Reset	Description
31:13	R	0	Reserved
12	R/W	0	T_SATA<0>_CHXCFG4_CHX_SW_COMWAKE_PI: NOTE: this field is reset by Cold Reset 0h SW_COMWAKE_PI_INIT (default)
11:8	R/W	0	T_SATA<0>_CHXCFG4_CHX_PHY_ALIGN_NUM_CNT: The PHY_ALIGN_NUM_CNT field configures the number of ALIGN primitive pairs that are inserted by the phy interface block into the output stream. The field value represents a number which is one less than the number of ALIGN pairs to send. So, for eg, a value of 0 (default) would send 1 ALIGN pair (i.e 2 ALIGNs) every PHY_ALIGN_DWORD_CNT DWORDs. In other words, every PHY_ALIGN_DWORD_CNT DWORDs, the phy-interface sends out (PHY_ALIGN_NUM_CNT+1)*2 ALIGNs NOTE: this field is reset by Cold Reset 0h PHY_ALIGN_NUM_CNT_INIT (default)
7:0	R/W	0Ah	T_SATA<0>_CHXCFG4_CHX_PHY_ALIGN_DWORD_CNT: The PHY_ALIGN_DWORD_CNT field configures the number of DWORDs sent before the required (PHY_ALIGN_NUM_CNT + 1) number of ALIGN primitive pairs are inserted by the phy-interface block into the output stream. For example, the default PHY_ALIGN_DWORD_CNT setting of 254 and default PHY_ALIGN_NUM_CNT of 0 implies an output stream of 254 DWORDs, 2 ALIGNs, 254 DWORDs, 2 ALIGNs, and so on. To disable insertion of ALIGN primitives, set this field to zero. NOTE: this field is reset by Cold Reset Ah PHY_ALIGN_DWORD_CNT_INIT (default)

T_SATA<0>_PRBS_CHX

This register contains control bits for the IOBIST PRBS generator and checker. Setting PI_LOOPBACK will select the PRBS as the TX data source. Setting PRBS_EN will cause the PRBS to start running. PRBS_SEED contains the 10-bit initial value for the PRBS.

Offset: 0x714 | Read/Write: R/W | Reset: 0xXXXXX001

Bit	R/W	Reset	Description
31:16	R	None	T_SATA<0>_PRBS_CHX_ERROR_COUNT:

31.7.5.3 DMA Control Registers

I/O Mapped Registers behind a BAR.

T_SATA_PRI_CMD

Bus Master SATA Primary Channel Command Register

The Primary command register allows host to control the SATA primary channel bus mastering.

Offset: 0x000 | Read/Write: R/W | Reset: 0x0X

Bit	R/W	Reset	Description
7:4	R	0	Reserved
3	R/W	0h	T_SATA_PRI_CMD_BM_RW:

Bit	R/W	Reset	Description
			Read or Write Control. This bit sets the direction of the bus master transfer. When set to zero, PCI bus master reads are performed. When set to one, PCI bus master writes are performed. This bit must NOT be changed when the bus master function is active. 0h BM_RW_READ (default) 1h BM_RW_WRITE
2:1	R	0	Reserved
0	RW1C	None	T_SATA_PRI_CMD_BM_SS: Start/Stop Bus Master. Writing a '1' to this bit enables bus master operation of the controller. Bus master operation begins when this bit is detected changing from a zero to a one. The controller will transfer data between the SATA device and memory only when this bit is set. Master operation can be halted by writing a '0' to this bit. All state information is lost when a '0' is written; Master mode operation cannot be stopped and then resumed. If this bit is reset while bus master operation is still active (i.e., the Bus Master SATA Active bit of the Bus Master SATA Status register for that SATA channel is set) and the drive has not yet finished its data transfer (The Interrupt bit in the Bus Master SATA Status register for that SATA channel is not set), the bus master command is said to be aborted and data transferred from the drive may be discarded before being written to system memory. This bit is intended to be reset after the data transfer is completed, as indicated by either the Bus Master SATA Active bit or the Interrupt bit of the Bus Master SATA Status register for that SATA channel being set, or both. 0h BM_SS_STOP 1h BM_SS_START

T_SATA_PRI_STS

Bus Master SATA Primary Channel Status Register

The Primary channel status registers allows host to check the capabilities and the status of Primary channel bus mastering.

Offset: 0x002 | Read/Write: R/W | Reset: 0xXX

Bit	R/W	Reset	Description
7	R	0h	T_SATA_PRI_STS_SMPLX: Simplex only. This read-only bit is a 0. This indicates that both bus master channels (primary and secondary) can be operated at the same time. 0h SMPLX_NO 1h SMPLX_YES
6	R/W	0h	T_SATA_PRI_STS_DMA1: Drive 1 DMA Capable. This read/write bit is set by device dependent code (BIOS or device driver) to indicate that drive 1 for this channel is capable of DMA transfers, and that the controller has been initialized for optimum performance. 0h DMA1_NO (default) 1h DMA1_YES
5	R/W	0h	T_SATA_PRI_STS_DMA0: Drive 0 DMA Capable. This read/write bit is set by device dependent code (BIOS or device driver) to indicate that drive 0 for this channel is capable of DMA transfers, and that the controller has been initialized for optimum performance. 0h DMA0_NO (default) 1h DMA0_YES
4:3	R	0	Reserved
2	RW1C	0h	T_SATA_PRI_STS_INTR: Interrupt. This bit is set by the rising edge of the SATA interrupt line. This bit is cleared when a '1' is written to it by software. Software can use this bit to determine if an SATA device has asserted its interrupt line. When this bit is read as a one, all data transferred from the drive is visible in system memory. 0h INTR_NO (default) 1h INTR_YES 1h INTR_CLEAR
1	R	0h	T_SATA_PRI_STS_ERR: Error status '0' = No error '1' = Error occured

Bit	R/W	Reset	Description
			0h ERR_NO 1h ERR_YES
0	R	0h	T_SATA_PRI_STS_BMSATAA: Bus Master SATA Active. This bit is set when the Start bit is written to the Command register. This bit is cleared when the last transfer for a region is performed, where EOT for that region is set in the region descriptor. It is also cleared when the Start bit is cleared in the Command register. When this bit is read as a zero, all data transferred from the drive during the previous bus master command is visible in system memory, unless the bus master command was aborted. 0h BMSATAA_NACTV (default) 1h BMSATAA_ACTV

T_SATA_PRI_PRD_ADD

Primary Channel Descriptor Table Pointer Register

Offset: 0x004 | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:2	R/W	0h	T_SATA_PRI_PRD_ADD_DW: Base address of Descriptor table. Corresponds to A[31:2] 0h DW_0 (default)
1:0	R	0	Reserved

T_SATA_SEC_CMD

Bus Master SATA Secondary Channel Command Register

The Secondary command register allows host to control the SATA Secondary channel bus mastering.

Offset: 0x008 | Read/Write: R/W | Reset: 0x0X

Bit	R/W	Reset	Description
7:4	R	0	Reserved
3	R/W	0h	T_SATA_SEC_CMD_BM_RW: Read or Write Control. This bit sets the direction of the bus master transfer. When set to zero, PCI bus master reads are performed. When set to one, PCI bus master writes are performed. This bit must NOT be changed when the bus master function is active. 0h BM_RW_READ (default) 1h BM_RW_WRITE
2:1	R	0	Reserved
0	RW1C	None	T_SATA_SEC_CMD_BM_SS: Start/Stop Bus Master. Writing a '1' to this bit enables bus master operation of the controller. Bus master operation begins when this bit is detected changing from a zero to a one. The controller will transfer data between the SATA device and memory only when this bit is set. Master operation can be halted by writing a '0' to this bit. All state information is lost when a '0' is written; Master mode operation cannot be stopped and then resumed. If this bit is reset while bus master operation is still active (i.e., the Bus Master SATA Active bit of the Bus Master SATA Status register for that SATA channel is set) and the drive has not yet finished its data transfer (The Interrupt bit in the Bus Master SATA Status register for that SATA channel is not set), the bus master command is said to be aborted and data transferred from the drive may be discarded before being written to system memory. This bit is intended to be reset after the data transfer is completed, as indicated by either the Bus Master SATA Active bit or the Interrupt bit of the Bus Master SATA Status register for that SATA channel being set, or both. 0h BM_SS_STOP 1h BM_SS_START

T_SATA_SEC_STS

Bus Master SATA Secondary Channel Status Register

The Secondary channel status registers allows host to check the capabilities and the status of Secondary channel Bus mastering

Offset: 0x00a | Read/Write: R/W | Reset: 0xXX

Bit	R/W	Reset	Description
7	R	0h	T_SATA_SEC_STS_SMPLX: Simplex only. This read-only bit is a 0. This indicates that both bus master channels (primary and secondary) can be operated at the same time. 0h SMPLX_NO 1h SMPLX_YES
6	R/W	0h	T_SATA_SEC_STS_DMA1: Drive 1 DMA Capable. This read/write bit is set by device dependent code (BIOS or device driver) to indicate that drive 1 for this channel is capable of DMA transfers, and that the controller has been initialized for optimum performance. 0h DMA1_NO (default) 1h DMA1_YES
5	R/W	0h	T_SATA_SEC_STS_DMA0: Drive 0 DMA Capable. This read/write bit is set by device dependent code (BIOS or device driver) to indicate that drive 0 for this channel is capable of DMA transfers, and that the controller has been initialized for optimum performance. 0h DMA0_NO (default) 1h DMA0_YES
4:3	R	0	Reserved
2	RW1C	0h	T_SATA_SEC_STS_INTR: Interrupt. This bit is set by the rising edge of the SATA interrupt line. This bit is cleared when a '1' is written to it by software. Software can use this bit to determine if an SATA device has asserted its interrupt line. When this bit is read as a one, all data transferred from the drive is visible in system memory. 0h INTR_NO (default) 1h INTR_YES 1h INTR_CLEAR
1	R	0h	T_SATA_SEC_STS_ERR: Error status '0' = No error '1' = Error occurred 0h ERR_NO 1h ERR_YES
0	R	0h	T_SATA_SEC_STS_BMSATAA: Bus Master SATA Active. This bit is set when the Start bit is written to the Command register. This bit is cleared when the last transfer for a region is performed, where EOT for that region is set in the region descriptor. It is also cleared when the Start bit is cleared in the Command register. When this bit is read as a zero, all data transferred from the drive during the previous bus master command is visible in system memory, unless the bus master command was aborted. 0h BMSATAA_NACTV (default) 1h BMSATAA_ACTV

T_SATA_SEC_PRD_ADD

Secondary Channel Descriptor Table Pointer Register

Secondary channel PRD table address provides a pointer to base Physical Resource Descriptor Table in the memory. The table is doubleword aligned and must not cross a 64K byte boundary. Also addresses and count in the PRD table are assumed to be aligned are even numbers.

Offset: 0x00c | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:2	R/W	0h	T_SATA_SEC_PRD_ADD_DW: Base address of Descriptor table. Corresponds to A[31:2] 0h DW_0 (default)

Bit	R/W	Reset	Description
1:0	R	0	Reserved

T_SATA_PRI_COMMAND_0

Offset: 0x1f0 | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:24	R/W	0h	T_SATA_PRI_COMMAND_0_LBA_LOW: 0h LBA_LOW_INIT (default)
23:16	R/W	0h	T_SATA_PRI_COMMAND_0_SECTOR_COUNT: 0h SECTOR_COUNT_INIT (default)
15:8	R/W	0h	T_SATA_PRI_COMMAND_0_FEATURE_ERR: 0h FEATURE_ERR_INIT (default)
7:0	R/W	0h	T_SATA_PRI_COMMAND_0_DATA: 0h DATA_INIT (default)

T_SATA_PRI_COMMAND_1

Offset: 0x1f4 | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:24	R/W	0h	T_SATA_PRI_COMMAND_1_COMMAND_STATUS: 0h COMMAND_STATUS_INIT (default)
23:16	R/W	0h	T_SATA_PRI_COMMAND_1_DEVICE: 0h DEVICE_INIT (default)
15:8	R/W	0h	T_SATA_PRI_COMMAND_1_LBA_HIGH: 0h LBA_HIGH_INIT (default)
7:0	R/W	0h	T_SATA_PRI_COMMAND_1_LBA_MID: 0h LBA_MID_INIT (default)

T_SATA_PRI_CONTROL

Offset: 0x3f4 | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:24	R	0	Reserved
23:16	R/W	0h	T_SATA_PRI_CONTROL_DEVICE_ALTERNATE_STATUS: 0h DEVICE_ALTERNATE_STATUS_INIT (default)
15:0	R	0	Reserved

T_SATA_SEC_COMMAND_0

Offset: 0x170 | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:24	R/W	0h	T_SATA_SEC_COMMAND_0_LBA_LOW: 0h LBA_LOW_INIT (default)
23:16	R/W	0h	T_SATA_SEC_COMMAND_0_SECTOR_COUNT: 0h SECTOR_COUNT_INIT (default)
15:8	R/W	0h	T_SATA_SEC_COMMAND_0_FEATURE_ERR: 0h FEATURE_ERR_INIT (default)

Bit	R/W	Reset	Description
7:0	R/W	0h	T_SATA_SEC_COMMAND_0_DATA: 0h DATA_INIT (default)

T_SATA_SEC_COMMAND_1

Offset: 0x174 | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:24	R/W	0h	T_SATA_SEC_COMMAND_1_COMMAND_STATUS: 0h COMMAND_STATUS_INIT (default)
23:16	R/W	0h	T_SATA_SEC_COMMAND_1_DEVICE: 0h DEVICE_INIT (default)
15:8	R/W	0h	T_SATA_SEC_COMMAND_1_LBA_HIGH: 0h LBA_HIGH_INIT (default)
7:0	R/W	0h	T_SATA_SEC_COMMAND_1_LBA_MID: 0h LBA_MID_INIT (default)

T_SATA_SEC_CONTROL

Offset: 0x374 | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:24	R	0	Reserved
23:16	R/W	0h	T_SATA_SEC_CONTROL_DEVICE_ALTERNATE_STATUS: 0h DEVICE_ALTERNATE_STATUS_INIT (default)
15:0	R	0	Reserved

31.7.6 SATA Aux Registers

31.7.6.1 SATA_AUX_MISC_CNTL_1_0

MISC_CNTL_1 Register

Offset: 0x1108 | Read/Write: R/W | Reset: 0x00016XX0 (0bxxxxxxxxxxxxxx0010110xxx00xx00000)

Bit	R/W	Reset	Description
18	RW	0x0	AUX_RX_IDLE_STATUS_MASK: Set this bit to mask the aux_rx_idle_status input to the SATA core to 0. 0 = Do not mask the rx_stat_idle input to the SATA core 1 = Mask the rx_stat_idle input to the SATA core to 0. 0 = DISABLE 1 = ENABLE
18	RW	0x0	AUX_OR_CORE_IDLE_STATUS_SEL: This bit is used to select the rx_idle status from either AUX or CORE for interrupt generation. 0 = Take the AUX idle status for interrupt generation 1 = Take the CORE idle status for interrupt generation
17	RW	0x0	DEVSLP_OVERRIDE: Set this bit to override the DEVSLP output from the SATA core. 0 = Assertion of DEVSLP is controlled by the SATA core 1 = DEVSLP is asserted irrespective of the state of DEVSLP from the SATA core. 0 = DISABLE 1 = ENABLE
16	RW	0x1	DSP_SUPPORT: Set this bit to set the AHCI's PxDEVSLP.DSP register bit. 0 = Indicates the SATA port does not support device sleep 1 = Indicates the SATA port supports device sleep. 0 = CLEAR 1 = SET
15	RW	0x0	DESO_SUPPORT: Set this bit to set the AHCI's CAP2.DESO register bit. 0 = Indicates the SATA core has the capability to enter DevSleep from any link state 1 = Indicates the SATA core only has the capability to enter DevSleep from the slumber link state. 0 = CLEAR 1 = SET
14	RW	0x1	SADM_SUPPORT: Set this bit to set the AHCI's CAP2.SADM register bit. 0 = Indicates the SATA core does not have the capability to support hardware assertion of the DEVSLP 1 = Indicates the SATA core has the capability to support hardware assertion of the DEVSLP. 0 = CLEAR 1 = SET
13	RW	0x1	SDS_SUPPORT: Set this bit to set the AHCI's CAP2.SAS register bit. 0 = Indicates the SATA core does not support device sleep 1 = Indicates the SATA core supports device sleep. 0 = CLEAR 1 = SET

Bit	R/W	Reset	Description
12	RW	0x0	RX_STAT_IDLE_MASK: Set this bit to mask the rx_stat_idle input to the SATA core to 0. 0 = Do not mask the rx_stat_idle input to the SATA core 1 = Mask the rx_stat_idle input to the SATA core to 0. 0 = DISABLE 1 = ENABLE
11	RO	X	SATA2IPSM_DEVSLP: Indicates if the SATA link is in DEVSLP. Used for debug purposes.
10:9	RO	X	SATA2IPSM_ST: Indicates whether the SATA link is in partial/slumber modes. Used for debug purposes.
8	RW	0x0	NVA2SATA_OOB_ON_SCONTROL_SPD_WR: If this bit is set to 1, the SATA controller will do an OOB and go through speed negotiation with the drive whenever its SCONTROL_SPD register is written. 0 = NO 1 = YES
7	RW	0x0	NVA2SATA_OOB_ON_POR: Controls whether or not SATA controllers do an OOB sequence automatically when they come out of reset. 0 = NO 1 = YES
6:5	RO	X	L0_RX_IDLE_T_SAX: l0_rx_idle_t value from the SATA controller When the SAX partition is power-gated, this field shows a clamped value. 0 = NORMAL
4:3	RW	0x0	L0_RX_IDLE_T_NPG: Sets the l0_rx_idle_t value for the SATA PHY from apb_misc (non-power-gated logic). Before the SAX partition is power-gated, SATA_l0_rx_idle_t_npg needs to have the same value as SATA_l0_rx_idle_t_sax, then set SATA_l0_rx_idle_t_mux to '1'. This ensures that the SATA PHY is still receiving the correct threshold setting for OOB detection when the SAX is power-gated. After SAX power is restored, the same value is restored to the l0_rx_idle_t register in the SATA controller, then SATA_l0_rx_idle_t_mux can be set back to '0'. 0 = NORMAL
2	RW	0x0	L0_RX_IDLE_T_MUX: Select l0_rx_idle_t driving source for SATA PHY 0: From the SATA controller 1 : From apb_misc 0 = FROM_SATA 1 = FROM_APB_MISC
1	RW	0x0	PMU2SATA_ACCLMTR_TRIG: This config bit is used inside SATA to select between the two accelerometer triggers, between the external trigger and the PMU's trigger. 0 : External trigger disable 1 : External trigger enable 0 = DISABLE 1 = ENABLE
0	RW	0x0	DEVICE_DIS_SATA0: Serial ATA Interface 0 Disable 1 = Internal Serial ATA Interface 0 disabled (Not seen as part of PCI space) 0 = Internal Serial ATA Interface 0 enabled. 0 = ENABLE 1 = DISABLE

31.7.6.2 SATA_AUX_RX_STAT_INT_0

RX_STAT_INT Register

Offset: 0x110c | Read/Write: R/W | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxx0xx0xx0xx)

Bit	R/W	Reset	Description
8	RW	0x0	SATA_DEVSLP_INT_DISABLE: SATA devslp interrupt disable 1 = Disables interrupt assertion when devslp interrupt status is set 0 = Enables interrupt assertion when devslp interrupt status is set 0 = ENABLE

Bit	R/W	Reset	Description
			1 = DISABLE
7	RO	X	SATA_DEVSLP: SATA devslp state interrupt status 1 = SATA link is in the devslp state 0 = SATA link is not in the devslp state 0 = NO 1 = YES
6	RO	X	SATA_DEVSLP_INT_STATUS: SATA devslp state interrupt status 1 = devslp interrupt is pending 0 = devslp interrupt is not pending 0 = NONE 1 = PENDING
5	RW	0x0	SATA_DEV_ATTEN_INT_DISABLE: SATA device attention interrupt disable 1 = Disable interrupt assertion when dev_atten interrupt status is set 0 = Enable interrupt assertion when dev_atten interrupt status is set 0 = ENABLE 1 = DISABLE
4	RO	X	SATA_DEVICE_ATTENTION: SATA device attention status. 1 : device attention input is asserted 0 : device attention input is cleared. 0 = NO 1 = YES
3	RO	X	SATA_DEV_ATTEN_INT_STATUS: SATA device attention interrupt status from GPIO. 1 = Device attention interrupt is pending 0 = Device attention interrupt is not pending 0 = NONE 1 = PENDING
2	RW	0x0	SATA_RX_STAT_INT_DISABLE: SATA rx_stat interrupt disable 1 = Disables interrupt assertion when rx_stat interrupt status is set 0 = Enables interrupt assertion when rx_stat interrupt status is set 0 = ENABLE 1 = DISABLE
1	RO	X	SATA_L0_RX_STAT_IDLE: SATA pad L0 rx_stat_idle status 1 : Rx path is idle 0 : Rx path is active 0 = NO 1 = YES
0	RO	X	SATA_RX_STAT_INT_STATUS: SATA rx_stat interrupt status from the SATA pad 1 = rx_stat interrupt is pending 0 = rx_stat interrupt is not pending 0 = NONE 1 = PENDING

31.7.6.3 SATA_AUX_RX_STAT_SET_0

RX_STAT_SET Register

Offset: 0x1110 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000)

Bit	Reset	Description
2	0x0	SATA_DEVSLP_INT_SET: SATA devslp interrupt is set (this bit is auto-cleared). Set the interrupt status bit to '1' when register is written. The read back value is always '0'.
1	0x0	SATA_DEV_ATTEN_INT_SET: SATA dev_atten interrupt is set (this bit is auto-cleared). Set the interrupt status bit to '1' when register is written. The read back value is always '0'.
0	0x0	SATA_RX_STAT_INT_SET: SATA rx_stat interrupt is set (this bit is auto-cleared). Set the interrupt status

Bit	Reset	Description
		bit to '1' when register is written. The read back value is always '0'.

31.7.6.4 SATA_AUX_RX_STAT_CLR_0

RX_STAT_CLR Register

Offset: 0x1114 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000)

Bit	Reset	Description
2	0x0	SATA_DEVSLP_INT_CLR: SATA devslp interrupt is cleared (this bit is auto-cleared). Clear the interrupt status bit to '1' when register is written. The read back value is always '0'.
1	0x0	SATA_DEV_ATTEN_INT_CLR: SATA dev_atten interrupt is cleared (this bit is auto-cleared). Clear the interrupt status bit to '1' when register is written. The read back value is always '0'.
0	0x0	SATA_RX_STAT_INT_CLR: SATA rx_stat interrupt is cleared (this bit is auto-cleared). Clear the interrupt status bit to '1' when register is written. The read back value is always '0'.

31.7.6.5 SATA_AUX_SPARE_CFG0_0

SPARE_CFG0 Register

Offset: 0x1118 | Read/Write: R/W | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxx0000000xxxxxxxx)

Bit	R/W	Reset	Description
14	RW	0x0	MDAT_TIMER_AFTER_PG_VALID: Indicates that the MDAT timer value in the above field is to be loaded in the SATA register space.
13:8	RW	0x0	MDAT_TIMER_AFTER_PG: MDAT timer value to be updated by the SW (PEP driver) before power-ungating the SATA controller.
5:0	RO	X	MDAT_TIMER_BEFORE_PG: MDAT timer value loaded from the SATA register space before SATA is power-gated.

31.7.6.6 SATA_AUX_SPARE_CFG1_0

SPARE_CFG1 Register

Offset: 0x111c | Read/Write: R/W | Reset: 0xffff0000 (0b11111111111111110000000000000000)

Bit	Reset	Description
31:0	-65536	SPARE: Spare register bits

31.7.6.7 SATA_AUX_PAD_PLL_CTRL_0_0

SATA PAD PLL Control Register

Offset: 0x1120 | Read/Write: R/W | Reset: 0x3X3X0000 (0bxx11xxx0xx11xxx100000x0000000000)

Bit	R/W	Reset	Description
29:28	RW	0x3	PLL1_REFCLK_NDIV
27	RO	X	PLL1_LOCKDET
24	RW	0x0	PLL1_MODE
21:20	RW	0x3	PLL0_REFCLK_NDIV: Select feedback divider for PLL.

Bit	R/W	Reset	Description
19	RO	X	PLL0_LOCKDET: Status signal indicating whether PLL is locked within the desired resolution. Forced high when the PLL is in test modes enabled by either PLL_BYPASS_EN or PLL_EMULATION_ON. 0 = Not locked 1 = Locked 0 = NOT_LOCKED 1 = LOCKED
16	RW	0x1	PLL0_MODE
15:12	RW	0x0	REFCLK_SEL: 00 = Internal CML reference clock 01 = Internal CMOS reference clock 1x = External reference clock 0 = INT_CML 1 = INT_CMOS 2 = EXT
11	RW	0x0	REFCLK_TERM100
9	RW	0x0	PLL_CKBUFPD_OVRD
8	RW	0x0	PLL_CKBUFPD_M
7	RW	0x0	PLL_CKBUFPD_BL
6	RW	0x0	PLL_CKBUFPD_BR
5	RW	0x0	PLL_CKBUFPD_TL
4	RW	0x0	PLL_CKBUFPD_TR
3	RW	0x0	SPARE_BIT_2: Reserved bit.
2	RW	0x0	PLL_EMULATION_RSTN: Digital reset for clock divider during emulation mode, hold low (reset) and release to High to set divider phase. No effect during normal operation. 0 = Reset hold 1 = Reset released/active 0 = ASSERT 1 = DEASSERT
1	RW	0x0	SPARE_BIT_1: Reserved bit.
0	RW	0x0	SPARE_BIT_0: Reserved bit. 0 = LOW 1 = HIGH

31.7.6.8 SATA_AUX_PAD_PLL_CTRL_1_0

Offset: 0x1124 | Read/Write: R/W | Reset: 0xXX441020 (0bxxxxxxxx010001000x01000000100000)

Bit	R/W	Reset	Description
31:24	RO	X	PLL_MISC_OUT: Reserved.
23:20	RW	0x4	PLL1_CP_CNTL: Charge-pump current control for PLL1.
19:16	RW	0x4	PLL0_CP_CNTL: Charge-pump current control for PLL0.
15	RW	0x0	PLL_BYPASS_EN: Bypass PLL serial output clocks with input reference clock.
13	RW	0x0	PLL_EMULATION_ON: Enable clock bypass for emulation mode.
12	RW	0x1	TCLKOUT_EN: Enable test clock output pads, TSTCLKP/N.
11:8	RW	0x0	TCLKOUT_SEL: Select internal clock source to bring out through the TSTCLKP/N pads.
7	RW	0x0	XDIGCLK4P5_EN: Enable XDIGCLK4P5 clock output to core.
6	RW	0x0	REFCLKBUF_EN: Enable REFCLKBUF clock output to core.

Bit	R/W	Reset	Description
5	RW	0x1	TXCLKREF_EN: Enable TXCLKREF clock to core.
4	RW	0x0	TXCLKREF_SEL: Select the post divider for TXCLKREF clock.
3	RW	0x0	XDIGCLK_EN: Enable XDIGCLK output clock.
2:0	RW	0x0	XDIGCLK_SEL: Select the output frequency of XDIGCLK.

31.7.6.9 SATA_AUX_PAD_PLL_CTRL_2_0

Offset: 0x1128 | Read/Write: R/W | Reset: 0x0000XX80 (0b0000xxxx00000000x0xxxxxx1xx00000)

Bit	R/W	Reset	Description
31:28	RW	0x0	PLL_TEMP_CNTL
23:18	RW	0x0	PLL_BW_CNTL
17:16	RW	0x0	PLL_BGAP_CNTL
15	RO	X	RCAL_DONE: Status signal to indicate calibration status.
14	RW	0x0	RCAL_RESET: Reset the resistor calibration logic.
12:8	RO	X	RCAL_VAL: Setting of current active resistor calibration code
7	RW	0x1	RCAL_BYPASS: Bypass resistor calibration logic.
4:0	RW	0x0	RCAL_CODE: Sets resistor calibration code when logic is bypassed.

31.7.6.10 SATA_AUX_PAD_PLL_CTRL_3_0

Offset: 0x112c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxx000000000000)

Bit	Reset	Description
11:0	0x0	PLL_MISC_CNTL

31.7.6.11 SATA_AUX_PAD_L0_AUX_CTRL_0_0

Offset: 0x1130 | Read/Write: R/W | Reset: 0x00000X00 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx000000)

Bit	R/W	Reset	Description

1	RW	0x0	AUX_TX_RDET_EN
0	RW	0x0	AUX_TX_TERM_EN

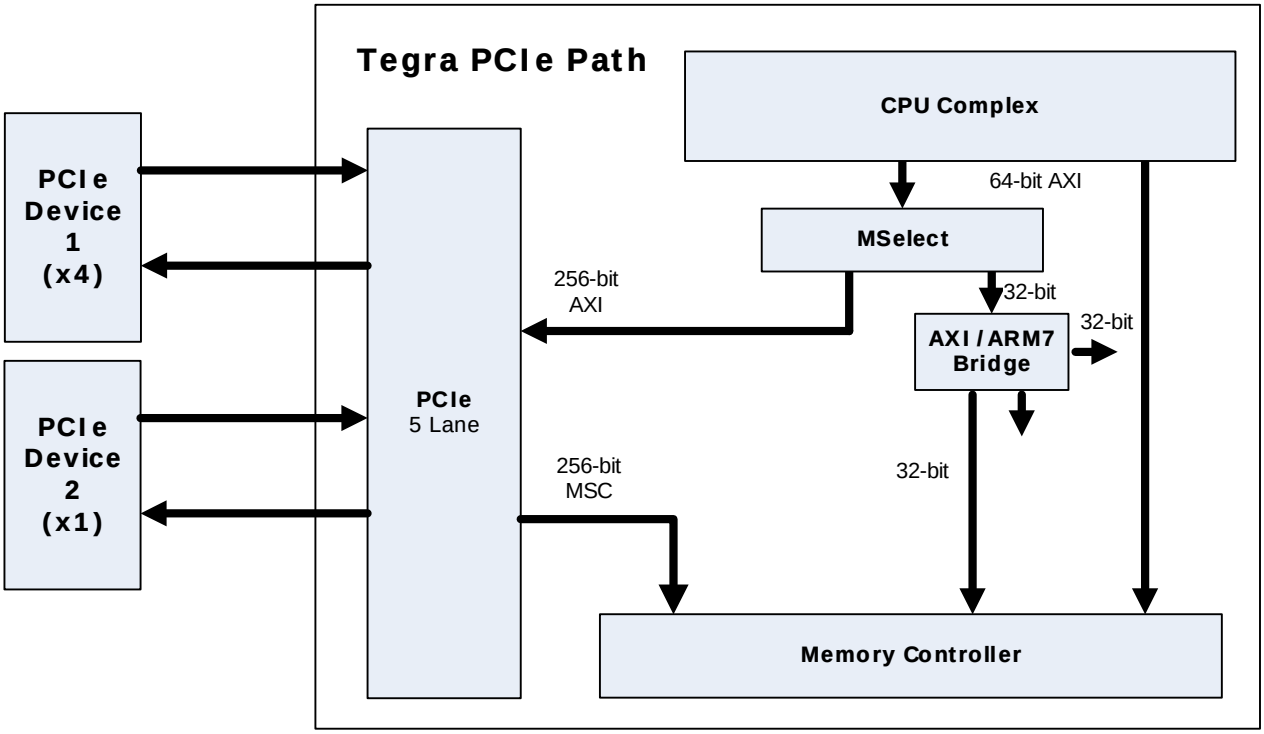
[THIS PAGE INTENTIONALLY LEFT BLANK]

32.0 PCI EXPRESS (PCIe) CONTROLLER

The Tegra® K1 devices incorporate a 5-lane PCIe® root port controller with support for both upstream and downstream AXI interfaces that serves as the control path from Tegra K1 device to the external PCIe device. The PCIe controller enables a connection to one or two PCIe endpoints.

Gen1 (2.5 GT/s) and Gen2 (5.0 GT/s) speeds are supported.

Figure 119: PCIe Interface



32.1 Supported Configurations

The lane mappings for the configurations are internal to the PCIe root port controller. The supported configurations are indicated in the following table.

Use Case	Lane 4	Lane 3	Lane 2	Lane 1	Lane 0
XUSB PADCTL Lane Mapping	Lane 0	Lane 1	Lane 2	Lane 3	Lane 4
Automotive/ Clamshell 1	PCIE x1 (Controller 1)	PCIE x4 (Controller 0)			

32.2 Programming Guidelines

32.2.1 Cold Boot

32.2.1.1 PAD, Clocks and Resets

The AFI clock and the FPCI clocks of the PCIe bridge are sourced from the MSELECT clock, with the clock source and divisor programming determined by MSELECT.

The AFI and PCIe clocks are enabled by setting the following register bits:

- CLK_RST_CONTROLLER_CLK_ ENB_U_SET_0[SET_CLK_ENB_AFI] = 1’b1
- CLK_RST_CONTROLLER_CLK_ ENB_U_SET_0[SET_CLK_ENB_PCIE] = 1’b1

AFI and PCIe resets are deasserted by setting the following register bits:

- CLK_RST_CONTROLLER_RST_DEV_U_CLR_0[CLR_AFI_RST] = 1’b1
- CLK_RST_CONTROLLER_RST_DEV_U_CLR_0[CLR_PCIE_RST] = 1’b1

IOPHYs are brought out of IDDQ by setting the following register bits. Only lanes owned by PCIe should be programmed.

- XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK0] = 1’b1
- XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK1] = 1’b1
- XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK2] = 1’b1
- XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK3] = 1’b1
- XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK4] = 1’b1

32.2.1.2 AFI Initialization

The following register fields should be programmed to match the platform configuration of PCIe:

- AFI_PCIE_CONFIG_0[SM2TMS0_XBAR_CONFIG]
- AFI_PCIE_CONFIG_0[PCIEC1_DISABLE_DEVICE]
- AFI_PCIE_CONFIG_0[PCIEC0_DISABLE_DEVICE]
- AFI_FUSE_0[FUSE_PCIE_T0_GEN2_DIS]

The following register bits should be programmed to match the platform address apertures:

- APBDEV_PMC_GLB_AMAP_CFG_0[PCIE_A3]
- APBDEV_PMC_GLB_AMAP_CFG_0[PCIE_A2]
- APBDEV_PMC_GLB_AMAP_CFG_0[PCIE_A1]

The following register bit should be set to enable FPCI transactions to PCIe:

AFI_CONFIGURATION_0[EN_FPCI] = 1’b1

Refer to the Address Map section in this TRM for Tegra K1 addresses allocated to AFI and PCIe. The following table lists the apertures used by internal AFI and PCIe registers:

Base Address	Size	Usage
0x0100_0000	4KB	PCIe Controller 0 config registers
0x0100_1000	4KB	PCIe Controller 1 config registers
0x0100_2000	256B	PCA 0
0x0100_2100	256B	PCA 1

Base Address	Size	Usage
0x0100_3000	2KB	PCIe Pads
0x0100_3800	2KB	AFI

32.2.1.3 PCIe Root Port Initialization

The following register bit should be set to enable PCIe mastering and accepting memory and I/O requests:

- T_PCIE2_RP_DEV_CTRL_BUS_MASTER = 1'b1
- T_PCIE2_RP_DEV_CTRL_MEMORY_SPACE = 1'b1
- T_PCIE2_RP_DEV_CTRL_IO_SPACE = 1'b1

32.2.1.4 PCIe Hierarchy Enumeration

The configuration register space of the PCIe hierarchy below each PCIe root port is accesses by using the AFI address mapping to convert the Tegra MMIO addresses to PCIe config addresses. The following PCIe registers should be programmed accordingly for access configuration register spaces below the root ports:

- T_PCIE2_RP_BN_LT_SEC_BUS_NUMBER
- T_PCIE2_RP_BN_LT_SUB_BUS_NUMBER

The I/O register space of the PCIe hierarchy below each PCIe root port is accesses by using the AFI address mapping to convert the Tegra MMIO addresses to PCIe I/O addresses. The following PCIe registers should be programmed accordingly for access I/O register spaces below the root ports:

- T_PCIE2_RP_IO_BL_SS_IO_BASE
- T_PCIE2_RP_IO_BL_SS_IO_LIMIT

The I/O register space of the PCIe hierarchy below each PCIe root port is accesses by using the AFI address mapping to shift the Tegra MMIO addresses to PCIe MMIO addresses. The following PCIe registers should be programmed accordingly for access MMIO register spaces below the root ports:

- T_PCIE2_RP_MEM_BL_MEM_BASE
- T_PCIE2_RP_MEM_BL_MEM_LIMIT
- T_PCIE2_RP_PRE_BL_PREFETCH_MEM_BASE
- T_PCIE2_RP_PRE_BL_PREFETCH_MEM_LIMIT

32.2.2 ELPG and LP0

32.2.2.1 Context Save/Restore

Since the PCIe links would be put to L2/L3 when PCIe is put to ELPG or LP0, where the PCIe hierarchy would be reset to exit L2/L3, instead of performing context save/reset, software can reinitialize AFI, PCIe Root Ports, and the PCIe hierarchy after exiting ELPG or LP0.

32.2.2.2 Power Gating Entry

IOPHY are put to IDDQ by setting the following register bits. Only lanes owned by PCIe should be programmed.

- XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK0] = 1'b0
- XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK1] = 1'b0
- XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK2] = 1'b0
- XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK3] = 1'b0

- XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK4] = 1’b0

AFI and PCIe resets are asserted by setting the following register bits:

- CLK_RST_CONTROLLER_RST_DEV_U_SET_0[SET_AFI_RST] = 1’b1
- CLK_RST_CONTROLLER_RST_DEV_U_SET_0[SET_PCIE_RST] = 1’b1

AFI and PCIe clocks are enabled by setting the following register bits:

- CLK_RST_CONTROLLER_CLK_ ENB_U_SET_0[SET_CLK_ENB_AFI] = 1’b1
- CLK_RST_CONTROLLER_CLK_ ENB_U_SET_0[SET_CLK_ENB_PCIE] = 1’b1

AFI and PCIe power is removed by setting the following register fields:

- APBDEV_PMC_PWRGATE_TOGGLE_0[START] to ‘enable’
- APBDEV_PMC_PWRGATE_TOGGLE_0[PARTID] to ‘PCX’

Then confirm the power removal by reading the following field:

APBDEV_PMC_PWRGATE_STATUS_0[PCX] equals ‘OFF’

32.2.2.3 Power Gating Exit

AFI and PCIe power are restored by setting the following register fields:

- APBDEV_PMC_PWRGATE_TOGGLE_0[START] to ‘enable’
- APBDEV_PMC_PWRGATE_TOGGLE_0[PARTID] to ‘PCX’

Then confirm the power restore by reading the following field:

APBDEV_PMC_PWRGATE_STATUS_0[PCX] equals ‘ON’

AFI and PCIe clocks are enabled by setting the following register bits:

- CLK_RST_CONTROLLER_CLK_OUT_ENB_U_SET_0[SET_CLK_ENB_AFI] = 1’b1
- CLK_RST_CONTROLLER_CLK_OUT_ENB_U_SET_0[SET_CLK_ENB_PCIE] = 1’b1

AFI and PCIe power clamping are removed by setting the following register field:

APBDEV_PMC_REMOVE_CLAMPING_CMD_0 [PCX]

Then confirm the power clamps’ removal by reading the following field:

APBDEV_PMC_REMOVE_CLAMPING_CMD_0 [PCX] equals ‘0’

AFI and PCIe resets are deasserted by setting the following register bits:

- CLK_RST_CONTROLLER_RST_DEV_U_CLR_0[CLR_AFI_RST] = 1’b1
- CLK_RST_CONTROLLER_RST_DEV_U_CLR_0[CLR_PCIE_RST] = 1’b1

IOPHYs are brought out of IDDQ by setting the following register bits. Only lanes owned by PCIe should be programmed.

- XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK0] = 1’b1
- XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK1] = 1’b1
- XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK2] = 1’b1
- XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK3] = 1’b1
- XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK4] = 1’b1

32.2.2.4 PE_WAKE# in LP0

During LP0, PCIe devices can assert PE_WAKE# to indicate a wake event. Wake from LP0 by asserting PE_WAKE# is enabled by programming the following register fields before entering LP0:

- APBDEV_PMC_WAKE_LVL_0[EVENT[14] to 'ACTIVE_LOW'
- APBDEV_PMC_WAKE_MASK_0[EVENT[14] to 'ENABLE'

After exiting LP0, the PE_WAKE# event should be disabled and the wake status should be cleared by programming the following register fields:

- APBDEV_PMC_WAKE_MASK_0[EVENT[14] to 'DISABLE'
- APBDEV_PMC_WAKE_STATUS_0[EVENT[14] to 1'b1

32.2.2.5 PE_WAKE# in ELPG

When PCIe is under ELPG, PCIe devices can assert PE_WAKE# to signal wake event. Wake from PE_WAKE# assertion when PCIe is under ELPG is enabled by programming the following register fields:

- GPIO_CNF_0.DD[BIT_3] to 'GPIO'
- GPIO_CNF_0.DD[LOCK_3] to 'DISABLE'
- GPIO_OE_0.DD[BIT_3] to 'TRI_STATE'
- GPIO_INT_LVL_0.DD[EDGE_3] to '0'
- GPIO_INT_LVL_0.DD[BIT_3] to 'LOW'
- GPIO_INT_ENB_0.DD[BIT_3] to 'ENABLE'

After exiting LP0, the PE_WAKE# event should be disabled and the wake status should be cleared by programming the following register fields:

- GPIO_INT_ENB_0.DD[BIT_3] to 'DISABLE'
- GPIO_INT_CLR_0.DD[BIT_3] to 'CLEAR'

32.2.3 PLL Power Down

For devices that do not support CLKREQ#, PCIe cannot signal PLL power down during L1. For devices that support CLKREQ#, PCIe should signal PLL power down during L1 if the device deasserts CLKREQ#. PCIe should always signal PLL power down during L2/3.

Whether a device supports CLKREQ# is a platform design time decision. Thus platform software should have the information if CLKREQ# is used. In both cases, software should program the following bits to enable PCIe observing CLKREQ#:

- AFI_PLLE_CONTROL_0[BYPASS_PADS2PLLE_CONTROL] = 1'b0
- AFI_PLLE_CONTROL_0[PADS2PLLE_CONTROL_EN] = 1'b1
- AFI_PEX0_CTRL_0[PEX0_CLKREQ_EN] = 1'b0 for controller 0
- AFI_PEX1_CTRL_0[PEX1_CLKREQ_EN] = 1'b0 for controller 1

32.2.3.1 L1 with Devices Not Supporting CLKREQ#

Software should enable the internal pull-down of the CLKREQ# pin to keep CLKREQ# always asserted if the device does not support CLKREQ#. This will prevent PCIe from signaling PLL power down when link is in L1 because PCIe would consider CLKREQ# always asserted.

- PINMUX_AUX_PEX_L0_CLKREQ_N_0[PUPD] = 'PD'
- PINMUX_AUX_PEX_L1_CLKREQ_N_0[PUPD] = 'PD'

32.2.3.2 L1 with Devices Supporting CLKREQ#

If the platform board does not use an external pull-up on the CLKREQ# pin, software should enable the internal pull-up of the CLKREQ# pin. PCIe will indicate PLL power down when the link is in L1 and CLKREQ# is deasserted.

- PINMUX_AUX_PEX_L0_CLKREQ_N_0[PUPD] = 'PU'
- PINMUX_AUX_PEX_L1_CLKREQ_N_0[PUPD] = 'PU'

32.2.3.3 L2/3

After putting the link to L2/L3, software should program the following bit to override CLKREQ# so PCIe will signal PLL power down irrespective to CLKREQ#.

AFI_PLLE_CONTROL_0[BYPASS_PADS2PLLE_CONTROL] = 1'b1

Software should clear the above bit to 1'b0 before bringing the link back to L0.

32.2.4 MSI and PCIe Messages

32.2.4.1 MSI Handling

Set up MSI Interrupt

Software programs MSI_BAR_SZ to 0x0000F to allocate 64KB to MSI address space.

Software programs MSI_FPCI_BAR_START to 0x00_FEE0_0 to assign the MSI starting address.

For each vector that software programs into the MSI DATA register of the PCIe device, software should also set the corresponding bit in the MSI ENABLE VECTOR[7:0] registers.

Access MSI Vector

Software reads MSI_VECTOR[7:0] registers to identify the bit(s) set to 1 by AFI/IPFS, indicating AFI/IPFS received MSI(s) with matched vector(s), and notify the corresponding interrupt service routine(s).

After software finishes handling the interrupt from the PCIe device, software writes 0 to the vector corresponding bit MSI_VECTOR[7:0] to clear the vector.

32.2.4.2 Message Handling (AFI Only)

Access Message

Software reads the INT_CODE register and determines that the interrupt is for SM_MSG.

Software reads the revised PME register to identify the bit(s) set to 1 by the AFI, indicating the AFI received messages with a matched type.

The INTA/B/C/D PCIe messages and the Root Port Interrupt messages are virtual wires to reflect the status of the interrupts from the source of the interrupts. Thus they are defined as read-only registers to reflect the interrupt status.

If the INTA, INTB, INTC, or INTD bit is set, software should notify the interrupt service routing, where the PCIe devices will send deassert_INTA/B/C/D messages, and the AFI will clear the INTA, INTB, INTC, or INTD bit. If the Root Port Interrupt bits are set, software should notify the interrupt service routing, where the PCIe root ports will send Root_Port_Interrupt_Deassertion messages, and the AFI will clear the Root Port Interrupt bits.

The non-interrupt messages are used for event notifications and reporting. Similar to MSIs, multiple events can be collapsed when there are pending events of the same type (that is, new messages being dropped when the status bits are already set).

If the non-interrupt bits are set, software should handle the messages accordingly, and then write 1s to the bits to clear them.

After the message bit(s) are all cleared, software sets INT_CODE to CLEAR to cause the AFI to deassert the interrupt or move to report the next interrupt source.

32.2.5 PCIe Sideband Signals

32.2.5.1 Removal of PRSNT#

The Tegra K1 does not support dedicated pins for the PCIe PRSNT# pins. To allow presence detection and hot plug support, PCIe should implement software overrides for the PRSNT# inputs of each of controller.

To support presence detection and hot plug, GPIO pins can be allocated to connect to the PRSNT# pins of the PCIe sockets. After being notified that the GPIO pins are pulled to ground as a result of attachment of PCIe cards, software can set the software overrides to signal the event to the PCIe controllers.

32.2.5.2 Control of PE_RST#

Each controller's PE_RST# signal is controlled directly by software programming the following AFI registers:

- Controller 0: AFI_PEX0_CTRL_0[PEX0_RST_L]
- Controller 1: AFI_PEX1_CTRL_0[PEX1_RST_L]

32.2.5.3 Control of CLKREQ# and Reference Clock

The reference clock of each controller is controlled directly by software programming the following AFI registers:

- Controller 0: AFI_PEX0_CTRL_0[PEX0_REFCLK_EN]
- Controller 1: AFI_PEX1_CTRL_0[PEX1_REFCLK_EN]

The reference clock of each controller can be controlled by CLKREQ# by software programming the following AFI registers:

- Controller 0: AFI_PEX0_CTRL_0[PEX0_CLKREQ_EN]
- Controller 1: AFI_PEX1_CTRL_0[PEX1_CLKREQ_EN]

The state of CLKREQ can be read from the following AFI registers:

- Controller 0: AFI_PEX0_STATUS_0[PEX0_CLKREQ_L]
- Controller 1: AFI_PEX1_STATUS_0[PEX1_CLKREQ_L]

Software can enable the AFI interrupt by setting the following bit:

- AFI_AFI_INTR_ENABLE_0[EN_PE_CLKREQ_SENSE]

32.2.6 L1 Clock Gating

Software should set the following register to ensure PCIe can exit from L1:

NV_PROJ__PCIE2_RP_PRIV_MISC_CTLR_CLK_CLAMP_THRESHOLD = 0xF

32.3 PCIe Registers

The PCI Express® registers are located as follows:

Name	Location	Description
NV_PCIE_AXI_RP_T0C0	NV_ADDRESS_MAP_PCIE_BASE	Start of PCIe extended config space for controller 0

Name	Location	Description
NV_PCIE_AXI_RP_T0C1	(NV_PCIE_AXI_RP_T0C0) + 4096	Start of PCIe extended config space for controller 1
NV_PCIE_AXI_PCA_UFPCI_T0C0	(NV_PCIE_AXI_RP_T0C1) + 4096	Start of PCIe pca0 space
NV_PCIE_AXI_PCA_XCLK_T0C0	(NV_PCIE_AXI_PCA_UFPCI_T0C0) + 256)	Start of PCIe pca1 space
NV_PCIE_AXI_PADS	(NV_PCIE_AXI_RP_T0C1) + 8192	Start of PCIe pads space

32.3.1 PCI Compatible Configuration Registers

32.3.1.1 T_PCIE2_RP_DEV_ID

This register implements the Device ID and Vendor ID registers as defined by the PCI 2.0 Specification.

Device ID and Vendor ID Register

Offset: 0x00 | Read/Write: RO | Reset:

Bit	Reset	Description
31:16	None	T_PCIE2_RP_DEV_ID_DEVICE_ID: The DEVICE_ID bits identify the particular device. This identifier is allocated by the vendor. NVIDIA uses unique Device IDs for Root Complexes with different Maximum Link Widths. E1Ch: DEVICE_ID_TMS0_CTLR0_W4 E1Dh: DEVICE_ID_TMS0_CTLR1_W2 E1Dh: DEVICE_ID_TMS0_CTLR2_W2
15:0	10DEh	T_PCIE2_RP_DEV_ID_VENDOR_ID: The VENDOR_ID bits identify the manufacturer of the device. Valid vendor identifiers are allocated by the PCI SIG to ensure uniqueness. 10DEh: VENDOR_ID_NVIDIA (default)

32.3.1.2 T_PCIE2_RP_DEV_CTRL

Command and Status Register

Offset: 0x04 | Read/Write: R/W

Bit	R/W	Reset	Description
31	RW1C	0h	T_PCIE2_RP_DEV_CTRL_DETECTED_PERR: This bit is set by the Primary side device whenever it receives a Poisoned TLP, regardless of the state the Parity Error Response bit in the Command register. 0h: DETECTED_PERR_NOT_ACTIVE (default) 1h: DETECTED_PERR_ACTIVE 1h: DETECTED_PERR_SET
30	RW1C	0h	T_PCIE2_RP_DEV_CTRL_SIGNALED_SERR: This bit is set when the Primary side device sends an ERR_FATAL or ERR_NONFATAL message, and the SERR Enable bit is set. 0h: SIGNALED_SERR_NOT_ACTIVE (default) 1h: SIGNALED_SERR_ACTIVE 1h: SIGNALED_SERR_SET

Bit	R/W	Reset	Description
29	RW1C	0h	T_PCIE2_RP_DEV_CTRL_RECEIVED_MASTER: This bit is set when the Primary side Requestor receives a Completion with Unsupported Request Completion Status. 0h: RECEIVED_MASTER_NO_ABORT (default) 1h: RECEIVED_MASTER_ABORT 1h: RECEIVED_MASTER_SET
28	RW1C	0h	T_PCIE2_RP_DEV_CTRL_RECEIVED_TARGET: This bit is set when the Primary side Requestor receives a Completion with Completer Abort Completion Status. 0h: RECEIVED_TARGET_NO_ABORT (default) 1h: RECEIVED_TARGET_ABORT 1h: RECEIVED_TARGET_SET
27	RW1C	0h	T_PCIE2_RP_DEV_CTRL_SIGNALED_TARGET: This bit is set when the Primary side device completes a Request using Completer Abort Completion Status. 0h: SIGNALED_TARGET_NO_ABORT (default) 1h: SIGNALED_TARGET_ABORT 1h: SIGNALED_TARGET_SET
26:25	R	0h	T_PCIE2_RP_DEV_CTRL_DEVSEL_TIMING: Does not apply to PCI Express. Hardwired to 0. 0h: DEVSEL_TIMING_FAST (default) 1h: DEVSEL_TIMING_MEDIUM 2h: DEVSEL_TIMING_SLOW
24	RW1C	0h	T_PCIE2_RP_DEV_CTRL_MASTER_DATA_PERR: Master Data Parity Error bit. This bit is set by the Primary side Requestor if the Parity Error Response bit in the Command register is 1b and either of the following two conditions occurs: * Requestor receives a Completion marked poisoned * Requestor poisons a write Request If the Parity Error Response bit is 0b, this bit is never set. 0h: MASTER_DATA_PERR_NOT_ACTIVE (default) 1h: MASTER_DATA_PERR_ACTIVE 1h: MASTER_DATA_PERR_SET
23	R	0h	T_PCIE2_RP_DEV_CTRL_FAST_BACK2BACK: Does not apply to PCI Express. Hardwired to 0. 0h: FAST_BACK2BACK_INCAPABLE (default) 1h: FAST_BACK2BACK_CAPABLE
22	R	0	Reserved
21	R	0h	T_PCIE2_RP_DEV_CTRL_66MHZ: Does not apply to PCI Express. Hardwired to 0. 0h: 66MHZ_INCAPABLE (default) 1h: 66MHZ_CAPABLE
20	R	1h	T_PCIE2_RP_DEV_CTRL_CAPLIST: The CAPLIST bit indicates that the device configuration space includes a capabilities list. Hardwired to 1. 1h: CAPLIST_PRESENT (default) 0h: CAPLIST_NOT_PRESENT
fs19	R	0h	T_PCIE2_RP_DEV_CTRL_INTR_STATUS: The INTR_STATUS bit indicates that an INTx interrupt message is pending internally to the device. 0h: INTR_STATUS_NOT_ACTIVE (default) 1h: INTR_STATUS_ACTIVE
18:11	R	0	Reserved

Bit	R/W	Reset	Description
10	R/W	0h	T_PCIE2_RP_DEV_CTRL_INTR_DISABLE: The INTR-DISABLE bit controls the ability of the device to generate INTx interrupt messages. When set, devices are prevented from generating INTx interrupt messages. 0h: INTR_DISABLE_INIT (default) 1h: INTR_DISABLE_YES 0h: INTR_DISABLE_NO
9	R	0h	T_PCIE2_RP_DEV_CTRL_BACK2BACK: Does not apply to PCI Express. Hardwired to 0. 0h: BACK2BACK_DISABLED (default) 1h: BACK2BACK_ENABLED
8	R/W	0h	T_PCIE2_RP_DEV_CTRL_SERR: SERR Enable bit. This bit, when set, enables reporting of Non-fatal and Fatal errors detected by the Root Complex. In addition, this bit, when set, enables transmission by the primary interface of ERR_NONFATAL and ERR_FATAL error messages forwarded from the secondary interface. This bit does not affect the transmission of forwarded ERR_COR messages. 0h: SERR_DISABLED (default) 1h: SERR_ENABLED
7	R	0h	T_PCIE2_RP_DEV_CTRL_STEP: Does not apply to PCI Express. Hardwired to 0. 0h: STEP_DISABLED (default) 1h: STEP_ENABLED
6	R/W	0h	T_PCIE2_RP_DEV_CTRL_PERR: Parity Error Response bit. This bit, when set, controls the reporting of parity errors detected by the root complex (see Master Data Parity Error bit in the Status register). 0h: PERR_DISABLED (default) 1h: PERR_ENABLED
5	R	0h	T_PCIE2_RP_DEV_CTRL_PALETTE_SNOOP: Does not apply to PCI Express. Hardwired to 0. 0h: PALETTE_SNOOP_DISABLED (default) 1h: PALETTE_SNOOP_ENABLED
4	R	0h	T_PCIE2_RP_DEV_CTRL_WRITE_AND_INVAL: Does not apply to PCI Express. Hardwired to 0. 0h: WRITE_AND_INVAL_DISABLED (default) 1h: WRITE_AND_INVAL_ENABLED
3	R	0h	T_PCIE2_RP_DEV_CTRL_SPECIAL_CYCLE: Does not apply to PCI Express. Hardwired to 0. 0h: SPECIAL_CYCLE_DISABLED (default) 1h: SPECIAL_CYCLE_ENABLED
2	R/W	0h	T_PCIE2_RP_DEV_CTRL_BUS_MASTER: The BUS_MASTER bit controls the ability of the root complex to issue memory and I/O read/write requests. It controls forwarding of memory or I/O requests from the secondary interface to the primary interface. 0h: BUS_MASTER_DISABLED (default) 1h: BUS_MASTER_ENABLED
1	R/W	0h	T_PCIE2_RP_DEV_CTRL_MEMORY_SPACE: The MEMORY_SPACE bit indicates that the device will respond to memory space accesses on the primary interface. A value of 0 disables the device response on the primary interface. A value of 1 allows the device to forward memory transactions from the primary interface to the secondary interface. 0h: MEMORY_SPACE_DISABLED (default) 1h: MEMORY_SPACE_ENABLED

Bit	R/W	Reset	Description
0	R/W	0h	T_PCIE2_RP_DEV_CTRL_IO_SPACE: The IO_SPACE bit indicates that the device will respond to I/O space accesses on the primary interface. A value of 0 disables the device response on the primary interface. A value of 1 allows forwarding of I/O accesses from the primary interface to the secondary interface. 0h: IO_SPACE_DISABLED (default) 1h: IO_SPACE_ENABLED

32.3.1.3 T_PCIE2_RP_REV_CC

This register implements the Revision ID and Class Code registers as defined by the PCI 2.0 Specification.

Revision ID and Class Code Registers

Offset: 0x08 | Read/Write: RO

Bit	Reset	Description
31:8	6040XXh	T_PCIE2_RP_REV_CC_CLASS_CODE: The CLASS_CODE bits identify the generic function of the device and (in some cases) a specific register-level programming interface. The register is broken into three byte-size fields. The upper byte (bits 31:24) is a base class code which broadly classifies the type of function the device performs. The middle-byte (bits 23:16) is a sub-class code which identifies more specifically the function of the device. The lower byte (bits 15:8) identifies a specific register-level programming interface, if any, so that device independent software can interact with the device. 60400h: CLASS_CODE_HOST (default) 60400h: CLASS_CODE_P2P
7:0	None	T_PCIE2_RP_REV_CC_REVISION_ID: The REVISION_ID bits specify a device specific revision identifier. The top nibble is the Major Revision and the bottom nibble is the Minor Revision. The Major Revision is changed every time there is an all layer change to the Controller (A, B, C ...). The Minor Revision is updated through metal edits each time there is a metal revision changing the functionality of this block. A1h: REVISION_ID_VAL

32.3.1.4 T_PCIE2_RP_MISC_1

This register implements the Cache Line Size, Latency Timer, Header Type, and BIST registers as defined by the PCI 2.0 Specification.

Cache Line Size, Latency Timer, Header Type, and BIST Registers

Offset: 0x0c | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R	0h	T_PCIE2_RP_MISC_1_BIST: The BIST register field is optional and not used. Hardwired to 0. 0h: BIST_ZERO (default)
23	R	0h	T_PCIE2_RP_MISC_1_HEADER_TYPE1: The HEADER_TYPE bits identify the layout of the bytes 10h through 3Fh in configuration space and also whether or not the device contains multiple functions. Bit 23 in this register is used to identify a multi-function device. If the bit is 0, then the device is single function. If the bit is 1, then the device has multiple functions. 0h: HEADER_TYPE1_SINGLEFUNC (default) 1h: HEADER_TYPE1_MULTIFUNC

Bit	R/W	Reset	Description
22:16	R	1h	T_PCIE2_RP_MISC_1_HEADER_TYPE0: The HEADER_TYPE bits identify the layout of the bytes 10h through 3Fh in configuration space and also whether or not the device contains multiple functions. Bits 22:16 in this register specify the layout of bytes 10h through 3Fh. PCI-Express Root Port Devices always employ Type 1 headers, hence this field is hardwired to 1h. 0h: HEADER_TYPE0_NON_BRIDGE 1h: HEADER_TYPE0_P2P_BRIDGE (default)
15:11	R	0h	T_PCIE2_RP_MISC_1_PLATENCY_TIMER: The primary/master latency timer does not apply to PCI Express. Hardwired to 0. 0h: PLATENCY_TIMER_0_CLOCKS (default)
10:8	R	0	Reserved
7:0	R/W	0h	T_PCIE2_RP_MISC_1_CACHE_LINE_SIZE: The cache line size register is set by the system firmware and the operating system to system cache line size. However, note that legacy PCI software may not always be able to program this field correctly especially in case of Hot-Plug devices. This field is implemented by PCI Express devices as a read-write field for legacy compatibility purposes but has no impact on any PCI Express device functionality. 0h: CACHE_LINE_SIZE_0_BYTES (default)

32.3.1.5 T_PCIE2_RP_BAR_0

This register implements the Base Address Register 0 as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2. It is unused and hardwired to 0.

Base Address Register 0

Offset: 0x10 | Read/Write: RO

Bit	Reset	Description
31:0	0h	T_PCIE2_RP_BAR_0_RESERVED: 0h: RESERVED_0 (default)

32.3.1.6 T_PCIE2_RP_BAR_1

This register implements the Base Address Register 1 as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2. It is unused and hardwired to 0.

Base Address Register 1

Offset: 0x14 | Read/Write: RO

Bit	Reset	Description
31:0	0h	T_PCIE2_RP_BAR_1_RESERVED: 0h: RESERVED_0 (default)

32.3.1.7 T_PCIE2_RP_BN_LT

This register implements the Primary Bus Number, Secondary Bus Number, Subordinate Bus Number, and Secondary Latency Timer registers as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

Primary Bus, Secondary Bus, Subordinate Bus Numbers, and Secondary Latency Timer Registers

Offset: 0x18 | Read/Write: R/W

Bit	R/W	Reset	Description
31:27	R	0h	T_PCIE2_RP_BN_LT_SLATENCY_TIMER: This field does not apply to PCI Express. Hardwired to 0. 0h: SLATENCY_TIMER_0_CLOCKS (default)
26:24	R	0	Reserved
23:16	R/W	0h	T_PCIE2_RP_BN_LT_SUB_BUS_NUMBER: The Subordinate Bus Number field is used to record the bus number of the highest numbered PCI bus segment which is behind the bridge. Configuration software programs the value in this field. The bridge uses this field in conjunction with the Secondary Bus Number field to determine when to respond to a Type 1 configuration transaction on the primary interface. 0h: SUB_BUS_NUMBER_0 (default) 1h: SUB_BUS_NUMBER_1 2h: SUB_BUS_NUMBER_2 FFh: SUB_BUS_NUMBER_255
15:8	R/W	0h	T_PCIE2_RP_BN_LT_SEC_BUS_NUMBER: The Secondary Bus Number field is used to record the bus number of the PCI bus segment to which the secondary interface of the bridge is connected. Configuration software programs the value in this field. The bridge uses this field to decode Type 1 configuration transactions on the primary interface and convert them to Type 0 accesses on the secondary interface. 0h: SEC_BUS_NUMBER_0 (default) 1h: SEC_BUS_NUMBER_1 2h: SEC_BUS_NUMBER_2 FFh: SEC_BUS_NUMBER_255
7:0	R/W	0h	T_PCIE2_RP_BN_LT_PRI_BUS_NUMBER: The Primary Bus Number field is used to record the bus number of the PCI bus segment to which the primary interface of the bridge is connected. Configuration software programs the value in this field. The bridge uses this field to decode Type 1 configuration transactions on the secondary interface that must be converted to Special Cycle transactions on the primary interface. 0h: PRI_BUS_NUMBER_0 (default)

32.3.1.8 T_PCIE2_RP_IO_BL_SS

This register implements the I/O Base, I/O Limit, and Secondary Status register as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

The I/O Base and I/O Limit fields define an address range that is used by the bridge to determine when to forward I/O transactions from one interface to the other.

The Secondary Status field is similar in function and bit definition to the Command and Status register defined above; however, its bits reflect status conditions of the secondary interface (the Command and Status register reflects the status conditions of the primary interface).

I/O Base, I/O Limit and Secondary Status Register

Offset: 0x1c | Read/Write: R/W

Bit	R/W	Reset	Description
31	RW1C	0h	T_PCIE2_RP_IO_BL_SS_DETECTED_PERR: This bit is set when the Secondary side device receives a Poisoned TLP, regardless of the state the Parity Error Response bit in the Bridge Control register. 0h: DETECTED_PERR_NOT_ACTIVE (default) 1h: DETECTED_PERR_ACTIVE 1h: DETECTED_PERR_SET
30	RW1C	0h	T_PCIE2_RP_IO_BL_SS_RECEIVED_SERR: This bit is set when the Secondary side device receives an ERR_FATAL or ERR_NONFATAL message. 0h: RECEIVED_SERR_NOT_ACTIVE (default) 1h: RECEIVED_SERR_ACTIVE 1h: RECEIVED_SERR_SET
29	RW1C	0h	T_PCIE2_RP_IO_BL_SS_RECEIVED_MASTER: This bit is set when the Secondary side device receives a Completion with Unsupported Request Completion Status. 0h: RECEIVED_MASTER_NO_ABORT (default) 1h: RECEIVED_MASTER_ABORT 1h: RECEIVED_MASTER_SET
28	RW1C	0h	T_PCIE2_RP_IO_BL_SS_RECEIVED_TARGET: This bit is set when the Secondary side device receives a Completion with Completer Abort Completion Status. 0h: RECEIVED_TARGET_NO_ABORT (default) 1h: RECEIVED_TARGET_ABORT 1h: RECEIVED_TARGET_SET
27	RW1C	0h	T_PCIE2_RP_IO_BL_SS_SIGNALED_TARGET: This bit is set when the Secondary side device completes a Request using Completer Abort Completion Status. 0h: SIGNALED_TARGET_NO_ABORT (default) 1h: SIGNALED_TARGET_ABORT 1h: SIGNALED_TARGET_SET
26:25	R	0h	T_PCIE2_RP_IO_BL_SS_DEVSEL_TIMING: Does not apply to PCI Express. Hardwired to 0. 0h: DEVSEL_TIMING_FAST (default) 1h: DEVSEL_TIMING_MEDIUM 2h: DEVSEL_TIMING_SLOW
24	RW1C	0h	T_PCIE2_RP_IO_BL_SS_MASTER_DATA_PERR: Master Data Parity Error bit. This bit is set by the Secondary side Requestor if the Parity Error Response Enable bit in the Bridge Control register is 1b and either of the following two conditions occurs: * Requestor receives a Completion marked poisoned * Requestor poisons a write Request If the Parity Error Response bit is 0b, this bit is never set. 0h: MASTER_DATA_PERR_NOT_ACTIVE (default) 1h: MASTER_DATA_PERR_ACTIVE 1h: MASTER_DATA_PERR_SET
23	R	0h	T_PCIE2_RP_IO_BL_SS_FAST_BACK2BACK: Does not apply to PCI Express. Hardwired to 0. 0h: FAST_BACK2BACK_INCAPABLE (default) 1h: FAST_BACK2BACK_CAPABLE
22	R	0	Reserved
21	R	0h	T_PCIE2_RP_IO_BL_SS_66MHZ: Does not apply to PCI Express. Hardwired to 0. 0h: 66MHZ_INCAPABLE (default) 1h: 66MHZ_CAPABLE

Bit	R/W	Reset	Description
20:16	R	0	Reserved
15:12	R/W	0h	T_PCIE2_RP_IO_BL_SS_IO_LIMIT: This field corresponds to address bits AD[15:12] of the I/O limit. For the purpose of address decoding, the bridge assumes that the lower 12 address bits of the I/O limit are 0xFFF. The I/O Limit field can be programmed to a smaller value than the I/O Base register if there are no I/O addresses on the secondary side of the bridge. 0h: IO_LIMIT_ADDRESS_0 (default) 1h: IO_LIMIT_ADDRESS_256 2h: IO_LIMIT_ADDRESS_512 Fh: IO_LIMIT_ADDRESS_64K
11:8	R	1h	T_PCIE2_RP_IO_BL_SS_IO_LIMIT_SUPPORT: Identifies the I/O addressing support. When 0h, the device supports only 16-bit addressing. When 1h, it supports 32-bit addressing, in which case the I/O Limit Upper 16 Bits register is used to extend the I/O limit to 32 bits. Hardwired to 1h. 0h: IO_LIMIT_SUPPORT_16 1h: IO_LIMIT_SUPPORT_32 (default)
7:4	R/W	0h	T_PCIE2_RP_IO_BL_SS_IO_BASE: This field corresponds to address bits AD[15:12] of the I/O base address. For the purpose of address decoding, the bridge assumes that the lower 12 address bits, AD[11:0], of the I/O base address are zero. 0h: IO_BASE_ADDRESS_0 (default) 1h: IO_BASE_ADDRESS_256 2h: IO_BASE_ADDRESS_512 Fh: IO_BASE_ADDRESS_64K
3:0	R	1h	T_PCIE2_RP_IO_BL_SS_IO_BASE_SUPPORT: Identifies the I/O addressing support. When 0h, the device only supports 16-bit addressing. When 1h, it supports 32-bit addressing, in which case the I/O Base Upper 16 Bits register is used to extend the I/O base address to 32 bits. Hardwired to 1h. 0h: IO_BASE_SUPPORT_16 1h: IO_BASE_SUPPORT_32 (default)

32.3.1.9 T_PCIE2_RP_MEM_BL

This register implements the Memory Base and Memory Limit registers as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

The Memory Base and Memory Limit fields define an address range that is used by the bridge to determine when to forward memory-mapped I/O transactions from one interface to the other.

Memory Base and Memory Limit Registers

Offset: 0x20 | Read/Write: R/W

Bit	R/W	Reset	Description
31:20	R/W	0h	T_PCIE2_RP_MEM_BL_MEM_LIMIT: This field corresponds to address bits AD[31:20] of the memory-mapped I/O limit. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, AD[19:0], of the memory-mapped I/O limit are 0xFFFFF. The Memory Limit field must be programmed to a smaller value than the Memory Base field if there are no memory-mapped I/O addresses on the secondary side of the bridge. 0h: MEM_LIMIT_ADDRESS_0 (default) 1h: MEM_LIMIT_ADDRESS_1MEG 2h: MEM_LIMIT_ADDRESS_2MEG FFFh: MEM_LIMIT_ADDRESS_4GIG
19:16	R	0	Reserved

Bit	R/W	Reset	Description
15:4	R/W	1h	T_PCIE2_RP_MEM_BL_MEM_BASE: This field corresponds to address bits AD[31:20] of the memory-mapped I/O base address. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, AD[19:0], of the memory-mapped I/O base address are zero. 0h: MEM_BASE_ADDRESS_0 1h: MEM_BASE_ADDRESS_1MEG (default) 2h: MEM_BASE_ADDRESS_2MEG FFFh: MEM_BASE_ADDRESS_4GIG
3:0	R	0	Reserved

32.3.1.10 T_PCIE2_RP_PRE_BL

This register implements the Prefetchable Memory Base and Prefetchable Memory Limit registers as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

The Prefetchable Memory Base and Prefetchable Memory Limit fields define an address range that is used by the bridge to determine when to forward prefetchable memory transactions from one interface to the other.

Prefetchable Memory Base and Prefetchable Memory Limit Registers

Offset: 0x24 | Read/Write: R/W

Bit	R/W	Reset	Description
31:20	R/W	0h	T_PCIE2_RP_PRE_BL_PREFETCH_MEM_LIMIT: This field corresponds to address bits AD[31:20] of the prefetchable memory limit. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, AD[19:0], of the prefetchable memory limit are 0xFFFFF. The Prefetchable Memory Limit field must be programmed to a smaller value than the Prefetchable Memory Base field if there is no prefetchable memory on the secondary side of the bridge. 0h: PREFETCH_MEM_LIMIT_ADDRESS_0 (default) 1h: PREFETCH_MEM_LIMIT_ADDRESS_1MEG 2h: PREFETCH_MEM_LIMIT_ADDRESS_2MEG FFFh: PREFETCH_MEM_LIMIT_ADDRESS_4GIG
19:16	R	1h	T_PCIE2_RP_PRE_BL_L64BIT: Identifies the prefetchable memory addressing support. When 0h, the device supports only 32-bit addressing. When 1h, it supports 64-bit addressing, in which case the Prefetchable Limit Upper 32 Bits register is used to extend the prefetchable memory limit to 64 bits. Hardwired to 1h. 1h: L64BIT_YES (default)
15:4	R/W	1h	T_PCIE2_RP_PRE_BL_PREFETCH_MEM_BASE: This field corresponds to address bits AD[31:20] of the prefetchable memory base address. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, AD[19:0], of the Prefetchable memory base address are zero. 0h: PREFETCH_MEM_BASE_ADDRESS_0 1h: PREFETCH_MEM_BASE_ADDRESS_1MEG (default) 2h: PREFETCH_MEM_BASE_ADDRESS_2MEG FFFh: PREFETCH_MEM_BASE_ADDRESS_4GIG
3:0	R	1h	T_PCIE2_RP_PRE_BL_B64BIT: Identifies the prefetchable memory addressing support. When 0h, the device supports only 32-bit addressing. When 1h, it supports 64-bit addressing, in which case the Prefetchable Base Upper 32 Bits register is used to extend the prefetchable memory base address to 64 bits. Hardwired to 1h. 1h: B64BIT_YES (default)

32.3.1.11 T_PCIE2_RP_PRE_BU32

This register implements the Prefetchable Memory Base Upper 32 Bits register as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

Prefetchable Memory Base Upper 32 Bits Register

Offset: 0x28 | Read/Write: R/W

Bit	Reset	Description
31:0	0h	T_PCIE2_RP_PRE_BU32_BASE_UPPER_BITS: This register specifies the upper 32 bits, corresponding to AD[63:32], of the 64-bit prefetchable memory base address. 0h: BASE_UPPER_BITS_0 (default)

32.3.1.12 T_PCIE2_RP_PRE_LU32

This register implements the Prefetchable Memory Limit Upper 32 Bits register as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

Prefetchable Memory Limit Upper 32 Bits Register

Offset: 0x2c | Read/Write: R/W

Bit	Reset	Description
31:0	0h	T_PCIE2_RP_PRE_LU32_LIMIT_UPPER_BITS: This register specifies the upper 32 bits, corresponding to AD[63:32], of the 64-bit prefetchable memory limit. 0h: LIMIT_UPPER_BITS_0 (default)

32.3.1.13 T_PCIE2_RP_IO_BL_U16

This register implements the I/O Base Upper 16 Bits and I/O Limit Upper 16 Bits registers as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

I/O Base Upper 16 Bits and I/O Limit Upper 16 Bits Register

Offset: 0x30 | Read/Write: R/W

Bit	Reset	Description
31:16	0h	T_PCIE2_RP_IO_BL_U16_LIMIT_UPPER_BITS: This field specifies the upper 16 bits, corresponding to AD[31:16], of the 32-bit I/O limit. 0h: LIMIT_UPPER_BITS_0 (default)
15:0	0h	T_PCIE2_RP_IO_BL_U16_BASE_UPPER_BITS: This field specifies the upper 16 bits, corresponding to AD[31:16], of the 32-bit I/O base address. 0h: BASE_UPPER_BITS_0 (default)

32.3.1.14 T_PCIE2_RP_CAP_PTR

This register implements the Capabilities Pointer register as defined by the PCI 2.0 Specification.

Capabilities Pointer

Offset: 0x34 | Read/Write: RO

Bit	Reset	Description
31:8	0	Reserved
7:0	40h	T_PCIE2_RP_CAP_PTR_CAP_PTR: The CAP_PTR bits indicate the offset into configuration space where the capabilities list begins. 40h: CAP_PTR_PM (default)

32.3.1.15 T_PCIE2_RP_ROM_BA

This register implements the optional Expansion ROM Base Address register as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2. It is unused and hardwired to 0.

Expansion ROM Base Address Register

Offset: 0x38 | Read/Write: RO

Bit	Reset	Description
31:0	0h	T_PCIE2_RP_ROM_BA_RESERVED: 0h: RESERVED_0 (default)

32.3.1.16 T_PCIE2_RP_INTR_BCR

This register implements the Interrupt Line, Interrupt Pin, and Bridge Control registers as defined by the PCI 2.0 Specification and PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

Interrupt Line, Interrupt Pin, and Bridge Control Registers

Offset: 0x3c | Read/Write: R/W

Bit	R/W	Reset	Description
31:28	R	0	Reserved
27	R	0h	T_PCIE2_RP_INTR_BCR_DIS_TIMER_SERR: Does not apply to PCI Express. Hardwired to 0. 0h: DIS_TIMER_SERR_DISABLED (default) 1h: DIS_TIMER_SERR_ENABLED
26	R	0h	T_PCIE2_RP_INTR_BCR_DIS_TIMER_STATUS: Does not apply to PCI Express. Hardwired to 0. 0h: DIS_TIMER_STATUS_NOT_ACTIVE (default) 1h: DIS_TIMER_STATUS_ACTIVE
25	R	0h	T_PCIE2_RP_INTR_BCR_SECONDARY_DIS_TIMER: Does not apply to PCI Express. Hardwired to 0. 0h: SECONDARY_DIS_TIMER_LONG (default) 1h: SECONDARY_DIS_TIMER_SHORT
24	R	0h	T_PCIE2_RP_INTR_BCR_PRIMARY_DIS_TIMER: Does not apply to PCI Express. Hardwired to 0. 0h: PRIMARY_DIS_TIMER_LONG (default) 1h: PRIMARY_DIS_TIMER_SHORT
23	R	0h	T_PCIE2_RP_INTR_BCR_FAST_B2B: Does not apply to PCI Express. Hardwired to 0. 0h: FAST_B2B_DISABLED (default) 1h: FAST_B2B_ENABLED
22	R/W	0h	T_PCIE2_RP_INTR_BCR_SB_RESET: Setting this bit triggers a hot reset on the corresponding PCI Express Port. 0h: SB_RESET_DISABLED (default) 1h: SB_RESET_ENABLED
21	R	0h	T_PCIE2_RP_INTR_BCR_MABORT: Does not apply to PCI Express. Hardwired to 0. 0h: MABORT_DISABLED (default) 1h: MABORT_ENABLED

Bit	R/W	Reset	Description
20	R/W	0h	T_PCIE2_RP_INTR_BCR_VGA_16BITIO: When enabled, allows full 16-bit decode of I/O address range for VGA. 0h: VGA_16BITIO_DISABLED (default) 1h: VGA_16BITIO_ENABLED
19	R/W	0h	T_PCIE2_RP_INTR_BCR_VGA_ADDRESS: When enabled the P2P bridge will claim all of the legacy VGA addresses. Memory address range: 000A_0000 - 000B_FFFF I/O address ranges: 3B0-3BB, 3C0-3DF (including all aliases if VGA_16BITIO is not set). 0h: VGA_ADDRESS_DISABLED (default) 1h: VGA_ADDRESS_ENABLED
18	R/W	0h	T_PCIE2_RP_INTR_BCR_ISA_ADDRESS: Modifies the response by the bridge to ISA I/O addresses. This applies only to I/O addresses that are enabled by the I/O Base and I/O Limit registers and are in the first 64 KB of PCI I/O address space (0000 0000h to 0000 FFFFh). If this bit is set, the bridge will block any forwarding from primary to secondary of I/O transactions addressing the last 768 bytes in each 1-KB block. 0h: ISA_ADDRESS_DISABLED (default) 1h: ISA_ADDRESS_ENABLED
17	R/W	0h	T_PCIE2_RP_INTR_BCR_SERR_FORWARD: This bit controls forwarding of ERR_COR, ERR_NONFATAL and ERR_FATAL from secondary to primary. 0h: SERR_FORWARD_DISABLED (default) 1h: SERR_FORWARD_ENABLED
16	R/W	0h	T_PCIE2_RP_INTR_BCR_PERR_RESP: This bit controls the response to Poisoned TLPs. 0h: PERR_RESP_DISABLED (default) 1h: PERR_RESP_ENABLED
15:8	R	1h	T_PCIE2_RP_INTR_BCR_INTR_PIN: This field contains the interrupt pin the device (or device function) uses. A value of 1 corresponds to INTA#. A value of 2 corresponds to INTB#. A value of 3 corresponds to INTC#. A value of 4 corresponds to INTD#. Devices (or device functions) that do not use an interrupt pin must put a 0 in this field. 0h: INTR_PIN_NONE 1h: INTR_PIN_INTA (default) 2h: INTR_PIN_INTB 3h: INTR_PIN_INTC 4h: INTR_PIN_INTD
7:0	R/W	0h	T_PCIE2_RP_INTR_BCR_INTR_LINE: This field contains the interrupt routing information. The field must be implemented by any device (or device function) that uses an interrupt pin. POST software will write the routing information into this field as it initializes and configures the system. The value in this field tells which input of the system interrupt controller(s) the device's interrupt pin is connected to. Device drivers and operating systems can use this information to determine priority and vector information. INTR_LINE is written to 0xff (no connection) by software if the bridge does not use an interrupt pin. Some PCI BIOSes cannot handle aliased INTR_LINEs. Some PCI BIOSes cannot handle INTR_LINE initialized to 0xff. 0h: INTR_LINE_IRQ0 (default) 1h: INTR_LINE_IRQ1 Fh: INTR_LINE_IRQ15 FFh: INTR_LINE_UNKNOWN

32.3.2 PCI Subsystem ID and Subsystem Vendor ID Capability Registers

32.3.2.1 T_PCIE2_RP_SS_0

This register implements the first register of the Subsystem ID and Subsystem Vendor ID Capability list item, as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

Subsystem ID and Subsystem Vendor ID Capability Register 0

Offset: 0x40 | Read/Write: RO

Bit	Reset	Description
31:16	0	Reserved
15:8	48h	T_PCIE2_RP_SS_0_NEXT_PTR: This read-only field points to the next capabilities list item. 48h: NEXT_PTR_PM (default)
7:0	Dh	T_PCIE2_RP_SS_0_CAP_ID: This read-only field is used to detect the presence of the SSID/SSVID registers in a PCI-to-PCI bridge. Hardwired to 0Dh. Dh: CAP_ID_SS (default)

32.3.2.2 T_PCIE2_RP_SS_1

This register implements the second register of the .Subsystem ID and Subsystem Vendor ID Capability list item, as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

Subsystem ID and Subsystem Vendor ID Capability Register 1

Offset: 0x44 | Read/Write: RO

Bit	Reset	Description
31:16	0h	T_PCIE2_RP_SS_1_SSID: The SSID identifies the particular add-in card or subsystem and is assigned by the vendor. 0h: SSID_INIT (default)
15:0	10DEh	T_PCIE2_RP_SS_1_SSVID: The SSVID identifies the manufacturer of the add-in card or subsystem. The SSVID is assigned by PCI-SIG to ensure uniqueness (the Vendor ID is used as the SSVID also). 10DEh: SSVID_INIT (default)

32.3.3 PCI Power Management Capability Structure Registers

32.3.3.1 T_PCIE2_RP_PM_0

This register implements the Power Management Capabilities register as defined in Section 7.6 of PCI Express Specifications.

Power Management Capabilities Register

Offset: 0x48 | Read/Write: RO

Bit	Reset	Description
31:27	1Fh	T_PCIE2_RP_PM_0_PME_SUPPORT: This 5-bit field indicates the power states in which the function may assert PME#. A value of 0b for any bit indicates that the function is not capable of asserting the PME# signal while in that power state. bit(11) XXXX1b = PME# can be asserted from D0 bit(12) XXX1Xb = PME# can be asserted from D1 bit(13) XX1XXb = PME# can be asserted from D2 bit(14) X1XXXb = PME# can be asserted from D3hot bit(15) 1XXXXb = PME# can be asserted from D3cold Bits 31, 30, and 27 must be set to 1b for PCI-PCI Bridge structures representing Ports on Root Complexes/Switches to indicate that the Bridge will forward PME Messages. 1Fh: PME_SUPPORT_YES (default) 0h: PME_SUPPORT_NO

Bit	Reset	Description
26	0h	T_PCIE2_RP_PM_0_D2_SUPPORT: If this bit is a "1", this function supports the D2 Power Management State. 1h: D2_SUPPORT_YES 0h: D2_SUPPORT_NO (default)
25	0h	T_PCIE2_RP_PM_0_D1_SUPPORT: If this bit is a "1", this function supports the D1 Power Management State. 1h: D1_SUPPORT_YES 0h: D1_SUPPORT_NO (default)
24:22	0h	T_PCIE2_RP_PM_0_AUX_CURRENT: This 3 bit field reports the 3.3Vaux auxiliary current requirements for the PCI function. Bit 3.3Vaux 8 7 6 Max. Current Required 1 1 1 375 mA 1 1 0 320 mA 1 0 1 270 mA 1 0 0 220 mA 0 1 1 160 mA 0 1 0 100 mA 0 0 1 55 mA 0 0 0 0 (self powered) 0h: AUX_CURRENT_0 (default)
21	0h	T_PCIE2_RP_PM_0_DEV_SPEC_INIT: The Device Specific Initialization bit indicates whether special initialization of this function is required (beyond the standard PCI configuration header) before the generic class device driver is able to use it. Note that this bit is not used by some operating systems. Microsoft Windows and Windows NT, for instance, do not use this bit to determine whether to use D3. Instead, they use the driver's capabilities to determine this. A "1" indicates that the function requires a device specific initialization sequence following transition to the D0 uninitialized state. 0h: DEV_SPEC_INIT_NOT_NEEDED (default) 1h: DEV_SPEC_INIT_NEEDED
20	0	Reserved
19	0h	T_PCIE2_RP_PM_0_PME_CLOCK: Does not apply to PCI Express. Must be hardwired to 0. 0h: PME_CLOCK_NOT_NEEDED (default) 1h: PME_CLOCK_NEEDED
18:16	3h	T_PCIE2_RP_PM_0_PCIPM_REV: A value of 010b indicates that this function complies with Revision 1.1 of the PCI Power Management Interface Specification. 3h: PCIPM_REV_12 (default) 2h: PCIPM_REV_11
15:8	50h	T_PCIE2_RP_PM_0_NEXT_PTR: This read-only field points to the next capabilities list item. 50h: NEXT_PTR_MSI (default)
7:0	1h	T_PCIE2_RP_PM_0_CAP_ID: This read-only field is used to detect the presence of the Power Management Capability registers in a PCI-to-PCI bridge. Hardwired to 01h. 1h: CAP_ID_PM (default)

32.3.3.2 T_PCIE2_RP_PM_1

This register implements the Power Management Status/Control register as defined in Section 7.6 of PCI Express Specification.

Power Management Status/Control Register

Offset: 0x4c | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R	0h	T_PCIE2_RP_PM_1_PME_DATA: The PME Data register is not implemented. Hardwired to 0. 0h: PME_DATA_UNS (default)
23	R	0h	T_PCIE2_RP_PM_1_PME_BPCC: The bus power/clock control mechanism is not used. Hardwired to 0. 0h: PME_BPCC_UNS (default)
22	R	0h	T_PCIE2_RP_PM_1_PME_B2B3: The bus power/clock control mechanism is not used. Therefore the B2/B3 support bit is hardwired to 0. 0h: PME_B2B3_UNS (default)
21:16	R	0	Reserved
15	RW1C	0h	T_PCIE2_RP_PM_1_PME_STATUS: This bit is set when the function would normally assert the PME# signal independent of the state of the PME_En bit. Writing a "1" to this bit will clear it and cause the function to stop asserting a PME# (if enabled). Writing a "0" has no effect. This bit is sticky and must be explicitly cleared by the operating system each time the operating system is initially loaded. NOTE: This field is reset by Cold Reset 0h: PME_STATUS_NOT_ACTIVE (default) 1h: PME_STATUS_ACTIVE 1h: PME_STATUS_SET
14:13	R	0h	T_PCIE2_RP_PM_1_PME_DATA_SCALE: The PME Data register is not implemented. Hardwired to 0. 0h: PME_DATA_SCALE_UNS (default)
12:9	R	0h	T_PCIE2_RP_PM_1_PME_DATA_SEL: The PME Data register is not implemented. Hardwired to 0. 0h: PME_DATA_SEL_UNS (default)
8	R/W	0h	T_PCIE2_RP_PM_1_PME: A "1" enables the function to assert PME#. When "0", PME# assertion is disabled. This bit is sticky and must be explicitly cleared by the operating system each time it is initially loaded. NOTE: This field is reset by Cold Reset 0h: PME_DISABLE (default) 1h: PME_ENABLE
7:2	R	0	Reserved
1:0	R/W	0h	T_PCIE2_RP_PM_1_PWR_STATE: This 2-bit field is used both to determine the current power state of a function and to set the function into a new power state. The definition of the field values is given below. 00b - D0 01b - D1 10b - D2 11b - D3hot If software attempts to write an unsupported, optional state to this field, the write operation must complete normally on the bus; however, the data is discarded and no state change occurs. 0h: PWR_STATE_D0 (default) 1h: PWR_STATE_D1 2h: PWR_STATE_D2 3h: PWR_STATE_D3HOT

32.3.4 PCI MSI Capability Structure Registers

32.3.4.1 T_PCIE2_RP_MSI_CTRL

The MSI capability structure is required for all PCI Express devices that are capable of generating interrupts.

MSI enables a device to request service by writing a system-specified message to a system-specified address. The transaction address specifies the message destination and the transaction data specifies the message. System software initializes the message destination and message during device configuration.

MSI Control and Capability Registers

Offset: 0x50 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R	0h	T_PCIE2_RP_MSI_CTRL_RSVD: The RSVD field is reserved by the specification. 0h: RSVD_0 (default)
23	R	1h	T_PCIE2_RP_MSI_CTRL_64BIT_CAP: The 64BIT_CAP field indicates if the function is capable of generating a 64-bit message address. If 1, the function is capable. 1h: 64BIT_CAP_TRUE (default)
22:20	R/W	0h	T_PCIE2_RP_MSI_CTRL_MULT_EN: The MULT_EN field indicates the number of allocated messages. It is always aligned to a power of 2. 0h: MULT_EN_CODE0 (default) 1h: MULT_EN_CODE2 2h: MULT_EN_CODE4 3h: MULT_EN_CODE8
19:17	R	1h	T_PCIE2_RP_MSI_CTRL_MULT_CAP: The MULT_CAP field determines the number of requested messages. It should always be a power of 2. 1h: MULT_CAP_CODE2 (default)
16	R/W	0h	T_PCIE2_RP_MSI_CTRL_MSI: The MSI bit controls if the function is permitted to use message signaled interrupt to request service. If 1, the function is permitted to use MSI and prohibits the use of INTx messages. 0h: MSI_DISABLE (default) 1h: MSI_ENABLE
15:8	R	None	T_PCIE2_RP_MSI_CTRL_NEXT_PTR: The NEXT_PTR field points to the next item in the capabilities list. 60h: NEXT_PTR_MSIMAP 80h: NEXT_PTR_PCIEXP
7:0	R	5h	T_PCIE2_RP_MSI_CTRL_CAP_ID: This read-only field is used to detect the presence of the Message Signaled Interrupt Capability registers in a PCI-to-PCI bridge. Hardwired to 05h. 5h: CAP_ID_MSI (default)

32.3.4.2 T_PCIE2_RP_MSI_LOW_ADDR

The contents of this register specify the lower 32 bits of the Dword aligned address for the MSI memory write transaction.

MSI Message Lower Address Register

Offset: 0x54 | Read/Write: R/W

Bit	R/W	Reset	Description
31:2	R/W	0h	T_PCIE2_RP_MSI_LOW_ADDR_DWORD: Bits 31:2 of the address. 0h: DWORD_0 (default)

Bit	R/W	Reset	Description
1:0	R	0h	T_PCIE2_RP_MSI_LOW_ADDR_RSVD: The address is always DWORD aligned, hence bits 1:0 of this register are hardwired to 0. 0h: RSVD_0 (default)

32.3.4.3 T_PCIE2_RP_MSI_UPPER_ADDR

The contents of this register specify the upper 32 bits of the 64-bit MSI message address.

MSI Message Upper Address Register

Offset: 0x58 | Read/Write: R/W

Bit	Reset	Description
31:0	0h	T_PCIE2_RP_MSI_UPPER_ADDR_DWORD: Bits 63:32 of the address. 0h: DWORD_0 (default)

32.3.4.4 T_PCIE2_RP_MSI_DATA

The contents of this register specify the data that is written to the MSI message address.

MSI Message Data Register

Offset: 0x5c | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R	0h	T_PCIE2_RP_MSI_DATA_RSVD: 0h: RSVD_0 (default)
15:0	R/W	0h	T_PCIE2_RP_MSI_DATA_DATA: The MSI message data. 0h: DATA_0 (default)

32.3.5 PCI Express Capability Structure Registers

32.3.5.1 T_PCIE2_RP_PCI_EXPRESS_CAPABILITY

The PCI Express Capability List register enumerates the PCI Express Capability Structure in PCI 2.3 configuration space capability list. It also identifies PCI Express device type and associated capabilities.

PCI Express Capability List Register

Offset: 0x80 | Read/Write: RO

Bit	Reset	Description
31:30	0	Reserved
29:25	0h	T_PCIE2_RP_PCI_EXPRESS_CAPABILITY_INTERRUPT_MESSAGE_NUMBER: If this function is allocated more than one MSI interrupt number, this register is required to contain the offset between the base Message Data and the MSI Message that is generated when any of the status bits in either the Slot Status register or the Root Port Status register of this capability structure are set. Hardware is required to update this field so that it is correct if the number of the MSI Messages assigned to the device changes. 0h: INTERRUPT_MESSAGE_NUMBER_ZERO (default)

Bit	Reset	Description
24	1h	T_PCIE2_RP_PCI_EXPRESS_CAPABILITY_SLOT_IMPLEMENTED: This bit when set indicates that the PCI Express Link associated with this port is connected to a slot (as compared to being connected to an integrated component or being disabled). This field is valid for the following PCI Express device/Port Types: * Root Port of PCI Express Root Complex. * Downstream Port of PCI Express Switch. 1h: SLOT_IMPLEMENTED_INIT (default)
23:20	4h	T_PCIE2_RP_PCI_EXPRESS_CAPABILITY_DEVICE_PORT_TYPE: Indicates the type of PCI Express logical device. Defined encodings are: 0000b = PCI Express Endpoint device. 0001b = Legacy PCI Express Endpoint device. 0100b = Root Port of PCI Express Root Complex. 0101b = Upstream Port of PCI Express Switch. 0110b = Downstream Port of PCI Express Switch. 0111b = PCI Express-to-PCI/PCI-X Bridge. 1000b = PCI/PCI-X to PCI Express Bridge 4h: DEVICE_PORT_TYPE_INIT (default)
19:16	2h	T_PCIE2_RP_PCI_EXPRESS_CAPABILITY_VERSION: Indicates PCI_SIG defined PCI Express capability structure version number. Must be 1h for versions 1.0a and 1.1 of the PCI-Express Specification. Must be 2h for devices compliant to the Express Capabilities Register Expansion ECN. 2h: VERSION_INIT (default) 1h: VERSION_1 2h: VERSION_2
15:8	0h	T_PCIE2_RP_PCI_EXPRESS_CAPABILITY_LIST_NEXT_CAPABILITY_PTR: The offset to the next PCI capability structure or 0h if no other items exist in the linked list of capabilities. 0h: LIST_NEXT_CAPABILITY_PTR_INIT (default)
7:0	10h	T_PCIE2_RP_PCI_EXPRESS_CAPABILITY_LIST_CAPABILITY_ID: Indicates PCI Express Capability Structure. This field must return a Capability ID of 10h indicating that this is a PCI Express Capability Structure. 10h: LIST_CAPABILITY_ID_INIT (default)

32.3.5.2 T_PCIE2_RP_DEVICE_CAPABILITY

The Device Capabilities register identifies PCI Express device specific capabilities.

Device Capabilities Register

Offset: 0x84 | Read/Write: RO

Bit	Reset	Description
31:28	0	Reserved
27:26	0h	T_PCIE2_RP_DEVICE_CAPABILITY_CAPTURED_SLOT_POWER_LIMIT_SCALE: Specifies the scale used for the Slot Power Limit Value. Range of Values: 00b = 1.0x 01b = 0.1x 11b = 0.01x 11b = 0.001x This value is set by the Set_Slot_Power_Limit message or hardwired to 00b. The default value is all 00b. 0h: CAPTURED_SLOT_POWER_LIMIT_SCALE_INIT (default)
25:18	0h	T_PCIE2_RP_DEVICE_CAPABILITY_CAPTURED_SLOT_POWER_LIMIT_VALUE: In combination with the Slot Power Limit Scale value, specifies the upper limit on power supplied by slot. Power limit (in Watts) is calculated by multiplying the value in this field by the value in the Slot Power Limit Scale field. This value is set by the Set_Slot_Power_Limit message or hardwired to 0000_0000b. The default value is 0000_0000b. 0h: CAPTURED_SLOT_POWER_LIMIT_VALUE_INIT (default)

Bit	Reset	Description
17:16	0	Reserved
15	1h	T_PCIE2_RP_DEVICE_CAPABILITY_ROLE_BASED_ERR_REPORTING: This bit, when set, indicates that the device implements the functionality originally defined in the Error Reporting ECN for PCI Express Base Specification 1.0a and later incorporated into PCI Express Base Specification 1.1. 1h: ROLE_BASED_ERR_REPORTING_INIT (default)
14	0h	T_PCIE2_RP_DEVICE_CAPABILITY_POWER_INDICATOR_PRESENT: This bit, when set, indicates that a Power Indicator is implemented on the card or module. 0h: POWER_INDICATOR_PRESENT_INIT (default)
13	0h	T_PCIE2_RP_DEVICE_CAPABILITY_ATTENTION_INDICATOR_PRESENT: This bit, when set, indicates that an Attention Indicator is implemented on the card or module. 0h: ATTENTION_INDICATOR_PRESENT_INIT (default)
12	0h	T_PCIE2_RP_DEVICE_CAPABILITY_ATTENTION_BUTTON_PRESENT: This bit when set indicates that an Attention Button is implemented on the card or module. 0h: ATTENTION_BUTTON_PRESENT_INIT (default)
11:9	0h	T_PCIE2_RP_DEVICE_CAPABILITY_ENDPOINT_L1_ACCEPTABLE_LATENCY: This field indicates acceptable latency that an Endpoint can withstand due to the transition from L1 state to the L0 state. It is essentially an indirect measure of the Endpoint's internal buffering. • 000b -- Less than 1 µs. • 001b -- 1 µs to less than 2 µs. • 010b -- 2 µs to less than 4 µs. • 011b -- 4 µs to less than 8 us. • 100b – 8 µs to less than 16 µs. • 101b -- 16 µs to less than 32 µs. • 110b -- 32 µs-64 µs. • 111b -- More than 64 µs. 0h: ENDPOINT_L1_ACCEPTABLE_LATENCY_INIT (default)
8:6	0h	T_PCIE2_RP_DEVICE_CAPABILITY_ENDPOINT_L0S_ACCEPTABLE_LATENCY: This field indicates the acceptable total latency that an Endpoint can withstand due to the transition from L0s state to the L0 state. It is essentially an indirect measure of the Endpoint's internal buffering. • 000b -- Less than 64 ns. • 001b -- 64 ns to less than 128 ns. • 010b -- 128 ns to less than 256 ns. • 011b -- 256 ns to less than 512 ns. • 100b -- 512 ns to less than 1 µs. • 101b -- 1 µs to less than 2 µs. • 110b -- 2 µs-4µs. • 111b -- More than 4 µs. 0h: ENDPOINT_L0S_ACCEPTABLE_LATENCY_INIT (default)
5	None	T_PCIE2_RP_DEVICE_CAPABILITY_EXTENDED_TAG_FIELD_SIZE: This field indicates the maximum supported size of the Tag field. Defined encodings are: 0b = 5-bit Tag field supported. 1b = 8-bit Tag field supported.

Bit	Reset	Description
4:3	0h	T_PCIE2_RP_DEVICE_CAPABILITY_PHANTOM_FUNCTIONS_SUPPORTED: This field indicates the support for use of unclaimed function numbers to extend the number of outstanding transactions allowed by logically combining unclaimed function numbers (called Phantom Functions) with the Tag identifier. This field indicates the number of most significant bits of the function number portion of Requester ID that are logically combined with the Tag identifier. Defined encodings are: • 00b -- No function number bits used for Phantom Functions; device may implement all function numbers. • 01b -- First most significant bit of the function number in Requester ID used for Phantom Functions; device may implement functions 0-3. Functions 0, 1, 2 and 3 may claim functions 4, 5, 6, and 7 as Phantom Functions respectively. • 10b -- First two most significant bits of the function number in Requestor ID used for Phantom Functions; device may implement functions 0-1. Function 0 may claim functions 2, 4 and 6 as Phantom Functions, function 1 may claim functions 3, 5 and 7 as Phantom Functions. • 11b -- All three bits of function number in Requester ID used for Phantom Functions; device must be a single function 0 device that may claim all other functions as Phantom Functions. Note: The Phantom Function support for the device must be enabled by the corresponding control field in the Device Control Register. 0h: PHANTOM_FUNCTIONS_SUPPORTED_INIT (default)
2:0	0h	T_PCIE2_RP_DEVICE_CAPABILITY_MAX_PAYLOAD_SIZE: This field indicates the maximum payload size that the device can support for TLP's. • 000b --128B maximum payload size • 001b -- 256B maximum payload size • 010b -- 512B maximum payload size • 011b -- 1024B maximum payload size • 100b -- 2048B maximum payload size • 101b -- 4096B maximum payload size • 110b -- Reserved • 111b -- Reserved 0h: MAX_PAYLOAD_SIZE_INIT (default)

32.3.5.3 T_PCIE2_RP_DEVICE_CONTROL_STATUS

The Device Control register controls PCI Express device specific parameters. It also provides information about PCI Express device specific parameters.

Device Control and Device Status Registers

Offset: 0x88 | Read/Write: R/W

Bit	R/W	Reset	Description
31:22	R	0	Reserved
21	R	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_TRANSACTIONS_PENDING: This bit when set indicates that a device has issued Non Posted requests which have not been completed. A device reports this bit cleared only when all Completions for any outstanding Non-Posted Requests have been received. 0h: TRANSACTIONS_PENDING_INIT (default)
20	R	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_AUX_POWER_DETECTED: Devices that require AUX power report this bit as set if AUX power is detected by the device. 0h: AUX_POWER_DETECTED_INIT (default)
19	RW1C	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_UNSUPP_REQUEST_DETECTED: This bit indicates that the device received an Unsupported Request. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control Register. NOTE: This field is reset by Cold Reset 0h: UNSUPP_REQUEST_DETECTED_INIT (default) 1h: UNSUPP_REQUEST_DETECTED_SET

Bit	R/W	Reset	Description
18	RW1C	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_FATAL_ERROR_DETECTED: This bit indicates status of fatal errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. For devices supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the correctable error mask register. 0h: FATAL_ERROR_DETECTED_INIT (default) 1h: FATAL_ERROR_DETECTED_SET
17	RW1C	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_NON_FATAL_ERROR_DETECTED: This bit indicates status of non-fatal errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. For devices supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the correctable error mask register. NOTE: This field is reset by Cold Reset 0h: NON_FATAL_ERROR_DETECTED_INIT (default) 1h: NON_FATAL_ERROR_DETECTED_SET
16	RW1C	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_CORR_ERROR_DETECTED: This bit indicates status of correctable errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. For devices supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the correctable error mask register. Default value of this field is 0. NOTE: This field is reset by Cold Reset 0h: CORR_ERROR_DETECTED_INIT (default) 1h: CORR_ERROR_DETECTED_SET
15	R	0	Reserved
14:12	R/W	2h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_MAX_READ_REQUEST_SIZE: This field sets the maximum Read Request size for the Device as a Requester. The Device must not generate read requests with size exceeding the set value. Defined encodings for this field are: 000b -- 128B maximum payload size 001b -- 256B maximum payload size 010b -- 512B maximum payload size 011b -- 1024B maximum payload size 100b -- 2048B maximum payload size 101b -- 4096B maximum payload size 110b -- Reserved 111b – Reserved Devices that do not generate Read Requests larger than 128 bytes are permitted to implement this field as Read Only (RO) with: a value of 000b. 2h: MAX_READ_REQUEST_SIZE_INIT (default)
11	R/W	1h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_ENABLE_NO_SNOOP: If this bit is set to 1, the device is permitted to set the No Snoop Bit in the Requester Attributes of transactions it initiates that do not require hardware enforced cache coherency. Even when this bit is set to 1, a device may only set the No Snoop attribute on a transaction when it can guarantee that the address of the transaction is not stored in any cache in the system. This bit may be hardwired to 0 if a device never sets the No Snoop attribute in transactions it initiates. 1h: ENABLE_NO_SNOOP_INIT (default)
10	R/W	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_AUXILLARY_POWER_PM_ENABLE: This bit when set enables a device to draw AUX power independent of PME AUX power. AUX power is allocated as requested in the AUX_Current field of the Power Management Capabilities Register (PMC), independent of the PME_En bit in the Power Management Control/Status Register (PMCSR). For multi-function devices, a component is allowed to draw AUX power if at least one of the functions has this bit set. Devices that do not implement this capability hardwire this bit to 0. NOTE: This field is reset by Cold Reset 0h: AUXILLARY_POWER_PM_ENABLE_INIT (default)

Bit	R/W	Reset	Description
9	R	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_PHANTOM_FUNCTIONS_ENABLE: When set, this bit enables a device to use unclaimed functions as Phantom Functions to extend the number of outstanding transaction identifiers. If the bit is cleared, the device is not allowed to use Phantom Functions. Devices that do not implement this capability hardwire this bit to 0. 0h: PHANTOM_FUNCTIONS_ENABLE_INIT (default)
8	R/W	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_EXTENDED_TAG_FIELD_ENABLE: When set, this bit enables a device to use an 8-bit Tag field as a requester. If the bit is cleared, the device is restricted to a 5-bit Tag field. Devices that do not implement this capability hardwire this bit to 0. 0h: EXTENDED_TAG_FIELD_ENABLE_INIT (default)
7:5	R/W	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_MAX_PAYLOAD_SIZE: This field sets the maximum TLP payload size for the device. As a receiver, the device must handle TLP's as large as the set value; as transmitter, the device must not generate TLPs exceeding the set value. Permissible values that can be programmed are indicated by the Max_Payload_Size supported in the Device Capabilities register. Defined encodings for this field are: • 000b -- 128B maximum payload size • 001b -- 256B maximum payload size • 010b -- 512B maximum payload size • 011b -- 1024B maximum payload size • 100b -- 2048B maximum payload size • 101b -- 4096B maximum payload size • 110b -- Reserved • 111b -- Reserved 0h: MAX_PAYLOAD_SIZE_INIT (default)
4	R/W	1h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_ENABLE_RELAXED_ORDERING: If this bit is set, the device is permitted to set the Relaxed Ordering bit in the Attributes field of transactions it initiates that do not require strong write ordering. This bit may be hardwired to 0 if a device never sets the Relaxed Ordering Attribute in transactions it initiates as a requester. 1h: ENABLE_RELAXED_ORDERING_INIT (default)
3	R/W	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_UNSUPP_REQ_REPORTING_ENABLE: This bit enables reporting of Unsupported Requests when set. For a multi-function device, this bit controls error reporting for each function from point-of-view of the respective function. Note: The reporting of error messages (ERR_COR, ERR_NONFATAl, ERR_FATAL) received by Root Port is controlled exclusively by Root Control Register. 0h: UNSUPP_REQ_REPORTING_ENABLE_INIT (default)
2	R/W	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_FATAL_ERROR_REPORTING_ENABLE: This bit controls reporting of fatal errors. For a multi-function device, this bit controls error reporting for each function from point-of-view of the respective function. 0h: FATAL_ERROR_REPORTING_ENABLE_INIT (default)
1	R/W	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_NON_FATAL_ERROR_REPORTING_ENABLE: This bit controls reporting of non-fatal errors. For a multi-function device, this bit controls error reporting for each function from point-of-view of the respective function. 0h: NON_FATAL_ERROR_REPORTING_ENABLE_INIT (default)
0	R/W	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_CORR_ERROR_REPORTING_ENABLE: This bit controls reporting of correctable errors. For a multi-function device, this bit controls error reporting for each function from point-of-view of the respective function. 0h: CORR_ERROR_REPORTING_ENABLE_INIT (default)

32.3.5.4 T_PCIE2_RP_LINK_CAPABILITIES

The Link Capabilities Register identifies PCI Express Link specific capabilities.

Link Capabilities Register

Offset: 0x8c | Read/Write: RO

Bit	Reset	Description
31:24	None	T_PCIE2_RP_LINK_CAPABILITIES_PORT_NUMBER: This field indicates the PCI Express port number for the given PCI Express Link.
23:22	None	T_PCIE2_RP_LINK_CAPABILITIES_RESERVED: Reserved.
21	0h	T_PCIE2_RP_LINK_BW_NOTIFY: 0h: INIT (default)
20	1h	T_PCIE2_RP_LINK_CAPABILITIES_LINKACTV_REPORTING: For a Downstream Port, this bit must be set to 1b if the component supports the optional capability of reporting the DL_Active state of the Data Link Control and Management State Machine. For a hot-plug capable Downstream Port (as indicated by the Hot-Plug Capable field of the Slot Capabilities register), this bit must be set to 1b. 1h: LINKACTV_REPORTING_INIT (default)
19	0h	T_PCIE2_RP_LINK_CAPABILITIES_SURPRISE_DOWN_ERPT_CAP: For a Downstream Port, this bit must be set to 1b if the component supports the optional capability of detecting and reporting a Surprise Down error condition. 0h: SURPRISE_DOWN_ERPT_CAP_INIT (default)
18	0h	T_PCIE2_RP_LINK_CAPABILITIES_CLOCK_PM: A value of 1b in this bit indicates that the component tolerates the removal of any reference clock(s) via the "clock request" (CLKREQ#) mechanism when the link is in the L1 and L2/3 Ready link states. A value of 0b indicates the component does not have this capability and that reference clock(s) must not be removed in these link states. This capability is applicable only in form factors that support "clock request" (CLKREQ#) capability. 0h: CLOCK_PM_INIT (default)
17:15	2h	T_PCIE2_RP_LINK_CAPABILITIES_L1_EXIT_LATENCY: This field indicates the L1 exit latency for the given PCI Express Link. The value reported indicates the lenght of time this Port requires to complete transition from L1 to L0. Defined encodings are: • 000b -- Less than 1 µs. • 001b -- 1 µs to less than 2 µs. • 010b -- 2 µs to less than 4 µs. • 011b -- 4 µs to less than 8 µs. • 100b -- 8 µs to less than 16 µs. • 101b -- 16 µs to less than 32 µs. • 110b -- 32 µs-64 µs. • 111b -- More than 64 us. 2h: L1_EXIT_LATENCY_INIT (default)
14:12	3h	T_PCIE2_RP_LINK_CAPABILITIES_L0S_EXIT_LATENCY: This field indicates the L0s exit latency for the given PCI Express Link. The value reported indicates the length of time this Port requires to complete transition from L0s state to L0. Defined encodings are: • 000b -- Less than 64 ns. • 001b -- 64 ns to less than 128 ns. • 010b -- 128 ns to less than 256 ns. • 011b -- 256 ns to less than 512 ns. • 100b -- 512 ns to less than 1 µs. • 101b -- 1 µs to less than 2 µs. • 110b -- 2 µs-4 µs. • 111b -- Reserved. 3h: L0S_EXIT_LATENCY_INIT (default)

Bit	Reset	Description
11:10	11h	T_PCIE2_RP_LINK_CAPABILITIES_ACTIVE_STATE_LINK_PM_SUPPORT: This field indicates the level of active state power management supported on the given PCI Express Link. Defined encodings are: • 00b -- Reserved • 01b -- L0s Entry Supported • 10b -- Reserved • 11b -- L0s and L1 Supported 11h: ACTIVE_STATE_LINK_PM_SUPPORT_INIT (default)
9:4	None	T_PCIE2_RP_LINK_CAPABILITIES_MAX_LINK_WIDTH: This field indicates the maximum width of the given PCI Express Link. Defined encodings are: • 000000b -- Reserved • 000001b -- x1 • 000010b -- x2 • 000100b -- x4 • 001000b -- x8 • 001100b -- x12 • 010000b -- x16 • 100000b -- x32
3:0	1h	T_PCIE2_RP_LINK_CAPABILITIES_MAX_LINK_SPEED: This field indicates the maximum link speed of the given PCI Express Link. Defined encodings are: 0001b = 2.5 Gb/s Link 0010b = 5.0 Gb/s Link All other encodings are reserved. 2h: MAX_LINK_SPEED_INIT (default)

32.3.5.5 T_PCIE2_RP_LINK_CONTROL_STATUS

The Link Control register controls PCI Express Link specific parameters. It also provides information about PCI Express Link specific parameters.

Link Control and Link Status Registers

Offset: 0x90 | Read/Write: R/W

Bit	R/W	Reset	Description
31	RW1C	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_AUTO_BANDWIDTH: NOTE: this field is reset by Cold Reset 0h: AUTO_BANDWIDTH_TRUE (default) 1h: AUTO_BANDWIDTH_FALSE 1h: AUTO_BANDWIDTH_SET
30	RW1C	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_BW_MANAGEMENT: NOTE: this field is reset by Cold Reset 0h: BW_MANAGEMENT_TRUE (default) 1h: BW_MANAGEMENT_FALSE 1h: BW_MANAGEMENT_SET
29	R	None	T_PCIE2_RP_LINK_CONTROL_STATUS_DL_LINK_ACTIVE: This bit indicates the status of the Data Link Control and Management State Machine. It returns a 1b to indicate the DL_Active state, 0b otherwise. This bit must be implemented if the corresponding Data Link Layer Active Capability bit is implemented. Otherwise, this bit must be hardwired to 0b.
28	R	None	T_PCIE2_RP_LINK_CONTROL_STATUS_SLOT_CLOCK_CONFIG: This bit indicates that the component uses the same physical reference clock that the platform provides on the connector. If the device uses an independent clock irrespective of the presence of a reference on the connector, this bit must be clear.
27	R	None	T_PCIE2_RP_LINK_CONTROL_STATUS_LINK_TRAINING: This read-only bit indicates that Link training is in progress; hardware clears this bit once training is complete.

Bit	R/W	Reset	Description
			Note: This field is not applicable and reserved for endpoint devices and Upstream Ports of Switches.
26	R	None	T_PCIE2_RP_LINK_CONTROL_STATUS_UNDEFINED: The value read from this bit is undefined. In previous versions of this specification, this bit was used to indicate a Link Training Error. System software must ignore the value read from this bit. System software is permitted to write any value to this bit.
25:20	R	None	T_PCIE2_RP_LINK_CONTROL_STATUS_NEG_LINK_WIDTH: This field indicates the negotiated width of the given PCI Express Link. Defined encodings are: • 000001b -- x1 • 000010b -- x2 • 000100b -- x4 • 001000b -- x8 • 001100b -- x12 • 010000b -- x16 • 100000b -- x32
19:16	R	1h	T_PCIE2_RP_LINK_CONTROL_STATUS_LINK_SPEED: This field indicates the negotiated Link Speed of the given PCI Express Link. Defined encodings are: 0001b = 2.5 Gb/s PCI Express Link 0010b = 5.0 Gb/s PCI Express Link All other encodings are reserved. 1h: LINK_SPEED_GEN1 (default) 2h: LINK_SPEED_GEN2 (default)
15:12	R	0	Reserved
11	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_AUTO_BANDWIDTH_INT_EN: 0h: AUTO_BANDWIDTH_INT_EN_INIT (default)
10	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_BW_MANAGEMENT_INT_EN: 0h: BW_MANAGEMENT_INT_EN_INIT (default)
9	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_HW_AUTO_WIDTH_DISABLE: 0h: HW_AUTO_WIDTH_DISABLE_DEFAULT (default)
8	R	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_CLOCK_PM: 0h: CLOCK_PM_DEFAULT (default)
7	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_EXTENDED_SYNCH: This bit when set forces extended transmission of FTS ordered sets in FTS and extra TS2 at exit from L1 prior to entering L0. This mode provides external devices monitoring the link time to achieve bit and symbol lock before the link enters L0 state and resumes communication. Default value for this bit is 0. 0h: EXTENDED_SYNCH_INIT (default)
6	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_COMMON_CLOCK_CONFIGURATION: This bit when set indicates that this component and the component at the opposite end of this Link are operating with a distributed common reference clock. A value of 0 indicates that this component and the component at the opposite end of this Link are operating with asynchronous reference clock. Components utilize this common clock configuration information to report the correct L0s and L1 Exit Latencies. 0h: COMMON_CLOCK_CONFIGURATION_INIT (default)
5	R	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_RETRAIN_LINK: This bit initiates Link retraining when set. This field is not applicable and reserved for endpoint devices and Upstream Ports of a Switch. This bit always returns 0 when read. 0h: RETRAIN_LINK_INIT (default)
4	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_LINK_DISABLE: This bit disables the Link when set to 1b. This field is not applicable and reserved for endpoint devices and Upstream Ports of a Switch. Writes to this bit are immediately reflected in the value read from the bit, regardless of the actual Link State. 0h: LINK_DISABLE_INIT (default)
3	R	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_READ_COMPLETION_BOUNDARY: Encodings are:

Bit	R/W	Reset	Description
			0b = 64 byte 1b = 128 byte This field is hardwired for a Root Port and returns its RCB support capabilities. Devices that do not implement this feature must hardwire the field to 0b. This field is R/W for devices other than Root Ports. 0h: READ_COMPLETION_BOUNDARY_INIT (default)
2	R	0	Reserved
1:0	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_ACTIVE_STATE_LINK_PM_CONTROL: This field controls the level of active state PM supported on the given PCI Expres Link. Defined encodings are: • 00b -- Reserved • 01b -- L0s Entry Supported • 10b -- Reserved • 11b -- L0s and L1 Supported 0h: ACTIVE_STATE_LINK_PM_CONTROL_INIT (default)

32.3.5.6 T_PCIE2_RP_SLOT_CAPABILITIES

The Slot Capabilities register identifies PCI Express slot specific capabilities.

Slot Capabilities Register

Offset: 0x94 | Read/Write: RO

Bit	Reset	Description
31:19	None	T_PCIE2_RP_SLOT_CAPABILITIES_PHYSICAL_SLOT_NUMBER: This hardware initialized field indicates the physical slot number attached to this Port. This field must be hardware initialized to a value that assigns a slot number that is globally unique within the chassis. These registers should be initialized to 0 for ports connected to devices that are either integrated on the system board or integrated within the same silicon as the Switch device or Root Port.
18	0h	T_PCIE2_RP_SLOT_CAPABILITIES_NO_CMD_COMPLETED_SUPPORT: When set to 1, this bit indicates that this slot does not generate software notification when an issued command is completed by the Hot Plug Controller. 0h: NO_CMD_COMPLETED_SUPPORT_INIT (default)
17	0h	T_PCIE2_RP_SLOT_CAPABILITIES_ELECTROMECHANICAL_INTERLOCK_PRESENT: Indicates that the ElectroMechanical Interlock mechanism is implemented. 0h: ELECTROMECHANICAL_INTERLOCK_PRESENT_NO (default)
16:15	None	T_PCIE2_RP_SLOT_CAPABILITIES_SLOT_POWER_LIMIT_SCALE: This field Specifies the scale used for the Slot Power Limit Value. Range of values: 00b = 1.0x 01b = 0.1x 10b = 0.01x 11b = 0.001x This field must be implemented if the Slot Implemented bit is set. The default value prior to hardware/firmware initialization is 00b.
14:7	None	T_PCIE2_RP_SLOT_CAPABILITIES_SLOT_POWER_LIMIT_VALUE: In combination with the Slot Power Limit Scale value, this field specifies the upper limit on power supplied by slot. Power limit (in watts) is calculated by multiplying the value in this field by the value in the Slot Power Limit Scale field. This field must be implemented if the Slot Implemented bit is set. The default value prior to hardware/firmware initialization is 0000_0000b.
6	0h	T_PCIE2_RP_SLOT_CAPABILITIES_HOT_PLUG_CAPABLE: This bit when set indicates that this slot is capable of supporting Hot-plug operations. 0h: HOT_PLUG_CAPABLE_NO (default)
5	0h	T_PCIE2_RP_SLOT_CAPABILITIES_HOT_PLUG_SURPRISE: This bit when set indicates that a device present in this slot might be removed from the system without any prior notification.

Bit	Reset	Description
		0h: HOT_PLUG_SURPRISE_NO (default)
4	0h	T_PCIE2_RP_SLOT_CAPABILITIES_POWER_INDICATOR_PRESENT: This bit when set indicates that a Power Indicator is implemented on the chassis for this slot. 0h: POWER_INDICATOR_PRESENT_NO (default)
3	0h	T_PCIE2_RP_SLOT_CAPABILITIES_ATTENTION_INDICATOR_PRESENT: This bit when set indicates that an Attention Indicator is implemented on the chassis for this slot. 0h: ATTENTION_INDICATOR_PRESENT_NO (default)
2	0h	T_PCIE2_RP_SLOT_CAPABILITIES_MRL_SENSOR_PRESENT: This bit when set indicates that an Attention Indicator is implemented on the chassis for this slot. 0h: MRL_SENSOR_PRESENT_NO (default)
1	0h	T_PCIE2_RP_SLOT_CAPABILITIES_POWER_CONTROLLER_PRESENT: This bit when set indicates that a Power Controller is implemented for this slot. 0h: POWER_CONTROLLER_PRESENT_NO (default)
0	0h	T_PCIE2_RP_SLOT_CAPABILITIES_ATTENTION_BUTTON_PRESENT: This bit when set indicates that an Attention Button is implemented on the chassis for this slot. 0h: ATTENTION_BUTTON_PRESENT_NO (default)

32.3.5.7 T_PCIE2_RP_SLOT_CONTROL_STATUS

The Slot Control Register controls PCI Express Slot specific parameters. It also provides information about PCI Express Slot specific parameters.

Slot Control and Slot Status Registers

Offset: 0x98 | Read/Write: R/W

Bit	R/W	Reset	Description
31:25	R	0	Reserved
24	RW1C	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_DL_LAYER_STATE_CHANGED: When set to 1, this field enables software notification when Data Link Layer Active field is changed 0h: DL_LAYER_STATE_CHANGED_INIT (default) 1h: DL_LAYER_STATE_CHANGED_SET
23	R	None	T_PCIE2_RP_SLOT_CONTROL_STATUS_ELECTROMECHANICAL_INTERLOCK_STATE: This bit when set physically locks the add-in card which the user is trying to remove, till software releases it by resetting the bit. Indicates the current state of the interlock, that is, whether the card is electro-mechanically engaged or disengaged 0b : disengaged 1b : engaged Software reads this bit to determine what state the card is in 1h: ELECTROMECHANICAL_INTERLOCK_STATE_YES
22	R	None	T_PCIE2_RP_SLOT_CONTROL_STATUS_PRESENCE_DETECT_STATE: This bit indicates the presence of a card in the slot. The bit reflects the Presence Detect status determined via an in-band mechanism or via the Present Detect pins as defined in the PCI Express Card Electromechanical Specification. Defined encodings are: 0b = Slot Empty. 1b = Card Present in slot. This field is required to be implemented on all Switch devices and Root Ports. The presence detect field for Switch devices or Root Ports not connected to slots should be hardwired to 1. This field is required if a slot is implemented. 1h: PRESENCE_DETECT_STATE_YES
21	R	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_MRL_SENSOR_STATE: This bit reports the status of the MRL sensor if it is implemented. Defined encodings are: 0b = MRL Closed. 1b = MRL Open. 0h: MRL_SENSOR_STATE_INIT (default)
20	RW1C	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_COMMAND_COMPLETED: This bit is set when the hot plug controller completes an issued command.

Bit	R/W	Reset	Description
			0h: COMMAND_COMPLETED_INIT (default) 1h: COMMAND_COMPLETED_SET
19	RW1C	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_PRESENCE_DETECT_CHANGED: This bit is set when a Presence Detect change is detected. 0h: PRESENCE_DETECT_CHANGED_INIT (default) 1h: PRESENCE_DETECT_CHANGED_SET
18	RW1C	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_MRL_SENSOR_CHANGED: This bit is set when a MRL Sensor state change is detected. 0h: MRL_SENSOR_CHANGED_INIT (default) 1h: MRL_SENSOR_CHANGED_SET
17	RW1C	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_POWER_FAULT_DETECTED: This bit is set when the Power Controller detects a power fault at this slot. 0h: POWER_FAULT_DETECTED_INIT (default) 1h: POWER_FAULT_DETECTED_SET
16	RW1C	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_ATTN_BUTTON_PRESSED: This bit is set when the attention button is pressed. 0h: ATTN_BUTTON_PRESSED_INIT (default) 1h: ATTN_BUTTON_PRESSED_SET
15:13	R	0	Reserved
12	R/W	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_DL_LAYER_STATE_CHANGED_ENABLE: This bit is set when the value reported in the Data Link Layer Link Active field of the Link Status register is changed 0h: DL_LAYER_STATE_CHANGED_ENABLE_INIT (default)
11	R	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_ELECTROMECHANICAL_INTERLOCK_CONTROL: indicates that the slot supports electromechanical interlock mechanism 0h: ELECTROMECHANICAL_INTERLOCK_CONTROL_INIT (default)
10	R/W	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_POWER_CONTROLLER_CONTROL: When read this bit returns the current state of the Power applied to the slot; when written sets the power state of the slot per the defined encodings. 0b = Power On. 1b = Power Off. 0h: POWER_CONTROLLER_CONTROL_INIT (default)
9:8	R/W	1h	T_PCIE2_RP_SLOT_CONTROL_STATUS_POWER_INDICATOR_CONTROL: Reads to this bit return the current state of the Power Indicator; writes to this bit set the Power Indicator. 00b = Reserved 01b = On 10b = Blink 11b = Off Writes to this bit also cause the Port to send the appropriate POWER_INDICATOR_* messages. 1h: POWER_INDICATOR_CONTROL_INIT (default)
7:6	R/W	3h	T_PCIE2_RP_SLOT_CONTROL_STATUS_ATTN_INDICATOR_CONTROL: Reads to this field return the current state of the Attention Indicator; writes to this field set the Attention Indicator. Defined encodings are: 00b = Reserved 01b = On 10b = Blink 11b = Off Writes to this field also cause the Port to send the appropriate ATTENTION_INDICATOR_* messages. 3h: ATTN_INDICATOR_CONTROL_INIT (default)
5	R/W	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_HOT_PLUG_INTERRUPT_ENABLE: This bit when set enables generation of hot plug interrupt on enabled hot plug events. 0h: HOT_PLUG_INTERRUPT_ENABLE_INIT (default)
4	R/W	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_COMMAND_COMPLETED_INTERRUPT_ENABLE: This bit when set enables the generation of hot plug interrupt when a command is completed by the Hot plug controller. 0h: COMMAND_COMPLETED_INTERRUPT_ENABLE_INIT (default)

Bit	R/W	Reset	Description
3	R/W	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_PRESENCE_DETECT_CHANGED_ENABLE: This bit when set enables the generation of hot plug interrupt or wake message on a presence detect changed event. 0h: PRESENCE_DETECT_CHANGED_ENABLE_INIT (default)
2	R/W	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_MRL_SENSOR_CHANGED_ENABLE: This bit when set enables the generation of hot plug interrupt or wake message on a MRL sensor changed event. 0h: MRL_SENSOR_CHANGED_ENABLE_INIT (default)
1	R/W	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_POWER_FAULT_DETECTED_ENABLE: This bit when set enables the generation of hot plug interrupt or wake message on a power fault event. 0h: POWER_FAULT_DETECTED_ENABLE_INIT (default)
0	R/W	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_ATTN_BUTTON_PRESSED_ENABLE: This bit when set enables the generation of hot plug interrupt or wake message on an attention button pressed event. 0h: ATTN_BUTTON_PRESSED_ENABLE_INIT (default)

32.3.5.8 T_PCIE2_RP_RCR

The Root Control Register controls PCI Express Root Complex specific parameters. Bit positions 31:4 of this address are reserved.

Root Control Register

Offset: 0x9c | Read/Write: R/W

Bit	R/W	Reset	Description
31:4	R	0	Reserved
3	R/W	0h	T_PCIE2_RP_RCR_PME_INT: The PME_INT bit is enable bit for generating interrupt upon receipt of a PME message as reflected in the PMESTAT bit of Root Status Register. 0h: PME_INT_DIS (default)
2	R/W	0h	T_PCIE2_RP_RCR_SERR_FAT: The SERR_FAT bit is enable bit for generating System Error if a fatal error (ERR_FATAL) is reported by any of the devices in the hierarchy associated with this Root Port, or by the Root Port itself. 0h: SERR_FAT_DIS (default)
1	R/W	0h	T_PCIE2_RP_RCR_SERR_NONFAT: The SERR_NONFAT bit is enable bit for generating System Error if a non-fatal error (ERR_NONFATAL) is reported by any of the devices in the hierarchy associated with this Root Port, or by the Root Port itself. 0h: SERR_NONFAT_DIS (default)
0	R/W	0h	T_PCIE2_RP_RCR_SERR_COR: The SERR_COR bit is enable bit for generating System Error if a correctable error (ERR_COR) is reported by any of the devices in the hierarchy associated with this Root Port, or by the Root Port itself. 0h: SERR_COR_DIS (default)

32.3.5.9 T_PCIE2_RP_RSR

The Root Status Register provides information about PCI Express device specific parameters. Bit positions 31:18 are reserved.

Root Status Register

Offset: 0xA0 | Read/Write: R/W

Bit	R/W	Reset	Description
31:18	R	0	Reserved
17	R	None	T_PCIE2_RP_RSR_PMEPEND: The PMEPEND bit indicates that another PME is pending when the PMESTAT bit is set. When the PMESTAT bit is cleared by software, the PME is delivered by hardware by setting the PMESTAT bit again and updating the REQID appropriately. The PMEPEND bit is cleared by hardware if no more PMEs are pending.
16	RW1C	0h	T_PCIE2_RP_RSR_PMESTAT: The PMESTAT bit indicates that PME was asserted by the requester ID indicated in the PME Requester ID field. Subsequent PMEs are kept pending untill the status register is cleared by software by writing a 1. 0h: PMESTAT_NOT_ACTIVE (default) 1h: PMESTAT_ACTIVE 1h: PMESTAT_SET
15:0	R	None	T_PCIE2_RP_RSR_REQID: The REQID field indicates the PCI requester ID of the last PME requestor.

32.3.5.10 T_PCIE2_RP_DEVICE_CAPABILITIES_2

Offset: 0xA4 | Read/Write: RO

Bit	Reset	Description
31:5	0h	T_PCIE2_RP_DEVICE_CAPABILITIES_2_RESERVED: Unused bits in this register. 0h: RESERVED_0 (default)
4	1h	T_PCIE2_RP_DEVICE_CAPABILITIES_2_CPL_TO_DIS_SUP: Support disabling the completion timeout mechanism. 1h: CPL_TO_DIS_SUP_0 (default)
3:0	3h	T_PCIE2_RP_DEVICE_CAPABILITIES_2_CPL_TO_RANGES_SUP: Completion timeout ranges supported by the Root Port. Ranges A and B are currently supported by the PCIe 2.0 design. 3h: CPL_TO_RANGES_SUP_0 (default)

32.3.5.11 T_PCIE2_RP_DEVICE_CONTROL_STATUS_2

This register is primarily used for Root Port Completion Timeout values. Bits 31:5 are reserved.

Offset: 0xA8 | Read/Write: R/W

Bit	Reset	Description
31:5	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_2_RESERVED: Unused bits in this register. 0h: RESERVED_INIT (default)
4	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_2_CPL_TO_DISABLE: Disables completion timeout, making the Root Port always wait endlessly for a completion to a request. 0h: CPL_TO_DISABLE_DEFAULT (default)

Bit	Reset	Description
3:0	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_2_CPL_TO_VALUE: This field determines the range and hence the timeout values for Completions expected from the endpoint. • Range A: 50 µs to 100 ms (80 µs in design) 1 ms to 10 ms (5 ms in design) • Range B: 16 ms to 55 ms (40 ms in design) 65 ms to 210 ms (140 ms in design) • Default: 50 µs to 50 ms (10 ms in design) Note: When CPL_TO_OVERRIDE is enabled, the value in this field is ignored, and the value in CPL_TO_CUSTOM_VALUE is used. 1h: CPL_TO_VALUE_RANGE_A_LO 2h: CPL_TO_VALUE_RANGE_A_HI 5h: CPL_TO_VALUE_RANGE_B_LO 6h: CPL_TO_VALUE_RANGE_B_HI 0h: CPL_TO_VALUE_DEFAULT (default)

32.3.5.12 T_PCIE2_RP_LINK_CAPABILITIES_2

This is a placeholder register and is hardwired to 0. There are no capabilities that require this register.

Offset: 0xac | Read/Write: RO

Bit	Reset	Description
31:0	0h	T_PCIE2_RP_LINK_CAPABILITIES_2_BITS: 0h: BITS_0

32.3.5.13 T_PCIE2_RP_LINK_CONTROL_STATUS_2

Offset: 0xB0 | Read/Write: R/W

Bit	R/W	Reset	Description
31:17	R	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_2_RESERVED_STATUS: 0h: RESERVED_STATUS_DEFAULT (default)
16	R	None	T_PCIE2_RP_LINK_CONTROL_STATUS_2_CURRENT_DEEMPHASIS_LEVEL: 1h: CURRENT_DEEMPHASIS_LEVEL_3P5 0h: CURRENT_DEEMPHASIS_LEVEL_6
15:13	R	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_2_RESERVED_CONTROL: 0h: RESERVED_CONTROL_DEFAULT (default)
12	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_2_COMPLIANCE_DEEMPHASIS: NOTE: This field is reset by Cold Reset. 0h: COMPLIANCE_DEEMPHASIS_INIT (default)
11	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_2_COMPLIANCE_SOS: NOTE: This field is reset by Cold Reset. 0h: COMPLIANCE_SOS_INIT (default)
10	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_2_ENTER_MODIFIED_COMPLIANCE: When this bit is set to 1, the device transmits the modified compliance pattern if the LTSSM enters Polling. Compliance state. Default value is 0b. NOTE: This field is reset by Cold Reset. 0h: ENTER_MODIFIED_COMPLIANCE_INIT (default)

Bit	R/W	Reset	Description
9:7	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_2_TRANSMIT_MARGIN: This field controls the value of the non-deemphasized voltage level at the transmitter pins. Encodings: 000b: 800-1200mV for full swing and 400-600mV for half-swing 001b-010b: Values must be monotonic with a non-zero slope 011b: 200-400mV for full-swing and 100-200mV for half-swing 100b-111b: reserved Default value is 0b. NOTE: This field is reset by Cold Reset. 0h: TRANSMIT_MARGIN_INIT (default)
6	R	None	T_PCIE2_RP_LINK_CONTROL_STATUS_2_SELECTABLE_DEEMPHASIS: When link is operating at 5GT/s speed, selects the level of de-emphasis. This value is initialized by hardware and/or BIOS. Encodings: 1b: -3.5dB 0b: -6dB Default value is 1b.
5	R	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_2_HW_AUTO_SPEED_DISABLE: Link speed change is disabled if set to 1b. Default value is 0b. 0h: HW_AUTO_SPEED_DISABLE_INIT
4	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_2_ENTER_COMPLIANCE: If set to 1b forces link to enter compliance mode at the speed indicated by Target Link Speed field. Default value is 0b. NOTE: This field is reset by Cold Reset. 0h: ENTER_COMPLIANCE_INIT (default)
3:0	R/W	2h	T_PCIE2_RP_LINK_CONTROL_STATUS_2_TARGET_LINK_SPEED: This field sets an upper limit on the link operational speed by restricting the values advertised in training sequences. Defined encodings: 0001b: 2.5GT/s (Gen1) 0010b: 5GT/s (Gen2) Other encodings are reserved. Default value is 0. NOTE: This field is reset by Cold Reset. 0h: TARGET_LINK_SPEED_GEN2_DIS 1h: TARGET_LINK_SPEED_2P5 2h: TARGET_LINK_SPEED_5P0 (default)

32.3.5.14 T_PCIE2_RP_SLOT_CAPABILITIES_2

This is a placeholder register and is hardwired to 0. There are no capabilities that require this register.

Offset: 0xB4 | Read/Write: RO

Bit	Reset	Description
31:0	0h	T_PCIE2_RP_SLOT_CAPABILITIES_2_BITS: 0h: BITS_0

32.3.5.15 T_PCIE2_RP_SLOT_CONTROL_STATUS_2

This is a placeholder register and is hardwired to 0. There are no capabilities that require this register.

Offset: 0xB8 | Read/Write: RO

Bit	Reset	Description

5	R	1h	T_PCIE2_RP_ERPTCAP_ADV_ERR_CAP_CNTL_ECRC_GEN_CAP: 1h: ECRC_GEN_CAP_TRUE (default)
4:0	R	None	T_PCIE2_RP_ERPTCAP_ADV_ERR_CAP_CNTL_ERR_PTR:

32.3.6.8 T_PCIE2_RP_ERPTCAP_HDR_LOG_DW0

This register is 16 bytes wide. The header is captured such that the fields of the header read by software in the same way the headers are presented in the specification, when the register is read using Dword accesses. Therefore, byte 0 of the header is located in byte 3 of the Header Log register, byte 1 of the header is in the byte 2 of the header Log register, and so forth.

Offset: 0x11C | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	None	T_PCIE2_RP_ERPTCAP_HDR_LOG_DW0_0:

32.3.6.9 T_PCIE2_RP_ERPTCAP_HDR_LOG_DW1

Offset: 0x120 | Read/Write: R

31:0	R	None	T_PCIE2_RP_ERPTCAP_HDR_LOG_DW0_1:

32.3.6.10 T_PCIE2_RP_ERPTCAP_HDR_LOG_DW2

Offset: 0x124 | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	None	T_PCIE2_RP_ERPTCAP_HDR_LOG_DW0_2:

32.3.6.11 T_PCIE2_RP_ERPTCAP_HDR_LOG_DW3

Offset: 0x128 | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	None	T_PCIE2_RP_ERPTCAP_HDR_LOG_DW0_3:

32.3.6.12 T_PCIE2_RP_ERPTCAP_ERR_CMD

This is the Root Error Command register.

Offset: 0x12C | Read/Write: R/W

Bit	R/W	Reset	Description
31:3	R	0	Reserved
2	R/W	0h	T_PCIE2_RP_ERPTCAP_ERR_CMD_FATAL_ERR_RPT_EN: 0h: FATAL_ERR_RPT_EN_FALSE (default) 1h: FATAL_ERR_RPT_EN_TRUE
1	R/W	0h	T_PCIE2_RP_ERPTCAP_ERR_CMD_NONFATAL_ERR_RPT_EN: 0h: NONFATAL_ERR_RPT_EN_FALSE (default) 1h: NONFATAL_ERR_RPT_EN_TRUE
0	R/W	0h	T_PCIE2_RP_ERPTCAP_ERR_CMD_COR_ERR_RPT_EN: 0h: COR_ERR_RPT_EN_FALSE (default) 1h: COR_ERR_RPT_EN_TRUE

32.3.6.13 T_PCIE2_RP_ERPTCAP_ERR_STS

This is the Root Error Status register.

Offset: 0x130 | Read/Write: R/W

Bit	R/W	Reset	Description
31:27	R	None	T_PCIE2_RP_ERPTCAP_ERR_STS_ADV_ERR_INTR_MSG_NUM: If this function is allocated more than one MSI interrupt number, this register is required to contain the offset between the base message data and the MSI message that is generated when any of the status bits of this capacbility are set. Hardware is required to update this field so that it is correct if the number of MSI messages assigned to the device changes. 1h: ADV_ERR_INTR_MSG_NUM_ONE
26:7	R/W	0	Reserved
6	RW1C	0h	T_PCIE2_RP_ERPTCAP_ERR_STS_FATAL_RCVD: Set when one or more fatal uncorrectable error messages have been received. NOTE: this field is reset by Cold Reset 0h: FATAL_RCVD_FALSE (default) 1h: FATAL_RCVD_TRUE 1h: FATAL_RCVD_CLEAR

Bit	R/W	Reset	Description
5	RW1C	0h	T_PCIE2_RP_ERPTCAP_ERR_STS_NONFATAL_RCVD: Set when one or more non-fatal uncorrectable error messages have been received. NOTE: this field is reset by Cold Reset 0h: NONFATAL_RCVD_FALSE (default) 1h: NONFATAL_RCVD_TRUE 1h: NONFATAL_RCVD_CLEAR
4	RW1C	0h	T_PCIE2_RP_ERPTCAP_ERR_STS_FIRST_FATAL_RCVD: Set when the first uncorrectable error message received is for a fatal error. NOTE: this field is reset by Cold Reset 0h: FIRST_FATAL_RCVD_FALSE (default) 1h: FIRST_FATAL_RCVD_TRUE 1h: FIRST_FATAL_RCVD_CLEAR
3	RW1C	0h	T_PCIE2_RP_ERPTCAP_ERR_STS_MULT_UNCOR_RCVD: Set when either a fatal or a non-fatal error is received and UNCOR_RCVD is already set. NOTE: this field is reset by Cold Reset 0h: MULT_UNCOR_RCVD_FALSE (default) 1h: MULT_UNCOR_RCVD_TRUE 1h: MULT_UNCOR_RCVD_CLEAR
2	RW1C	0h	T_PCIE2_RP_ERPTCAP_ERR_STS_UNCOR_RCVD: Set when either a fatal or a non-fatal error message is received and this bit is not already set. NOTE: this field is reset by Cold Reset 0h: UNCOR_RCVD_FALSE (default) 1h: UNCOR_RCVD_TRUE 1h: UNCOR_RCVD_CLEAR
1	RW1C	0h	T_PCIE2_RP_ERPTCAP_ERR_STS_MULT_COR_RCVD: Set when a correctable error message is received and COR_RCVD is already set. NOTE: this field is reset by Cold Reset 0h: MULT_COR_RCVD_FALSE (default) 1h: MULT_COR_RCVD_TRUE 1h: MULT_COR_RCVD_CLEAR
0	RW1C	0h	T_PCIE2_RP_ERPTCAP_ERR_STS_COR_RCVD: Set when a correctable error message is received and this bit is not already set. NOTE: this field is reset by Cold Reset 0h: COR_RCVD_FALSE (default) 1h: COR_RCVD_TRUE 1h: COR_RCVD_CLEAR

32.3.6.14 T_PCIE2_RP_ERPTCAP_ERR_ID

This is the Error Source Identification register. This register identifies the source (Requestor ID) of first correctable and uncorrectable (non-fatal/fatal) errors reported in the Root Error Status register.

Offset: 0x134 | Read/Write: R

Bit	R/W	Reset	Description
31:16	R	None	T_PCIE2_RP_ERPTCAP_ERR_ID_ERR_COR: 0h: ERR_COR_DEFAULT (default)
15:0	R	None	T_PCIE2_RP_ERPTCAP_ERR_ID_ERR_UNCOR: 0h: ERR_UNCOR_DEFAULT (default)

32.3.6.15 T_PCIE2_RP_PRIV_XP_DL_0

The T_PCIE2_RP_PRIV_XP_DL_0 register controls various configurable registers in the Data Link layer.

Offset: 0x494 | Read/Write: R/W

Bit	R/W	Reset	Description
31:30	R	0	Reserved
29:19	R/W	0h	T_PCIE2_RP_PRIV_XP_DL_0_GEN2_REPLAY_TIMER_LIMIT: Setting this field to a non-zero value will cause the DL to use the programmed value as the replay timer limit instead of the default value which is based on the negotiated width as described in section 3.5.2.1 of the PCI Express Base Specification, Rev 1.0a. The replay timer limit corresponds to the Unadjusted Replay Transmission Latency Limit listed in table 3-4 of the specification, except that it should include the Rx_L0s_Adjustment. This field takes effect in 5.0GT/s speed of operation when T_PCIE2_RP_PRIV_XP_DL_1_GEN2_DL_TIMERS_DISABLE is programmed to 0. It has no effect when T_PCIE2_RP_PRIV_XP_DL_1_GEN2_DL_TIMERS_DISABLE is programmed to 1. 0h: GEN2_REPLAY_TIMER_LIMIT_INIT (default)
18.10	R/W	0h	T_PCIE2_RP_PRIV_XP_DL_0_GEN2_ACK_TIMER_LIMIT: Setting this field to a non-zero value will cause the DL to use the programmed value as the ack timer limit instead of the default value which is based on the negotiated width as described in section 3.5.3.1 of the PCI Express Base Specification, Rev 1.0a. The ack timer limit corresponds to the Unadjusted Ack Transmission Latency Limit listed in table 3-5 of the specification, except that it should include the Tx_L0s_Adjustment, and should *not* include the Internal Delay. This field takes effect in 5.0GT/s speed of operation when T_PCIE2_RP_PRIV_XP_DL_1_GEN2_DL_TIMERS_DISABLE is programmed to 0. It has no effect when T_PCIE2_RP_PRIV_XP_DL_1_GEN2_DL_TIMERS_DISABLE is programmed to 1. 0h: GEN2_ACK_TIMER_LIMIT_INIT (default)
9:1	R/W	0h	T_PCIE2_RP_PRIV_XP_DL_0_GEN2_UPDATE_FC_THRESHOLD: Setting this field to a non-zero value will cause the DL to use the programmed value as the update fc frequency instead of the default value which is based on the negotiated width as described in section 2.6.1.2 of the PCI Express Base Specification, Rev 2.0. This field takes effect in 5.0GT/s speed of operation when T_PCIE2_RP_PRIV_XP_DL_1_GEN2_DL_TIMERS_DISABLE is programmed to 0. It has no effect when T_PCIE2_RP_PRIV_XP_DL_1_GEN2_DL_TIMERS_DISABLE is programmed to 1. 0h: GEN2_UPDATE_FC_THRESHOLD_INIT (default)
0	R/W	0	T_PCIE2_RP_PRIV_XP_DL_0_GEN2_DL_TIMERS_DISABLE: Setting this field enables the Gen2 DL timer settings to take effect in 5.0GT/s speed of operation. 0h: GEN2_DL_TIMERS_DISABLE_INIT (default)

32.3.6.16 T_PCIE2_RP_PIPE_CTL

This register controls (enabling /disabling) the pipelines added to meet timing on various interfaces. A value of 0 disable the extra pipeline.

Offset: 0xD5C | Read/Write: R/W

Bit	R/W	Reset	Description
31:9	R	0	Reserved
8	R/W	1h	T_PCIE2_RP_PIPE_CTL_UFA2WRR_PWTOP: 1h: UFA2WRR_PWTOP_INIT (default)
7	R/W	1h	T_PCIE2_RP_PIPE_CTL_UBFI2DFI_P2P: 1h: UBFI2DFI_P2P_INIT (default)
6	R/W	1h	T_PCIE2_RP_PIPE_CTL_TXBA2DFI_WR: 1h: TXBA2DFI_WR_INIT (default)
5	R/W	1h	T_PCIE2_RP_PIPE_CTL_CMDQ2UFARB: 1h: CMDQ2UFARB_INIT (default)
4	R/W	1h	T_PCIE2_RP_PIPE_CTL_UBFI2DFI_NTT: 1h: UBFI2DFI_NTT_INIT (default)

Bit	R/W	Reset	Description
3	R/W	1h	T_PCIE2_RP_PIPE_CTL_PCA: 1h: PCA_INIT (default)
2	R/W	1h	T_PCIE2_RP_PIPE_CTL_DFIREQ: 1h: DFIREQ_INIT (default)
1	R/W	1h	T_PCIE2_RP_PIPE_CTL_DFIRSP: 1h: DFIRSP_INIT (default)
0	R/W	1h	T_PCIE2_RP_PIPE_CTL_DFI2UBFI: 1h: DFI2UBFI_INIT (default)

32.3.7 Vendor-Defined Registers

32.3.7.1 T_PCIE2_RP_RX_HDR_LIMIT

These register defines the upstream header logical partition sizes. These buffers reside in UBFI. RXL provides the write interface. The buffers constitute asynchronous boundary of xclk -> ufpci_clk.

Offset: 0xE00 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R	0	Reserved
23:16	R/W	0h	T_PCIE2_RP_RX_HDR_LIMIT_CPL: Programs the size of the Completion Header Buffer. This field must be programmed with an even value. 0h: CPL_INIT (default)
15:8	R/W	0h	T_PCIE2_RP_RX_HDR_LIMIT_PW: Programs the size of the Posted Write Header Buffer. When ISO PWs are enabled, this field must be halved, and programmed before both ufpci_reset_ and xreset_. This field must be programmed with an even value. 0h: PW_INIT (default)
7:0	R/W	0h	T_PCIE2_RP_RX_HDR_LIMIT_NP: Programs the size of the Non-Posted (Read and Write) Header Buffer. When ISO NPs are enabled, this field must be halved, and programmed before both ufpci_reset_ and xreset_. This field must be programmed with an even value. 0h: NP_INIT (default)

32.3.7.2 T_PCIE2_RP_RX_DATA_LIMIT

These buffers reside in UBFI. RXL provides the write interface. The buffers constitute asynchronous boundary of xclk -> ufpci_clk.

Offset: 0xE04 | Read/Write: R/W

Bit	R/W	Reset	Description
31:28	R	0	Reserved
27:20	R/W	0h	T_PCIE2_RP_RX_DATA_LIMIT_CPL: Programs the size of the Completions Data Buffer. This field must be programmed with an even value. 0h: CPL_INIT (default)

Bit	R/W	Reset	Description
19:8	R/W	0h	T_PCIE2_RP_RX_DATA_LIMIT_PW: Programs the size of the Posted Writes Data Buffer. When ISO PWs are enabled, this field must be halved, and programmed before both ufpci_reset_ and xreset_. This field must be programmed with an even value. 0h: PW_INIT (default)
7:0	R/W	0h	T_PCIE2_RP_RX_DATA_LIMIT_NP: Programs the size of the Non-Posted Write Header Buffer. This field must be programmed with an even value. 0h: NP_INIT (default)

32.3.7.3 T_PCIE2_RP_TX_HDR_LIMIT

These buffers reside in TXBA. DFI provides the write interface. These buffers constitute an asynchronous boundary of dfpci_clk -> xclk.

Offset: 0xE08 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R	0	Reserved
23:16	R/W	0h	T_PCIE2_RP_TX_HDR_LIMIT_NP: Programs the size of the downstream Non Posted Header Buffer. This should be programmed with the same value as TX_DATA_LIMIT_NP. 0h: NP_INIT (default)
15:8	R/W	0h	T_PCIE2_RP_TX_HDR_LIMIT_PW: Programs the size of the downstream Posted Writes Header Buffer. 0h: PW_INIT (default
7:0	R/W	0h	T_PCIE2_RP_TX_HDR_LIMIT_NP: Programs the size of the downstream Non Posted Header Buffer. This should be programmed with the same value as TX_DATA_LIMIT_NP. 0h: NP_INIT (default)

32.3.7.4 T_PCIE2_RP_TX_DATA_LIMIT

These buffers reside in TXBA. DFI provides the write interface. These buffers constitute an asynchronous boundary of dfpci_clk -> xclk.

Offset: 0xE0C | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R	0	Reserved
15:8	R/W	0h	T_PCIE2_RP_TX_DATA_LIMIT_PW: Programs the size of the downstream Posted Writes Data Buffer. 0h: PW_INIT (default)
7:0	R/W	0h	T_PCIE2_RP_TX_DATA_LIMIT_NP: Programs the size of the downstream Non Posted Data Buffer. This should be programmed with same value as TX_HDR_LIMIT_NP. 0h: NP_INIT (default)

32.3.7.5 T_PCIE2_RP_UFPCI

This register controls upstream FPCI control and arbitration in UBFI and performance fields.

Offset: 0xE10 | Read/Write: R/W

Bit	R/W	Reset	Description
31:28	R	0	Reserved
27:23	R/W	0h	T_PCIE2_RP_UFPCI_ISO_WEIGHT: 0h: ISO_WEIGHT_INIT (default)
22	R/W	0h	T_PCIE2_RP_UFPCI_ISO_CONTROL_ENABLE: 0h: ISO_CONTROL_ENABLE_INIT (default)
21	R/W	0h	T_PCIE2_RP_UFPCI_ISOPW2HPISO: If set, converts posted writes with TC >= tc2isomap to HP_ISO writes instead of ISO writes. 0h: ISOPW2HPISO_INIT (default)
20	R/W	0h	T_PCIE2_RP_UFPCI_ISONP2HPISO: If set, converts nonposted reads with TC >= tc2isomap to HP_ISO reads instead of ISO reads. 0h: ISONP2HPISO_INIT (default)
19:12	R/W	0h	T_PCIE2_RP_UFPCI_REQ_PEND_PERIOD: The following timers are reset when they hit the value in REQ_PEND_PERIOD 1. noniso_timer - feeds into tms*2sm_iso_pending if system_stutter is supported 2. iso_timer - feeds into tms*2sm_noniso_pending if system_stutter is supported 3. coh_timer - feeds into tms*2sm_coh_request_pend 4. noncoh_timer - feeds into tms*2sm_noncoh_request_pend 0h: REQ_PEND_PERIOD_INIT (default)
11:10	R/W	1h	T_PCIE2_RP_UFPCI_WRR_GRANT_BURST: This field controls the length of time for which a particular controller gets arbitration within a TMS. It relates to time multiplexed inter-TMS arbitration for controllers within a TMS. 1h: WRR_GRANT_BURST_INIT (default)
9:5	R/W	0h	T_PCIE2_RP_UFPCI_PW_PRI_OVR_COUNT: If a posted write has received this number of grants when the priority was swapped to posted write, its priority will be reset. 0h: PW_PRI_OVR_COUNT_INIT (default)
4:0	R/W	0h	T_PCIE2_RP_UFPCI_PW_STARV_COUNT: If an NP has received this number of grants over a posted write while there are posted writes pending, then swap the priority to the posted write. 0h: PW_STARV_COUNT_INIT (default)

32.3.7.6 T_PCIE2_RP_MISC0

This register controls miscellaneous fields.

Offset: 0xE14 | Read/Write: R/W

Bit	R/W	Reset	Description
31	R/W	0h	T_PCIE2_RP_MISC0_SHORT_RXL_TIMER: This bit is used for simulations only, to test the completion timeout feature in RXL. It shortens the wait period for a completion to 1 µs. 0h: SHORT_RXL_TIMER_INIT (default)
30	R/W	0h	T_PCIE2_RP_MISC0_P2P_SMALL_ISA_HOLE: When set, this bit controls the peer2peer settings on address ranges 64'hA_0000 to 64'hF_FFFF. It is used to omit address ranges A, B, C, D, E and F from being peer2peer. 0h: P2P_SMALL_ISA_HOLE_INIT (default)

Bit	R/W	Reset	Description
29	R/W	0h	T_PCIE2_RP_MISC0_P2P_F: If 0 and P2P_SMALL_ISA_HOLE=1, all transactions falling within ranges 64'hF_0000 and 64'hF_FFFF will have the fpci2ufa_cmd_peer2peer bit equal to 0. Else the fpci2ufa_cmd_peer2peer bit will be set according to TOM1 and TOM2 registers. 0h: P2P_F_INIT (default)
28	R/W	0h	T_PCIE2_RP_MISC0_P2P_E: If 0 and P2P_SMALL_ISA_HOLE=1, all transactions falling within ranges 64'hE_0000 and 64'hE_FFFF will have the fpci2ufa_cmd_peer2peer bit equal to 0. Else the fpci2ufa_cmd_peer2peer bit will be set according to TOM1 and TOM2 registers. 0h: P2P_E_INIT (default)
27	R/W	0h	T_PCIE2_RP_MISC0_P2P_D: If 0 and P2P_SMALL_ISA_HOLE=1, all transactions falling within ranges 64'hD_0000 and 64'hD_FFFF will have the fpci2ufa_cmd_peer2peer bit equal to 0. Else the fpci2ufa_cmd_peer2peer bit will be set according to TOM1 and TOM2 registers. 0h: P2P_D_INIT (default)
26	R/W	0h	T_PCIE2_RP_MISC0_P2P_C: If 0 and P2P_SMALL_ISA_HOLE=1, all transactions falling within ranges 64'hC_0000 and 64'hC_FFFF will have the fpci2ufa_cmd_peer2peer bit equal to 0. Else the fpci2ufa_cmd_peer2peer bit will be set according to TOM1 and TOM2 registers. 0h: P2P_C_INIT (default)
25	R/W	0h	T_PCIE2_RP_MISC0_P2P_B: If 0 and P2P_SMALL_ISA_HOLE=1, all transactions falling within ranges 64'hB_0000 and 64'hB_FFFF will have the fpci2ufa_cmd_peer2peer bit equal to 0. Else the fpci2ufa_cmd_peer2peer bit will be set according to TOM1 and TOM2 registers. 0h: P2P_B_INIT (default)
24	R/W	0h	T_PCIE2_RP_MISC0_P2P_A: If 0 and P2P_SMALL_ISA_HOLE=1, all transactions falling within ranges 64'hA_0000 and 64'hA_FFFF will have the fpci2ufa_cmd_peer2peer bit equal to 0. Else the fpci2ufa_cmd_peer2peer bit will be set according to TOM1 and TOM2 registers. 0h: P2P_A_INIT (default)
23	R/W	0h	T_PCIE2_RP_MISC0_NISONC2HPISO: When set, all upstream Noniso, Non-coherent, Non-peer2peer reads will be upgraded to HPISO Reads. This upgrade is available for all controllers in a TMS if any one of the controllers has iso buffers. 0h: NISONC2HPISO_INIT (default)
22	R	0	Reserved
21	R/W	1h	T_PCIE2_RP_MISC0_AUTO_XCLK_FREQ_EN: When set, the xclk for a TMS will switch dynamically (by hardware itself) between 250 and 500. 250: if all root ports in that TMS are in Gen1. 500: If any root port in that TMS is in Gen2. This bit is valid only for Root Port 0 of that TMS, and don't care for others. 1h: AUTO_XCLK_FREQ_EN_INIT (default)
20	R/W	0h	T_PCIE2_RP_MISC0_RXL_CLEAR_DROP: Clears the DROP ALL status of the receiver. DROP ALL occurs on fatal errors such as Receiver Overflow and Malformed TLPs. Once set, RXL will not allow any other transactions upstream. 0h: RXL_CLEAR_DROP_INIT (default)
19:4	R/W	FFh	T_PCIE2_RP_MISC0_P2P_BURST_SIZE: Unused/unconnected. FFh: P2P_BURST_SIZE_INIT (default)
3	R/W	0h	T_PCIE2_RP_MISC0_ISO_PW_ENABLE: Enables ISO posted write transactions for packets with TC >= TC2ISOMAP, on controllers that have iso buffers. 0h: ISO_PW_ENABLE_INIT (default)

Bit	R/W	Reset	Description
2	R/W	1h	T_PCIE2_RP_MISC0_ISO_NP_ENABLE: Enables ISO NP transactions for packets with TC >= TC2ISOMAP, on controllers that have iso buffers. 0h: ISO_NP_ENABLE_INIT (default)
1	R/W	0h	T_PCIE2_RP_MISC0_NATIVE_P2P_ENABLE: Enables native peer2peer transactions on controllers that support it. Posted Write peer2peer transactions will use a shortcut through the design to enable high performance peer2peer accesses. 0h: NATIVE_P2P_ENABLE_INIT (default)
0	R/W	0h	T_PCIE2_RP_MISC0_ENABLE_CLUMPING: When set, enables unitid clumping on controllers that support it. Controllers that support unitid clumping will resort to using its unitid+1 and an additional 32 source tags when it has exhausted its allotted use of first 32 source tags. 0h: ENABLE_CLUMPING_INIT (default)

32.3.7.7 T_PCIE2_RP_TXBA0

This register is specific to the TXBA sub-unit in PCIe 2.0 and controls:

- Replay buffer limits
- Completion merging limits
- Replay timer control fields

Offset: 0xE18 | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R/W	0h	T_PCIE2_RP_TXBA0_REPLAY_TIMER_EXPIRY: When TXBA0_USE_REPLAY_TIMER_OFFSET is 1, the value programmed into TXBA0_REPLAY_TIMER_EXPIRY is added to the replay timer that hardware calculates. When this bit is 0, the value in TXBA0_REPLAY_TIMER_EXPIRY is selected (if its non-zero) instead of the hardware value. 0h: REPLAY_TIMER_EXPIRY_INIT (default)
15:13	R	0	Reserved
12	R/W	0h	T_PCIE2_RP_TXBA0_USE_REPLAY_TIMER_OFFSET: 0h: USE_REPLAY_TIMER_OFFSET_INIT (default)
11	R/W	0h	T_PCIE2_RP_TXBA0_CMPL_MERGE_UPTO_64DW: Similar to above field, but the upper limit is 64 DW. When neither 32DW/64DW is set, nor completion merging is enabled, maximum merging supported is 128DW. 0h: CMPL_MERGE_UPTO_64DW_INIT (default)
10	R/W	0h	T_PCIE2_RP_TXBA0_CMPL_MERGE_UPTO_32DW: When set, split completions that have payloads up to 32 DWs will be merged. Completions that belong to the same read request, but have payloads greater than 32 DWs will have one fragment merged up to 32 DWs, in addition to one or more packets containing the rest of the payload (which will also be merged using the same rule). 0h: CMPL_MERGE_UPTO_32DW_INIT (default)
9	R/W	1h	T_PCIE2_RP_TXBA0_CMPL_MERGE_DISABLE: Disables completion merging. By default, completion merging is disabled. 1h: CMPL_MERGE_DISABLE_INIT (default)
8:0	R/W	0h	T_PCIE2_RP_TXBA0_REPLAY_BUF_LIMIT: This field exists per controller. It decides how much of the replay buffer (which is shared among all the controllers in a TMS) is used for the controller. The range of values can be anything from 0 (when controller is disabled) to full depth of the replay buffer size (when there are no other controllers). 0h: REPLAY_BUF_LIMIT_INIT (default)

32.3.7.8 T_PCIE2_RP_TXBA1

This register is specific to the TXBA sub-unit in PCIe 2.0.It controls:

- Replay buffer limits
- Completion merging limits
- Replay timer control fields

Offset: 0xE1C | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R	0	Reserved
15:8	R/W	0	T_PCIE2_RP_TXBA1_CMPL_MERGE_THRESHOLD: Completion merging is enabled only if the number of valid completions exceeds this programmed register. This is used to control the bandwidth vs. latency consideration. The maximum meaningful value of this field is the maximum number of outstanding completions (which is also size of header buffer allocated to the controller). 0h: CMPL_MERGE_THRESHOLD_INIT (default)
7:4	R/W	4h	T_PCIE2_RP_TXBA1_CM_OVER_PW_BURST: This field and the PW_OVER_CM_BURST field are input into the downstream arbiter. If there are several downstream posted writes and downstream Completion Merges (CMs), the TXBA arbiter runs PW_OVER_CM_BURST many posted writes before switching to CM. Once the arbiter starts running completions, it runs CM_OVER_PW_BURST completions before switching back to posted writes. 4h: CM_OVER_PW_BURST_INIT (default)
3:0	R	4h	T_PCIE2_RP_TXBA1_PW_OVER_CM_BURST: This field and the CM_OVER_PW_BURST field are inputs into the downstream arbiter. If there are several downstream posted writes and downstream CMs, the TXBA arbiter runs PW_OVER_CM_BURST many posted writes before switching to CM. Once the arbiter starts running completions, it runs CM_OVER_PW_BURST completions before switching back to PW. 4h: PW_OVER_CM_BURST_INIT (default)

32.3.7.9 T_PCIE2_RP_FORCEFC

This register updates FC priority flip threshold. Updated FCs become high priority (equivalent priority to UpdateFC timer expiring) if the number of outstanding credits to return for each type exceeds the set threshold.

If the threshold is set to 0, this feature is disabled.

Offset: 0xE20 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	0h	T_PCIE2_RP_FORCEFC_NPD_UNRET_THRESH: 0h: NPD_UNRET_THRESH_INIT (default)
23:16	R/W	0h	T_PCIE2_RP_FORCEFC_NPH_UNRET_THRESH: 0h: NPH_UNRET_THRESH_INIT (default)
15:8	R/W	0h	T_PCIE2_RP_FORCEFC_PWD_UNRET_THRESH: 0h: PWD_UNRET_THRESH_INIT (default)
7:0	R/W	0h	T_PCIE2_RP_FORCEFC_PWH_UNRET_THRESH: 0h: PWH_UNRET_THRESH_INIT (default)

32.3.7.10 T_PCIE2_RP_TIMEOUT0

This is the LINK LTSSM Timeout 0 register.

Note: The value of this register is correct only for the default frequency of clk25m. If the clk25m frequency is changed, then software is responsible for changing the value of this register.

Offset: 0xE24 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	7h	T_PCIE2_RP_TIMEOUT0_PAD_SPDCHNG_GEN2: Amount of time to wait for pads to change speed from Gen1 to Gen2. Measured in units of clk25m clock periods. Default value is 7 (~500 ns).. 7h: PAD_SPDCHNG_GEN2_INIT (default) 7h: PAD_PWRUP_GEN2_12MHZ_CLK25M 7h: PAD_PWRUP_GEN2_13MHZ_CLK25M 9h: PAD_PWRUP_GEN2_16_8MHZ_CLK25M Ah: PAD_PWRUP_GEN2_19_2MHZ_CLK25M Dh: PAD_PWRUP_GEN2_24MHZ_CLK25M Eh: PAD_PWRUP_GEN2_26MHZ_CLK25M
23:8	R/W	F0h	T_PCIE2_RP_TIMEOUT0_PAD_PWRUP_CM: Amount of time to wait for pads to power up (e.g., L1 wake) if common-mode voltage was not maintained during power down (i.e., L1P). Measured in units of clk25m clock periods. Default value is 0xF0 (~20 µs). F0h: PAD_PWRUP_CM_INIT (default) F0h: PAD_PWRUP_CM_12MHZ_CLK25M 104h: PAD_PWRUP_CM_13MHZ_CLK25M 150h: PAD_PWRUP_CM_16_8MHZ_CLK25M 180h: PAD_PWRUP_CM_19_2MHZ_CLK25M 1E0h: PAD_PWRUP_CM_24MHZ_CLK25M 208h: PAD_PWRUP_CM_26MHZ_CLK25M
7:0	R/W	7h	T_PCIE2_RP_TIMEOUT0_PAD_PWRUP: Amount of time to wait for pads to power up (e.g., L1 wake) if common-mode voltage was maintained during power down (i.e., L1). Measured in units of clk25m clock periods (83 ns when using a 12 MHz clk25m clock). Default value is 7 (~500 ns).. 7h: PAD_PWRUP_INIT (default) 7h: PAD_PWRUP_12MHZ_CLK25M 7h: PAD_PWRUP_13MHZ_CLK25M 9h: PAD_PWRUP_16_8MHZ_CLK25M Ah: PAD_PWRUP_19_2MHZ_CLK25M Dh: PAD_PWRUP_24MHZ_CLK25M Eh: PAD_PWRUP_26MHZ_CLK25M

32.3.7.11 T_PCIE2_RP_TIMEOUT1

This is the LINK LTSSM Timeout 1 register.

Offset: 0xE28 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	49h	T_PCIE2_RP_TIMEOUT1_RCVRY_SPD_UNSUCCESS_EIDLE: Amount of time to wait in E-Idle after an unsuccessful speed change. Measured in units of clk25m clock periods (83 ns when using a 12 MHz clock). Note: This value is correct only for the default frequency of clk25m. If the clk25m frequency is changed, then software is responsible for changing the value of this field. 49h: RCVRY_SPD_UNSUCCESS_EIDLE_INIT (default) 49h: UNSUCCESS_EIDLE_12MHZ_CLK25M 4Eh: UNSUCCESS_EIDLE_13MHZ_CLK25M 65h: UNSUCCESS_EIDLE_16_8MHZ_CLK25M 74h: UNSUCCESS_EIDLE_19_2MHZ_CLK25M 91h: UNSUCCESS_EIDLE_24MHZ_CLK25M 9Dh: UNSUCCESS_EIDLE_26MHZ_CLK25M

Bit	R/W	Reset	Description
23:16	R/W	Ah	T_PCIE2_RP_TIMEOUT1_RCVRY_SPD_SUCCESS_EIDLE: Amount of time to wait in E-Idle after a successful speed change. Measured in units of clk25m clock periods. Note: This value is correct only for the default frequency of clk25m. If the clk25m frequency is changed, then software is responsible for changing the value of this field. Ah: RCVRY_SPD_SUCCESS_EIDLE_INIT (default) Ah: SUCCESS_EIDLE_12MHZ_CLK25M Bh: SUCCESS_EIDLE_13MHZ_CLK25M Eh: SUCCESS_EIDLE_16_8MHZ_CLK25M 10h: SUCCESS_EIDLE_19_2MHZ_CLK25M 14h: SUCCESS_EIDLE_24MHZ_CLK25M 15h: SUCCESS_EIDLE_26MHZ_CLK25M
15:0	R/W	2E8h	T_PCIE2_RP_TIMEOUT1_PAD_SPDCHNG_GEN1: Amount of time to wait for pads to change speed from Gen2 to Gen1. Measured in units of 1 µs. 2E8h: PAD_SPDCHNG_GEN1_INIT (default)

32.3.7.12 T_PCIE2_RP_PRBS

This is the PRBS Results register.

Offset: 0xE34 | Read/Write: R

Bit	R/W	Reset	Description
31:16	R	None	T_PCIE2_RP_PRBS_LOCKED: Each bit indicates that particular lane has locked onto the incoming PRBS pattern and is beginning to count bit errors. For example, if LOCKED[n] is set, lane n has successfully locked onto the incoming PRBS pattern.
15:0	R	None	T_PCIE2_RP_PRBS_ERR_COUNT_OVERFLOW: Each bit indicates number of bit mismatches during PRBS run exceeded 65K for that particular lane. For example, if ERR_COUNT_OVERFLOW[n] is set, lane n registers > 65K bit mismatches.

32.3.7.13 T_PCIE2_RP_PRBS_ERR_COUNT

This is the PRBS Results register.

Offset: 0xE38 | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R	0h	T_PCIE2_RP_LANE_PRBS_ERR_COUNT: Number of bit errors detected in the incoming PRBS stream after achieving PRBS lock for the selected lane programmed in ERR_SELECT register.
15:4	R	0	Reserved
3:0	R/W	0h	T_PCIE2_RP_LANE_PRBS_ERR_SELECT: Selects which lane number's Error Count shows up in the ERR_COUNT register 0h: SELECT_INIT (default)

32.3.7.14 T_PCIE2_RP_EIDLE_INFER_TO_0

This is an EIDLE inference timeout register.

Offset: 0xE3C | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R/W	500h	T_PCIE2_RP_EIDLE_INFER_TO_0_RCVRCFG_SUC_SPEED: Infer E-Idle after this amount of time while in Recovery.RcvrCfg or Recovery. Speed and successful_speed_negotiation = 1. Measured in units of UI (Rx symbol times). 500h: RCVRCFG_SUC_SPEED_INIT (default)
15:0	R/W	80h	T_PCIE2_RP_EIDLE_INFER_TO_0_L0_LPBK: Infer E-Idle after this amount of time while in L0 or Loopback. Active Slave. Measured in units of µs. 80h: L0_LPBK_INIT (default)

32.3.7.15 T_PCIE2_RP_EIDLE_INFER_TO_1

This is an EIDLE inference timeout register.

Offset: 0xE40 | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R/W	3E80h	T_PCIE2_RP_EIDLE_INFER_TO_1_UNSUC_SPEED_GEN2: Infer E-Idle after this amount of time while in Recovery. Speed and successful_speed_negotiation = 0 and operating in Gen2 speed. Measured in units of UI (rx symbol times). 3E80h: UNSUC_SPEED_GEN2_INIT (default)
15:0	R/W	7D0h	T_PCIE2_RP_EIDLE_INFER_TO_1_UNSUC_SPEED_GEN1: Infer E-Idle after this amount of time while in Recovery. Speed and successful_speed_negotiation = 0 and operating in Gen1 speed. Measured in units of UI (rx symbol times). 7D0h: UNSUC_SPEED_GEN1_INIT (default)

32.3.7.16 T_PCIE2_RP_LTSSM_DBGREG

This is the LTSSM debug register.

Offset: 0xE44 | Read/Write: R/W

Bit	R/W	Reset	Description
31	RW1C	0h	T_PCIE2_RP_LTSSM_DBGREG_LINKFSM31: 0h: LINKFSM31_INIT (default) 1h: LINKFSM31_CLEAR
30	RW1C	0h	T_PCIE2_RP_LTSSM_DBGREG_LINKFSM30: 0h: LINKFSM30_INIT (default) 1h: LINKFSM30_CLEAR
29	RW1C	0h	T_PCIE2_RP_LTSSM_DBGREG_LINKFSM29: 0h: LINKFSM29_INIT (default) 1h: LINKFSM29_CLEAR
28	RW1C	0h	T_PCIE2_RP_LTSSM_DBGREG_LINKFSM28: 0h: LINKFSM28_INIT (default) 1h: LINKFSM28_CLEAR
27	RW1C	0h	T_PCIE2_RP_LTSSM_DBGREG_LINKFSM27: 0h: LINKFSM27_INIT (default) 1h: LINKFSM27_CLEAR

Bit	R/W	Reset	Description
26	RW1C	0h	T_PCIE2_RP_LTSSM_DBGREG_LINKFSM26: 0h: LINKFSM26_INIT (default) 1h: LINKFSM26_CLEAR
25	RW1C	0h	T_PCIE2_RP_LTSSM_DBGREG_LINKFSM25: 0h: LINKFSM25_INIT (default) 1h: LINKFSM25_CLEAR
24	RW1C	0h	T_PCIE2_RP_LTSSM_DBGREG_LINKFSM24: 0h: LINKFSM24_INIT (default) 1h: LINKFSM24_CLEAR
23	RW1C	0h	T_PCIE2_RP_LTSSM_DBGREG_LINKFSM23: 0h: LINKFSM23_INIT (default) 1h: LINKFSM23_CLEAR
22	RW1C	0h	T_PCIE2_RP_LTSSM_DBGREG_LINKFSM22: 0h: LINKFSM22_INIT (default) 1h: LINKFSM22_CLEAR
21	RW1C	0h	T_PCIE2_RP_LTSSM_DBGREG_LINKFSM21: 0h: LINKFSM21_INIT (default) 1h: LINKFSM21_CLEAR

0	R/W	1h	T_PCIE2_RP_PRIV_ERRMSK_LCRC_ERR_EN: 1h: LCRC_ERR_EN_INIT (default) 0h: LCRC_ERR_EN_OFF 1h: LCRC_ERR_EN_ON

32.3.7.19 T_PCIE2_RP_LTSSM_TRACE_CONTROL

This is the LTSSM Trace Control register. LTSSM state changes are stored in a RAM. This register controls storing of this change in the RAM.

Offset: 0xE50 | Read/Write: R/W

Bit	R/W	Reset	Description
31:14	R	0	Reserved
13:11	R/W	0h	T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_PRX_LTSSM_MINOR: 0h: TRIG_PRX_LTSSM_MINOR_INIT (default)
10:8	R/W	0h	T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_PTX_LTSSM_MINOR: 0h: TRIG_PTX_LTSSM_MINOR_INIT (default)
7:4	R/W	0h	T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_LTSSM_MAJOR: 0h: TRIG_LTSSM_MAJOR_INIT (default)

Bit	R/W	Reset	Description
3	R/W	0h	T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_ON_EVENT: when this bit is set, LTSSM changes will start storing only after its state has reached the state specified in T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_LTSSM_MAJOR, T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_PTX_LTSSM_MINOR and T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_PRX_LTSSM_MINOR state. T_PCIE2_RP_LTSSM_ 0h: TRIG_ON_EVENT_INIT (default)
2	R/W	0h	T_PCIE2_RP_LTSSM_TRACE_CONTROL_CLEAR_RAM: When written with 1, will clear all entries in RAM. 0h: CLEAR_RAM_INIT (default)
1	R/W	0h	T_PCIE2_RP_LTSSM_TRACE_CONTROL_WRAP_EN: When this bit is set, the RAM is updated every time LTSSM state change happens irrespective of whether the write pointer has wrapped around. When this bit is clear, the RAM update is stopped when the RAM is full. RAM needs to be cleared by writing to T_PCIE2_RP_LTSSM_TRACE_CONTROL_CLEAR_RAM before it can start storing new trace. 0h: WRAP_EN_INIT (default) 0h: WRAP_EN_CLEAR 1h: WRAP_EN_SET
0	R/W	1h	T_PCIE2_RP_LTSSM_TRACE_CONTROL_STORE_EN: This bit controls whether RAM needs to be updated whenever an ltssm_state change happens. 1h: STORE_EN_INIT (default) 0h: STORE_EN_CLEAR 1h: STORE_EN_SET

32.3.7.20 T_PCIE2_RP_LTSSM_TRACE_STATUS

This register helps to check the LTSSM trace which has been stored in RAM.

Offset: 0xE54 | Read/Write: R/W

Bit	R/W	Reset	Description
31:22	R	0	Reserved
21:19	R	None	T_PCIE2_RP_LTSSM_TRACE_STATUS_PRX_LTSSM_MINOR: This field returns the data prx_ltssm_minor in ltssm_trace RAM point by T_PCIE2_RP_LTSSM_TRACE_STATUS_READ_ADDR
18:16	R	None	T_PCIE2_RP_LTSSM_TRACE_STATUS_PTX_LTSSM_MINOR: This field returns the data ptx_ltssm_minor in ltssm_trace RAM point by T_PCIE2_RP_LTSSM_TRACE_STATUS_READ_ADDR
15:12	R	None	T_PCIE2_RP_LTSSM_TRACE_STATUS_LTSSM_MAJOR: This field returns the data ltssm_major in ltssm_trace RAM point by T_PCIE2_RP_LTSSM_TRACE_STATUS_READ_ADDR
11	R	None	T_PCIE2_RP_LTSSM_TRACE_STATUS_READ_DATA_VALID: This field returns the data_valid in ltssm_trace RAM point by T_PCIE2_RP_LTSSM_TRACE_STATUS_READ_ADDR. Data valid bit is set an entry is written to that location of RAM.
10:6	R/W	0h	T_PCIE2_RP_LTSSM_TRACE_STATUS_READ_ADDR: This is the read address to LTSSM trace RAM 0h: READ_ADDR_INIT (default)
5:1	R	None	T_PCIE2_RP_LTSSM_TRACE_STATUS_WRITE_PTR: This field indicates the current location of write pointer. This is especially useful when writing to this RAM is enabled even when RAM is full and write pointer is allowed to wrap around.

Bit	R/W	Reset	Description
0	R	None	T_PCIE2_RP_LTSSM_TRACE_STATUS_RAM_FULL: This field indicates whether all entries in RAM have been written. This is especially useful when writing to this RAM is enabled even when RAM is full and write pointer is allowed to wrap around.

32.3.7.21 T_PCIE2_RP_PG

This register helps power gate the PCIe TMS in NVIDIA-specific ways.

Offset: 0xE58 | Read/Write: R/W

Bit	R/W	Reset	Description
31:3	R	0	Reserved
2	R/W	0h	T_PCIE2_RP_PG_RCVD_PME_TO_ACK_INTR_EN: This field enables generation of interrupt on reception of PME TO ACK TLP. 1h RCVD_PME_TO_ACK_INTR_EN_ENABLED 0h RCVD_PME_TO_ACK_INTR_EN_DISABLED (default)
1	R/W	0h	T_PCIE2_RP_PG_RCVD_PME_TO_ACK: When the root port receives a PME TO ACK TLP, it sets this field. software can write 1 to this field to clear it to 0. NOTE: this field is reset by Cold Reset 0h RCVD_PME_TO_ACK_INIT (default) 1h RCVD_PME_TO_ACK_CLEAR
0	R/W	0h	T_PCIE2_RP_PG_SEND_PME_TO_MSG: Writing 1 to this field when from previous value of 0 causes the root port to send a PME TO message downstream. When the PME TO message is sent to lower stages of the root port (txtf), this field is automatically cleared to 0 by the root port. 0h SEND_PME_TO_MSG_INIT (default) 1h SEND_PME_TO_MSG_SEND_NOW

32.3.7.22 T_PCIE2_RP_VAR_RANGE0

The PCIe Legacy I/O Decode Range Control Registers allow a programmable I/O address range below 4K to be redirected to a PCIe bus downstream from a RP. This is normally not possible due to the definition of the standard I/O Base/Limit registers in the P2P register set. The purpose is to allow legacy devices on PCIe endpoints to operate at their PC legacy default address ranges.

The range is controlled by a pair of generic 12 bit base/limit address register. The ranges can be mapped anywhere in the lower 4K I/O address space. I/O addresses above 4K can be allocated via standard PCI PnP mechanisms.

Offset: 0xE5C | Read/Write: R/W

Bit	R/W	Reset	Description
31:18	R/W	0h	T_PCIE2_RP_VAR_RANGE0_LIMIT: Top address for the variable range positive decode addresses. This will be set to the highest address in the range that the PCIE RP is to decode. Both this range and the base must be set properly for any cycles to be decoded. LIMIT[1:0] always 11'b 0h: LIMIT_DEFAULT (default)
17:16	R	0h	T_PCIE2_RP_VAR_RANGE0_RSVD1: 0h: RSVD1_ZER0 (default)

Bit	R/W	Reset	Description
15:2	R/W	0h	T_PCIE2_RP_VAR_RANGE0_BASE: Base address for the variable range positive decode addresses. This will be set to the lowest address in the range that the PCIE RP is to decode. Both the base and the limit must be set properly for any cycles to be decoded. BASE must be DWORD aligned 0h: BASE_DEFAULT (default)
1	R	0h	T_PCIE2_RP_VAR_RANGE0_RSVD0: 0h: RSVD0_ZER0 (default)
0	R/W	0h	T_PCIE2_RP_VAR_RANGE0_ENABLE: If set then positively decode the variable I/O address range defined in T_PCIE2_VAR_RANGE0. 1h: ENABLE_YES 0h: ENABLE_NO (default)

32.3.7.23 T_PCIE2_RP_VAR_RANGE1

The PCIe Legacy I/O Decode Range Control Registers allow a programmable I/O address range below 4K to be redirected to a PCIe bus downstream from a RP. This is normally not possible due to the definition of the standard I/O Base/Limit registers in the P2P register set. The purpose is to allow legacy devices on PCIe endpoints to operate at their PC legacy default address ranges.

The range is controlled by a pair of generic 12-bit base/limit address register. The ranges can be mapped anywhere in the lower 4K I/O address space. I/O addresses above 4K can be allocated via standard PCI PnP mechanisms.

Offset: 0xE60 | Read/Write: R/W

Bit	R/W	Reset	Description
31:18	R/W	0h	T_PCIE2_RP_VAR_RANGE1_LIMIT: Top address for the variable range positive decode addresses. This will be set to the highest address in the range that the PCIe RP is to decode. Both this range and the base must be set properly for any cycles to be decoded. LIMIT[1:0] always 11'b 0h: LIMIT_DEFAULT (default)
17:16	R	0h	T_PCIE2_RP_VAR_RANGE1_RSVD1: 0h: RSVD1_ZER0 (default)
15:2	R/W	0h	T_PCIE2_RP_VAR_RANGE1_BASE: Base address for the variable range positive decode addresses. This will be set to the lowest address in the range that the PCIe RP is to decode. Both the base and the limit must be set properly for any cycles to be decoded. BASE must be DWORD aligned 0h: BASE_DEFAULT (default)
1	R	0h	T_PCIE2_RP_VAR_RANGE1_RSVD0: 0h: RSVD0_ZER0 (default)
0	R/W	0h	T_PCIE2_RP_VAR_RANGE1_ENABLE: If set then positively decode the variable I/O address range defined in T_PCIE2_RP_VAR_RANGE1. 1h: ENABLE_YES 0h: ENABLE_NO (default)

32.3.7.24 T_PCIE2_RP_VEND_XP

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: 0xF00 | Read/Write: R/W

Bit	R/W	Reset	Description
31	R/W	0h	T_PCIE2_RP_VEND_XP_FORCE_COMPLIANCE: 0h: FORCE_COMPLIANCE_INIT (default)
30	R	None	T_PCIE2_RP_VEND_XP_DL_UP: This read-only bit tells status of Data Link Layer in XP. This bit was added before the DL Link Active Reporting feature was introduced in the official PCI-Express Specification. It asserts when the DL enters the InitFC2 phase of training. This means that DL_UP will assert before the DL_LINK_ACTIVE bit asserts.
29	R/W	0h	T_PCIE2_RP_VEND_XP_INTERLEAVE_DLLPS: Setting this bit will cause the DL to schedule Ack and UpdateFC packets earlier or later than their respective timer expiration times in order to decrease the likelyhood of loosing efficiency by sending two DLLPs consecutively. 0h: INTERLEAVE_DLLPS_INIT (default)
28	R/W	0h	T_PCIE2_RP_VEND_XP_OPPORTUNISTIC_UPDATEFC: If this bit is set, the DL will send any pending UpdateFC packet whenever it has nothing else to send, instead of waiting for the UpdateFC timer to expire. 0h: OPPORTUNISTIC_UPDATEFC_INIT (default)
27	R/W	0h	T_PCIE2_RP_VEND_XP_OPPORTUNISTIC_ACK: If this bit is set, the DL will send pending Acks whenever it has nothing else to send, instead of waiting for the Ack Timer to expire. 0h: OPPORTUNISTIC_ACK_INIT (default)
26	R/W	0h	T_PCIE2_RP_VEND_XP_TRAIN_ERR_ENABLE: Enables reporting of training errors. 0h: TRAIN_ERR_ENABLE_INIT (default)
25:18	R/W	0h	T_PCIE2_RP_VEND_XP_UPDATE_FC_THRESHOLD: This field specifies an override for the UpdateFC frequency. Setting this field to a non-zero value will cause the TL to use the programmed value MULTIPLIED BY TWO as the UpdateFC timer limit instead of the default value which is based on the negotiated width as described in section 2.6.1.2 of the PCI Express Base Specification, Rev 1.0a. The UpdateFC timer limit corresponds to the UpdateFC Transmission Latency Limit listed in table 2-28 of the specification, except that it should *not* include the InternalDelay. 0h: UPDATE_FC_THRESHOLD_INIT (default)
17:2	R	None	T_PCIE2_RP_VEND_XP_PRBS_STAT: This field returns the results of loopback mode testing. Each bit represents the status of one lane (1 == PASS).
1	R/W	0h	T_PCIE2_RP_VEND_XP_PRBS_EN: Enables the root port as loopback master using PRBS-23 as the test pattern. 0h: PRBS_EN_DISABLED (default) 1h: PRBS_EN_ENABLED
0	R/W	0h	T_PCIE2_RP_VEND_XP_EMULATION: Enables emulation mode operation. 0h: EMULATION_OFF (default) 1h: EMULATION_ON

32.3.7.25 T_PCIE2_RP_VEND_XP1

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: 0xF04 | Read/Write: R/W

Bit	R/W	Reset	Description
31:29	R/W	2h	T_PCIE2_RP_VEND_XP1_L1_EXIT_LATENCY: This field indicates the L1 exit latency for the given PCI Express Link. The value reported indicates the lenght of time this Port requires to complete transition from L1 to L0. The value is reflected in the LINK_CAPABILITIES register. Defined encodings are: • 000b: Less than 1 µs. • 001b: 1 µs to less than 2 µs. • 010b: 2 µs to less than 4 µs. • 011b: 4 µs to less than 8 µs. • 100b: 8 µs to less than 16 µs. • 101b: 16 µs to less than 32 µs. • 110b: 32 µs-64 µs. • 111b: More than 64 µs. 2h: L1_EXIT_LATENCY_INIT (default) 0h: L1_EXIT_LATENCY_LT_1 1h: L1_EXIT_LATENCY_LT_2 2h: L1_EXIT_LATENCY_LT_4 3h: L1_EXIT_LATENCY_LT_8 7h: L1_EXIT_LATENCY_GT_64
28	R/W	0h	T_PCIE2_RP_VEND_XP1_FORCE_DOWNSTREAM_NO_SNOOP: When this bit is set and ENABLE_NO_SNOOP bit is also set, NO_SNOOP bit is set on all downstream TLPs (except for I/O and Config, for which NO_SNOOP is never set) 1h: FORCE_DOWNSTREAM_NO_SNOOP_YES 0h: FORCE_DOWNSTREAM_NO_SNOOP_NO (default)
27	R/W	0h	T_PCIE2_RP_VEND_XP1_FORCE_UPSTREAM_NONCOH: When set this bit causes all upstream memory traffic (except MSI) to be non-coherent. 0h: FORCE_UPSTREAM_NONCOH_INIT (default) 1h: FORCE_UPSTREAM_NONCOH_ENABLED 0h: FORCE_UPSTREAM_NONCOH_DISABLED

Bit	R/W	Reset	Description
26:19	R/W	0h	T_PCIE2_RP_VEND_XP1_LINK_PVT_CTL: bit[0] : ACK_L1_NO_WAIT Enable behavior described in the Errata C7 of the PCI Express Base Specification, v1.0a, 7 October 2003. Software should always set this bit to 1. When this bit is set to 1 on an upstream component, that component will not wait to accumulate the minimum number of credits required to send the largest possible packet for any FC type before sending PM_Request_Ack DLLPs downstream. After receiving a PM_Enter_L1 DLLP, it will begin sending PM_Request_Ack DLLPs as soon as it has received acknowledgement for the last TLP that has been sent. bit [1] : L23_READY_NO_D3 Enable entry into the L2/3 Ready state when the component is not in the D3 PMCSR state. If this bit is set to 0, the component will not allow the link to enter the L2/3 Ready state if it is not in D3. If the bit is set to 1, the link will enter L2/3 Ready after the component receives a PME_Turn_Off message, regardless of the PMCSR state. bit [2] : L1_ASPM_SUPPORT This bit determines the reported value of L1 ASPM support in the link capability register (ACTIVE_STATE_LINK_PM_SUPPORT, bit 11). bit [3] : DONT_MERGE_PMASNAK With the default setting for this bit (0), a group of PM_Active_State_Request_L1 DLLPs from the endpoint will cause a single PM_ASPM_Nak TLP to be sent. If this bit is set to 1, multiple PM_ASPM_Nak TLP messages will be sent, possibly as many as one PM_ASPM_Nak TLP for each PM_Active_State_Request_L1 DLLP. bit [4] : IGNORE_L0S This bit overrides the L0s setting for the Active Sate PM Control register. If bit[4] == 0 (do not override), then bit 0 of the T_PCIE2_RP_LINK_CONTROL_STATUS register is used to determine if the Tx side drivers should enter L0s or not. If bit[4] == 1 (override), then bit 0 of T_PCIE2_RP_LINK_CONTROL_STATUS is ignored, and Tx.L0s is not entered. bit [7] : NP_REQ_TIMEOUT If set, disable downstream NP request timeout. This is for debug purposes to hang instead of timeout. 0h: LINK_PVT_CTL_INIT (default)
18:10	R/W	0h	T_PCIE2_RP_VEND_XP1_ACK_TIMER_LIMIT: This field overrides the Ack Timer Limit for this root port. Setting this field to a non-zero value will cause the DL to use the programmed value for the Ack Timer Limit instead of the default value, which is based on the negotiated width as described in section 3.5.3.1 of the PCI Express Base Specification, Rev 1.0a. The Ack Timer Limit corresponds to the Unadjusted Ack Transmission Latency Limit listed in table 3-5 of the specification, except that it should include the Tx_L0s_Adjustment, and should *not* include the InternalDelay. 0h: ACK_TIMER_LIMIT_INIT (default)
9	R	0	Reserved
8	R/W	1h	T_PCIE2_RP_VEND_XP1_RNCTRL_GEN2_WAIT_FOR_FIRST_EIES: When this bit is programmed to 1, in the Config.LinkWidth.Start state, the inactive lanes that are activated will wait for the next EIEOS transmission before sending the first packet. If programmed to 0, it will not wait for the next EIEOS transmission before sending the first packet. 1h: RNCTRL_GEN2_WAIT_FOR_FIRST_EIES_INIT (default)
7	R	0h	T_PCIE2_RP_VEND_XP1_RNCTRL_EN: When this bit is programmed to a 1, it triggers the dynamic link width re-negotiation procedure in XP. This bit is a constant and always returns a value of 0 on a read. 0h: RNCTRL_EN_ZERO (default)
6	R/W	1h	T_PCIE2_RP_VEND_XP1_RNCTRL_GEN2_LINK_UPGRADE: When this bit is programmed to 1, it selects the 2.0-compliant link width upgrade protocol. If programmed to 0, it selects the NV-proprietary link width upgrade protocol. 1h: RNCTRL_GEN2_LINK_UPGRADE_INIT (default)
5:0	R/W	10h	T_PCIE2_RP_VEND_XP1_RNCTRL_MAXWIDTH: This field inidcates the maximum link width required at the end of dynamic link width re-negotiation process. The default value is 16. 10h: RNCTRL_MAXWIDTH_INIT (default)

32.3.7.26 T_PCIE2_RP_VEND_XP2

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: 0xF08 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	0h	T_PCIE2_RP_VEND_XP2_L0S_UPDATE_WAKE: Setting this field to a non-zero value will cause the DL to wake the PL out of L0s in advance of sending it an UpdateFC packet. When the DL sees that there are fewer cycles left in the UpdateFC timer than the value in the L0S_UPDATE_WAKE register, it will tell the PL to wake out of L0s. 0h: L0S_UPDATE_WAKE_INIT (default)
23:18	R	0	Reserved
17:8	R/W	3FFh	T_PCIE2_RP_VEND_XP2_L0S_THRESHOLD: This field controls the idle time required for TxL0s entry from L0, in symbol times (250 MHz clocks). Once the XP detects that it has no more DLLPs/TLPs to send, it will insert precisely (L0S_THRESHOLD + 1) logical idles between the END symbol of the last DLLP/TLP and the COM of the IDL Ordered Set. If L0S_THRESHOLD == 0x3FF, the L0s entry latency is instead (endpoint N_FTS)*4 symbol times, where (endpoint N_FTS) is the N_FTS value advertised by the endpoint during training. Therefore, the threshold can be set to anywhere from 1 to 1023 symbol times (4ns to 4092ns). 3FFh: L0S_THRESHOLD_INIT (default) 3FFh: L0S_THRESHOLD_REMOTE_NFTS
7:0	R/W	0h	T_PCIE2_RP_VEND_XP2_L0S_ACK_WAKE: Setting this field to a non-zero value will cause the DL to wake the PL out of L0s in advance of sending it an Ack packet. When the DL sees that there are fewer cycles left in the Ack timer than the value in the L0S_ACK_WAKE register, it will tell the PL to awaken from L0s. 0h: L0S_ACK_WAKE_INIT (default)

32.3.7.27 T_PCIE2_RP_VEND_XV_TIMEOUT

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: 0xF0C | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	0300 00FAh	Reserved

32.3.7.28 T_PCIE2_RP_VEND_SLOT_STRAP

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

This is a back-door register used to set various bits in the Slot Capabilities Register, which is part of the PCI-Express Capability Structure, as defined by the PCI-Express Specification. The bits listed here map 1:1 with the bits in the Slot Capabilities Register.

NOTE: Bits marked "Reserved" may actually be writable in some chips. Therefore writes to this register must not change the default POR values for the bits marked "Reserved".

Offset: 0xF20 | Read/Write: R/W

Bit	R/W	Reset	Description
31:19	R/W	0h	T_PCIE2_RP_VEND_SLOT_STRAP_PHYSICAL_SLOT_NUMBER: The physical numbering of the slots is left up to the board designer. The board designer must communicate the physical slot numbers to the SBIOS developer as well. 0h: PHYSICAL_SLOT_NUMBER_INIT (default)
18:17	R	0	Reserved
16:15	R/W	0h	T_PCIE2_RP_VEND_SLOT_STRAP_SLOT_POWER_LIMIT_SCALE: This field must be programmed according to the unique power-rail capabilities of each board design. Board designers are responsible for communicating the power limits of each slot to the SBIOS developers. 0h: SLOT_POWER_LIMIT_SCALE_INIT (default)
14:7	R/W	0h	T_PCIE2_RP_VEND_SLOT_STRAP_SLOT_POWER_LIMIT_VALUE: This field must be programmed according to the unique power-rail capabilities of each board design. Board designers are responsible for communicating the power limits of each slot to the SBIOS developers. 0h: SLOT_POWER_LIMIT_VALUE_INIT (default)
6:0	R	0	Reserved

32.3.7.29 T_PCIE2_RP_ECTL_2_R1

Offset: 0xF34 | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R/W	0h	T_PCIE2_RP_ECTL_2_R1_RX_DFE_1C: 0h: R1_RX_DFE_1C_DEFAULT
15:8	R/W	0h	T_PCIE2_RP_ECTL_2_R1_RX_EQ_1C: 0h: R1_RX_EQ_1C_DEFAULT
7:0	R/W	88h	T_PCIE2_RP_ECTL_2_R1_CDR_CNTL_1C: 88h: R1_CDR_CNTL_1C_DEFAULT

32.3.7.30 T_PCIE2_RP_ECTL_3_R1

Offset: 0xF38 | Read/Write: R/W

Bit	R/W	Reset	Description
11:8	R/W	0h	T_PCIE2_RP_ECTL_3_R1_TX_PEAK_PRE_1C: 0h: R1_TX_PEAK_PRE_1C_DEFAULT
4:0	R/W	Ah	T_PCIE2_RP_ECTL_3_R1_TX_PEAK_ 1C: Ah: R1_TX_PEAK_1C_DEFAULT

32.3.7.31 T_PCIE2_RP_ECTL_2_R2

Offset: 0xF3C | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R/W	0h	T_PCIE2_RP_ECTL_2_R2_RX_DFE_1C: 0h: R2_RX_DFE_1C_DEFAULT
15:8	R/W	0h	T_PCIE2_RP_ECTL_2_R2_RX_EQ_1C: 0h: R2_RX_EQ_1C_DEFAULT

Bit	R/W	Reset	Description
7:0	R/W	88h	T_PCIE2_RP_ECTL_2_R2_CDR_CNTL_1C: 88h: R2_CDR_CNTL_1C_DEFAULT

32.3.7.32 T_PCIE2_RP_ECTL_3_R2

Offset: 0xF40 | Read/Write: R/W

Bit	R/W	Reset	Description
27:24	R/W	0h	T_PCIE2_RP_ECTL_3_R2_TX_PEAK_PRE_SEL1_1C: 0h: R2_TX_PEAK_PRE_SEL1_1C_DEFAULT
20:16	R/W	Ah	T_PCIE2_RP_ECTL_3_R2_TX_PEAK_SEL1_1C: Ah: R2_TX_PEAK_SEL1_1C_DEFAULT
11:8	R/W	0h	T_PCIE2_RP_ECTL_3_R2_TX_PEAK_PRE_SEL0_1C: 0h: R2_TX_PEAK_PRE_SEL0_1C_DEFAULT
4:0	R/W	Eh	T_PCIE2_RP_ECTL_3_R2_TX_PEAK_SEL0_1C: Eh: R2_TX_PEAK_SEL0_1C_DEFAULT

32.3.7.33 T_PCIE2_RP_VEND_CTL1

This register contains fields unique to NVIDIA's implementation of PCI Express devices. This is a control register for general feature and function control.

Offset: 0xF48 | Read/Write: R/W

Bit	R/W	Reset	Description
31:22	R	0	Reserved
21	R/W	1h	T_PCIE2_RP_VEND_CTL1_POLLING_RESET_FIX_EN: 1h: POLLING_RESET_FIX_EN_INIT (default) 1h: POLLING_RESET_FIX_EN_ENABLE 0h: POLLING_RESET_FIX_EN_DISABLE
20	R/W	1h	T_PCIE2_RP_VEND_CTL1_HOTPLUG_IN_TRAFFIC_EN: 1h: HOTPLUG_IN_TRAFFIC_EN_INIT (default) 1h: HOTPLUG_IN_TRAFFIC_EN_ENABLE 0h: HOTPLUG_IN_TRAFFIC_EN_DISABLE
19	R/W	0h	T_PCIE2_RP_VEND_CTL1_NISO2ISO: When set to 1, all upstream non-ISO-PW and non-ISO-NP will be upgraded to ISO. 0h: NISO2ISO_INIT (default) 1h: NISO2ISO_ENABLE 0h: NISO2ISO_DISABLE
18	R/W	0h	T_PCIE2_RP_VEND_CTL1_ALLOW_UPSTREAM_CMPL_OVERTAKE_PW: When set to 1, the UBFI allows the CPL to bypass posted writes regardless of the RO bit 0h: ALLOW_UPSTREAM_CMPL_OVERTAKE_PW_DIS (default) 1h: ALLOW_UPSTREAM_CMPL_OVERTAKE_PW_EN
17	R/W	0h	T_PCIE2_RP_VEND_CTL1_SPLIT_ARB_BLOCK_COH: When set to 0, take the single ufpci2fpci_arb_block_coherent as input. When set to 1, take the separate inputs of ufa2fpci_arb_block_coherent_pw and ufa2fpci_arb_block_coherent_np. 0h: SPLIT_ARB_BLOCK_COH_INIT (default) 0h: SPLIT_ARB_BLOCK_COH_DIS 1h: SPLIT_ARB_BLOCK_COH_EN

Bit	R/W	Reset	Description
16	R/W	0h	T_PCIE2_RP_VEND_CTL1_HIDE_MSIMAP: 0h: HIDE_MSIMAP_DIS (default) 1h: HIDE_MSIMAP_EN
15	R/W	1h	T_PCIE2_RP_VEND_CTL1_LINKACTV_REPORTING: This is a backdoor bit for setting the Data Link Layer Link Active Reporting Capable bit (bit 20 of the Link Capabilities Register). This bit *MUST* be set whenever hot-plug is enabled. Otherwise, it can be set as desired. 1h: LINKACTV_REPORTING_CAPABLE (default) 0h: LINKACTV_REPORTING_NOT_CAPABLE
14	R/W	1h	T_PCIE2_RP_VEND_CTL1_P2P_ISO2NISO: If set, forces upstream peer-to-peer ISO requests to be peer-to-peer NONISO. 1h: P2P_ISO2NISO_EN (default) 0h: P2P_ISO2NISO_DIS
13	R/W	0h	T_PCIE2_RP_VEND_CTL1_ERPT: This bit, when 0, hides the entire AER Capability structure from the capabilities list. It causes the "next pointer" of the previous capability to point to NULL. Normally, AER is the last capability in the list. 1h: ERPT_EN 0h: ERPT_DIS (default)
12	R/W	0h	T_PCIE2_RP_VEND_CTL1_HIDE_MSI_CAP: This bit, when 1, hides the entire MSI Capability structure from the capabilities list. It causes the "next pointer" of the previous capability to point to the capability that comes after MSI. 0h: HIDE_MSI_CAP_DIS (default) 1h: HIDE_MSI_CAP_EN
11:5	R	0	Reserved
4	R/W	0h	T_PCIE2_RP_VEND_CTL1_ACCEPT_MSGD1: When set, allows acceptance of NVIDIA specific vendor type message with data. 0h: ACCEPT_MSGD1_DIS (default) 1h: ACCEPT_MSGD1_EN
3:1	R/W	7h	T_PCIE2_RP_VEND_CTL1_TC2ISO_MAP: This field specifies TC2ISO_MAP[2:0]. Upstream traffic with TC[2:0] >= TC2ISO_MAP[2:0] are sent as ISO requests on UFPCI Since TC[2:0] == 0 can never be sent to ISO channel, TC2ISO_MAP[2:0] == 0 is used to force ALL traffic to NONISO 7h: TC2ISO_MAP_7 (default)
0	R/W	0h	T_PCIE2_RP_VEND_CTL1_P2P_BLOCK_P2P_ONLY: When set, ignores ufa2fpci_arb_block_coherent for upstream peer2peer requests. 1h: P2P_BLOCK_P2P_ONLY_EN 0h: P2P_BLOCK_P2P_ONLY_DIS (default)

32.3.7.34 T_PCIE2_RP_VEND_XP_BIST

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

IOBIST and Characterization Control Register

Offset: 0xF4C | Read/Write: R/W

Bit	R/W	Reset	Description
31	R	0	Reserved

Bit	R/W	Reset	Description
30	R/W	0h	T_PCIE2_RP_VEND_XP_BIST_GOTO_DETECT_ON_SURPRISE_EIDLE: 0h: GOTO_DETECT_ON_SURPRISE_EIDLE_INIT (default)
29	R/W	0h	T_PCIE2_RP_VEND_XP_BIST_ENABLE_SERR_REPORTING: 0h: ENABLE_SERR_REPORTING_INIT (default)
28	R/W	0h	T_PCIE2_RP_VEND_XP_BIST_GOTO_L1_L2_AFTER_DLLP_DONE: 0h: GOTO_L1_L2_AFTER_DLLP_DONE_INIT (default)
27	R/W	0h	T_PCIE2_RP_VEND_XP_BIST_CTRL_IGNORE_LPBK_EXIT: 0h: CTRL_IGNORE_LPBK_EXIT_INIT (default)
26	R/W	0h	T_PCIE2_RP_VEND_XP_BIST_CTRL_RELAX_LPBK_ENTRY: 0h: CTRL_RELAX_LPBK_ENTRY_INIT (default)
25	R/W	0h	T_PCIE2_RP_VEND_XP_XP_BIST_CTRL_FORCE_PRBS_RST: 0h: INIT (default)
24	R/W	0h	T_PCIE2_RP_VEND_XP_FORCE_DEEMPHASIS_ADVERTISED_EN: 0h: INIT (default)
23	R	0h	Reserved
22	R/W	0h	T_PCIE2_RP_VEND_XP_FORCE_RECEIVER_COMPLIANCE_EN: 0h: INIT (default)
21	R/W	0h	T_PCIE2_RP_VEND_XP_FORCE_COMPLIANCE_GEN2_SPEED_EN: 0h: INIT (default)
20	R/W	0h	T_PCIE2_RP_VEND_XP_BIST_FORCE_COMPLIANCE_AND_ADVERTISE_MODE: 0h: FORCE_COMPLIANCE_AND_ADVERTISE_MODE_INIT (default)
19:0	R	0	Reserved

32.3.7.35 T_PCIE2_RP_VEND_XP_FTS

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: 0xF54 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	80h	T_PCIE2_RP_VEND_XP_FTS_TS_DETECT_START: 80h: TS_DETECT_START_INIT (default)
23:16	R/W	40h	T_PCIE2_RP_VEND_XP_FTS_FTS_DETECT_START: This field represents the number of symbol times to wait before the root port begins looking at FTS ordered sets when exiting L0s -- the incoming data is essentially ignored during this time. 40h: FTS_DETECT_START_INIT (default)
15:8	R	None	T_PCIE2_RP_VEND_XP_FTS_N_FTS_REMOTE: NV_XVE_PRIV_XP_N_FTS_REMOTE represents the N_FTS value advertised by the remote device as recorded from the N_FTS symbol of the received TS ordered sets.
7:0	R/W	1Fh	T_PCIE2_RP_VEND_XP_FTS_N_FTS: This field represents the N_FTS value to advertise to the device on the other side of the link. NOTE: If this field is modified from its default (POR) value, the Replay Timer Limit in T_PCIE2_RP_VEND_XP1 must be adjusted accordingly. 1Fh: N_FTS_INIT (default)

32.3.7.36 T_PCIE2_RP_VEND_XP_STATS0

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: 0xF58 | Read/Write: R/W

Bit	R/W	Reset	Description
31:29	R	0	Reserved
28	R/W	0h	T_PCIE2_RP_VEND_XP_STATS0_FAILED_L0S_EXITS_INF: When set to 1, the failed L0s exits counter accumulates indefinitely (i.e. the one millisecond timer is ignored). 0h: FAILED_L0S_EXITS_INF_INIT (default)
27:25	R	0	Reserved
24	R	0h	T_PCIE2_RP_VEND_XP_STATS0_FAILED_L0S_EXITS_LC: Loads the current value from the failed L0s exits counter into the VEND_XP_STATS1 register, and then clears the failed L0s exits counter. The counter begins counting again immediately after it is cleared. Write a 1 to this field to trigger the load-and-clear operation. 0h: FAILED_L0S_EXITS_LC_INIT (default)
23:21	R	0	Reserved
20	r/w	0h	T_PCIE2_RP_VEND_XP_STATS0_NAKS_RCVD_INF: When set to 1, the NAKs received counter accumulates indefinitely (i.e. the 64 microsecond timer is ignored). 0h: NAKS_RCVD_INF_INIT (default)
19:17	R	0	Reserved
16	R	0h	Loads the current value from the NAKs received counter into the VEND_XP_STATS1 register, and then clears the NAKs received counter. The counter begins counting again immediately after it is cleared. Write a 1 to this field to trigger the load-and-clear operation. 0h: NAKS_RCVD_LC_INIT (default)
15:13	R	0	Reserved
12	R/W	0h	T_PCIE2_RP_VEND_XP_STATS0_CRC_ERRORS_INF: When set to 1, the CRC error counter accumulates indefinitely (i.e. the 64 microsecond timer is ignored). 0h: CRC_ERRORS_INF_INIT (default)
11:9	R	0	Reserved
8	R	0h	T_PCIE2_RP_VEND_XP_STATS0_CRC_ERRORS_LC: Loads the current value from the CRC error counter into the VEND_XP_STATS1 register, and then clears the CRC error counter. The counter begins counting again immediately after it is cleared. Write a 1 to this field to trigger the load-and-clear operation. 0h: CRC_ERRORS_LC_INIT (default)
7:5	R	0	Reserved
4	R/W	0h	T_PCIE2_RP_VEND_XP_STATS0_8B10B_ERRORS_INF: When set to 1, the 8b/10b error counter accumulates indefinitely (i.e. the one microsecond timer is ignored). 0h: 8B10B_ERRORS_INF_INIT (default)
3:1	R	0	Reserved

Bit	R/W	Reset	Description
0	R	0h	T_PCIE2_RP_VEND_XP_STATS0_8B10B_ERRORS_LC: Loads the current value from the 8B/10B error counter into the VEND_XP_STATS1 register, and then clears the 8b/10b error counter. The counter begins counting again immediately after it is cleared. Write a 1 to this field to trigger the load-and-clear operation. Note: This counter will count the number of 8b10b errors in a time window of size 14 clk25m clock periods from the time a 1 is written into this field. Depending on the clock frequency of clk25m, this window will be sized differently. Default is 12 clock periods (1 us). 0h: 8B10B_ERRORS_LC_INIT (default)

32.3.7.37 T_PCIE2_RP_VEND_XP_STATS1

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: 0xF5C | Read/Write: R

Bit	R/W	Reset	Description
31:24	R	None	T_PCIE2_RP_VEND_XP_STATS1_8B10B_ERRORS: Counts the number of 8b/10b errors detected in one microsecond. Saturates at 255 (counter does not roll over to 0).
23:16	R	None	T_PCIE2_RP_VEND_XP_STATS1_CRC_ERRORS: Counts the number of CRC errors detected in 64 microseconds. Saturates at 255 (counter does not roll over to 0).
15:8	R	None	T_PCIE2_RP_VEND_XP_STATS1_NAKS_RCVD: Counts the number of NAKs received from the endpoint in 64 microseconds. Saturates at 255 (counter does not roll over to 0).
7:0	R	None	T_PCIE2_RP_VEND_XP_STATS1_FAILED_L0S_EXITS: Counts the number of times the RX side of the XP went into Recovery in one millisecond, due to a failed attempt to exit L0s. Saturates at 255 (counter does not roll over to 0).

32.3.7.38 T_PCIE2_RP_VEND_ERROR_COUNT

This register contains 8-bit saturating counters for some of RXL and TXBA reported errors.

Offset: 0xF60 | Read/Write: R

Bit	R/W	Reset	Description
31:24	R	0	Reserved
23:16	R	None	T_PCIE2_RP_VEND_ERROR_COUNT_REPLAY: Counts the number of times that TXBA replays. Saturates at 8'hFF. Can be cleared by writing 1 to PRIV_ERRSTS_REPLAY_STARTED_ERR.
15:8	R	None	T_PCIE2_RP_VEND_ERROR_COUNT_BAD_TLP: Counts bad tlps reported by RXL (sum of lcrcl_err and bad_seq). Saturates at 8'hFF. Can be cleared by writing 1 to ERPTCAP_CERR_BAD_TLP
7:0	R	None	T_PCIE2_RP_VEND_ERROR_COUNT_LCRC_ERR: Counts LCRCL Errors reported by RXL. Saturates at 8'hFF. Can be cleared by writing 1 to PRIV_ERRSTS_LCRC_ERR.

32.3.7.39 T_PCIE2_RP_CFG_MISC

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: 0xF64 | Read/Write: R/W

Bit	R/W	Reset	Description
31:8	R	0	Reserved
7:0	R/W	0h	T_PCIE2_RP_CFG_MISC_MUTE_IDLE: MUTE mode is a power management feature in which cpu_clk and m2clk can be gated, if all the units are idle. A particular unit is idle when it has no outstanding transactions to be sent out. The MUTE_IDLE field is used to delay the idle assertion from xvr to clk. It should be programmed to cover the synchronization delay from cpu_clk to m2clk. 0h: MUTE_IDLE_MIN (default) FFh: MUTE_IDLE_MAX

32.3.7.40 T_PCIE2_RP_PRIV_XP_INIT_RECOVERY

Each new time frame, the number of 8B/10B errors is counted. As soon as the number of 8B/10B errors is equal to the threshold, the link is sent into recovery. If at the end of the time frame, the number of 8B/10B errors is smaller than the threshold, a new time frame is started in which the 8B/10B errors are counted.

Offset: 0xF68 | Read/Write: R/W

Bit	R/W	Reset	Description
31	R/W	0h	T_PCIE2_RP_PRIV_XP_INIT_RECOVERY_8B10B_ERROR_ENABLE: This bit enables the feature T_PCIE2_RP_ERRORRATE_8B10B_ENABLE_OFF disables the feature T_PCIE2_RP_ERRORRATE_8B10B_ENABLE_ON enables the feature 0h: 8B10B_ERROR_ENABLE_INIT (default)
30:20	R/W	64h	T_PCIE2_RP_PRIV_XP_INIT_RECOVERY_8B10B_ERROR_WINDOW: Programs the timeframe in multiples of 1 microsecond. 64h: 8B10B_ERROR_WINDOW_100US (default)
19:0	R/W	9C4h	T_PCIE2_RP_PRIV_XP_INIT_RECOVERY_8B10B_ERROR_THRESHOLD: Bit [21:1] programs the 8B/10B error threshold. If the number of errors in the programmed timeframe is equal to the threshold, the link is sent into recovery. 9C4h: 8B10B_ERROR_THRESHOLD_2500 (default)

32.3.7.41 T_PCIE2_RP_PRIV_XP_LCTRL_2

Offset: 0xF6C | Read/Write: R/W

Bit	R/W	Reset	Description
31	R	None	T_PCIE2_RP_PRIV_XP_LCTRL_2_UPCONFIGURE_CAPABLE: Gen2 link width up-configure capability of remote device as recorded from data rate id of received TS ordered sets.
30	R/W	0h	T_PCIE2_RP_PRIV_XP_LCTRL_2_REV2P0_COMPLIANCE_DIS: To disable advertising rev2.0 support and link width up-configure capability. 0h: REV2P0_COMPLIANCE_DIS_INIT (default)
29	R/W	1h	T_PCIE2_RP_PRIV_XP_LCTRL_2_EIDLE_INFERENCE_EN: To disable electrical idle inference. It is enabled by default. 1h: EIDLE_INFERENCE_EN_INIT (default)

Bit	R/W	Reset	Description
28	R/W	1h	T_PCIE2_RP_PRIV_XP_LCTRL_2_SURPRISE_IDLE_USE_STAT_IDLE: When set, use idle status signals from the pad to detect surprise electrical idle entry when running in Gen1 speed. 1h: SURPRISE_IDLE_USE_STAT_IDLE_INIT (default)
27	R/W	1h	T_PCIE2_RP_PRIV_XP_LCTRL_2_ALLOW_SPEED_CHANGE_FROM_L1: When set to 1, allow speed change to be initiated from the L1 or Rx_L0s link states. 1h: ALLOW_SPEED_CHANGE_FROM_L1_INIT (default)
26:24	R/W	0h	T_PCIE2_RP_PRIV_XP_LCTRL_2_RECOVERY_SPEED_TIMEOUT_ADJ: To adjust the minimum length of time the transmitter stays in electrical idle in the Recover.Sped state. The value denotes the time in microseconds added. 0h: RECOVERY_SPEED_TIMEOUT_ADJ_INIT (default)
23:20	R/W	6h	T_PCIE2_RP_PRIV_XP_LCTRL_2_N_EIE_SYMBOLS: This represents the number of K28.7 symbols transmitted prior to transmitting the first FTS ordered set in the Tx.L0s.FTS state when running in Gen2 speed. 6h: N_EIE_SYMBOLS_INIT (default)
19	R/W	0h	T_PCIE2_RP_PRIV_XP_LCTRL_2_DEEMPHASIS_STRAP: This is the backdoor register for BIOS to write an initial value to the HWInit register PCIE2_RP_LINK_CONTROL_STATUS_2_SELECTABLE_DEEMPHASIS. 0 = -6db 1 = -3.5db 0h: DEEMPHASIS_STRAP_INIT (default)
18	R/W	0h	T_PCIE2_RP_PRIV_XP_LCTRL_2_ENFORCE_DEEMPHASIS: Forces root port to use de-emphasis value specific in Link Control 2 Selectable De-emphasis field instead of the value requested by the endpoint (advertised in TSs). This bit is reserved for endpoint. Default value is 0b. Functionality of this bit is no longer needed since TX_PEAK_R2_SEL1/SEL0 registers provide complete control over AMP/PEAK/PEAK_PRE settings in gen2. NOTE: this field is reset by Cold Reset 0h: ENFORCE_DEEMPHASIS_INIT (default)
17	R/W	0h	T_PCIE2_RP_PRIV_XP_LCTRL_2_POLLING_PREDETERMINED_LANES: When set to 1, only lane 0 or 15 needs to detect an exit from electrical idle before moving from Polling.Active to Polling.Config. This bit is not yet implemented. 0h: POLLING_PREDETERMINED_LANES_DISABLE (default)
16	R/W	0h	T_PCIE2_RP_PRIV_XP_LCTRL_2_AUTONOMOUS_CHANGE: When set to 1, it indicates that the Upstream port-initiated link width/speed change is not caused by a link reliability issue. 0h: AUTONOMOUS_CHANGE_INIT (default)
15:12	R	1h	T_PCIE2_RP_PRIV_XP_LCTRL_2_DATA_RATE_SUPPORTED_REMOTE: Gen2 data rate supported by other side as recorded from data rate identifier of received TS ordered sets. 1h: DATA_RATE_SUPPORTED_REMOTE_2P5 (default) 2h: DATA_RATE_SUPPORTED_REMOTE_5P0_2P5
11:8	R/W	2h	T_PCIE2_RP_PRIV_XP_LCTRL_2_DATA_RATE_SUPPORTED: When set to 4'b01, the supported link speed reported in the Link Capabilities Register is 2.5Gb/s. When set to 4'b10, the supported link speeds reported in the Link Capabilities Register are 5.0Gb/s and 2.5Gb/s. 1h: DATA_RATE_SUPPORTED_2P5 2h: DATA_RATE_SUPPORTED_5P0_2P5 (default)

Bit	R/W	Reset	Description
7:4	R/W	2h	T_PCIE2_RP_PRIV_XP_LCTRL_2_TARGET_LINK_SPEED: Specifies the link rate to change to. This is reflected in the data rate advertised in the data rate identifier field of TS ordered sets. 1h: TARGET_LINK_SPEED_2P5 2h: TARGET_LINK_SPEED_5P0 (default)
3	R/W	0h	T_PCIE2_RP_PRIV_XP_LCTRL_2_CTL_TX_MARGIN_OVERRIDE: 0h: CTL_TX_MARGIN_OVERRIDE_DISABLED (default) 1h: CTL_TX_MARGIN_OVERRIDE_ENABLED
2	R	0	Reserved
1	R/W	0h	T_PCIE2_RP_PRIV_XP_LCTRL_2_ADVERTISED_RATE_CHANGE: A write of 1 to this bit triggers the LTSSM to enter Recovery state, without setting the speed change bit, to change the advertised rate. This bit returns a value of 0 on a read. 0h: ADVERTISED_RATE_CHANGE_ZERO (default)
0	R/W	0h	T_PCIE2_RP_PRIV_XP_LCTRL_2_SPEED_CHANGE: A write of 1 to this bit triggers the link speed negotiation procedure. This bit returns a value of 0 on a read. 0h: SPEED_CHANGE_ZERO (default)

32.3.7.42 T_PCIE2_RP_PRIV_XP_PAD_PWRUP

Offset: 0xF74 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R	0	Reserved
23:16	R/W	0h	T_PCIE2_RP_PRIV_XP_PAD_PWRUP_PMRX_PWRUP_THRESHOLD: It is the time to hold CDR at reset in Recovery.RcvrLock while waiting for power rails to be stable 0h: PMRX_PWRUP_THRESHOLD_INIT (default)
15:0	R	0	Reserved

32.3.7.43 T_PCIE2_RP_PRIV_XP_RECOVERY_REASONS

This register records the reasons for going into the recovery state. Each bit represents a different reason. Search for "recovery_reason" in the linkfsm to see what each bit means, as it likely will change from project to project. Writing a 0 clears the register and enters into "record ALL recoveries encountered" mode. Writing a 1 clears the register and enters into "record NEXT recovery encountered" mode. The default mode is "record ALL".

Offset: 0xF84 | Read/Write: R/W

Bit	R/W	Reset	Description
31:0	R/W	0h	T_PCIE2_RP_PRIV_XP_RECOVERY_REASONS_VALUE: 0h: VALUE_INIT (default) 0h: VALUE_REC_ALL 1h: VALUE_REC_NEXT

32.3.7.44 T_PCIE2_RP_PRIV_XP_RECOVERY_COUNT

This register reflects the number of RECOVERY STATE entries in XP by the XVR. It is reset whenever it is read. If the count saturates before it is read then it remains saturated till it is read.

Offset: 0xF88 | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	0h	T_PCIE2_RP_PRIV_XP_RECOVERY_COUNT_VALUE: 0h: VALUE_INIT (default)

32.3.7.45 T_PCIE2_RP_PRIV_XP_RX_L0S_ENTRY_COUNT

This register reflects the number of entries from L0 to L0s at LTSSM RX side. It is reset whenever it is read. If the count saturates before it is read then it remains saturated till it is read.

Offset: 0xF8C | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	0h	T_PCIE2_RP_PRIV_XP_RX_L0S_ENTRY_COUNT_VALUE: 0h: VALUE_INIT (default)

32.3.7.46 T_PCIE2_RP_PRIV_XP_TX_L0S_ENTRY_COUNT

This register reflects the number of entries from L0 to L0s at LTSSM TX side. It is reset whenever it is read. If the count saturates before it is read then it remains saturated till it is read.

Offset: 0xF90 | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	0h	T_PCIE2_RP_PRIV_XP_TX_L0S_ENTRY_COUNT_VALUE: 0h: VALUE_INIT (default)

32.3.7.47 T_PCIE2_RP_PRIV_XP_L1_ENTRY_COUNT

This register reflects the number of entries from L0 to L1 It is reset whenever it is read. If the count saturates before it is read then it remains saturated till it is read

Offset: 0xF94 | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	0h	T_PCIE2_RP_PRIV_XP_L1_ENTRY_COUNT_VALUE: 0h: VALUE_INIT (default)

32.3.7.48 T_PCIE2_RP_PRIV_XP_L1_TO_RECOVERY_COUNT

This register reflects the number of entries from L1 to Recovery. It is reset whenever it is read. If the count saturates before it is read then it remains saturated till it is read.

Offset: 0xF98 | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	0h	T_PCIE2_RP_PRIV_XP_L1_TO_RECOVERY_COUNT_VALUE: 0h: VALUE_INIT (default)

32.3.7.49 T_PCIE2_RP_PRIV_XP_L0_TO_RECOVERY_COUNT

This register reflects the number of entries from L0 to Recovery. It is reset whenever it is read. If the count saturates before it is read then it remains saturated till it is read.

Offset: 0xF9C | Read/Write: R/W

Bit	R/W	Reset	Description
31:9	R	0	Reserved
8	R/W	0h	T_PCIE2_RP_PRIV_XP_L0_TO_RECOVERY_COUNT_REASON: 0h: REASON_INIT (default) 0h: REASON_ALL 1h: REASON_ERR
7:0	R	0h	T_PCIE2_RP_PRIV_XP_L0_TO_RECOVERY_COUNT_VALUE: 0h: VALUE_INIT (default)

32.3.7.50 T_PCIE2_RP_PRIV_XP_L1P_ENTRY_COUNT

This register reflects the number of entries from L0 to Deep L1. It is reset whenever it is read. If the count saturates before it is read then it remains saturated till it is read.

Offset: 0xFA0 | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	0h	T_PCIE2_RP_PRIV_XP_L1P_ENTRY_COUNT_VALUE: 0h: VALUE_INIT (default)

32.3.7.51 T_PCIE2_RP_PRIV_XP_ASLM_COUNT

This register reflects the number of switching between x1 and x16 for Gen2 Only. It is reset whenever it is read. If the count saturates before it is read then it remains saturated till it is read.

Offset: 0xFA4 | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	0h	T_PCIE2_RP_PRIV_XP_ASLM_COUNT_VALUE: 0h: VALUE_INIT (default)

32.3.7.52 T_PCIE2_RP_RP_VEND_CTL2

This register contains miscellaneous control fields.

Offset: 0xFA8 | Read/Write: R/W

Bit	R/W	Reset	Description
31:25	R	0h	Reserved
24	R/W	0h	T_PCIE2_RP_VEND_CTL2_COMPLIANCE_X8_DELAY: CTL for compliance delay pattern If set to 0, delay pattern will wrap as soon as the pattern hits lane n - 1 where n is the maximum width of the controller for the current xbar configuration. This ensures that there is always at least one lane sending a delay pattern during compliance. If set to 1, delay pattern will wrap when the pattern hits lane 8 or 16 (mod 8) even if its maximum width is narrower than x8. This means there will be stretches when no lane is sending a delay pattern during compliance. 0h: COMPLIANCE_X8_DELAY_INIT (default)

Bit	R/W	Reset	Description
23	R/W	1h	T_PCIE2_RP_VEND_CTL2_IGNORE_ATTENTION_BUTTON_MSG: When this bit is set, the DUT will ignore upstream Attention button pressed message which has been sent by the endpoint. PCIe specification 1.1 specifies that this message should be ignored. 0h: IGNORE_ATTENTION_BUTTON_MSG_FALSE 1h: IGNORE_ATTENTION_BUTTON_MSG_TRUE (default)
22	R/W	0h	T_PCIE2_RP_VEND_CTL2_UNBLOCK_UP_TRANSACTIONS: When an upstream error has occurred which causes all further upstream transactions to be blocked, writing one to this bit will clean blocking of all upstream transacton. 0h: UNBLOCK_UP_TRANSACTIONS_FALSE (default) 1h: UNBLOCK_UP_TRANSACTIONS_TRUE
21	R/W	0h	T_PCIE2_RP_VEND_CTL2_BLOCK_UP_TRANSACTIONS_ON_ERR: To block all upstream transactions after an Error has been detected and forwarding of packet after the error can cause data corruption or break programming paradigm. 0h: BLOCK_UP_TRANSACTIONS_ON_ERR_EN (default) 1h: BLOCK_UP_TRANSACTIONS_ON_ERR_DIS

0	R	0	Reserved

32.3.7.53 T_PCIE2_RP_PRIV_XP_CONFIG

Offset: 0xFAC | Read/Write: R/W

Bit	R/W	Reset	Description
31:2	R	0	Reserved
1:0	R/W	0h	T_PCIE2_RP_PRIV_XP_CONFIG_LOW_PWR_DURATION: Meant for selection of different types of the information logging for the Health and Performance counters. Primarily, this register supports the selection of different information for the low power duration count. It is used for selecting the Low power information to be presented in the T_PCIE2_RP_PRIV_XP_DURATION_IN_LOW_PWR_100NS register. TX_L0S, RX_L0S and L1 collect the duration for which LTSSM was in that state. DURATION_IDLE selection gives following IDLE = Duration(TX_L0S && RX_L0S) + Duration of L1 0h: LOW_PWR_DURATION_TX_L0S (default) 1h: LOW_PWR_DURATION_RX_L0S 2h: LOW_PWR_DURATION_L1 3h: LOW_PWR_DURATION_IDLE

32.3.7.54 T_PCIE2_RP_PRIV_XP_DURATION_IN_LOW_PWR_100NS

This register counts the duration in multiples of 100ns for the type of low power information selected by the T_PCIE2_RP_PRIV_XP_CONFIG_LOW_PWR_DURATION register.

Note: This actually reports in multiples of clk25m time periods that fit into 100ns:

Actual time = int(100 / clk25m time period) * 100NS_VALUE

For example, when clk25m = 12 MHz, the time period is 83.33 ns, so this status register reports time = 100_NS_VALUE x 83.33 ns.

Offset: 0xFB0 | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	0h	T_PCIE2_RP_PRIV_XP_DURATION_IN_LOW_PWR_100NS_VALUE: 0h: VALUE_INIT (default)

32.3.7.55 T_PCIE2_RP_PRIV_XP_SKP_TIMEOUT

This register counts the duration in multiples of 100ns for the type of low power information selected by the T_PCIE2_RP_PRIV_XP_CONFIG_LOW_PWR_DURATION.

Offset: 0xFB4 | Read/Write: R/W

Bit	R/W	Reset	Description

25	R/W	0h	T_PCIE2_RP_XP_CTL_1_OLD_IOBIST_EN: This bit when set will enable old iobist, else it will enable new iobist. 0h: OLD_IOBIST_EN_INIT (default)
24:19	R/W	0h	T_PCIE2_RP_XP_CTL_1_EIOS_DEBOUNCE_TIMER: This is the number of xclks for which the rx_data_en signals need to be deasserted before asserting again. 0h: EIOS_DEBOUNCE_TIMER_INIT (default)
18	R/W	0h	T_PCIE2_RP_XP_CTL_1_DISABLE_RX_LANE_AFTER_EIOS: Disable rx_lane_en after EIOS is seen in any of the enabled lane during recovery.Rlock and Recovery.Config in order to avoid coupling. 0h: DISABLE_RX_LANE_AFTER_EIOS_INIT (default)
17	R/W	0h	T_PCIE2_RP_XP_CTL_1_ENABLE_DESKEW_FOR_SPDCH_NEGOTIATION: When set to 0, forces LTSSM to disable deskew in Recovery.RcvrCfg state if the transition from Recovery.RcvrLock to RcvrCfg state is due to LTSSM detecting eight consecutive training set on any of the lanes but not all of the lanes, and speed change bit is set to 1. When set to 1, LTSSM will always enable deskew in Recovery.RcvrCfg state. 0h: ENABLE_DESKEW_FOR_SPDCH_NEGOTIATION_INIT (default)
16	R/W	0h	T_PCIE2_RP_XP_CTL_1_BYPASS_CONFIG_PWRUP: When set to 0, forces LTSSM to go from Recovery.RcvrLock to Config.Pwrup if LTSSM sees training set on some but not all the active lanes. This bit only takes effect when the link is operating in dynamically reduced link width and specification-defined link width resize is enabled. When set to 1, LTSSM will go from Recovery.RcvrLock to Config.LinkStart directly, bypassing Config.Pwrup, when LTSSM sees training set on some but not all the active lanes. 0h: BYPASS_CONFIG_PWRUP_INIT (default)
15	R/W	0h	T_PCIE2_RP_XP_CTL_1_RESET_TS_CTRL_ON_ERROR: When set to 1, in Config.LinkStart state, LTSSM will reset the internal TS_CTRL0 register if an 8B/10B error is present on any symbol of the training set. When set to 0, in Config.LinkStart state, LTSSM will reset the internal TS_CTRL0 register if 8B/10B error is present on symbols 0, 4 or 5 only. 0h: RESET_TS_CTRL_ON_ERROR_INIT (default)
14	R/W	0h	T_PCIE2_RP_XP_CTL_1_RX_EIDLE_EXIT_TIMER_IN_CONFIG: When set to 1, T_PCIE2_RP_XP_IDLE_TIMER_1_RX_EIDLE_EXIT will be applied in Config.LinkStart only. When set to 0, T_PCIE2_RP_XP_IDLE_TIMER_1_RX_EIDLE_EXIT will be applied in Config.LinkStart, Recovery and Polling. 0h: RX_EIDLE_EXIT_TIMER_IN_CONFIG_INIT (default)
13	R/W	1h	T_PCIE2_RP_XP_CTL_1_FORCE_RESET_IN_CONFIG: When set to 1, LTSSM will force receiver logic to be reset when enabling lanes in Config.LinkStart state for PCIe 2.0 specification-defined link width upconfiguration. 1h: FORCE_RESET_IN_CONFIG_INIT (default)
12	R/W	1h	T_PCIE2_RP_XP_CTL_1_LINK_RESIZE_PWRDN_CTL: 1h: LINK_RESIZE_PWRDN_CTL_INIT (default)
11	R/W	1h	T_PCIE2_RP_XP_CTL_1_ALLOW_SPEED_CHANGE_FROM_L0S: When set to 1, LTSSM will initiate link speed/width/advertised rate change while RX side is in L0s link state. 1h: ALLOW_SPEED_CHANGE_FROM_L0S_INIT (default)

Bit	R/W	Reset	Description
10	R/W	0h	T_PCIE2_RP_XP_CTL_1_PRESERVE_TX_PACKET_ON_DL_RETRAIN: When set to 1, LTSSM will wait for framer to be idle before entering Recovery for DL initiated link retrain. Note: Setting this bit to 1 could prevent LTSSM to enter Recovery on a replay rollover event if the retry buffer is very full. 0h: PRESERVE_TX_PACKET_ON_DL_RETRAIN_INIT (default)
9	R/W	0h	T_PCIE2_RP_XP_CTL_1_PRESERVE_TX_PACKET_ON_RECOVERY: Note: Setting this bit to 1 does not work if L1 ASPM is enabled as it will cause hang during L1 negotiation if Root Port initiate entry to Recovery. Note: During DL init sequence, if link is retrained, setting this bit to 1 would hang the chip. 0h: PRESERVE_TX_PACKET_ON_RECOVERY_INIT (default)
8	R/W	1h	T_PCIE2_RP_XP_CTL_1_PRESERVE_TX_PACKET_ON_WIDTH_CHANGE: When set to 1, LTSSM will wait for framer to be idle before entering Recovery for link width change. 1h: PRESERVE_TX_PACKET_ON_WIDTH_CHANGE_INIT (default)
7	R/W	1h	T_PCIE2_RP_XP_CTL_1_PRESERVE_TX_PACKET_ON_SPEED_CHANGE: When set to 1, LTSSM will wait for framer to be idle before entering Recovery for link speed change or advertised rate change. 1h: PRESERVE_TX_PACKET_ON_SPEED_CHANGE_INIT (default)
6	R/W	0h	T_PCIE2_RP_XP_CTL_1_RESET_LANE_ENABLE_ORIG_IN_DETECT: This field will allow lane_enable_original to be reset in Detect state. 0h: RESET_LANE_ENABLE_ORIG_IN_DETECT_INIT (default)
5:2	R/W	0h	T_PCIE2_RP_XP_CTL_1_IDLE_TO_L0_DELAY: This field sets the number of clocks that the LTSSM will delay the transition from Recovery.Idle to L0.Normal link state or Config.Idle to L0.Normal link state. 0h: IDLE_TO_L0_DELAY_INIT (default)
1	R/W	0h	T_PCIE2_RP_XP_CTL_1_LWLO_HUNT_ON_BAD_TS1: When set to 1, the LWLOFSM hunt timer does not reset when any lane receives an error on the TS1 ordered set in the Config.LinkStart, Config.LinkAccept, Config.LaneWait, and Config.LaneAccept states. When set to 0, the LWLOFSM hunt timer will reset when any lane receives the first error on the TS1 ordered set after any lanes has locked and hunt timer has started counting in the Config.LinkStart, Config.LinkAccept, Config.LaneWait, and Config.LaneAccept states. 0h: LWLO_HUNT_ON_BAD_TS1_INIT (default)
0	R/W	0h	T_PCIE2_RP_XP_CTL_1_FORCE_SA_IN_CONFIG: When set to 1, enables symbol alignment in Config.LinkAccept, Config.LaneWait, Config.LaneAccept, and Config.Complete states. 0h: FORCE_SA_IN_CONFIG_INIT (default)

32.3.7.66 T_PCIE2_RP_PRIV_XP_L1BEACON

Offset: 0xFF0 | Read/Write: R/W

Bit	R/W	Reset	Description
31:10	R	0	Reserved
9:2	R/W	0h	T_PCIE2_RP_PRIV_XP_L1BEACON_N_EIE_SYMBOLS: It is the number of EIE symbols sent in L1 Beacon Entry/Exist state 40h: N_EIE_SYMBOLS_INIT (default)
1	R/W	0h	T_PCIE2_RP_PRIV_XP_L1BEACON_TX_BYP_CTRL: 0h: TX_BYP_CTRL_DEFAULT (default) 0h: TX_BYP_CTRL_ONLYL0 1h: TX_BYP_CTRL_ALLLANES

Bit	R/W	Reset	Description
0	R/W	0h	T_PCIE2_RP_PRIV_XP_L1BEACON_EN: 0h: EN_DEFAULT (default)

32.3.7.67 T_PCIE2_RP_TIMEOUT3

Offset: 0xFF4 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	Ch	T_PCIE2_RP_TIMEOUT3_RX_L0S_IDLE_TIME_GEN2: This field controls the amount of time LTSSM delays the detection of electrical idle exit in the RX_L0s state at Gen2 speed of operation. Ch: RX_L0S_IDLE_TIME_GEN2_INIT (default)
23:16	R/W	4h	T_PCIE2_RP_TIMEOUT3_RX_L0S_IDLE_TIME_GEN1: This field controls the amount of time LTSSM delays the detection of electrical idle exit in the RX_L0s state at Gen1 speed of operation. 4h: RX_L0S_IDLE_TIME_GEN1_INIT (default)
15:8	R/W	FFh	T_PCIE2_RP_TIMEOUT3_TX_L0S_IDLE_TIME: This field controls the minimum amount of time LTSSM stays in TX_L0S_IDLE state. Measured in units of clk25m clock periods (83 ns when using 12 MHz clock) scaled with xclk frequency. A setting of 8'hFF disables the delay. FFh: TX_L0S_IDLE_TIME_INIT (default)
7:4	R/W	0h	T_PCIE2_RP_TIMEOUT3_RX_EIDLE_EXIT_DELAY: This field controls the amount of time the LTSSM delays the detection of TS ordered set when exiting out of electrical idle state. Each increment represents 2^X microseconds. A setting of 0 disables the delay. 0h: RX_EIDLE_EXIT_DELAY_INIT (default)
3:0	R/W	0h	T_PCIE2_RP_TIMEOUT3_TX_EIDLE_EXIT_DELAY: This field controls the amount of time the LTSSM delays the transmission of TS ordered sets when exiting out of electrical idle state. Unit is in microseconds. Each increment represents 2^X microseconds. A setting of 0 disables the delay. 0h: TX_EIDLE_EXIT_DELAY_INIT (default)

32.3.7.68 T_PCIE2_RP_XP_CTL_2

This register contains controls bits used in XP.

Offset: 0xFF8 | Read/Write: R/W

Bit	R/W	Reset	Description
31:9	R	0	Reserved
8	R/W	0h	T_PCIE2_RP_XP_CTL_2_CONFIG_LINKSTART_REQUIRE_PAD_LANE_NUM. Forces the LTSSM training set detector to require PAD in the lane number symbol of training set in Config.LinkStart state: 0h: INIT (default)
7:0	R/W	40h	T_PCIE2_RP_XP_CTL_2_LOOPBACK_EXIT_THRESHOLD. Programs the maximum amount of time spent in the Loopback.Exit state as loopback slave. Units are in xclk. The setting of 0 disables the timer in Loopback.Exit state such that loopback slave relies on detection of electrical idle data to exit from Loopback. The default is 64 xclks: 40h: INIT (default)

32.3.7.69 T_PCIE2_RP_VEND_XP_STATS2

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: 0xFFC | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R	0	Reserved
15:0	R/W	0h	T_PCIE2_RP_VEND_XP_STATS2_8B10B_ERR_LANEMASK: Each individual bit represents the corresponding logical lane. When set to 1, the 8B/10B error from that specific lane will be masked out from the counter in T_PCIE2_RP_VEND_XP_STATS1_8B10B_ERRORS 0h: 8B10B_ERR_LANEMASK_INIT (default) FFFEh: 8B10B_ERR_LANEMASK_LN0 FFFDh: 8B10B_ERR_LANEMASK_LN1 FFFBh: 8B10B_ERR_LANEMASK_LN2 FFF7h: 8B10B_ERR_LANEMASK_LN3 FFEFh: 8B10B_ERR_LANEMASK_LN4 FFDFh: 8B10B_ERR_LANEMASK_LN5 FFBFh: 8B10B_ERR_LANEMASK_LN6 FF7Fh: 8B10B_ERR_LANEMASK_LN7

32.4 AFI Registers

32.4.1 AFI_AXI_BARi_SZ_0

There are 9 AXI BAR SIZE registers, where i = 0 through 8.

BAR0: Offset: 0x0 | Read/Write: R/W | Reset: 0x0003f000 (0b00111111000000000000)
BAR1 – BAR5: Offset: 0x4 + (i – 1) * 0x4, where i = 1 – 5 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000)
BAR6 – BAR8: Offset: 0x134 + (i – 6) * 0x4, where i = 6 – 8 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000)

Bit	Description
19:0	AXI_BARi_SIZE: The size of the address range associated with BARi is in 4K increments. A value of 0 signifies BARi is not used.

32.4.2 AFI_AXI_BARi_START_0

There are 9 AXI BAR START registers, where i = 0 through 8.

BAR0: Offset: 0x18 | Read/Write: R/W | Reset: 0x01000000 (0b00000001000000000000)
BAR1 – BAR5: Offset: 0x1c + (i – 1) * 0x4, where i = 1 – 5 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000)
BAR6 – BAR8: Offset: 0x140 + (i – 6) * 0x4, where i = 6 – 8 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000)

Bit	Description
31:12	AXI_BARi_START: The start of AXI address space for BARi. The AXI target address is compared to start/size for each BAR to determine if the access is to that BAR.

32.4.3 AFI_FPCI_BARi_0

There are 9 FPCI BAR registers, where i = 0 through 8.

BAR0: Offset: 0x30 | Read/Write: R/W | Reset: 0x00010001 (0b00000000000000010000000000000xxx1)
BAR1 – BAR5: Offset: 0x34 + (i – 1) * 0x4, where i = 1 – 5 | Read/Write: R/W | Reset: 0x00000001 (0b00000000000000000000000000000xxx1)
BAR6 – BAR8: Offset: 0x14c + (i – 6) * 0x4, where i = 6 – 8 | Read/Write: R/W | Reset: 0x00000001 (0b00000000000000000000000000000xxx1)

Bit	Description
31:4	FPCI_BARi_START: The start of FPCI address space mapped into the BARi range of PCI memory space. The 40-bit FPCI address is determined by a shift left 8 of the value of this register.
0	FPCI_BARi_ACCESS_TYPE: Indicates if the address region is memory mapped versus configuration or I/O space. 1=Memory mapped access (PW only) 0=IO/config access (NPW only)

32.4.4 AFI_MSI_BAR_SZ_0

Do not use this reserved space.

MSI BAR Size

Offset: 0x60 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000)

Bit	Reset	Description
19:0	0x0	MSI_BAR_SIZE

32.4.5 AFI_MSI_FPCI_BAR_ST_0

MSI FPCI BAR Start

Offset: 0x64 | Read/Write: R/W | Reset: 0x58540000 (0b01011000010101000000000000000)

Bit	Reset	Description
31:4	0x5854000	MSI_FPCI_BAR_START: The start of upstream FPCI address space for MSI BAR. The upstream FPCI address is compared to start/1KB range for MSI BAR to determine if the access is MSI. Bits 31:4 of MSI BAR start correspond to UFPCI address bits 39:12.

32.4.6 AFI_MSI_AXI_BAR_ST_0

MSI AXI BAR Start

Offset: 0x68 | Read/Write: R/W | Reset: 0x80000000 (0b10000000000000000000)

Bit	Reset	Description
31:12	0x80000	MSI_AXI_BAR_START: The start of upstream AXI address space for MSI BAR. The upstream FPCI address is compared to start/1KB range for MSI BAR to determine if the access is MSI. Bits 31:12 of MSI BAR start correspond to AXI address bits 31:12.

32.4.7 AFI_MSI_VECi_0

MSI Vector

There are 8 MSI Vector registers (AFI_MSI_VECi), where i is a value from 0 to 7.

Offset: 0x6c + (i * 4) | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTORi: Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0.Vector7 corresponds to MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

32.4.8 AFI_MSI_EN_VEC0_0

MSI Enable Vector

There are 8 MSI Enable Vector registers (AFI_MSI_EN_VECi), where i is a value from 0 to 7.

Offset: 0x8c + (i * 4) | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTORi: Each vector register corresponds to the enable bit for 32of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

32.4.9 AFI_CONFIGURATION_0

Configuration

Offset: 0xac | Read/Write: R/W | Reset: 0x000XXX40 (0b0xxxxxxxxxxx1xxx10xxxxxx01000000)

Bit	R/W	Reset	Description
31	RW	0x0	CLKEN_OVERRIDE: This can override the clock enable in case of malfunction.
19	RW	0x1	PW_NO_DEVSEL_ERR_CYA: Setting this bit disables detection of DECERR due to no devsel for DS PWs only.
18	RO	X	INITIATOR_READ_IDLE: This read-only bit provides status reads on AFI upstream. A value of 1b indicates there are no outstanding reads to the initiator.
17	RO	X	INITIATOR_WRITE_IDLE: This read-only bit provides status writes on AFI upstream. A value of 1b indicates there are no outstanding writes to the initiator.
15	RW	0x1	WDATA_LEAD_CYA: This bit is used to enable/disable the handling of write data ahead of requests on mselect
14	RW	0x0	WR_INTRLV_CYA: This bit is used to enable/disable the handling of interleaved write requests on mselect
13	RO	X	PE1_PRSNT_L_IN: This read-only bit is 0 when a card is present in PCIe slot 1
12	RO	X	PE0_PRSNT_L_IN: This read-only bit is 0 when a card is present in PCIe slot 0
11	RO	X	TARGET_READ_IDLE: This read-only bit provides status reads to AFI target. A value of 1b indicates there are no outstanding reads to the downstream FPCI.
10	RO	X	TARGET_WRITE_IDLE: This read-only bit provides status writes to AFI target. A value of 1b indicates there are no outstanding writes to the downstream FPCI.
9	RO	X	MSI_VEC_EMPTY: This read-only bit provides status on whether MSI Vector registers have any valid active bits.
7	RW	0x0	UFPCI_MSIAW: MSI After Write ordering rule. 1 = whenever MSI is ready assert the interrupt 0 = default behavior, apply MSIAW ordering rule
6	RW	0x1	UFPCI_PWPASSPW: Input to upstream FPCI 1 = whenever write is ready, send it; 0 = write goes only when outstanding PWs outside of new write's region are retired (default).
5	RW	0x0	UFPCI_PASSPW: Input to upstream FPCI. Allow upstream FPCI reads to pass writes.
4	RW	0x0	UFPCI_PWPASSNPW: Used for upstream FPCI. Allow upstream FPCI PWs to pass NPWs.
3	RW	0x0	DFPCI_PWPASSNPW: Used for downstream FPCI. Allow downstream FPCI PWs to pass NPWs.
2	RW	0x0	DFPCI_RSPPASSPW: Input to downstream FPCI. Allow downstream FPCI responses to pass writes
1	RW	0x0	DFPCI_PASSPW: Input to downstream FPCI. Allow downstream FPCI reads to pass writes.
0	RW	0x0	EN_FPCI: When the PCI device block is disabled, it is completely invisible on the PCI bus, i.e., it does not even process PCI configuration accesses.

32.4.10 AFI_FPCI_ERROR_MASKS_0

FPCI Error Masks

Offset: 0xb0 | Read/Write: R/W | Reset: 0x00000000 (0b000)

Bit	Reset	Description
2	0x0	MASK_FPCI_MASTER_ABORT: This bit allows an FPCI error to be forwarded to AXI response when the FPCI error response indicates Master Abort. 1 = forward error 0 = return AXI OKAY response (2'b0)
1	0x0	MASK_FPCI_DATA_ERROR: This bit allows an FPCI error to be forwarded to AXI response when the FPCI error response indicates Data Error. 1 = forward error 0 = return AXI OKAY response (2'b0)
0	0x0	MASK_FPCI_TARGET_ABORT: This bit allows an FPCI error to be forwarded to AXI response when

Bit	Reset	Description
		FPCI error response indicates Target Abort. This bit also covers a decode error generated when there is no devsel received. 1 = forward error, 0 = return AXI OKAY response (2'b0)

32.4.11 AFI_INTR_MASK_0

Interrupt Masks

Offset: 0xb4 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxx0)

Bit	Reset	Description
8	0x0	MSI_MASK: MSI to MPCORE gated by mask.
0	0x0	INT_MASK: Interrupt to MPCORE gated by mask.

32.4.12 AFI_INTR_CODE_0

Interrupt Code

Detected errors are logged in an error signature register as specified here. The error signature register always stores the first error that occurred after enabling the error capture. The interrupt code register logs the interrupt ID shown in the ID column of Table 132. This register stores the ID for the associated interrupt when current ID in the register is zero. Software must write zero to the register to re-enable it to store subsequent interrupts. For ID=6, the capture information is the sideband message bits. There is an associated interrupt generated to the CPU. Since FPCI address is 40 bits, a separate capture register is used for the upper 8 bits of the address.

Offset: 0xb8 | Read/Write: R/W | Reset: 0x00000000 (0b00000)

Bit	Reset	Description
4:0	0x0	INT_CODE: If the code is 0, logging of the next interrupt is enabled. See Table 132 for the system messages. 0 = INT_CODE_CLEAR : Clear interrupt code 1 = INT_CODE_INI_SLVERR : Interrupt code for MPCORE AXI SLVERR response to AFI 2 = INT_CODE_INI_DECERR : Interrupt code for MPCORE AXI DECERR response to AFI 3 = INT_CODE_TGT_SLVERR : Interrupt code for PCIe endpoint FPCI target abort or data error response to AFI 4 = INT_CODE_TGT_DECERR : Interrupt code for PCIe2 FPCI master abort response to AFI 5 = INT_CODE_TGT_WRERR : Interrupt code for bufferable write to non-posted write address region 6 = INT_CODE_SM_MSG : Interrupt code for PCIe2 system management message 7 = INT_CODE_DFPCI_DECERR : Interrupt code for PCIe2 response to downstream request when the downstream FPCI address does not fall in a claimable downstream region 8 = INT_CODE_AXI_DECERR : Interrupt code for AFI response to downstream request when the mselect AXI address does not fall in any of AFI downstream BARs 9 = INT_CODE_FPCI_TIMEOUT : Interrupt code for FPCI Timeout 10 = INT_CODE_PE_PRSNT_SENSE : Interrupt code for Slot Present Pin Change 11 = INT_CODE_PE_CLKREQ_SENSE : Interrupt code for Slot Clock Request Change 12 = INT_CODE_CLKCLAMP_SENSE : Interrupt code for TMS Clock Clamp Change 13 = INT_CODE_RDY4PD_SENSE : Interrupt code for TMS Ready for power down 14 = INT_CODE_P2P_ERROR : Interrupt code for Peer2Peer errors

Table 132: System Messages

Error/Message	ID	Capture Information
AXI Slave error	1	Bits [31:2] of Initiator AXI address, direction of transaction
AXI Decode error	2	

Error/Message	ID	Capture Information
AXI Slave error – PCIe target abort or data error	3	Bits [39:2] of Target FPCI address, direction of transaction
AXI Decode error – PCIe master abort	4	
AXI Decode error – write to NPW address region > 4B	5	Bits[39:2] of Target AXI address, direction of transaction
PCIe 2.0 Sideband message	6	Sideband UnitID, Bits[4:0] of sideband message
FPCI Decode error – not in PCIe 2.0 memory space	7	Bits[39:2] of Target FPCI address, direction of transaction
AXI Decode error – not in AFI BAR or register space	8	Bits [31:2] of Target AXI address, direction of transaction
FPCI Timeout	9	None
Slot Present Pin Change	10	Bits [2:0] capture status of slots 2-0 present pin
Slot Clock Request Change	11	Bits [2:0] capture status of slots 2-0 clock request
TMS Clock Clamp Change	12	Bit [0] captures level of clock clamp
TMS Ready for power down	13	None – all 3 controllers are ready for power down
Peer-to-peer error	14	Error response from endpoint device (tms02ufa_cmd_error), Bits[39:2] of Target FPCI address, direction of transaction

32.4.13 AFI_INTR_SIGNATURE_0

Interrupt Signature

Offset: 0xbc | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000x0)

Bit	Reset	Description
31:2	0x0	INT_INFO: For interrupt codes 1-5/7-8, this field contains address bits [31:2], either in FPCI memory space or AXI space. If the interrupt code is 6, the information field INT_INFO[12:0] contains sideband information {sideband unitid, 3'b0, tms02sm_msg[4:0]}. For FPCI generated errors, the information field contains FPCI address. For AXI/AFI generated errors, the information field contains AXI address. For interrupt code 10, this field contains the status of slots 2-0 present pin. For interrupt code 11, this field contains the status of slots 2-0 clock request For interrupt code 12, this field contains level of clock clamp
0	0x0	DIR: Indicates the direction of the AXI/FPCI transaction. 1=rd 0=wr If signature type is 6 (sideband message), this field is 1. 0 = WRITE : Interrupt due to a write transaction 1 = READ : Interrupt due to a read transaction

32.4.14 AFI_UPPER_FPCI_ADDR_0

Upper FPCI Address

Offset: 0xc0 | Read/Write: R/W | Reset: 0x00000000 (0b00xxxxxxxx00000000)

Bit	Reset	Description
17:16	0x0	P2P_ERR_RESP: These 2 bits are for the captured endpoint device error response (tms02ufa_cmd_error) when the interrupt code is 14.

Bit	Reset	Description
7:0	0x0	INT_INFO_UPPER: These 8 bits are the upper byte of captured FPCI address (bits[39:32]) when the interrupt code is 3, 4, or 7. These bits determine the region in the Hypertransport Address Map that was accessed.

32.4.15 AFI_SM_INTR_ENABLE_0

Sideband Message Interrupt Enable

Offset: 0xc4 | Read/Write: R/W | Reset: 0x00000000 (0b0000000000000000)

Bit	Reset	Description
14:0	0x0	ENABLE_MESSAGE: Each bit in this register enables a corresponding message shown in thetable below.

[1:0]	[3:2]	[4]	Enable bit	MSG_TYPE	Description
00	00	1	0	Interrupt	INTA Assertion.
	01		1		INTB Assertion.
	10		2		INTC Assertion.
	11		3		INTD Assertion.
	00	0	4		INTA Deassertion
	01		5		INTB Deassertion
	10		6		INTC Deassertion
	11		7		INTD Deassertion
01	00	0	8	Error	Correctable Error
	01		9		Uncorrectable Non-Fatal Error
	10		10		Uncorrectable Fatal Error
10	00	0	11	PME	PME assertion.
10	01	0	12	Hotplug	Hotplug SCI assertion
11	00	1	13	Interrupt	Root Port Interrupt Assertion
11	00	0	14		Root Port Interrupt Deassertion

32.4.16 AFI_AFI_INTR_ENABLE_0

AFI Interrupt Enable

See the AFI_INTR_CODE_0 register for details on the interrupt codes.

Offset: 0xc8 | Read/Write: R/W | Reset: 0x00000000 (0b0000000000000)

Bit	Reset	Description
12	0x0	EN_P2P_ERR: Enable bit for interrupt code 14
11	0x0	EN_RDY4PD_SENSE: Enable bit for interrupt code 13
10	0x0	EN_CLKCLAMP_SENSE: Enable bit for interrupt code 12
9	0x0	EN_PE_CLKREQ_SENSE: Enable bit for interrupt code 11
8	0x0	EN_PE_PRSNT_SENSE: Enable bit for interrupt code 10
7	0x0	EN_FPCI_TIMEOUT: Enable bit for interrupt code 9

Bit	Reset	Description
6	0x0	EN_AXI_DECERR: Enable bit for interrupt code 8
5	0x0	EN_DFPCI_DECERR: Enable bit for interrupt code 7
4	0x0	EN_TGT_WRERR: Enable bit for interrupt code 5
3	0x0	EN_TGT_DECERR: Enable bit for interrupt code 4
2	0x0	EN_TGT_SLVERR: Enable bit for interrupt code 3
1	0x0	EN_INI_DECERR: Enable bit for interrupt code 2
0	0x0	EN_INI_SLVERR: Enable bit for interrupt code 1

32.4.17 AFI_FPCI_TIMEOUT_0

Do not use this reserved space.

FPCI Timeout

Offset: 0xd8 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
31	0x0	SM2TMS0_FPCI_TIMEOUT_EN
19:0	0x0	SM2ALL_FPCI_TIMEOUT_THRESH

32.4.18 AFI_PCIE_THROTTLE_0

PCIe Throttle

Offset: 0xec | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxxxxxxxxxx000000000000x000)

Bit	Reset	Description
31	0x0	SM2PCIE_THROT_EN: Override THERM MGMT
15:4	0x0	SM2PCIE_THROT_PERIOD: Override THERM MGMT period
2:0	0x0	SM2PCIE_THROT_DUTY_CYCLE: Override THERM MGMT duty cycle

32.4.19 AFI_PME_0

PCIe PME

Offset: 0xf0 | Read/Write: R/W | Reset: 0x00000XX0 (0bxxx0xxxxxxx0)

Bit	R/W	Reset	Description
11	RO	X	TMS0C12SM_PRESENCE_STATE: PCIe Link Presence State
10	RO	X	TMS0C12SM_PME_ACK: PCIe Endpoint PME Ack
9	RO	X	TMS0C12SM_PME: PCIe Endpoint PME message
8	RW	0x0	SM2TMS0C1_PME_TO: SM (system management) to PCIe PME Turn Off
6	RO	X	TMS0C02SM_PRESENCE_STATE: PCIe Link Presence State
5	RO	X	TMS0C02SM_PME_ACK: PCIe Endpoint PME Ack
4	RO	X	TMS0C02SM_PME: PCIe Endpoint PME message
0	RW	0x0	SM2TMS0C0_PME_TO: SM (system management) to PCIe PME Turn Off

32.4.20 AFI_REQ_PENDING_0

Request Pending

Offset: 0xf4 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxx)

Bit	Reset	Description
7	X	TMS0C12SM_NONISO_PENDING: SM (system management) status that a Non-ISO request is pending from PCIe to FPCI
6	X	TMS0C12SM_ISO_PENDING: SM (system management) status that an ISO request is pending from PCIE to FPCI
5	X	TMS0C12SM_NONCOH_REQUEST_PEND: SM (system management) status that a Non-coherent request is pending from PCIe to FPCI
4	X	TMS0C12SM_COH_REQUEST_PEND: SM (system management) status that a coherent request is pending from PCIe to FPCI
3	X	TMS0C02SM_NONISO_PENDING: SM (system management) status that a Non-ISO request is pending from PCIe to FPCI
2	X	TMS0C02SM_ISO_PENDING: SM (system management) status that an ISO request is pending from PCIe to FPCI
1	X	TMS0C02SM_NONCOH_REQUEST_PEND: SM (system management) status that a Non-coherent request is pending from PCIe to FPCI
0	X	TMS0C02SM_COH_REQUEST_PEND: SM (system management) status that a coherent request is pending from PCIe to FPCI

32.4.21 AFI_PCIE_CONFIG_0

PCIe Config

Offset: 0xf8 | Read/Write: R/W | Reset: 0x00003025 (0b0000xxx00011xxx00010x101)

Bit	Reset	Description
23:20	0x0	SM2TMS0_XBAR_CONFIG: SM (system management) configuration of PCIe crossbar. 1 = XBAR_4_1 : x4_x1 configuration 0 = XBAR_2_1 : x2_x1 configuration
16:12	0x3	UNITID_T0C1: T0C1 Upstream FPCI Unit ID. HyperTransport, upstream FPCI request. The downstream FPCI unit ID should remain 0.
8:4	0x2	UNITID_T0C0: T0C0 Upstream FPCI Unit ID. HyperTransport, upstream FPCI request
2	0x1	PCIEC1_DISABLE_DEVICE: Disables PCIe Controller 1 (default on)
1	0x0	PCIEC0_DISABLE_DEVICE: Disables PCIe Controller 0 (default off)
0	0x1	SM2TGIO_SLOT_EMPTY_PD_CYA: Indicates PCIe slot empty. Overrides PCIe slot present input.

32.4.22 AFI_REV_ID_0

Revision ID

Offset: 0xfc | Read/Write: R/W | Reset: 0x00000000 (0b00)

Bit	Reset	Description
1	0x0	CFG_REVID_WRITE_ENABLE: Write Enable for PCI backdoor rev ID override value.
0	0x0	CFG_REVID_OVERRIDE: Override for PCI config revision ID read-only register. This allows backdoor changes to rev ID for metal spins.

32.4.23 AFI_TOM_0

Top of Memory Limit

Offset: 0x100 | Read/Write: R/W | Reset: 0x3f3f0fff (0b111111001111111xxxx111111111111)

Bit	Reset	Description
29:16	0x3f3f	DLDT2ALL_TOM2: Top of Memory Limit 2. Determines peer-to-peer range as:{TOM2 :: 26'b0} to 0xFC_FFFF_FFFF
11:0	0xfff	DLDT2ALL_TOM1: Top of Memory Limit 1. Determines peer-to-peer range as:{TOM1 :: 26'b0} to 0xFFFF_FFFF (except MSI region)

32.4.24 AFI_FUSE_0

PCIe Fuse

Offset: 0x104 | Read/Write: R/W | Reset: 0x00000336 (0b011x011x11)

Bit	Reset	Description
10:8	0x3	FUSE_PCIE_WIDTH_T0C1: Configure PCIe as x1, x2, x4, x8, or x16. This should remain at 3'b011
6:4	0x3	FUSE_PCIE_WIDTH_T0C0: Configure PCIe as x1, x2, x4, x8, or x16. This should remain at 3'b011
2	0x1	FUSE_PCIE_T0_GEN2_DIS: Disable Gen 2 capability of PCIe.
1	0x1	FUSE_PCIE_SLI_DIS: Disable SLI capability for the GPU. This should remain on.

32.4.25 AFI_PMU_0

PMU Interface

Offset: 0x108 | Read/Write: R/W | Reset: 0x0XXXX000 (0bxxxxxxxxxxxxxx00000000xxx0)

Bit	R/W	Reset	Description
24	RO	X	CTLR_T0_C1_2PMU_TOG: PMU toggle response from PCIe
23:20	RO	X	CTLR_T0_C1_2PMU_STATUS: PMU Status
16	RO	X	CTLR_T0_C0_2PMU_TOG: PMU toggle response from PCIe
15:12	RO	X	CTLR_T0_C0_2PMU_STATUS: PMU Status
11:8	RW	0x0	PMU2CTLR_T0_C1_LOAD_INDICATOR_SCALE: PMU Load Indicator Scale for T0C1
7:4	RW	0x0	PMU2CTLR_T0_C0_LOAD_INDICATOR_SCALE: PMU Load Indicator Scale for T0C0
0	RW	0x0	PMU2ALL_LI_UPDATE_FAST_TOG: PMU Load Indicator Enable. This is used for wall-plug applications and should remain off.

32.4.26 AFI_PCIE_CLK_CONFIG_STATUS_0

PCIE2 CLK Config/Status

Offset: 0x10c | Read/Write: R/W | Reset: 0x0XXXXX00 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000)

Bit	R/W	Reset	Description
27:24	RO	X	PCIE2CLK_TMS0GRP2_PAD_MACRO_CLK_SEL: Clock select to pad macro. This should remain at 0.
23:20	RO	X	PCIE2CLK_TMS0GRP1_PAD_MACRO_CLK_SEL: Clock select to pad macro. This should remain at 0.
19:16	RO	X	PCIE2CLK_TMS0GRP0_PAD_MACRO_CLK_SEL: Clock select to pad macro. This should

Bit	R/W	Reset	Description
			remain at 0.
13	RO	X	PCIE2CLK_TMS0C1_DIS_XTXCLK1X: Request to gate T0C1 XTXCLK1X when in low power mode.
12	RO	X	PCIE2CLK_TMS0C0_DIS_XTXCLK1X: Request to gate T0C0 XTXCLK1X when in low power mode.
11	RO	X	PCIE2CLK_TMS0_CLAMP_CLK_L1: Request to gate TMS/FPCI clocks when in low power mode.
10	RO	X	PCIE2CLK_TMS0C1_SEL_XTXCLK1X_GEN2: Request to select Gen2 speed clock (500 MHz) for T0C1 XTXCLK1X. This is generated when register settings for PCIe2 specify Gen2 speed clocks.
9	RO	X	PCIE2CLK_TMS0C0_SEL_XTXCLK1X_GEN2: Request to select Gen2 speed clock (500 MHz) for T0C0 XTXCLK1X. This is generated when register settings for PCIe2 specify Gen2 speed clocks. This should remain low.
8	RO	X	PCIE2CLK_TMS0_SEL_XCLK_GEN2: Request to select Gen2 speed clock (500 MHz) for XCLK. This is generated when register settings for PCIe2 specify Gen2 speed clocks. This should remain low.
4	RW	0x0	CLK2PCIE_TMS0C1_OFF_XTXCLK1X: Acknowledge to disable T0C1 XTXCLK1X request. Used for clock gating.
3	RW	0x0	CLK2PCIE_TMS0C1_RDY_XTXCLK1X_GEN2: Acknowledge to select T0C1 XTXCLK1X Gen2 request. This should remain low.
2	RW	0x0	CLK2PCIE_TMS0C0_OFF_XTXCLK1X: Acknowledge to disable T0C0 XTXCLK1X request. Used for clock gating.
1	RW	0x0	CLK2PCIE_TMS0C0_RDY_XTXCLK1X_GEN2: Acknowledge to select T0C0 XTXCLK1X Gen2 request. This should remain low.
0	RW	0x0	CLK2PCIE_TMS0_RDY_XCLK_GEN2: Acknowledge to select XCLK Gen2 request. This should remain low.

32.4.27 AFI_PEX0_CTRL_0

PCIe PHY and Sideband Signal Interface

Offset: 0x110 | Read/Write: R/W | Reset: 0x00000000 (0b00x00)

Bit	Reset	Description
4	0x0	PEX0_REFCLK_OVERRIDE_EN: PEX0 enable to override refclk to be enabled always if PEX0_REFCLK_EN is set
3	0x0	PEX0_REFCLK_EN: PEX0 enable to clkout pad
1	0x0	PEX0_CLKREQ_EN: PEX0 enable clkreq to control clkout pad
0	0x0	PEX0_RST_L: PEX0 external pe0_rst_l register

32.4.28 AFI_PEX0_STATUS_0

Offset: 0x114 | Read/Write: RO | Reset: 0x0000000X (0bx)

Bit	Reset	Description
0	X	PEX0_CLKREQ_L: Status of the PEX0 pe0_clkreq_l input

32.4.29 AFI_PEX1_CTRL_0

Offset: 0x118 | Read/Write: R/W | Reset: 0x00000000 (0b00x00)

Bit	Reset	Description

Bit	Reset	Description
4	0x0	PEX1_REFCLK_OVERRIDE_EN: PEX1 enable to override refclk to be enabled always if PEX1_REFCLK_EN is set
3	0x0	PEX1_REFCLK_EN: PEX1 enable to clkout pad
1	0x0	PEX1_CLKREQ_EN: PEX1 enable clkreq to control clkout pad
0	0x0	PEX1_RST_L: PEX1 external pe1_rst_l register

32.4.30 AFI_PEX1_STATUS_0

Offset: 0x11c | Read/Write: RO | Reset: 0x0000000X (0bx)

Bit	Reset	Description
0	X	PEX1_CLKREQ_L: Status of the PEX1 pe1_clkreq_l input

32.4.31 AFI_INITIATOR_ISO_PW_RESP_PENDING_0

Initiator ISO PW Response Pending

Offset: 0x158 | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:8	X	NUM_INITIATOR_ISO_PW_RESP_PEND_T0C1: Number of pending initiator ISO PW responses for controller 1
7:0	X	NUM_INITIATOR_ISO_PW_RESP_PEND_T0C0:Number of pending initiator ISO PW responses for controller 0

32.4.32 AFI_INITIATOR_NISO_PW_RESP_PENDING_0

Initiator Non-ISO PW Response Pending

Offset: 0x15c | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:8	X	NUM_INITIATOR_NISO_PW_RESP_PEND_T0C1: Number of pending initiator NISO PW responses for controller 1
7:0	X	NUM_INITIATOR_NISO_PW_RESP_PEND_T0C0: Number of pending initiator NISO PW responses for controller 0

32.4.33 AFI_PLLE_CONTROL_0

PLLE Controls

Offset: 0x160 | Read/Write: R/W | Reset: 0x00000000 (0b00xxxxxx00)

Bit	Reset	Description
9	0x0	BYPASS_PADS2PLLE_CONTROL: Overrides PCIe PADS CLKREQ control of the PLLE.
8	0x0	BYPASS_PCIE2PLLE_CONTROL: Overrides PCIe2 CLOCK CLAMP control of the PLLE.
1	0x0	PADS2PLLE_CONTROL_EN: When active, all CLKREQs going inactive indicate DISABLE to the PLLE. When SATA, PCIe2, and PADS all indicate DISABLE to the PLLE, then the PLLE is disabled.
0	0x0	PCIE2PLLE_CONTROL_EN: When active, PCIE2 CLOCK CLAMP going active signal DISABLE to PLLE. When SATA, PCIe2, and PADS all indicate DISABLE to the PLLE, then the PLLE is disabled.

32.4.34 AFI_BUST_CONTROL_0

Bus Trace Module Controls

Offset: 0x164 | Read/Write: R/W | Reset: 0x00X00000 (0bx0xx00000000000000000)

Bit	R/W	Reset	Description
21	RO	X	PCIE_RXL_BUST_TRIG_OUT0_T0: Bus trigger from bus trace module in PCIe2
20	RW	0x0	TRACE_EXTERNAL_START: Start signal to bus trace module in PCIe2
17:16	RW	0x0	PCIE_RXL_BUST_BUS_TRACE_MUX_SEL_T0: MUX select to bus trace module in PCIe2
15:0	RW	0x0	CHIP_ID: Chip ID to bus trace module in PCIe2

32.4.35 AFI_PEXBIAS_CTRL_0

Offset: 0x168 | Read/Write: R/W | Reset: 0x00000001 (0b1)

Bit	Reset	Description
0	0x1	PEX_BIAS_PWRD: PEX clock bias pad power down

32.4.36 AFI_P2PBOM_CTRL_0

Offset: 0x16c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000)

Bit	Reset	Description
19:0	0x0	P2P_BASE:Peer-to-peer Bottom of Memory - connects to bits 39:20 of p2p_base_63_to_20 with the top bits tied to 0

32.4.37 AFI_P2PTOM_CTRL_0

Offset: 0x170 | Read/Write: R/W | Reset: 0x000003ff (0b00000000001111111111)

Bit	Reset	Description
19:0	0x3ff	P2P_LIMIT:Peer-to-peer Top of Memory - connects to bits 39:20 of p2p_limit_63_to_20 with the top bits tied to 0

32.4.38 AFI_CLKGATE_HYSTERESIS_0

Clock Gate Hysteresis

Offset: 0x174 | Read/Write: R/W | Reset: 0x00000014 (0b00010100)

Bit	Reset	Description
7:0	0x14	CLK_DISABLE_CNT: Number of AFI clock cycles to wait after clock gating criteria is met to disable the AFI/FPCI clocks

32.4.39 AFI_SPARE_REG0_0

Bit 31 is used as a Diagnostics bit to bypass both AXI target RAW and peer2peer RAW address comparison logic (default value is 1).

If 1, reads push all pending writes. Address range detection is bypassed.

If 0, reads only push pending writes that are in the same small address range.

Offset: 0x180 | Read/Write: R/W | Reset: 0xffff0000 (0b11111111111111110000000000000000)

Bit	Reset	Description
31:0	-65536	IPFS_SPARE_REG: Spare Register.

32.4.43 AFI_AFI_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control (where applicable) and Clock Gating Control Register

Note: The FIFO timing aspects of this register are no longer supported, but retained for software compatibility

The clock override/ovr_mode fields of this register control the second-level clock gating for the client and MC side of the MCCIF. All clock gating is enabled by default.

A '1' written to the rclk/wclk override field will result in one of the following:

- With wclk/rclk override mode = LEGACY, the clock reverts to legacy mode of operation where the clock is on whenever the client clock is enabled.
- With wclk/rclk override mode = ON, the clock is always on inside MCCIF and PC. A '1' written to the cclk override field keeps client's clock always on inside MCCIF.

Offset: 0x7cc | Read/Write: R/W | Reset: 0x00000000 (0b00000xxxxxxxxxxxx0000)

Bit	Reset	Description

[THIS PAGE INTENTIONALLY LEFT BLANK]

33.0 I2C CONTROLLER

The I^2C controller (I2C) implements an I^2C 3.0 specification-compliant I^2C master and slave controller. The I^2C controller supports multiple masters and slaves. It supports Standard mode (up to 100 Kbits/s), Fast mode (up to 400 Kbits/s), Fast mode plus (Fm+, up to 1 Mbits/s), and High-speed mode (up to 3.4 Mbits/s).

Tegra K1 devices have six instances of this controller. All six instances have identical I2C master functionality.

The I^2C controller supports DMA for the Master controller over the APB bus. There is no DMA support for the Slave controller. The I^2C controller also supports packet mode transfers where the data to be transferred is encapsulated in a predefined packet format as payload and sent to the I^2C controller over the APB bus. The header of the packet specifies the type of operation to be performed, the size and other parameters (described in detail in subsequent sections).

Features

- Standard (up to 100 Kbits/s), Fast (up to 400 Kbits/s), Fm+ (up to 1 Mbits/s), and High-speed (up to 3.4 Mbits/s) modes of operation.
- Clock stretching by the slave
- One to eight-word burst data transfers in DMA mode for the Master controller
- 4 Kbyte transfers in packet mode. Can be extended beyond 4 Kbytes by breaking up transfers into multiple packets (in both DMA and non-DMA modes)
- 7-bit or 10-bit addressing transactions
- Master is capable of data transfers to/from two or more slaves consecutively with a repeated-start condition
- Bus clear operations to address SDA issues
- General call addressing
- Recognition and transfer of data to peripherals that do not send an acknowledge (ACK)
- Master supports packet based DMA

Clocking

The I^2C controller has three clock domains:

- The Host interface runs on the APB clock (pclk). The APB clock is derived from the system clock and can be 1.0, ½, 1/3 or ¼ times the system clock (sclk).
- The I^2C interface controller clock runs on a frequency up to 136 MHz (maximum). The 136 MHz clock is derived from PLLP. Even though you can mux between PLLP, PLLC, PLLM, and OSC clocks, PLLP is always selected and used in normal operation.
- The time-out logic runs on a 32 kHz clock.

33.1 Functionality

The I^2C Master can be programmed for either a single slave transaction or a two-slave transaction. The two-slave transaction is generally useful in a random read from an external device. When reading from an external device, the random read-address needs to be set with an initial dummy-write to the device, followed by a repeated-start and a read transaction to the same device.

33.1.1 Bus Clear Master Operation

Bus clear logic helps to resolve I2C bus hang issues. If the data line (SDA) is permanently stuck low because a slave device is pulling it low continuously for some unknown reason, the I2C master loses the arbitration and stops driving the I2C bus. In this

case, software can use the Bus Clear master to get the SDA line released by sending clock pulses on the SCL line. Per the I2C specification, the device that held the bus Low should release it sometime within 9 clock pulses. But if the device needs more clock pulses than the default 9 pulses, software has an option to do so by programming a configurable register bit field (I2C_I2C_BUS_CLEAR_CONFIG_0[BC_SCLK_THRESHOLD]) to the required number of clock pulses.

Bus Clear Programming Procedure:

The Bus Clear operation starts with an ARB_LOST notification from the I^2C controller. The ARB_LOST notification could be due to many reasons. For example, in a multi-master platform, any other master could occupy the I2C bus already. When software initiates Tegra-I2C for a data transfer at this time, the master could backoff if it does not win the bus in the bus-arbitration procedure. Other cases for ARB_LOST are programming issues such as controller register configuration, pinmuxing, and pin tri-state clear.

If it was determined that ARB_LOST notification is due to a slave device continuously pulling the SDA line low, the bus clear operation can be initiated to recover the bus with the following steps:

1. Reset the I2C controller using module reset after the ARB_LOST notification from the controller.
2. Program the I2C_I2C_BUS_CLEAR_CONFIG_0[BC_SCLK_THRESHOLD] bit field to the required number of clock pulses.
3. Select the STOP or NO_STOP condition using the I2C_I2C_BUS_CLEAR_CONFIG_0[BC_STOP_COND] bit field.
4. Program I2C_I2C_BUS_CLEAR_CONFIG_0[BC_TERMINATE] as needed
5. Set the I2C_I2C_CONFIG_LOAD_0[MSTR_CONFIG_LOAD] register bit field to 1, and wait until this bit field is auto-cleared to zero by hardware.
6. Set the I2C_I2C_BUS_CLEAR_CONFIG_0[BC_ENABLE] bit field to start the bus clear operation. Hardware auto clears this bit after the bus clear operation is done.
7. Once enabled, the bus clear logic starts sending clock pulses on the SCL line.
8. Based on BC_TERMINATE settings, the Bus Clear logic:
   - IMMEDIATE: Sends clock pulses until SDA is released or the threshold count is reached, whichever is earlier or
   - THRESHOLD: Sends the threshold number of clock pulses irrespective of SDA line release status (released before threshold is reached or not-released with threshold count reached)
9. If SDA is released within the programmed number of clock pulses:
   - The Bus Clear logic terminates the transaction with STOP/NO-STOP condition based on the BC_STOP_COND settings.
   - Then it sets the bus_clear operation status in the I2C_I2C_BUS_CLEAR_STATUS_0[BC_STATUS] register bit field.
   - Finally, it sets the BUS_CLEAR DONE bit field in I2C_INTERRUPT_STATUS_REGISTER_0 and also interrupts the system if the corresponding interrupt enable bit is set in I2C_INTERRUPT_MASK_REGISTER_0. So software has to wait until it receives the BUS_CLEAR_DONE interrupt if the interrupt mechanism is used or the BUS_CLEAR_DONE status bit is set if the status-polling mechanism used before going for a BUS CLEAR operation successful/fail status check in I2C_I2C_BUS_CLEAR_STATUS_0[BC_STATUS].

33.1.2 Low-Power Operation

I^2C is a low-speed serial interface with only two bus lines (SCL, SDA) required. So from the I^2C specification side, there is no low-power operation specifically defined for the interface. But to save the power, use the lowest possible speed, if performance is not needed. The following bus speeds are supported by I^2C:

- Standard mode (Sm), with a bit rate up to 100 kbit/s
- Fast mode (Fm), with a bit rate up to 400 kbit/s
- Fast mode Plus (Fm+), with a bit rate up to 1 Mbit/s

- High-speed mode (Hs mode), with a bit rate up to 3.4 Mbit/s

33.1.2.1 Low Power Programming

Program the CLK_SOURCE_I2C register (for example: I2C1instance clock source address 0x60006124) and the I2C_CLK_DIVISOR registers such that the required data rate can be achieved at the minimum possible module clock so that power can be saved.

Below are the data relations for various modes of operation.

- Standard/Fast/Fm+:

  SCL = CLK_SOURCE.I2C / ((TLOW+THIGH+3)* (I2C_CLK_DIVISOR_STD_FAST_MODE+1)*I2C FREQUENCY DIVISOR) for lower values of I2C_CLK_DIVISOR_STD_FAST_MODE, up to 3

  SCL = CLK_SOURCE.I2C / ((TLOW+THIGH+2)* (I2C_CLK_DIVISOR_STD_FAST_MODE+1)*I2C FREQUENCY DIVISOR) for higher values of I2C_CLK_DIVISOR_STD_FAST_MODE, above 3

  Default values of I2C_I2C_INTERFACE_TIMING_0_0[TLOW] and I2C_I2C_INTERFACE_TIMING_0_0[THIGH] are 2 and 4 which would work for most of the data rates. So change them only when needed.
- HS mode:

  SCL = CLK_SOURCE.I2C / ((HS_TLOW+HS_THIGH+4) * (I2C_CLK_DIVISOR_HSMODE+1)*I2C FREQUENCY DIVISOR) for lower values of I2C_CLK_DIVISOR_HSMODE, up to 4

  SCL = CLK_SOURCE.I2C / ((HS_TLOW+HS_THIGH+2) * (I2C_CLK_DIVISOR_HSMODE+1)*I2C FREQUENCY DIVISOR) for higher values of I2C_CLK_DIVISOR_HSMODE, above 4The default values of I2C_I2C_HS_INTERFACE_TIMING_0_0[HS_TLOW] and I2C_I2C_HS_INTERFACE_TIMING_0_0[HS_THIGH] are 8 and 3 which would work for most of the data rates. So change them only when needed.

If there is a large rise time on the interface signals because of a weak pull-up or large load capacitance, then the SCL rate will be different from the above equations. The data rates will be slightly lower than expected.

33.1.2.2 IDLE Power Programming

When the module is not used or interface is idle, disable the module clock by clearing the CLK_ENB_I2C bits in the CAR module.

For example, the I2C1 clock enable bit is CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0[CLK_ENB_I2C1]. Software can clear this bit when it is seen that no transfers are needed from the I2C1 instance.

33.2 Software Interfaces

A typical peripheral controller might require the following steps to communicate or control an external peripheral:

1. Set up the registers
2. Program the ‘go’ bit to start the interaction with the external peripheral
3. The peripheral controller collects the response from the peripheral and interrupts software
4. Software reads the response

33.2.1 Packet Flow

The flow is a transport path that can be uniquely identified in the system. It is a virtual path or channel that carries a particular type of packets from a source to a destination. A flow carries logical information and is not dependent on the physical implementation.

Information exchange between the hardware peripheral controller and software as described above can be classified into:

- ‘Request’ flow which can represent the register writes

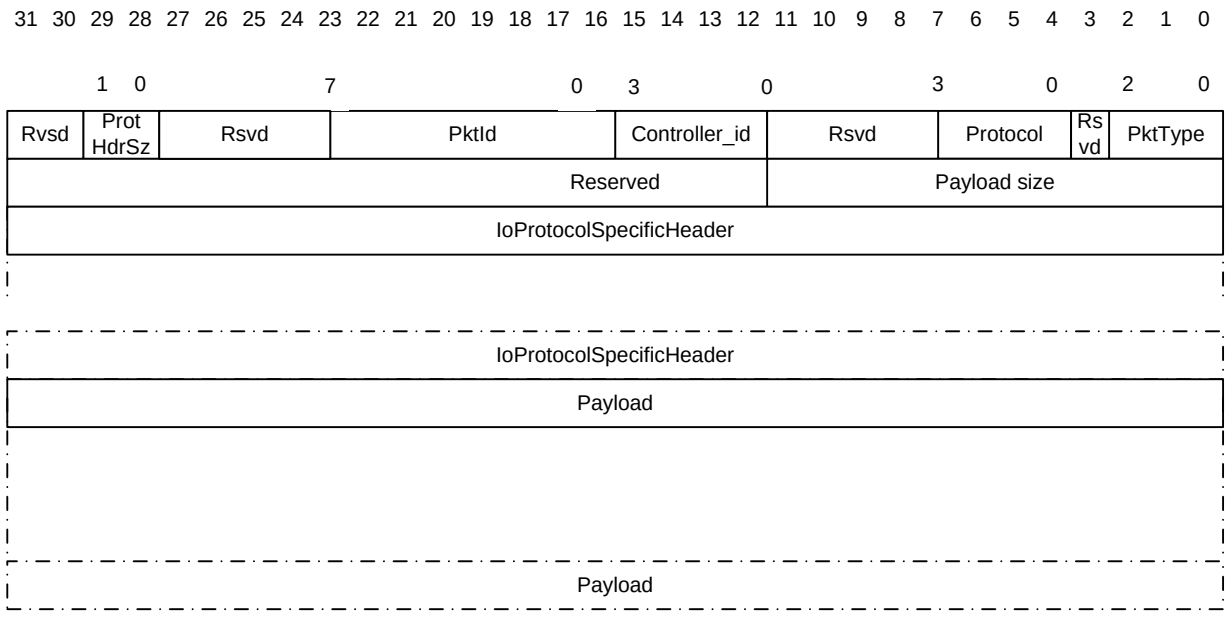
- ‘Response’ flow for peripheral controller responses sent back to software, and
- ‘Interrupt’ flow for out-of-band handshakes between hardware and software

Packets within a flow can be exchanged in a manner that requires full intervention from the CPU (PIO mode) or least intervention from the CPU (DMA mode). The I/O packet described below is a structure that can be used to represent various flows in the system.

33.2.2 I/O Packet Format

An I/O packet consists of a header and payload. The header consists of two parts: two words of generic header and 1-4 words of protocol-specific header.

Figure 120: I/O Packet



33.2.2.1 I/O Packet Word 0

Word 0 of the I/O packet contains the Generic Header Word 0. The contents of generic header word 0 are described in the table below.

Table 133: Generic I/O Header Word 0

Bits	Field Value	Description
31:30	Reserved	Reserved
29:28	ProtHdrSz	Size of the protocol-specific header in words 0 = 1 words 1 = 2 words 2= 3 words 3 = 4 words For I2C, ProtHdrSz = 0 for request packets and 1 for response packets
27:24	Reserved	Reserved
23:16	PktId	PktId is an 8-bit field that identifies the packet. A peripheral controller might choose to log the packet ID for a packet that causes errors
15:12	Controller ID	There might be multiple controllers supporting any format. For example, there might be 4 I2C controllers.

Bits	Field Value	Description
		The Controller ID field specifies the controller for which this packet is destined.
11:8	Reserved	Reserved
7:4	Protocol	The protocol is indicated in this field 0 = reserved 1= I2C 2-15 = reserved
3	Reserved	Reserved
2:0	PktType	Packet type information 0 = request 1 = response 2 = interrupt 3 = stop 4-7 = reserved

33.2.2.2 I/O Packet Word 1

Word 1 of the I/O packet contains Generic Header Word 1. The contents of Generic Header Word 1 are described in the table below.

Table 134: Generic I/O Header Word 1

Bits	Field Value	Description
31:12	Reserved	Reserved
11:0	PayloadSize	Payload size in bytes

Note about Payload Size:

For request packets that transmit data, the total packet size is payload_size + 8 bytes of generic header + protocol-specific header. However, for request packets with a read command, the payload size indicates the amount of data to be received. Hence the packet size = 8 bytes of generic header + protocol-specific header, because there is no payload in this packet, just the receive command.

33.2.3 Transferring Packets

Packets can be transferred using PIO or DMA modes. A peripheral controller can choose to implement one or both modes. The header is a minimum of three words with the first two words reserved for packet information and the third word reserved for protocol-specific requirements. A minimum of four words is needed to transfer one byte to the external peripheral.

33.2.4 Protocol-Specific Header

Depending on the implementation of the peripheral controller and the interface protocol, the header words can be defined. No restriction is placed on the organization of the fields or the number of protocol-specific words (a minimum of one word and a maximum of four words) that a particular implementation chooses.

I2C has one word with the Protocol-Specific Header. The contents of the I2C protocol-specific header are described in the next section.

33.2.5 I2C Master Packet Protocol Specific Headers

The I2C master supports two kinds of packets.

- Transmit packets that flow from Host to Controller.
- Receive data packets that flow from Controller to Host.

Table 135: I2C Master Transmit Packet Header

Bit	Name	Description
31:26	Reserved	Reserved
25	RESP_PKT_FREQ	Response packet frequency. This field is valid only if the I2C master is transmitting (READ/WRITE field below). If the I2C master is receiving, response packets are sent for every request packet received. 0: Send response packet at the end of last packet. 1: Send response packet for each packet transmitted.
24	RESP_PKT_ENABLE	Enable response packet. It qualifies RESP_PKT_FREQ field. 0: Do not send response packets (status has to be obtained via interrupt status bits). 1. Send response packet.
23	Reserved	Reserved
22	HS_MODE	Enable High speed mode (3.4 MHz operation)
21	CONTINUE_ON_NACK	Enable mode to handle devices that do not generate ACK upon the reception of a byte.
20	SEND_START_BYTE	1 = Send a start byte at the beginning of the transaction
19	READ/WRITE	1= READ
18	Address mode	1=10-bit mode 0 = 7-bit mode
17	IE	Generate interrupt upon packet completion
16	REPEAT_START/STOP	1 = Put a repeat start condition on the bus(to continue transaction) 0 = Put a stop condition on the bus
15	ContinueXfer	This bit overrides the REPEAT_START/STOP command above. 0: Introduce repeat start or stop condition based on bit 16. 1: Continue with current transfer without stop or repeat start condition.
14:12	HS_MASTER_ADDR	High Speed mode Master code
11:10	Reserved	Reserved
9:0	SLAVE_ADDR	Slave address. Bit 0 is ignored for 7-bit addressing, but should always match bit 19 (READ/WRITE).

Response packets contain the status of the I^2C controller. To accommodate that, the response packet header contains two words of the protocol-specific header.

Table 136: I2C Master Response Packet Header Word 0

Bit	Name	Description
31:27	Reserved	Reserved
26	RFIFO_OVF	Receive FIFO overflowed.
25	TFIFO_OVF	Transmit FIFO overflowed.
24	TRANSFER_COMPLETE	All the packets have been transferred successfully. The packet for which the “LAST PACKET” field is set has been transferred.
23:16	TRANSFER_PKT_ID	The current packet ID for which the transaction is happening on the bus
15:4	TRANSFER_BYTENUM	The number of bytes transferred in the current packet
3	NOACK_FOR_ADDR	1 = No ACK received for the address byte
2	NOACK_FOR_DATA	1 = No ACK received for the current data byte
1	ARB_LOST	1 = Arbitration lost
0	CONTROLLER_BUSY	1 = Controller is busy

33.3 Programming Guidelines

33.3.1 I2C Frequency Divisor Register

The FREQUENCY DIVISOR register (CLK_SOURCE_I2C register, whose address is: 0x60006124 for I2C1) must be programmed as a function of the CLK_SOURCE selected for I2C as follows:

```
Standard/Fast-mode/Fm+:
SCL = CLK_SOURCE.I2C / ((TLOW+THIGH+3)* (I2C_CLK_DIVISOR_STD_FAST_MODE+1)*I2C FREQUENCY DIVISOR) for
lower values of I2C_CLK_DIVISOR_STD_FAST_MODE, up to 3
SCL = CLK_SOURCE.I2C / ((TLOW+THIGH+2)* (I2C_CLK_DIVISOR_STD_FAST_MODE+1)*I2C FREQUENCY DIVISOR) for
higher values of I2C_CLK_DIVISOR_STD_FAST_MODE, above 3
Default values of I2C_I2C_INTERFACE_TIMING_0_0[TLOW] and I2C_I2C_INTERFACE_TIMING_0_0[THIGH] are 2 and 4
which works for most of the data rates. Change them only when needed.
High Speed mode:
SCL = CLK_SOURCE.I2C / ((HS_TLOW+HS_THIGH+4) * (I2C_CLK_DIVISOR_HSMODE+1)*I2C FREQUENCY DIVISOR) for
lower values of I2C_CLK_DIVISOR_HSMODE, up to 4
SCL = CLK_SOURCE.I2C / ((HS_TLOW+HS_THIGH+2) * (I2C_CLK_DIVISOR_HSMODE+1)*I2C FREQUENCY DIVISOR) for
higher values of I2C_CLK_DIVISOR_HSMODE, above 4
Default values of I2C_I2C_HS_INTERFACE_TIMING_0_0[HS_TLOW] and I2C_I2C_HS_INTERFACE_TIMING_0_0[HS_THIGH]
are 8 and 3 which works for most of the data rates. Change them only when needed.
If there is a large rise time on the interface signals because of a weak pull-up or large load
capacitance, the SCL rate would be different from the above equations. You would notice slightly lower
data rates than expected.
```

The clock enable (bit 12 of the CLK_OUT_ENB.L register) must also be given to the I^2C controller, before any of the registers are written.

Table 137: Recommended Settings for Various I2C Speeds

Source	PLLP_OUT0	I2C Source Div	Tlow+Thigh	SM/FM Div	HS Div	I2C Frequency	Debounce
PLLP	408MHz	3 (0x02)	12[1]	N/A	3 (0x02)	3.48MHz (HS)	0
PLLP	408MHz	3 (0x02)	8	17 (0x10)	N/A	1MHZ (FM+)	0
PLLP	408MHz	5 (0x04)	8	26 (0x19)	N/A	392KHz (FM)	2
PLLP	408MHz	20 (0x13)	8	26 (0x19)	N/A	98KHz (SM)	2

33. The HS_THIGH field in the I2C_I2C_HS_INTERFACE_TIMING_0_0 register must be set to 2 (from default 3) to achieve the full 3.48MHz speed in HS mode.

Debounce will impact the I2C interface data rate in the following way.

$$I2C\ SCL\ rate = \frac{CLK\_SOURCE}{SOURCE\_DIV * (Tlow + Thigh + 2 + Round\_Trip\_Delay) * STD\_or\_HS\_DIV}$$

Where:

$$Round\_Trip\_Delay\ in\ I2C\ Div\ \text{cycles} = \frac{(Chip\_internal\_delay + Load\_Delay + (((Debounce\_Cnt * 2 + 1) + Synchronizer) * I2C\_Clk\_Period))}{I2C\_Clk\_Period}$$

For example, if CLK_SOURCE = 408 MHz and Source Div = 5:

I2C_Clock frequency = 408/5 = 81.6 MHz ➔ I2C clock period = 12.25 ns

Chip internal delay = 10 ns, Load_Delay = 55 ns, Debounce = 2, Synchronizer Delay = 3

Round_Trip_Delay = (10 ns + 55 ns + 8*12.25 ns) = ~163 ns

FM+ speed case: STD_FM_Div = 10

STD_FM_Div * I2C_Clk_Period = 10*12.255 ns = 122.55 ns

Round_Trip_Delay in I2C_Div cycles = Round_Trip_Delay/(STD_FM_Div * I2C_Clk_Period) = 1.

So I2C SCL rate = $\frac{408MHz}{5*(8+1)*10}$ = 906 KHz

If Debounce is disabled, the Round_Trip_delay (in I2C_Div cycles) becomes zero.

So I2C SCL rate = $\frac{408MHz}{5*(8)*10}$ = 1002 KHz = 1.02 MHz

Table 138 I2C Data Rate Variation with Debounce

I2C Mode	Clock Source	Source Clock Frequency	I2C Source Divisor	SM/FM Divisor	Debounce Value	I2C SCL Frequency
FM+	PLLP_OUT0	408MHz	5 (0x04)	10 (0x9)	0	1016KHz
					[5:1]	906KHz
					[7:6]	816KHz
FM	PLLP_OUT0	408MHz	5 (0x4)	26 (0x19)	[7:0]	392KHz
SM	PLLP_OUT0	408MHz	20 (0x13)	26 (0x19)	[7:0]	98KHz
				HS Divisor		
HS	PLLP_OUT0	408MHz	3 (0x2)	3 (0x2)	0	3.48MHz
					[7:1]	Not allowed

33.3.2 I2C Command ADDR Registers

These registers, I2C_CMD_ADDR0 and I2C_CMD_ADDR1, contain the address of the slave with which a transaction is intended. The I^2C Master Controller can be programmed to transact with both 7-bit and 10-bit addressed slaves. Bit [0] of the I2C_CNFG register determines the size of the slave address to be transacted. If a 7-bit or a 10-bit slave address is chosen, the respective address is taken from I2C_CMD_ADDR0 [9:0], and the Read/Write command is taken from bits 6 and 7 of the I2C_CNFG Register. In a 2 Slave configuration, the slave 1 address (7-bit or 10-bit) is taken from I2C_CMD_ADDR0 [9:0] and Slave 2 address (7-bit or 10-bit) from I2C_CMD_ADDR1 [9:0]. The transfer length is the same in 2 slave operation and is taken from the I2C_CNFG [LENGTH] bit field. In 2-slave operation, the maximum possible transfer size is 4 bytes.

33.3.3 I2C Data Registers

There are two data registers, I2C_CMD_DATA1and I2C_CMD_DATA2, each with 32-bit length, which are to be loaded with the data to be transmitted or received (I2C_SL_RCVD register).

33.3.4 I2C Configuration Register

This register is to be configured with the following data:

- Number of bytes to be transmitted or received
- Select for 7-bit or 10-bit slave address
- Program to send a Start Byte
- Single or two slave operations
- Support of NOACK from an external peripheral

The I2C_CNGF [9] bit is used to issue a “Begin-Transaction” command to the I^2C Master Controller. This bit is auto cleared by the hardware, and other bits of the register are masked for writes, when this bit is programmed to be one. Hence, the firmware should first configure all the other registers and bits [8:0] of the I2C_CNFG register before the I2C_CNFG [9] bit is programmed to one.

33.3.5 I2C Configuration Load Register

This CONFIG load register transfers the software programmed configuration in the I2C registers to hardware internal registers used in the logic. It has three bit fields:

- MSTR_CONFIG_LOAD for regular master and Bus Clear master logic
- SLV_CONFIG_LOAD for slave controller logic
- TIMEOUT_CONFIG_LOAD for SMBUS timeout logic.

Software must set these fields to 1 for the actual register configuration to take effect. Thus software is programming only shadow registers through regular configuration. When these load_config bit fields are set to 1, it causes the regular/shadow registers configuration to be transferred to the hardware internal active registers. So software has to set these bit fields at the end of all regular register configurations. However, in normal or non-packet mode, these bit fields should be set to 1 before the I2C_I2C_CNFG_0[SEND] bit is set to 1. The I2C_I2C_CNFG_0[SEND] bit triggers a transfer on the I2C bus and should be programmed at the end of the entire configuration. These config_load bits are hardware auto-clear bits. Hardware clears these bit fields once the register configuration is moved to hardware internal active registers. So software must wait until these bits are auto-cleared before continuing with further programming.

Below are the register bit fields associated with each CONFIG_LOAD bit.

MSTR_CONFIG_LOAD needs to be set for the following registers:

- I2C_I2C_CNFG_0
- I2C_I2C_CMD_ADDR0_0
- I2C_I2C_CMD_ADDR1_0
- I2C_I2C_CMD_DATA1_0
- I2C_I2C_CMD_DATA2_0
- I2C_I2C_CLK_DIVISOR_REGISTER_0
- I2C_I2C_BUS_CLEAR_CONFIG_0
- I2C_I2C_INTERFACE_TIMING_0_0
- I2C_I2C_INTERFACE_TIMING_1_0
- I2C_I2C_HS_INTERFACE_TIMING_0_0
- I2C_I2C_HS_INTERFACE_TIMING_1_0

SLV_CONFIG_LOAD covers the following registers:

- I2C_I2C_SL_CNFG_0
- I2C_I2C_SL_ADDR1_0
- I2C_I2C_SL_ADDR2_0
- I2C_I2C_TLOW_SEXT_0[RST_SL_ON_TIMEOUT]
- I2C_I2C_SL_DELAY_COUNT_0

TIMEOUT_CONFIG_LOAD covers the following register bit fields:

- I2C_I2C_TLOW_SEXT_0[TIMEOUT]
- I2C_I2C_TLOW_SEXT_0[TLOW_SEXT]
- I2C_I2C_TLOW_SEXT_0[TLOW_MEXT]

- I2C_I2C_TLOW_SEXT_0[TIMEOUT_EN]
- I2C_I2C_TLOW_SEXT_0[TLOW_SEXT_EN]
- I2C_I2C_TLOW_SEXT_0[TLOW_MEXT_EN]

33.3.6 I2C Controller Status Register

This register (I2C_STATUS) gives the status of the I^2C Master operation. It includes the busy status of the I^2C controller and the completion status of the command executed.

33.3.7 I2C Interface Timing Registers

These registers provide flexibility to tune the I2C interface bus timing, if needed. Separate bit fields are provided for non-HS (STD/FM/FM+) and HS modes timing.

33.3.8 Interrupt Generation in Non-Packet (Normal) Mode

In non-packet mode, the I^2C controller generates interrupts upon the completion of transmission or reception of the specified number of bytes. A Master interrupt is generated when the number of bytes of the transaction, as programmed in the LENGTH field of the I2C_CNFG register, is complete.

33.3.8.1 Example Transfers in Normal Mode

Write Example:

This programming example is for 7 byte writes from master to an external slave.

Program the I2C_CLK_DIVISOR register to get the required data rate based on I2C CLK_SOURCE register programming in CAR module

- Write the slave address in the I2C_CMD_ADDR0 register based on 7-bit/10-bit addressing mode
- Write the first 4 bytes of data in the I2C_CMD_DATA1 register
- Write the remaining 3 bytes in I2C_CMD_DATA2 register
- Program I2C_CNFG[DEBOUNCE_CNT] to the required value as needed
- Set I2C_CNFG[A_MOD] to 7-bit or 10-bit addressing
- Program I2C_CNFG [LENGTH]. This bit field works in (n+1) fashion; so for a 7-byte transfer, 6 needs to be programmed in the LENGTH bit field
- Set I2C_CNFG [SLV2] = 0 as this is one slave access
- Set CMD1 = 0 for write operation
- Set NOACK to 0 or 1 based on Slave type
- Set the MSTR_CONFIG_LOAD bit in the I2C_CONFIG_LOAD register
- Finally, set I2C_CNFG [SEND] to 1 to begin a write transaction on the interface
- Wait unit the transaction is complete, either until an interrupt is received or the I2C_STATUS[BUSY] bit becomes zero.
- Check I2C_STATUS [CMD1_STAT] to see if the transaction is successful or there is a NOACK from the slave for any of the bytes transferred.

Read Example

A read operation is divided into two steps based on random read or immediate read after a write. In a typical random read:

1. Write command : Send slave register/memory index first from which the data needs to be read

2. Send read command to read the data. This operation can be done in two separate configurations or in a single configuration using Repeated Start in 2-slave config.

These steps are described in more detail below.

- Write: Sending slave's 1-byte register index first
  - Write the slave address in I2C_CMD_ADDR0 register based on 7-bit/10-bit addressing mode
  - Write the slave's internal register index (from which the data has to be read) in the I2C_CMD_DATA1 register
  - Program I2C_CNFG[DEBOUNCE_CNT] to the required value as needed
  - Set I2C_CNFG[A_MOD] to 7-bit or 10-bit addressing
  - Program I2C_CNFG[LENGTH] = 0 for a 1 byte register index transfer
  - Set I2C_CNFG[SLV2] = 0
  - Set I2C_CNFG[CMD1] = 0 for write operation
  - Set I2C_CNFG[NOACK] to 0 or 1 based on the Slave type
  - Finally, set I2C_CNFG[SEND] to begin the write transaction on the interface
  - Wait unit the transaction is complete (wait until either an interrupt is received or the I2C_STATUS [BUSY] bit becomes zero).
  - Check I2C_STATUS[CMD1_STAT] to see if the transaction is successful or there is a NOACK from the slave
- Read: Send read command
  - Program I2C_CNFG[LENGTH] = 6 for 7-bytes read
  - Set I2C_CNFG[SLV2] = 0 because this is one slave access
  - Set I2C_CNFG[CMD1] = 1 for read operation
  - Finally set I2C_CNFG[SEND] to begin write transaction on the interface
  - Wait unit the transaction is complete (wait until either an interrupt is received or the I2C_STATUS [BUSY] bit becomes zero).
  - Check I2C_STATUS[CMD1_STAT] to see if the transaction is successful or there is a NOACK from the slave
  - Read the first 4 bytes data in the I2C_CMD_DATA1 register
  - Read the remaining 3 bytes in the I2C_CMD_DATA2 register
- Read using repeated-start in 2-slave mode
  - Write the slave address in the I2C_CMD_ADDR0 register with the LSB bit set to "0"
  - Write the slave address in the I2C_CMD_ADDR1 register with the LSB bit set to "1"
  - Write the slave's internal register index byte (from which the data has to be read) in the I2C_CMD_DATA1 register
  - Program I2C_CNFG[DEBOUNCE_CNT] to the required value as needed
  - Set I2C_CNFG[A_MOD] to 7-bit or 10-bit addressing
  - Program I2C_CNFG[LENGTH] = 0 for 1 byte transfer
  - Set I2C_CNFG[SLV2] = 1
  - Set I2C_CNFG[CMD1] = 0 for write operation
  - Set I2C_CNFG[CMD2] = 1 for read operation
  - Set I2C_CNFG[NOACK] to 0 or 1 based on the Slave type
  - Finally set I2C_CNFG[SEND] to begin the write transaction on the interface
  - Wait unit the transaction is complete (wait until either an interrupt is received or the I2C_STATUS [BUSY] bit becomes zero).

- Check I2C_STATUS [CMD1_STAT] to see if the transaction is successful or there is a NOACK from the slave
- Read data from the I2C_CMD_DATA2 register

33.4 Programming Guidelines for Packet-Based Interface

33.4.1 Packet Based Interface Registers

The following registers are used for a packet based interface:

- I2C TX FIFO
- I2C RX FIFO
- PACKET TRANSFER STATUS
- FIFO CONTROL
- FIFO STATUS
- FIFO STATUS (common for both master and slave)
- Interrupt Mask Register (common for both master and slave)
- Interrupt Status Register (common for both master and slave)
- I2C Clock Divisor Register for master
- PACKET_MODE_EN, DEBOUNCE_CNT, and NEW_MASTER_FSM fields of I2C_CNFG Register
- CONFIG_LOAD bits in the I2C_CONFIG_LOAD register

All other registers/fields have no meaning in packet mode and should be used only normal mode.

33.4.2 Programming Packet Header and Payload

Software should program the I2C_TX_PACKET_FIFO register. It writes the packet header followed by the payload. The header size can vary from 3 to 5 words. For I2C, the size is 3 words for request packets and 4 words for response packets. The first two words of the header contain a generic header. The third word of the packet (and fourth as well for response packets) contains I2C transaction-specific information. The payload contains the actual data to be written to the slave. In case of read operations, payload is nil, and hence, the packet contains only a header.

33.4.3 Reading from the RX FIFO

The data received on the bus is pushed into the RX FIFO. In PIO mode, a request interrupt is generated when the attention level is reached, and software reads the RX_FIFO register to get the data. In DMA mode, a request is asserted to DMA after the attention level is reached.

33.4.4 Error Handling

The following steps describe what needs to happen when an error occurs due to a NOACK, loss of arbitration, TX FIFO overflow, or RX FIFO overflow before proceeding with any further transactions:

- When an error occurred due to a NOACK, a stop condition is put on the bus and an interrupt is generated
- The status register is updated with the current error packet ID at which the error occurred
- Software should reset the controller
- In case of a DMA transfer, DMA needs to be restarted

In packet mode, special care should be taken to handle error recovery. If an error occurs during the transfer of a packet, then the controller should be reset, DMA needs to be restarted (if using DMA transfers), and the entire packet needs to be resent since there is no accurate way of knowing how many bytes made it to the I2C slave.

The repeat start bit in packet mode can complicate the situation further. When back-to-back packets are sent to a slave with the repeat start bit set, and if an error occurs, it is not always known during which packet transfer the error occurred. Therefore, the entire stream of packets that were sent back to back using the repeat start bit need to be sent again.

Receives are simpler, since if an error occurs, and bytes for a packet have already been received, that packet can be deemed complete. Only incomplete transfers need to be retried.

33.4.5 Programming REPEAT_START/STOP

This field indicates whether or not to put a stop or repeated-start condition after the current transaction. By default, this bit is zero and a stop condition is put on the bus. If this bit is set, a repeat start is put on the bus before proceeding with the next packet. The REPEAT_START/STOP bit can be used for combining read operations and write operations within a single transaction with a repeat start, or to do transfers beyond the 4 Kbyte limit. This bit is present in the protocol-specific header.

33.4.6 Programming Continue-Xfer

The I^2C controller supports transfer sizes beyond 4 Kbytes without a repeat start condition, again by combining multiple packets. This is in addition to the ability to use a repeat start condition to do continuous transfers over 4 Kbyte limit. With the ContinueXfer field, the current transfer can continue without a stop or a repeat start condition.

33.4.7 FIFO Control

In DMA mode, TX_FIFO_TRIG indicates the number of words that need to be empty in the TX FIFO for the DMA trigger to be asserted. RX_FIFO_TRIG indicates the number of words that need to be full in the RX FIFO for the DMA trigger to be asserted.

In PIO mode, TFIFO_DATA_REQ in the Interrupt Status Register will be set if the TX FIFO empty count is more than the value programmed in TX_FIFO_TRIG. Similarly RFIFO_DATA_REQ in the Interrupt Status Register will be set if the RX FIFO full count is more than the value programmed in RX_FIFO_TRIG. The CPU will be interrupted if the status bits are set and their corresponding INT_EN bit is set in the Interrupt Mask Register. The depth of the TX and RX FIFOs is 8.

33.4.8 FIFO Status

This register indicates the number of entries that are empty in the TX FIFO (TX_FIFO_EMPTY_CNT) and the number of entries that are full in the RX FIFO(RX_FIFO_FULL_CNT).

33.4.9 Example Transfer

Here is a programming example for a 1 byte read followed by a 5-byte write

1. Program the PACKET_MODE_EN field to 1 and then set the corresponding LOAD_CONFIG bit fields to 1.
2. Write the generic packet header
3. Write the payload size = 0x0 (1 byte)
4. Write the I2C specific header read/write = 1 and repeat_start/stop = 1
5. Write the generic packet header
6. Write payload size = 0x4 (5 bytes)
7. Write the I2C specific header read/write = 0 and repeat_start/stop = 0
8. Write the 5 bytes (word aligned)

33.5 I2C Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

33.5.1 I2C_I2C_CNFG_0

IC Controller Configuration Register (Master)

The I2C_CNFG register is used to configure:

- the number of bytes to be transmitted or received
- the slave device type (either a 7-bit device or a 10-bit device)
- enable mode to send Start-byte or not
- to select either a single slave transaction or two slave transaction
- enable mode to handle devices that do not generate an ACK.

Offset: 0x0 | Read/Write: R/W | Reset: 0x00000800 (0bxxxxxxxxxxxxxxxx0000100000000000)

Bit	Reset	Description
15	0x0	MSTR_CLR_BUS_ON_TIMEOUT: When this bit is set, the I2C master will force the clock low for an extended period of time (>TIMEOUT) to force all SMB slaves to release the bus. 0 = Do not clear the bus on TLow: SEXT/TIMEOUT time-out 1 = Clear the bus on TLow: SEXT/TIMEOUT time-out
14:12	0x0	DEBOUNCE_CNT: Debounce period for SDA and SCL lines. 0 = No debounce 1 = 2T 2 = 4T 3 = 6T, etc. where T is the period of the fixed PLL clock source coming to I2C. Maximum debounce period is 14T. A debounce period of > 50 ns is desirable.
11	0x1	NEW_MASTER_FSM: Maintained for backward compatibility. 0 = DISABLE 1 = ENABLE
10	0x0	PACKET_MODE_EN: Write 1 to initiate transfer in packet mode. 0 = NOP 1 = GO
9	0x0	SEND: Writing a 1 causes the master to initiate the transaction in normal mode. This bit is cleared by hardware when the transaction is done. Other bits of the register are masked for writes when this bit is programmed to one. Thus, firmware should first configure all other registers and bits [8:0] of this register before this bit is programmed to one. 0 = NOP 1 = GO
8	0x0	NOACK: Enable mode to handle devices that do not generate an ACK. 1 = Do not look for an ACK at the end of the enable. 0 = DISABLE 1 = ENABLE
7	0x0	CMD2: Read/Write Command for Slave 2: 1 - Read Transaction; 0 - Write Transaction. For a 7-bit slave address, this bit must match with the LSB of address byte for slave 2. Valid only when bit 4 of this register is set.
6	0x0	CMD1: Read/Write Command for Slave 1: 1 - Read Transaction; 0 - Write Transaction. Command for Slave 1: For a 7-bit slave address, this bit must match with the LSB of address byte for slave 1.
5	0x0	START: 1 = Yes, a Start byte needs to be sent. 0 = DISABLE 1 = ENABLE
4	0x0	SLV2: 1 = Enables a two-slave transaction. 0 = No command for Slave 2 present.

Bit	Reset	Description
3:1	0x0	LENGTH: The number of bytes to be transmitted per transaction. 000 = 1 byte ... 111 = 8 bytes. In a two slave transaction, the number of bytes should be programmed to be less than 011.
0	0x0	A_MOD: Address mode defines whether a 7-bit or a 10-bit slave address is programmed. 1 = 10-bit device address. 0 = 7-bit device address.

33.5.2 I2C_I2C_CMD_ADDR0_0

I2C Slave-1 Address

I2C_CMD_ADDR0 is programmed with the 7-bit or 10-bit address of slave 1 to which the transaction is intended.

Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0000000000)

Bit	Reset	Description
9:0	0x0	ADDR0: For 7-bit mode, the address is written in I2C_CMD_ADDR0[7:1], and I2C_CMD_ADDR0[0] indicates the read/write transaction. The I2C_CMD_ADDR0[0] bit must match the I2C_CNFG[6] bit. For 10-bit mode, the address is written in I2C_CMD_ADDR0[9:0], and I2C_CNFG[6] indicates the read/write transaction.

33.5.3 I2C_I2C_CMD_ADDR1_0

I2C Slave-2 Address

I2C_CMD_ADDR1 is programmed with the 7-bit or 10-bit address of slave 2 to which the transaction is intended.

Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0000000000)

Bit	Reset	Description
9:0	0x0	ADDR1: For 7-bit mode, the address is written in I2C_CMD_ADDR0[7:1], and I2C_CMD_ADDR0[0] indicates the read/write transaction. The I2C_CMD_ADDR0[0] bit must match the I2C_CNFG[7] bit. For 10-bit mode, the address is written in I2C_CMD_ADDR0[9:0], and I2C_CNFG[7] indicates the read/write transaction.

33.5.4 I2C_I2C_CMD_DATA1_0

I2C Controller Data 1: Transmit/Receive

The four least significant bytes of data to be transmitted are loaded into this register when the I2C Master is in Write mode.

The four least significant bytes of data are read through this register when the I2C Master is in Read mode.

Offset: 0xc | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:24	0x0	DATA4: Fourth data byte to be sent/received
23:16	0x0	DATA3: Third data byte to be sent/received
15:8	0x0	DATA2: Second data byte to be sent/received
7:0	0x0	DATA1: First data byte to be sent/received

33.5.5 I2C_I2C_CMD_DATA2_0

I2C Controller Data 2: Transmit/Receive

The four most significant bytes of data to be transmitted are loaded into the register when the I2C Master is in Write mode.

The four most significant bytes of data are read through this register when the I2C Master is in Read mode.

Offset: 0x10 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:24	0x0	DATA8: Eighth data byte to be sent/received
23:16	0x0	DATA7: Seventh data byte to be sent/received
15:8	0x0	DATA6: Sixth data byte to be sent/received
7:0	0x0	DATA5: Fifth data byte to be sent/received

33.5.6 I2C_I2C_STATUS_0

I2C Controller Status (Master)

I2C_STATUS gives the status of the I2C Master operation.

Offset: 0x1c | Read/Write: RO | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
8	X	BUSY: 0 = NOT_BUSY 1 = BUSY
7:4	X	CMD2_STAT: Slave 2 status: Transaction for Slave 2 for byte x failed. x is 'h0 to 'ha. All other combinations are invalid. 0 = SL2_XFER_SUCCESSFUL 1 = SL2_NOACK_FOR_BYTE1 2 = SL2_NOACK_FOR_BYTE2 3 = SL2_NOACK_FOR_BYTE3 4 = SL2_NOACK_FOR_BYTE4 5 = SL2_NOACK_FOR_BYTE5 6 = SL2_NOACK_FOR_BYTE6 7 = SL2_NOACK_FOR_BYTE7 8 = SL2_NOACK_FOR_BYTE8 9 = SL2_NOACK_FOR_BYTE9 10 = SL2_NOACK_FOR_BYTE10
3:0	X	CMD1_STAT: Slave 1 status: Transaction for Slave 1 for byte x failed. x is 'h0 to 'ha. All other combinations are invalid. 0 = SL1_XFER_SUCCESSFUL 1 = SL1_NOACK_FOR_BYTE1 2 = SL1_NOACK_FOR_BYTE2 3 = SL1_NOACK_FOR_BYTE3 4 = SL1_NOACK_FOR_BYTE4 5 = SL1_NOACK_FOR_BYTE5 6 = SL1_NOACK_FOR_BYTE6 7 = SL1_NOACK_FOR_BYTE7 8 = SL1_NOACK_FOR_BYTE8 9 = SL1_NOACK_FOR_BYTE9 10 = SL1_NOACK_FOR_BYTE10

33.5.7 I2C_I2C_SL_CNFG_0

I2C Controller Configuration (Slave)

I2C_SL_CNFG register is used to configure, enable mode of slave ACK.

Enable mode of the slave response to the general call address.

The register should be programmed when the I^2C controller is configured as a slave.

Offset: 0x20 | Read/Write: R/W | Reset: 0x00000004 (0bxxxxxxxxxxxx00000000000000000100)

Bit	Reset	Description
20	0x0	FIFO_XFER_EN: If this bit is disabled, data is always communicated via the I2C_SL_RCVD register. If enabled, data is communicated through FIFOs 0 = DISABLE 1 = ENABLE
19:8	0x0	BUFFER_SIZE: Payload size in bytes
7	0x0	ACK_LAST_BYTE_VALID: Acknowledge the last byte valid (write-only). This bit qualifies the ACK_LAST_BYTE field. 0 = DISABLE 1 = ENABLE
6	0x0	ACK_LAST_BYTE: Acknowledge the last byte. 0 = DISABLE 1 = ENABLE
5	0x0	ACK_WITHHOLD_EN: ACK Withhold Feature Enable 0 = DISABLE 1 = ENABLE
4	0x0	PKT_MODE_EN: Packet Mode Enable 0 = DISABLE 1 = ENABLE
3	0x0	ENABLE_SL: By writing zero to this field, the slave can be turned off 0 = DISABLE 1 = ENABLE
2	0x1	NEWSL: New Slave. 1 - Use new slave. 0 = DISABLE 1 = ENABLE
1	0x0	NACK: Disable Slave ACK. 1 – The slave will not acknowledge reception of address or data byte. 0 = DISABLE 1 = ENABLE
0	0x0	RESP: Slave response to the general call address (zero address). 0 = DISABLE 1 = ENABLE

33.5.8 I2C_I2C_SL_RCVD_0

I2C Controller Slave Receive/Transmit Data (Slave)

Offset: 0x24 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	SL_DATA: Slave Received data

33.5.9 I2C_I2C_SL_STATUS_0

I2C Controller Slave Status (Slave)

Offset: 0x28 | Read/Write: R/W | Reset: 0x0000XX0X (0bxxxxxxxxxxxxxxxxxxxxxxxxx000000x0)

Bit	R/W	Reset	Description
14:8	RO	X	HW_MSTR_ADR: Hardware master address received via general call addressing. This field is meaningful only if HW_MSTR_INT is set.
7	RW	0x0	HW_MSTR_INT: 1 = Interrupt has been generated by slave. Hardware Master Address is received after General Call Address. Received Hardware Master Address. 0 = No event.
6	RW	0x0	REPROG_SL: 1 = Interrupt has been generated by the slave after the General Call Address is 0x04. Reprogram slave address. 0 = No action.
5	RW	0x0	RST_SL: 1 = Interrupt has been generated by slave after the General Call Address is 0x06. Reset and reprogram slave address. 0 = No action.
4	RW	0x0	END_TRANS: 1 = Interrupt has been generated by slave. Transaction completed as indicated by stop/repeat start condition. 0 = No transaction occurred or transaction in progress.
3	RW	0x0	SL_IRQ: 1 = Interrupt has been generated by slave. 0 = No interrupt generated. 0 = UNSET 1 = SET
2	RW	0x0	RCVD: New Transaction Received status. 1 = Transaction occurred. 0 = No transaction occurred. 0 = NO_TRANSACTION_OCCURED 1 = TRANSACTION_OCCURED
1	RO	X	RNW: Slave Transaction status. 0 = WRITE 1 = READ
0	RW	0x0	ZA: Zero Address Status 1 = Yes, slave responded. 0 = No, slave did not respond. 0 = NO_SLAVE_RESPONSE 1 = SLAVE_RESPONSE

33.5.10 I2C_I2C_SL_ADDR1_0

I2C Controller Slave Address 1 Register (Slave)

Offset: 0x2c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	SL_ADDR1: For a 10-bit slave address, this field is the least significant 8 bits.
7:0	0x0	SL_ADDR0: For a 10-bit slave address, this field is the least significant 8 bits.

33.5.11 I2C_I2C_SL_ADDR2_0

I2C Controller Slave Address 2 Register (Slave)

Offset: 0x30 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0xxxxx000xxxxx000)

Bit	Reset	Description
16	0x0	SELECT_SLAVE: 0 = Use slave addr0. 1 = Use slave addr1.
10:9	0x0	SL1_ADDR_HI: In 7-bit address mode, these bits are don't care. In 10-bit address mode, they represent the 2 MSBs of the address.
8	0x0	SL1_VLD: 0 = 7-bit addressing. 0 = SEVEN_BIT_ADDR_MODE 1 = TEN_BIT_ADDR_MODE
2:1	0x0	SL_ADDR_HI: In 7-bit address mode, these bits are don't care. In 10-bit address mode, they represent the 2 MSBs of the address.
0	0x0	VLD: 0 = 7-bit addressing. 1 - 10 bit addressing. 0 = SEVEN_BIT_ADDR_MODE 1 = TEN_BIT_ADDR_MODE

33.5.12 I2C_I2C_TLOW_SEXT_0

I2C Controller SMBUS Timeout Thresholds

Offset: 0x34 | Read/Write: R/W | Reset: 0x00000000 (0bxxxx00000000000000000000000000)

Bit	Reset	Description
27	0x0	RST_SL_ON_TIMEOUT: Reset Slave state machine on time-out
26	0x0	TLOW_MEXT_EN: Enable TLOW_MEXT counter
25	0x0	TLOW_SEXT_EN: Enable TLOW_SEXT counter
24	0x0	TIMEOUT_EN: Enable TIMEOUT counter
23:16	0x0	TLOW_MEXT: Cumulative clock low extend time (master device) accumulated over a byte transfer period in milliseconds (START to ACK, ACK to ACK, or ACK to STOP).
15:8	0x0	TLOW_SEXT: Cumulative clock low extend time (slave device) accumulated over a complete transfer (START till STOP)
7:0	0x0	TIMEOUT: Clock low time-out period in milliseconds

33.5.13 I2C_I2C_SL_DELAY_COUNT_0

I2C Slave Controller Delay Count

Offset: 0x3c | Read/Write: R/W | Reset: 0x0000001e (0bxxxxxxxxxxxxxxxx0000000000011110)

Bit	Reset	Description
15:0	0x1e	SL_DELAY_COUNT: The value determines the timing between an address cycle and a subsequent data cycle or two consecutive data cycles on the bus. The I2C_SL_DELAY_COUNT is valid only when an internal slave is accessed. I2C_SL_DELAY_COUNT has to be programmed such that TIMING = T * DLY, where T is the period of the clock source selected for I2C, DLY is I2C_SL_DELAY_COUNT, and TIMING is the desired timing. A value of >= 1250 ns is recommended.

33.5.14 I2C_I2C_SL_INT_MASK_0

I2C Controller Slave Mask (Slave)

Offset: 0x40 | Read/Write: R/W | Reset: 0x000000fd (0bxxxxxxxxxxxxxxxxxxxxxxxxx111111x1)

Bit	Reset	Description
7	0x1	HW_MSTR_INT: 0 = DISABLE 1 = ENABLE
6	0x1	REPROG_SL: 0 = DISABLE 1 = ENABLE
5	0x1	RST_SL: 0 = DISABLE 1 = ENABLE
4	0x1	END_TRANS: 0 = DISABLE 1 = ENABLE
3	0x1	SL_IRQ: 0 = DISABLE 1 = ENABLE
2	0x1	RCVD: 0 = DISABLE 1 = ENABLE
0	0x1	ZA: 0 = DISABLE 1 = ENABLE

33.5.15 I2C_I2C_SL_INT_SOURCE_0

I2C Controller Slave Source (Slave)

Offset: 0x44 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7	X	HW_MSTR_INT: 0 = UNSET 1 = SET
6	X	REPROG_SL: 0 = UNSET 1 = SET
5	X	RST_SL: 0 = UNSET 1 = SET
4	X	END_TRANS: 0 = UNSET 1 = SET
3	X	SL_IRQ: 0 = UNSET 1 = SET
2	X	RCVD: 0 = UNSET 1 = SET

Bit	Reset	Description
0	X	ZA: 0 = UNSET 1 = SET

33.5.16 I2C_I2C_SL_INT_SET_0

I2C Controller Slave Source (Slave)

Offset: 0x48 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx000000x0)

Bit	Reset	Description
7	0x0	HW_MSTR_INT: 0 = UNSET 1 = SET
6	0x0	REPROG_SL: 0 = UNSET 1 = SET
5	0x0	RST_SL: 0 = UNSET 1 = SET
4	0x0	END_TRANS: 0 = UNSET 1 = SET
3	0x0	SL_IRQ: 0 = UNSET 1 = SET
2	0x0	RCVD: 0 = UNSET 1 = SET
0	0x0	ZA: 0 = UNSET 1 = SET

Note: Program the field PACKET_MODE_EN of I2C_CNFG register while working in packet mode.

The set of registers given below describe the interface for packet mode only. With packet mode interface changes, normal mode registers and the operation are not affected. The transition from normal mode to packet mode is suggested because packet mode allows:

- There is no restriction on the number of bytes before and the after the repeated start
- The number of bytes that can be transferred with a single command is not limited to 8.

Though a packet can contain 4 Kbytes, because any number of packets can be pushed into the FIFO, there is no limit on the number of bytes that can be transferred.

- The transactions to different slaves can be chained together with repeat start and there is no limit on the number of slaves it can address.

33.5.17 I2C_I2C_TX_PACKET_FIFO_0

A packet contains header and payload. The header size is variable and could vary from 2 to 5 words. For I2C, the header size is 3 words. The first two words of the header contain generic information. The third word contains I2C transaction-specific information. The payload contains actual data to be written to the slave. For read operations, the payload is nil. Thus, the packet contains a header only.

Offset: 0x50 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	TX_PACKET: Software writes packets into this register. A packet may contain generic information

33.5.18 I2C_I2C_RX_FIFO_0

Header or I2C Specific Header or Data

Offset: 0x54 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	RD_DATA: Software reads data from this register, causes a pop

33.5.19 I2C_PACKET_TRANSFER_STATUS_0

Offset: 0x58 | Read/Write: RO | Reset: 0x0XXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
24	X	TRANSFER_COMPLETE: The packet transfer for which the last packet is set has been completed 0 = UNSET 1 = SET
23:16	X	TRANSFER_PKT_ID: The current packet ID for which the transaction is happening on the bus
15:4	X	TRANSFER_BYTENUM: The number of bytes transferred in the current packet
3	X	NOACK_FOR_ADDR: No ACK received for the address byte 0 = UNSET 1 = SET
2	X	NOACK_FOR_DATA: No ACK received for the data byte 0 = UNSET 1 = SET
1	X	ARB_LOST: Arbitration lost for the current byte 0 = UNSET 1 = SET
0	X	CONTROLLER_BUSY:1 = Controller is busy 0 = UNSET 1 = SET

33.5.20 I2C_FIFO_CONTROL_0

Offset: 0x5c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:13	0x0	SLV_TX_FIFO_TRIG: Slave Transmit FIFO trigger level. 000 = 1 word DMA trigger is asserted when at least one word is empty in the FIFO 001 = 2 word DMA trigger is asserted when at least 2 words are empty in the FIFO

Bit	Reset	Description
12:10	0x0	SLV_RX_FIFO_TRIG: Slave Receive FIFO trigger level. 000 = 1 word DMA trigger is asserted when at least one word is full in the FIFO. 001 = 2 word DMA trigger is asserted when at least 2 words are full in the FIFO
9	0x0	SLV_TX_FIFO_FLUSH:1 = Flush the TX FIFO. Cleared after the FIFO is flushed 0 = UNSET 1 = SET
8	0x0	SLV_RX_FIFO_FLUSH:1 = Flush the RX FIFO. Cleared after the FIFO is flushed 0 = UNSET 1 = SET

33.5.23 I2C_INTERRUPT_STATUS_REGISTER_0

This register indicates the status bit for which the interrupt is set. If the interrupt is set, write a 1 to clear it. However, the TFIFO_DATA_REQ and RFIFO_DATA_REQ fields depend on the FIFO trigger levels and cannot be cleared.

Slv_rd2wr indicates there is a switch from read to write by repeat start and the current read transaction needs to be closed and started with a write transaction. Similarly, slv_wr2rd indicates a switch from write to read.

13:8	0xb	HS_THD_STA: Hold time for a (repeated) START condition
5:0	0xb	HS_TSU_STA: Setup time for a Repeated START condition

34.0 UART AND VFIR CONTROLLER

There are four Universal Asynchronous Receiver/Transmitters (UARTs) built into the Tegra® K1 devices. These UARTs support both 16450 and 16550 compatible modes. VFIR functionality is also supported in UART B.

34.1 Functional Description

34.1.1 UARTs A through D

All UARTs provide serial data synchronization and data conversion (parallel-to-serial and serial-to-parallel) for both receiver and transmitter sections. Synchronization for serial data stream is accomplished by adding start and stop bits to the transmit data to form a data character. Data integrity is accomplished by attaching a parity bit to the data character. The parity bit can be checked by the receiver for any transmission bit errors.

The COM-HOST interface is fully programmable through an 8-bit CPU interface. The registers are 32-bit word aligned. The interface supports word lengths from five to eight bits, an optional parity bit, and one or two stop bits. If enabled, parity can be odd, even, or forced to a defined state. Interrupts can be generated from any of 10 sources.

The UARTs support both 16450 and 16550 compatible modes. The default mode is 16450. This mode provides independent 16-byte FIFOs for transmit and receive operations and is selected by the FIFO control register. It also includes a 16-bit programmable baud rate generator and an 8-bit scratch register, 8 modem control lines, and 2 DMA handshake lines that are used to indicate when the FIFOs are ready to transfer data to the CPU.

The UARTs support a device clock of up to 72 MHz. The maximum baud rate is 16 clock cycles per symbol or 4.5 Megabits per second.

UART B is identical to UART A with the exception that only two signals are connected to its pins. UART A, C, and D are identical.

34.1.2 VFIR Controller

The VFIR controller in the Tegra K1 device implements the control and data sections of the IrDA Physical layer version 1.4, handling handshaking and basic networking between devices, and interfaces to an external Infrared transceiver.

This controller implements three distinct speed ranges and protocols: 2400 to 115,200 bits per second (Serial IR or SIR), 4 Megabits per second (called Fast Infrared or FIR), and 16 Megabits per second (called Very Fast Infrared or VFIR). Initial communication starts at 9600 bits per second, and negotiations proceed either faster or slower as the link strength allows. Each of the three speed ranges has different communication protocols and encoding schemes.

The following table lists the IrDA supported protocols.

Table 139: Protocols Supported by the IrDA

Signaling Rate (bps)	IrDA Name	Frame Wrapper and Encoding	IrDA Status	Tegra K1 Device Support?
9.6 K	SIR	Async RZI (3/16)	Mandatory	Yes
2400 - 115.2K	SIR	Async RZI (3/16)	Recommended	Yes
576.0 K	MIR	Sync HDLC RZI (4/16)	Optional	No
1.152 M	MIR	Sync HDLC RZI (4/16)	Optional	No
4.0 M	FIR	Sync 4PPM	Optional	Yes

Signaling Rate (bps)	IrDA Name	Frame Wrapper and Encoding	IrDA Status	Tegra K1 Device Support?
16.0 M	VFIR	Sync HHH(1,13)	Optional	Yes

The VFIR controller can operate in three different encodings; each is implemented separately. In SIR mode, a pulse encoder/decoder is inserted in the transmit/receive path of a standard UART. FIR and VFIR modes have their own control blocks. The outputs of the three blocks are multiplexed based on the current operating mode (SIR, FIR, or VFIR), before they leave the Tegra K1 device processor. The input signals are demultiplexed in a similar fashion.

Note: The operating mode is selected with the Mode [2:0] bits of the VFIR.CTL register

Figure 121: UART Block Diagram with SIR Decoder and Encoder

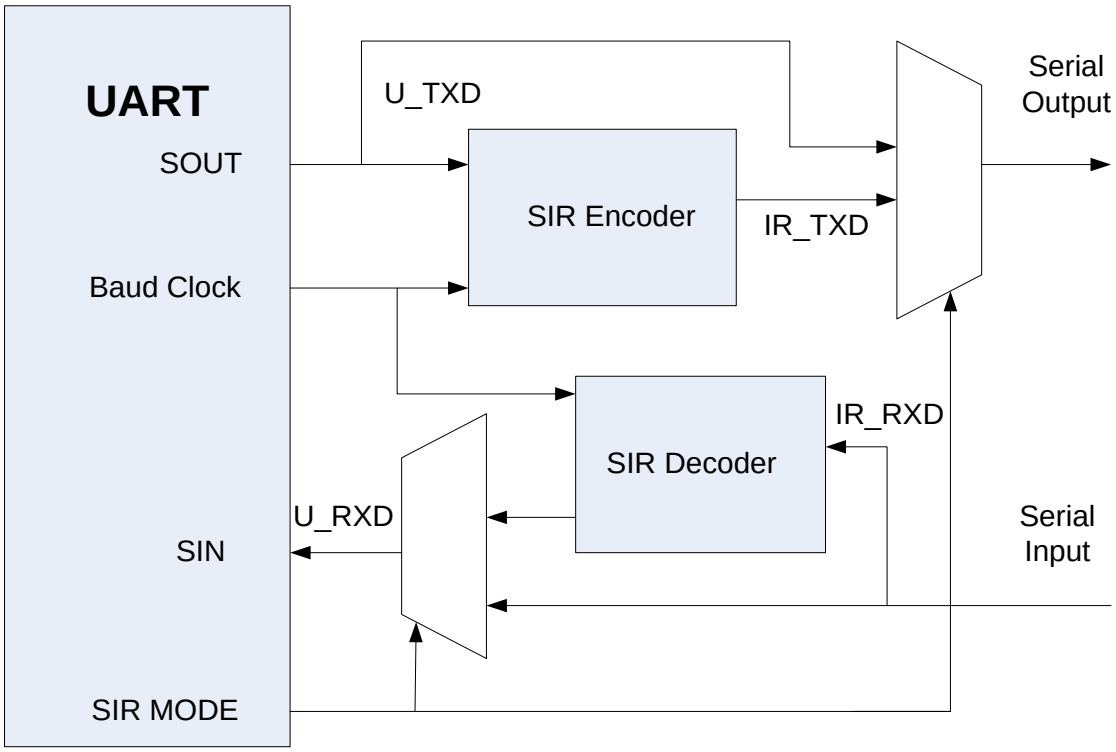

Figure 122: VFIR Controller Top-Level Block Diagram

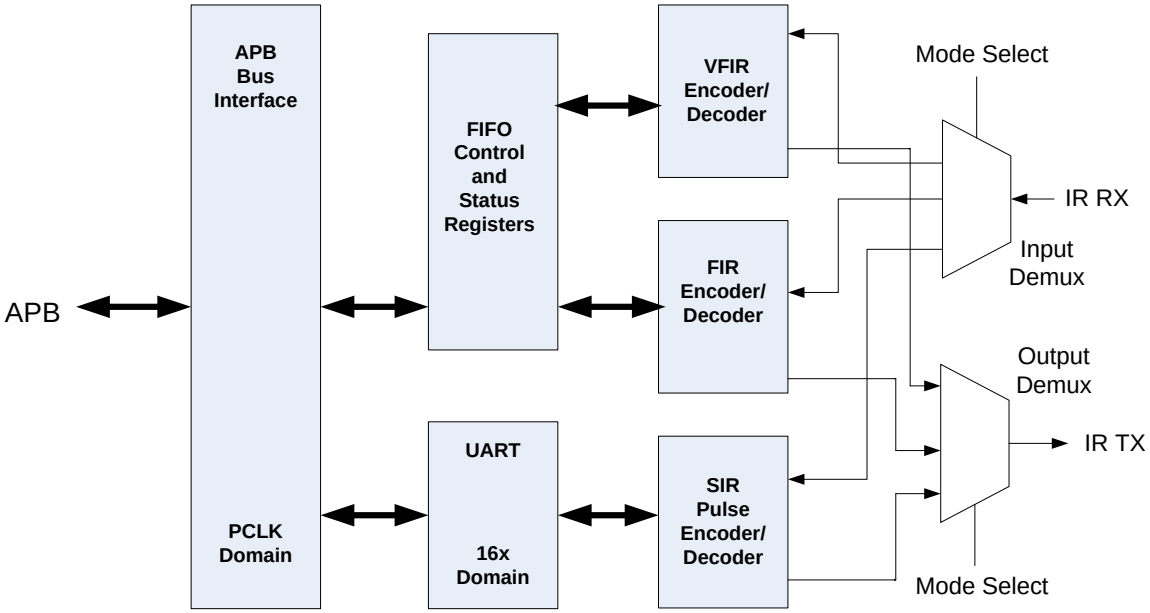


34.1.3 Hardware Features

The features supported by UART A, UART B, UART C, and UART D are:

- Synchronization for the serial data stream with start and stop bits to transmit data to and from a data character
- Data integrity by attaching a parity bit to the data character
- The COM-HOST interface is fully programmable through an 8-bit CPU interface
- Support for word lengths from 5 to 8 bits, an optional parity bit, and 1 or 2 stop bits
- Support for both 16450- and 16550-compatible modes. The default mode is 16450.
- DMA capable for both TX and RX
- 8 bit x 36 deep TX FIFO
- 11 bit x 36 deep RX FIFO
- Auto sense baud detection
- Timeout interrupts to indicate if the incoming stream stopped
- Flow control support on RTS and CTS

The features supported by the VFIR controller are:

- Supports IrDA version 1.0 SIR protocol with maximum baud rate to 115.2 Kilobits per second
- Supports IrDA version 1.3 FIR protocol (4 Megabits per second)
- Supports IrDA version 1.4 VFIR protocol (16 Megabits per second)
- Programmable polarities on all the interface pins
- DMA capable for both TX and RX
- 32 bit x 16 deep FIFO
- Diagnostics for loopback and error insertion
- Interface control, such as transceiver signal strength, must be performed through GPIOs
- The maximum frequency of the device clock is 72 MHz

34.1.4 Hardware Signaling

All UARTs in the Tegra K1 device are implemented by a hardware block that supports modem control signals such as DTR, DSR, and DCD. UART A is, however, the only UART that allows those signals to be used externally.

For UART A, when the pin-mux is configured for 4- or 2-pin UART operation, the DSR and DCD input signals are tied low (active).

For UART B, the DTR output is routed back into the DSR and DCD inputs in hardware. This means that if software changes DTR state, the UART may raise an interrupt due to DSR/DCD changing state.

For UARTs C and D, the DSR and DCD inputs are tied to an inactive value.

Table 140: Serial Bus Interface Signals

Signal Name	Description
Outputs	
TXD	Transmit Data Port
RTS	Request to Send
DTR	Data Terminal Ready
Inputs	
RXD	Receiver Data Port
CTS	Clear to Send
DSR	Data Set Ready
DCD	Data Carrier Detect
RI	Ring Indicator

Note: The DSR, DCD and RI MODEM control signals do not control any hardware other than generating interrupts and status on change.

34.2 UART Programming Guidelines

34.2.1 16450 Mode Programming

1. Program pin mux settings to select a UART
2. Enable the UART clocks
3. For enabling internal loopback, program MCR[4] to 1
4. Program FCR[0] to 0
5. Enable interrupts in the IER register as needed
6. Write data into the THR register
7. Wait for a THR interrupt, if enabled, or poll for LSR[5]
8. During a receive, wait for an RBR interrupt or poll for LSR[0]
9. Read the UART.LSR register to clear interrupts

34.2.2 16550 Mode Programming

1. Program pin mux settings to select a UART
2. Enable the UART clocks
3. For enabling internal loopback, program MCR[4] to 1
4. Program FCR[0] to 1
5. Program trigger levels as required
6. Enable interrupts in the IER register as needed
7. Write data into the THR register
8. Wait for a THR interrupt, if enabled, or poll for LSR[5]
9. During a receive, wait for an RBR interrupt or poll for LSR[0]
10. Read the UART.LSR register to clear interrupts
11. The APB-DMA requestor numbers for UARTs A, B, and C are 8, 9, and 10, respectively

34.2.3 Transmitter and Receiver Holding Registers

The serial transmitter section consists of a Transmit Hold Register (THR) and Transmit Shift Register (TSR). The status of transmit hold register is provided in the Line Status Register (LSR). Writing to this register (THR) transfers the contents of data bus (D [7:0]) to the Transmit Holding Register whenever the Transmitter Holding Register or Transmitter Shift Register is empty. The Transmit Holding Register empty flag is set to 1 when the transmitter is empty or data is transferred to the transmit shift register. Note that a write operation is performed when the Transmit Holding Register empty flag is set.

The serial receiver section also contains an 8-bit Receiver Holding/Buffer Register (RBR). Receive data is removed from the UART and received by the processor by reading the RBR. The receiver contains a mechanism for preventing false starts as follows: On the falling edge of the start bit, the receiver internal counter starts to count 7.5 clocks (16x clock), which is the center of the start bit. The start bit is valid if the RX is still low at the mid-bit sample of the start bit. Verifying the start bit prevents the receiver from assembling a false data character due to a low going noise spike on the RX input. Receiver status codes are posted in the Line Status Register.

34.2.4 FIFO Interrupt Mode Operation

When the receive FIFO (FCR bit 0 = 1) and receive interrupts (IER bit 0 = 1) are enabled, a receiver interrupt occurs as follows:

- The receive data available interrupts are issued to the CPU when the FIFO has reached its programmed trigger level; it is cleared as soon as the FIFO drops below its programmed trigger level.
- The ISR receive data available indication also occurs when the FIFO trigger level is reached, and like the interrupt, it is cleared when the FIFO drops below the trigger level.
- The data ready bit (LSR bit 0) is set as soon as a character is transferred from the shift register to the receiver FIFO. It is reset when the FIFO is empty.

34.2.5 FIFO Polled Mode Operation

When FCR bit 0 = 1; clearing IER bits [3:0] to zero puts the UART in the FIFO polled mode of operation. Since the receiver and transmitter are controlled separately, either one or both can be in the polled mode operation by using the line status register as follows:

- LSR bit 0 is set as long as there is one byte in the receive FIFO
- LST bits [4:1] specifies which error(s) have occurred
- LSR bit 5 indicates when the transmit FIFO is empty
- LSR bit 6 indicates when both transmit FIFO and transmit shift registers are empty
- LSR bit 7 indicates when there are any errors in the receive FIFO
- LSR bit 8 indicates when the transmit FIFO is full

The UART requires a two-step FIFO enable operation in order to enable receive trigger levels.

34.2.6 Programmable Baud Rate Generator

The UART contains a programmable baud rate generator that can take the UART clock input and divide it by any divisor from 1 to 2^{16}-1. Refer to the Clocking and Reset Controller section for definitions of the UART clocks. The output frequency of baudout is equal to 16X the transmission baud rate (Baudout=16 X baud rate). Customized baud rates are achieved by selecting proper divisor values for the MSB and LSB bits of the baud rate generator.

34.2.7 Enable Register (IER)

There is an Interrupt Enable Register for each UART (UART A Interrupt Enable and UART B Interrupt Enable). The Interrupt Enable Register(s) masks the incoming interrupts from the receiver ready, transmitter empty, line status, and modem status registers to the INT output pin.

34.2.8 Interrupt Identification Register (IIR)

The UART provides four level prioritized interrupt conditions to minimize software overhead during data character transfers. The Interrupt Identification Register (IIR) provides the source of the interrupt in a prioritized manner.

During the read cycle, the 16550 provides the highest interrupt level to be serviced by the CPU. No other interrupts are acknowledged until the particular interrupt is serviced. The prioritized interrupt levels are shown in the following table. The Receive Data Time-out mode is enabled when the UART is operating in the FIFO mode.

Receive time-out does not occur if receive FIFO is empty. The time-out counter is reset at the center of each stop bit received or each time the Receive Holding Register is read. The actual time out value is:

- T (Time out length in bits) = 4 X P (Programmed work length) + 12

To convert the time-out value to a character value, divide this number to its complete word length + parity (if used) + number of stop bits and start bit.

Example

If you program the word length = 7 with no parity and one stop bit, the time-out is:

- T = 4X7 (programmed word length) + 12 = 40 bits.
- Character time = 40/9
- [(Programmed word length = 7) + (stop bit = 1) + (start bit = 1)] =4.4 characters

Table 141 Prioritized Interrupt Levels

Priority	D3	D2	D1	D0	Interrupt Source Description
1	0	1	1	0	LSR (Receiver Line Status Register)
2	0	1	0	0	RXRDY (Received Data Ready)
2	1	1	0	0	RXRDY (Received Data Timeout)
3	0	0	1	0	TXRDY (Transmitter Holding Register)
4	0	0	0	0	MSR (Modem Status Register)

34.2.9 FIFO Control Register (FCR) Modes

The FIFO control register is used to enable the FIFOs, clear the FIFOs, set the receiver FIFO trigger level, and select the type of DMA signaling. The operation of the FCR in the four DMA modes is given below.

34.2.9.1 Transmit Operation in DMA Mode 0 or Mode 1

When the UART is in the 16450 mode (FCR bit 0 = 0) or in the FIFO mode (FCR bit 0 = 1, FCR bit 3 = 0) and when there are no characters in the transmit FIFO or transmit holding register, the TXRDY* pin goes low. Once active, the TXRDY* pin goes high (inactive) after the first character is loaded into the Transmit Holding Register.

34.2.9.2 Receive Operation in DMA Mode 0

When the UART is in 16450 mode (FCR bit 0 = 0) or in the FIFO mode (FCR bit 0 = 1,FCR bit 3 = 0) and there is at least 1 character in the receive FIFO, the RXRDY* pin goes low. Once active, the RXRDY* pin goes high (inactive) when there are no more characters in the receiver.

34.2.9.3 Receive Operation in DMA Mode 1

When the UART is in the FIFO mode (FCR bit 0 = 1, FCR bit 3 = 1) and the trigger level or the timeout has been reached, the RXRDY* pin goes low. Once it is activated, it goes high (inactive) when there are no more characters in the FIFO.

34.2.10 Line Control Register (LCR)

The Line Control Register is used to specify the asynchronous data communication format. The word length, stop bits, and parity can be selected by writing appropriate bits in this register.

34.2.11 Modem Control Register (MCR)

This register controls the interface with the modem or a peripheral device (RS232).

Loopback Mode

If MCR[4] = 1, the loopback mode is enabled, and the following occurs:

The transmitter output (TX) is set high (Mark condition), and the receiver input (RX), CTS, DSR, CD, and RI are disabled. Internally, the transmitter output is connected to the receiver input and DTR, RTS, OP1, and OP2 are connected to modem control inputs.

In this mode, the receiver and transmitter interrupts are fully operational, but the interrupt sources are now the lower four bits of the modem control register instead of the four modem control inputs. The interrupts are controlled by the IER register.

Table 142: Modem Control Register (MCR)

Bit	Name	Description
7	N/A	Not used. Set to 0 internally.
6	RTS_EN	1 = Enable Hardware Flow Control using RTS 0 = Disable Hardware Flow Control
5	CTS_EN	1 = Enable Hardware Flow Control using CTS 0 = Disable Hardware Flow Control
4	LOOP	0 = Normal operating mode. 1 = Enable local loop-back mode (diagnostic).
3	OUT2	nOUT2 polarity
2	OUT1	nOUT1 polarity
1	RTS	1 = Force RTS (Request to Send) low 0 = Force RTS to high
0	DTR	1 = Force DTR (Data Terminal Ready) to low 1 = Force to high

34.2.12 Line Status Register (LSR)

The Line Status Register provides the status of data transfer to the CPU.

34.2.13 Modem Status Register (MSR)

The modem status register provides the current state of the control lines from the modem or peripheral to the CPU. Four bits of this register are used to indicate the changed information. These bits are set to 1 whenever a control input from the modem changes state. They are set to 0 whenever the CPU reads the register.

34.2.14 Scratchpad Register (SR)

Eight bits of information can be stored in this register. Information in this register does not affect the operation of the device in any way.

34.2.15 Autobaud Sense Register (ASR)

The UART can automatically determine the correct baud divisor by using the Autobaud Sense Register (UART offsets 0x3C). The most significant bit of this register is the valid flag. A write to this register will clear the valid flag and enable the autobaud process. When the first RX edge occurs, a counter running at 24 MHz starts counting. When another rx_edge occurs, the "complete" flag is set, the value is frozen, and the Autobaud Sense Value register is updated with the count value. The low 20 bits of the ASR give the number of clocks within a single bit. Because the UART uses 16x oversampling, the resulting value needs to be adjusted by shifting right 4 bits, then loading the resulting count in the divisor latch of the UART. (In the code snippet below, the lower 4 bits are rounded to give slightly greater accuracy.)

Because the speed determination is made by measuring the start bit, special characters must be sent by the transmitting UART to guarantee that the next character after the start bit is a 1. Since bit 0 (rightmost bit) is sent first, the ASCII Carriage Return character (CR) is sufficient to enable proper speed sense.

The following code snippet returns the values for DLH and DLL in r9, r8:

```
       MOV     r0, #1  ; dummy write data
       STRB    r0, [r3, #U_ASR]; Start autobaud sense (r3 as uart_base)
; now poll the autobaud sense register MSB until Valid is true
wait4valid
       LDR     r2, [r3, #U_ASR]; Read ASR
       TST     r2, #0x80000000 ; the Valid bit (active high)
       BEQ     wait4valid
; autobaud sense check complete...
; r2 as number of 1x clocks in one bit time
; representing the number of 24MHz clocks in the start bit
; Since this represents 16 of the baud (16x) clocks, we
; will be dividing by 16 to get baud divisor, but first
; round to nearest by adding 8 before the divide:
       ADD     r4, r2, #8 ; add 1/2 resolution
       MOV     r6, r4, LSR #4 ; divide by 16... R6 will have total divisor
       AND     r8, r6, #0xFF  ; copy DLL to r8
       MOV     r9, r6, LSR #8 ; copy DLM to r9
       AND     r9, r9, #0xff ; mask upper bytes
```

34.2.16 Baud Rate Generator

The following table given below is a divisor table for the baud rate, assuming the oscillator is 24.000 MHz.

Table 143: Baud Rate Generator Programming

Baud Rate	Divisor
300	5000
1200	1250
2400	625
4800	312
9600	156
19.2K	78
38.4K	39
57.6K	26
115.2K	13

34.2.17 Power-up Defaults

The Power-Up defaults are defined below:

- IER = 0
- ISR = 1
- LCR = 0
- MCR = 0
- LSR = 60 HEX
- MSR = Bits 0-3 = 0, Bits 4-7 = inputs
- FCR = 0
- TX = High

- OP1 = High
- OP2 = High
- RTS = High
- DTR = High
- RXRDY = High
- TXRDY = Low
- INT = Low

34.3 VFIR Programming Guidelines

34.3.1 IRDA (FIR/VFIR)

The IRDA module includes a fully functional 16550 compatible UART for implementing the SIR protocol. The UART pins will be selected automatically when the VFIR.CTL Mode bits are set to UART or SIR mode. Set the UART IRDA.CSR register to SIR mode to convert the UART signals to SIR signals.

If the IRDA.CTL Mode bits are set the FIR or VFIR modes, the UART pins will be disabled, and the FIR/VFIR pins will be used.

34.3.2 APB Bus Interface to Control/Status/FIFO

The Control and Status registers, and the FIFO reside on the APB bus. The processor programs the Control registers to begin transactions, and can read progress and error status from the Status Register. FIFO access is normally performed via the APB_DMA module.

34.3.3 FIR Mode Programming

1. Set the CLK_SOURCE_VFIR for 48 MHz and enable the UART_B Clock
2. Program IR.TX and IR.RX pin-mux settings to select IR (UART B)
3. Set the VFIR.CTL Mode to binary 100 (FIR)
4. FIR mode is half-duplex. Set the VFIR.CTL Transmit bit to '1' for transmits, '0' for receives
5. Read the VFIR.STS register to clear inputs
6. Program the APB_DMA to transfer data to/from the VFIR module
7. Enable the DMA bit in the VFIR.CTL register
8. Enable interrupts as needed
9. Set the GO bit in the VFIR.CTL register to start the action
10. Wait for DONE status or an interrupt which indicates that the transaction has completed
11. Check for errors when reading the VFIR Status and Interrupt Identification register
12. Clear the status bits by writing a '1' to them before starting the next packet.
13. For receive operations, the Incoming Frame Data Length (IFDL) register will contain the number of bytes received. DMA should have read this many bytes from the FIFO.

34.3.4 VFIR Mode Programming

1. Set the CLK_SOURCE_VFIR for 48MHz and enable the UART_B Clock
2. Program IR.TX and IR.RX pin mux settings to select IR (UART B)
3. Set the VFIR.CTL Mode to binary 101 (VFIR)
4. VFIR mode is half-duplex. Set the VFIR Control register Transmit bit to '1' for transmits, and '0' for receives

5. Read the VFIR.STS register to clear inputs
6. Program the APB_DMA to transfer data to/from the VFIR module
7. Enable the DMA bit in the VFIR.CTL register
8. Enable interrupts as needed
9. Set the GO bit in the VFIR.CTL register to start the action
10. Wait for DONE status or an interrupt which indicates that the transaction has completed
11. Check for errors when reading the VFIR Status and Interrupt Identification register
12. Clear the status bits by writing a '1' to them before starting the next packet.
13. For receive operations, the Incoming Frame Data Length (IFDL) register will contain the number of bytes received. DMA should have read this many bytes from the FIFO.

34.3.5 SIR Interface

The SIR (COM-SLAVE) interface consists of a UART, which provides serial data synchronization and parallel-to-serial and serial-to-parallel data conversion for both receiver and transmitter sections. Synchronization for the serial data stream is accomplished by adding start and stop bits to the transmit data to form a data character. Data integrity is accomplished by attaching a parity bit to the data character. The parity bit can be checked by the receiver for any transmission bit errors.

The SIR interface is fully programmable by an 8-bit CPU interface. The registers are 32-bit Word aligned. The interface supports word lengths from 5 to 8 bits, an optional parity bit, and 1 or 2 stop bits. If enabled, the parity can be odd, even, or forced to a defined state. Interrupts can be generated from any of 10 sources.

The UART supports both 16450 and 16550 compatible modes. The default mode is the 16450. The 16550 mode, which provides independent 16-byte FIFOs for transmits and receives, is selected via the FIFO control register. It also includes a 16-bit programmable baud rate generator and an 8-bit Scratch register, 8 modem control lines, and two DMA handshake lines that are used to indicate when the FIFOs are ready to transfer data to the CPU.

Table 144: Serial Bus Interface Signals

Signal Name	Direction	Description
UB3_RXD	I	Receiver Data Port
UB3_TXD	O	Transmit Data Port

34.3.6 SIR Pulse Encoder/Decoder

The UART transmit (TX) data is passed through this module prior to being muxed out to the IR transmitter. This module converts transmitted zeros into a 3/16 Return-To-Zero (RZ) pulse.

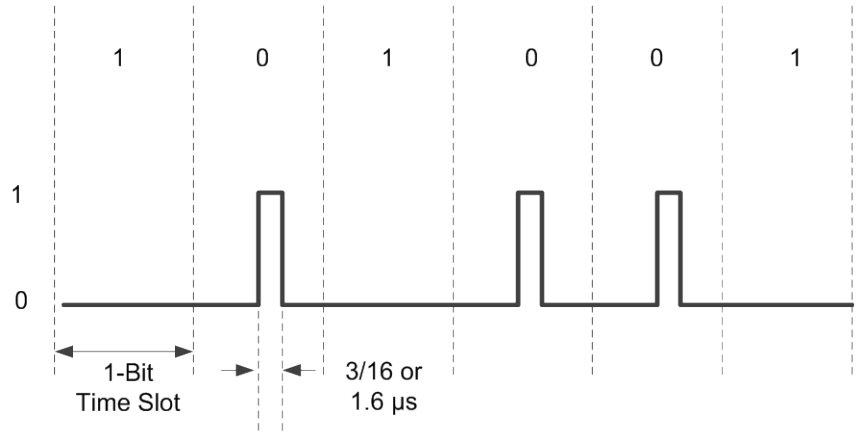
Similarly, received (RX) data is bit-synchronized using the 16X baud clock and the original serial data recovered from the IR bit stream. This data is then sent to the UART for reception.

The signal generated in SIR is as follows:

- On logic '1', the LED is off.
- On logic '0', a pulse is created starting the center of the bit time and lasting 3/16 of a bit time period or 1.6µs (3/16 bit times at 115.2 kbps) depending on the current settings.

The figure below displays the output for the input 101001 (in sending order) in SIR encoding.

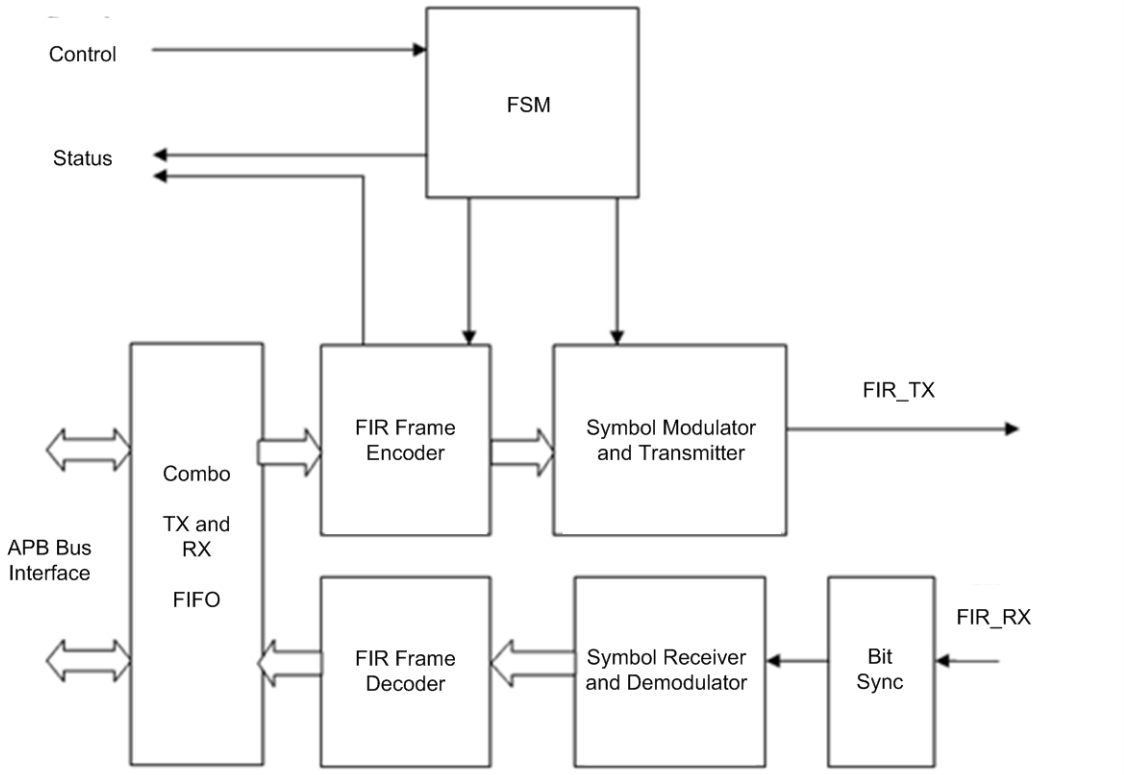
Figure 123: Output in Sending Order in SIR Encoding



34.3.7 FIR Encoder/Decoder

The figure below shows the micro-architecture for FIR and VFIR modes. Although the architecture is the same, the FIR and VFIR encoding schemes are very different.

Figure 124: Architecture for FIR and VFIR Modes



The Frame Level Encoder calculates CRC for the sent data, performs bit stuffing, creates start and stop sequences, and sends data down the line to the Data Shift Register. The Frame Level Decoder calculates the CRC on incoming data, performs bit de-stuffing, compares the calculated CRC to the received one, and reports any errors detected in the process.

The 1-symbol modulator creates the signal to be sent to the IR transceiver bit by bit as received from the UART in SIR mode, 2-bit signals in FIR mode, and 3-bit signals in VFIR mode.

FIR mode uses a Pulse Position Modulation code called 4PPM. The encoding sends one symbol every four time slices called "chips". Because there are four unique chip positions within each symbol in 4PPM, four independent symbols exist in which only one chip is logically a "one" while all other chips are logically a "zero." These four unique symbols are defined to be the only legal data symbols (DD) allowed in 4PPM. Each DD represents two bits of payload data, so that a byte of payload data can be represented by four DDs in sequence. The table below defines the chip pattern representation of the four unique DDs defined for 4PPM.

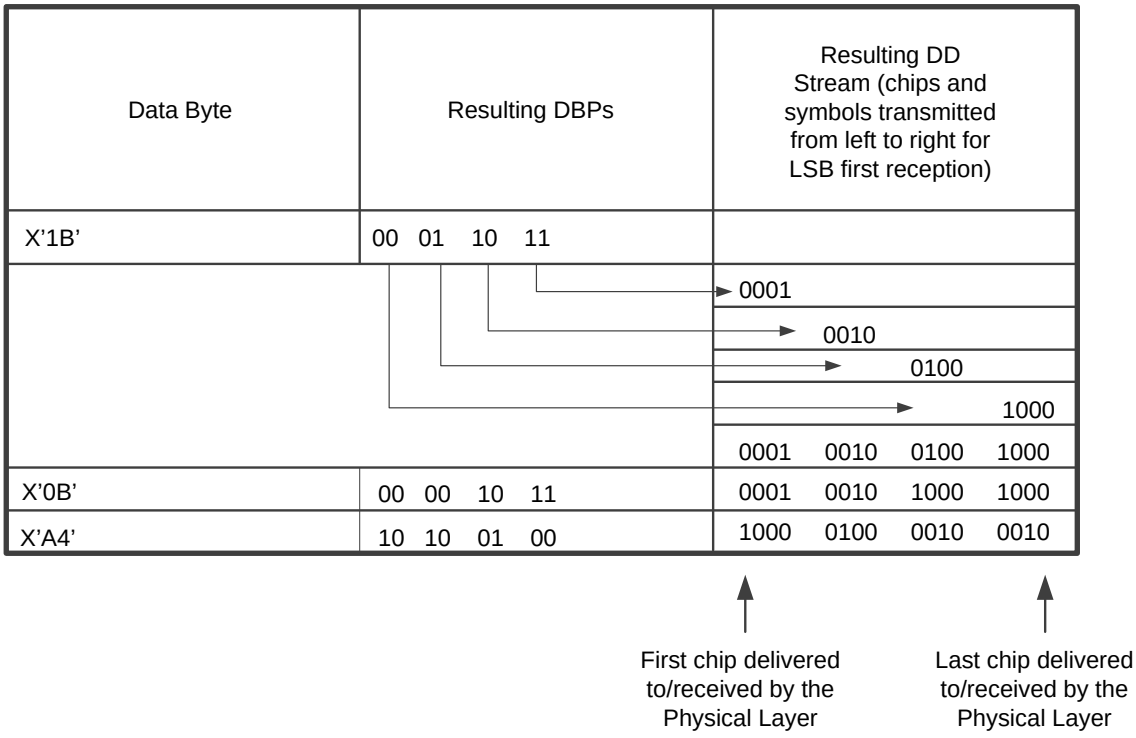
Table 145: Chip Pattern

Data Bit Pair	4PPM Data Symbol
00	1000
01	0100
10	0010
11	0001

A logical "1" represents a chip duration when the transmitting LED is emitting light, while a logical "0" represents a chip duration when the LED is off. Data encoding for transmission is done LSB first.

The figure below shows how various data bytes would be represented after encoding for transmission. In these examples transmission time increases from left to right so that chips and symbols farthest to the left are transmitted first.

Figure 125: Various Data Bytes After Encoding for Transmission



34.3.8 PPM Packet Format

For FIR 4PPM packets the data rate is 4 Megabits per second, and the signaling rate is 8.0 Mchips per second, where a chip is the smallest element of IrDA signaling. The packet format is defined below.

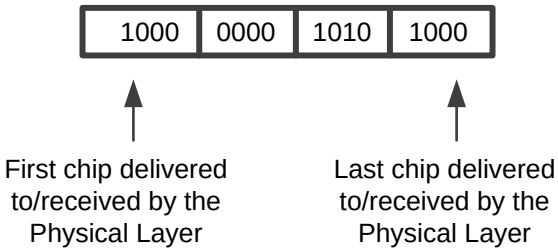
In this packet format, the payload data is encoded as described in the 4PPM encoding above, and the encoded symbols reside in the DD field. Maximum packet length is negotiated by the same mechanism as for the slower rates. The preamble field (PA) is used by the receiver to establish phase lock. During PA, the receiver begins to search for the start flag (STA) to establish symbol synchronization. If STA is received correctly, the receiver can begin to interpret the data symbols in the DD field. The receiver continues to receive and interpret data until the stop flag (STO) is recognized. STO indicates the end of a frame. The chip patterns and symbols for PA, STA, FCS field, and STO are defined below. Only complete packets that contain the entire format defined above are guaranteed to be decoded at the receiver (as for the lower rates, the information field, I, may be of zero length).

The 4PPM data encoding described above defines only the legal encoded payload data symbols. All other chip combinations are by definition illegal symbols for encoded payload data. Some of these illegal symbols are used in the definition of the preamble, start flag, and stop flag fields because they are unambiguously not data.

34.3.8.1 Preamble Field Definition

The preamble field (PA) consists of exactly 16 repeated transmissions of the following stream of symbols. In the PA field, transmission time increases from left to right so that chips and symbols on the left are transmitted first. See figure below.

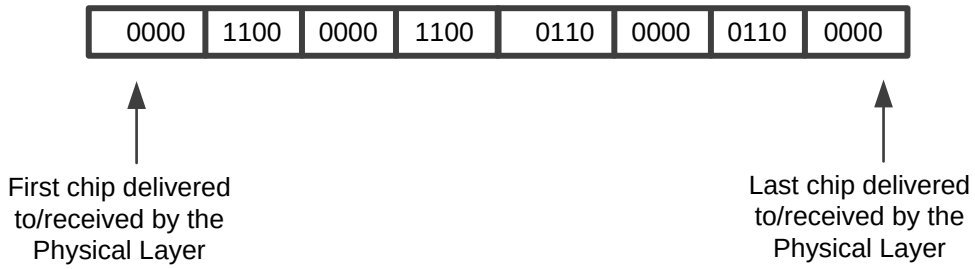
Figure 126: Preamble Field



34.3.8.2 Start Flag Definition

The start flag (STA) consists of exactly one transmission of the following stream of symbols. In the STA field, transmission time increases from left to right so that chips and symbols on the left are transmitted first. See figure below.

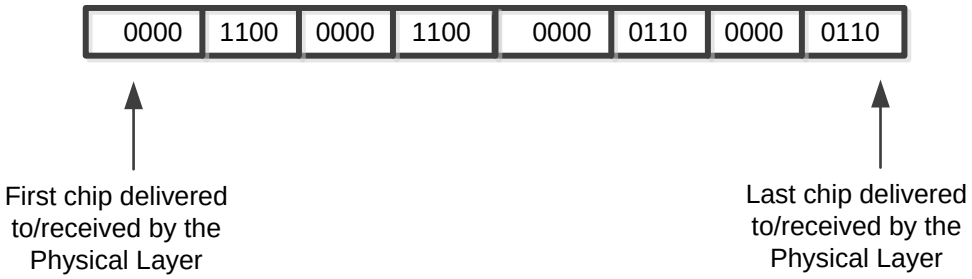
Figure 127: Start Flag



34.3.8.3 Stop Flag Definition

The stop flag (STO) consists of exactly one transmission of the following stream of symbols. In the STO field, transmission time increases from left to right so that chips and symbols on the left are transmitted first. See figure below.

Figure 128: Stop Flag



34.3.8.4 Frame Check Sequence Field Definition

The frame check sequence (FCS) field is a 32-bit field that contains a cyclic redundancy check (CRC) value. The CRC is a calculated, payload data dependent field, calculated before 4PPM encoding. It consists of the 4PPM encoded data resulting from the IEEE 802 CRC32 algorithm for cyclic redundancy check as applied to the payload data contained in the packet. The CRC32 polynomial is defined as follows:

$$CRC(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x + 1$$

The CRC32 calculated result for each packet is treated as four data bytes, and each byte is encoded in the same fashion as is payload data. Payload data bytes are input to this calculation in LSB first format. The 32-bit CRC register is preset to all "1's" prior to calculation of the CRC on the transmit data stream. When data has ended and the CRC is being shifted for transmission at the end of the packet, a "0" should be shifted in so that the CRC register becomes a virtual shift register.

Note: The inverse of the CRC register is what is shifted as defined in the polynomial.

34.3.8.5 Aborted Packets

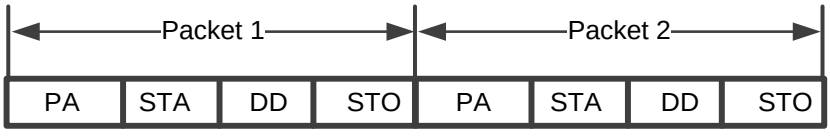
Receivers may only accept packets that have valid STA, DD, FCS, and STO fields as defined in the PPM Packet Format section. The PA field need not be valid in the received packet. All other packets are aborted and ignored.

Any packet may be aborted at any time after a valid STA but before transmission of a complete STO flag by two or more repeated transmissions of the illegal symbol "0000." Also, any packet may be aborted at any time after a valid STA by reception of any illegal symbol which is not part of a valid STO field.

34.3.8.6 Back-to-Back Packet Transmission

Back-to-back, or "brick-walled", packets are allowed, but each packet must be complete (i.e., containing PA, STA, DD, and STO fields). Brick-walled packets are illustrated in the figure below.

Figure 129: Back-to-Back (Brick-Walled) Packet Transmission



34.3.9 VFIR 16.0 Megabits per Second Rate

The 16.0 Megabits per second data transmission incorporates a new modulation code HHH (1,13) - low duty cycle, rate 2/3, (d,k) = (1, 13) run-length limited (RLL) code to achieve the specified data rate from a 24MHz reference clock. The HHH(1,13) code guarantees for at least one empty chip and at most 13 empty chips between chips containing pulses in the transmitted IR signal. The data transmission packet/frame is based on the 4.0 Megabits per second frame format with modifications introduced where necessary to accommodate the requirements that are specific to the new modulation code. The system

includes a simple scrambling/descrambling scheme to randomize the duty cycle statistics. The signaling rate of the 16.0 Megabits per second data rate is 24.0 Mchips per second, where a chip is the smallest element of IrDA signaling.

34.3.10 HHH (1, 13) Modulation Code

The HHH (1, 13) modulation code has the following salient features:

- Code Rate: 2/3 ,
- Maximal Duty Cycle: 1/3 (~33%) ,
- Average Duty Cycle: ~26% ,
- Minimal Duty Cycle: 1/12 (~8.3%) ,
- Run-Length Constraints: (d, k) = (1, 13) ,
- Longest Run of '10's: yyy'000'101'010'101'000'yyy ,
- Chip Rate @ Data Rate 16 Megabits per second: 24 Mchips per second ,
- System Clock @ Data Rate 16 Megabits per second: N X 12 MHz (where N ≥ 4)

The HHH(1,13) code is a Run Length Limited (RLL) code that provides both power efficiency and bandwidth efficiency at the high data rate. The signaling rate of the code is 24 Mchips per second allowing a rise and fall time of 19 ns. LED on time is further improved by having a 26% average duty cycle for random data. The lower duty cycle is achieved by scrambling the incoming data stream. The run length constraints (d, k) = (1, 13) ensure an inactive chip after each active chip, i.e. only single-chip-width pulses occur. This feature allows a source or a receiver to exhibit a long tail property. To take full advantage of the d = 1 feature of HHH(1, 13) in strong signal conditions, clock and data recovery circuitry ignores the level of the chip following an active chip and assumes these chips are inactive. The modulation code is enhanced with simple frame-synchronized scrambler/descrambler mechanisms as defined and described in later in this chapter.

34.3.10.1 HHH Data Encoding Definition

The encoding definition of the HHH (1, 13) code is provided by a state transition table described as follows:

Specific data pair D ≡ □D* = (d1, d2) arriving at the encoder input is first associated with a corresponding next state N □ N* This occurs as soon as the data D* bits have advanced into the positions of the internal data bits B1 = (b1, b2), i.e., when (b1, b2, b3, b4, b5, b6) is identical to (d1, d2, x, x, x, x). In a second step, during the next encoding cycle, the state S takes on the value of N*, i.e., S ≡ S* ← □N* so that S is now associated with (d1, d2). In the same cycle, the inner codeword C □C* carrying the information of D* is computed. Thus, referring the figure below, a given internal input vector (b1, b2, b3, b4, b5, b6) associates the bits (b1, b2) with the next state N and a given state S associates the data pair ahead of (b1, b2) to the output C. In other words, the pair-wise values for N and C as listed in the figure below are not associated with the same input data pair.

Encoder initialization: The state S = (s1, s2, s3) = (1, 0, 0) is also used as the initial state of the encoder, i.e., denoting with (α, β), the first pair of data bits to be encoded, the state S is forced to take on the value (1, 0, 0) when the bits (α, β) have advanced into the encoding circuits such that the internal inputs B1 = (b1, b2) is identical to (α, β)

Figure 130: Encoder Initialization

Present State: S = (s_1, s_2, s_3)	Next State/Internal Output: N = (n_1 n_2, n_3) / C = (c_1, c_2, c_3)							
	Internal Inputs: (b_1, b_2, b_3, b_4, b_5, b_6)							
	00xxxx	01xxxx	10xxxx	1100xx	1101xx	111011	1110(~~11~~)	1111xx
000	000/010	001/010	010/010	111/010	111/001	111/010	011/010	011/010
001	000/001	001/001	100/001	100/010	100/010	100/010	100/010	100/010
010	000/100	001/100	010/100	111/100	111/101	111/100	011/100	011/100

100	000/000	001/000	010/000	011/000	011/000	011/000	011/000	011/000
111	100/000	100/000	111/000	100/000	100/000	100/000	100/000	100/000

Note: Refer to the IrDA specification 1.4 for further details.

34.3.10.2 HHH (1, 13) Packet Format

The packet format for 16.0 Megabits per second HHH(1,13) has the following form:

PREAMBLE (PA)	START (STA)	IrLAP Frame	CRC	Flush Byte (FB)	STOP (STO)	NULL

The payload data is encoded as described in the HHH (1,13) encoding above, and the encoded symbols reside in the IrLAP Frame field. The preamble field (PA) is used by the receiver to establish phase lock. During PA, the receiver begins to search for the start flag (STA) to establish symbol synchronization. If STA is received correctly, the receiver can begin to interpret the data symbols in the IrLAP Frame field. The receiver continues to receive and interpret data until the stop flag (STO) is recognized. STO indicates the end of a frame. The chip patterns and symbols for PA, STA, CRC field, and STO are defined below.

Only complete packets that contain the entire format defined above are guaranteed to be decoded at the receiver (as for the lower rates, the information field, I, that is part of the IrLAP field, may be of zero length).

The 16.0 Megabits per second packet contains several fields for the purposes of clock recovery, synchronization, and data transmission. In concept, the packet format is similar to that used in 4.0 Megabits per second; however, there are specific controller elements like clock recovery, synchronization, and encoding/decoding circuits that need to be implemented specifically for 16.0 Megabits per second data rate.

34.3.10.3 Preamble Field Definition

The transmitted PREAMBLE (PA) is constructed by concatenating ten times (10X) the 24-chip (1 µs) PREAMBLE PERIOD (PP), where

PP = '100'010'010'001'001'001'000'100'

to form the complete 240-chip (10 µs) preamble

PA = 'PP'PP'PP'PP'PP'PP'PP'PP'PP'PP'

The left-most/right-most chip of PP and PA, respectively, is transmitted first/last and a '1' in PP means an active chip (pulse) and a '0' means an empty chip (no pulse).

34.3.10.4 Start (STA) Flag Definition

The transmitted START (STA) delimiter is the 48-chip (2 µs) chip sequence

STA = '100'101'010'100'100'010'000'001'001'010'101'001'000'001'010'000'

The left-most/right-most chip of STA is transmitted first/last and a '1' in STA means an active chip (pulse) and a '0' means an empty chip (no pulse). The Start Flag Delimiter allows for packet synchronization. A delimiter detection circuit should declare a flag as having been found when there is a perfect match between the receiver chip stream and a particular delimiter. The Start and Stop delimiters contain a subsequence '1001010101001' that violates the HHH (1,13) code. This subsequence occurs twice in the Start Flag delimiter and never occurs within the main HHH code.

34.3.10.5 IrLAP Frame

The structure remains unchanged from that defined in the IrLAP Specification, Version 1.1. The content of the IrLAP frame is first scrambled and then encoded with HHH(1,13). Note that the 32 CRC bits for the IrLAP frame are calculated before the IrLAP frame is scrambled. For reference, the IrLAP frame as the following structure:

| Address (8 bits) | Control (8 bits) | Information (M times 8 bits) |

34.3.10.6 CRC

Computation remains unchanged from the 32-bit CRC defined for the 4 Megabits per second data rate. The content of the CRC field is first scrambled with the scheme described later and then encoded with HHH(1, 13) as described previously. Note that the 32 CRC bits for the IrLAP frame are calculated before the IrLAP frame is scrambled. The transmitted CRC field is a 48-chip (2 µs) sequence.

34.3.10.7 FLUSH BYTE (FB)

The Flush Byte (FB) is the 8-bit sequence:

FB = '00'00'00'00'.

These 8 bits are not scrambled but directly sent to the HHH(1,13) encoder. The transmitted FB field is a 12-chip (0.5 µ s) sequence. Note that the FB field is required to enable complete decoding of the CRC field. The flush byte denotes the end of the main body. Since the flush byte is not scrambled, a well-balanced HHH(1,13) sequence precedes the STOP delimiter. This sequence would be equivalent to the UART "Break" command.

34.3.10.8 STOP (STO)

The transmitted STOP (STO) delimiter is the 48-chip (2 µs) sequence

STO = '001'001'010'101'001'000'100'000'100'101'010'100'100'000'100'000'.

The left-most/right-most chip of STO is transmitted first/last and a '1' in STO means an active chip (pulse) and a '0' means an empty chip (no pulse). As in the Start Flag delimiter, the Stop flag also contains a subsequence '1001010101001' that violates the HHH (1,13) code. This subsequence also occurs twice in the Stop Flag delimiter.

34.3.10.9 NULL Sequence

The transmitted NULL sequence is the 24-chip (1 µs) sequence

NULL = '000'000'000'000'000'000'000'000'.

The NULL field is a new field for the purpose of providing an HHH(1,13) code pattern violation that permits terminating reception of the packet in the event that the STO field is not recognized. The left-most/right-most chip in NULL is transmitted first/last and all chips of NULL are empty chips (no pulses). The NULL field increases the probability that the packet is terminated close to the STOP flag. The NULL field also reduces the probability that two back to back packets are interpreted as a single packet, should the STOP flag delimiter of the first packet be missed.

34.3.10.10 Scrambling and Descrambling Functions

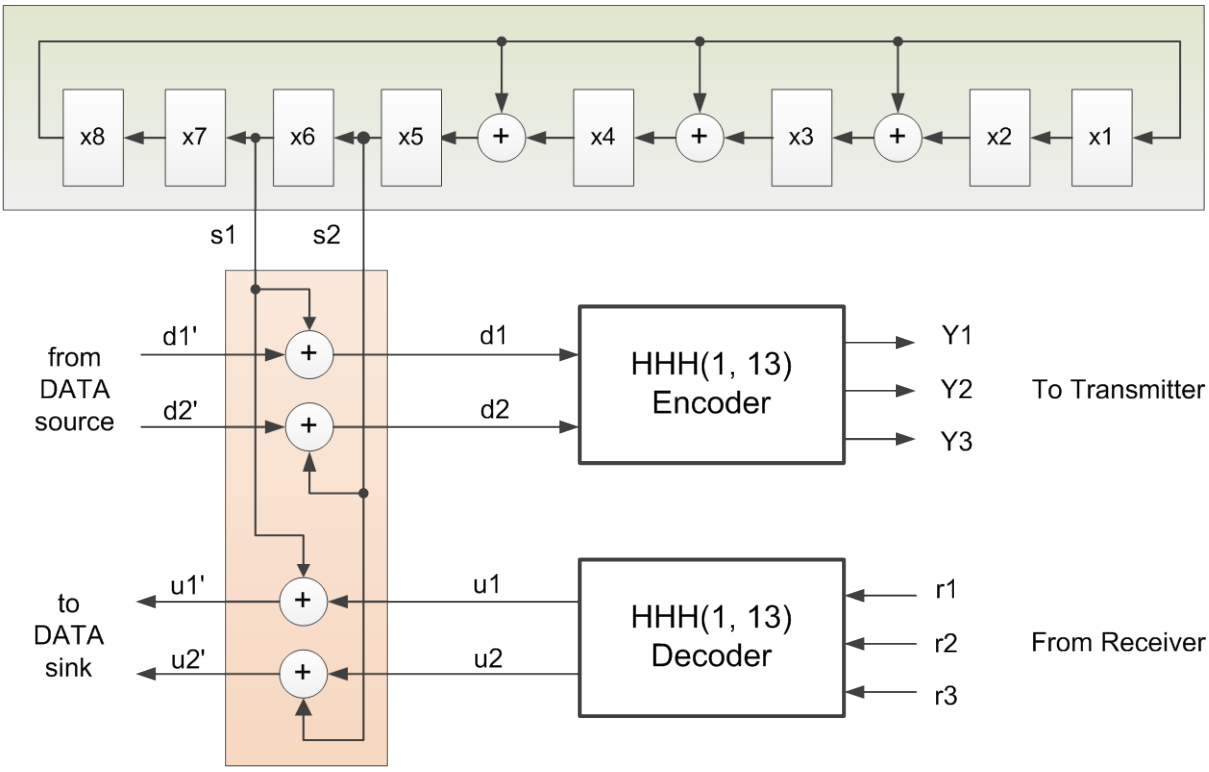
It is advantageous to enhance the encoder/decoder system with simple scrambler/descrambler functions.

The primitive polynomial: $x^8 \oplus x^4 \oplus x^3 \oplus x^2 \oplus 1$,

where $\oplus$ indicates a modulo-2 addition or, equivalently, a logic exclusive OR (XOR) operation. The operations of the proposed scrambling and descrambling functions are performed according to the principles of frame synchronized scrambling/descrambling (FSS) mechanisms. The scrambling/descrambling scheme is shown in the figure below. The linear feedback shift register (LFSR) produces a maximum-length pseudo-random sequence with period 255. The output of register cell x6 shown in the figure is defined to be the equivalent serial output of the LFSR.

The modulo-2 adders shown in the figure below correspond to logic XOR (exclusive OR) gates. During transmission, each new pair of source bits (d1', d2') is XOR-ed with a new pair of scrambling bits (s1, s2) to produce the scrambled data bit pair (d1, d2) entering the encoder. Similarly, during reception, each new pair of decoded bits (u1, u2) is XOR-ed with a new pair of descrambling bits (s1, s2) to produce the descrambled user bit pair (u1', u2') that is sent to the data sink. A scrambling/descrambling cycle has duration 3T seconds where T = 41.7 ns is the chip period.

Figure 131: Scrambling / Descrambling Scheme



34.3.10.11 Effects and Limits of Scrambling/Descrambling

By enhancing the system with scrambling/descrambling functions during data transmission/reception, one achieves generally better duty cycle statistics in the HHH(1,13) coded channel chip stream; the resulting duty cycle converges towards the average duty cycle of the code (≈ 26%) for typical payload data. Scrambling can greatly reduce the probability of occurrence of worst-case patterns.

34.3.10.12 Aborted Packets

Receivers may only accept packets that have valid STA, IrLAP frame, CRC, and STO fields as defined in the Packet Format section. The PA field need not be valid in the received packet. All other packets are aborted and ignored.

34.3.10.13 Back to Back Packet Transmission

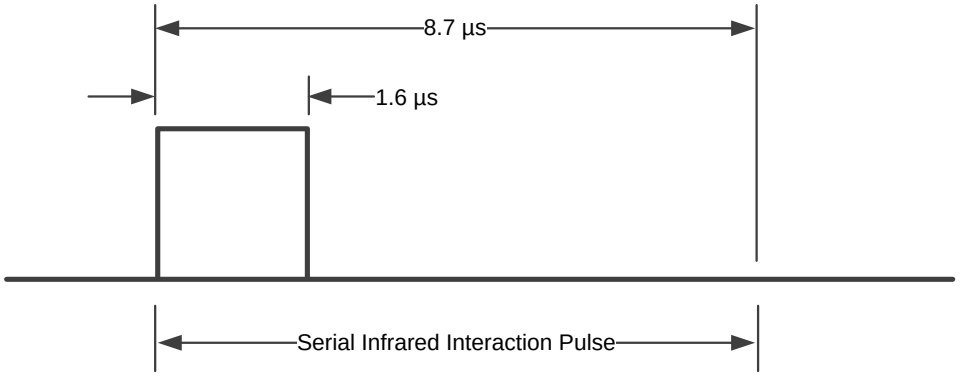
Back to back, or "brick-walled" packets are allowed, but each packet must be complete (i.e., containing PA, STA, IrLAP Frame, CRC and STO fields).

34.3.11 SIR - Serial Interaction Pulse

In order to guarantee non-disruptive coexistence with slower (up to 115.2 Kilobits per second) systems, once a higher speed (above 115.2 Kilobits per second) connection has been established, the higher speed system must emit a Serial infrared Interaction Pulse (SIP) at least once every 500 ms as long as the connection lasts to quiet slower systems that might interfere with the link. The pulse can be transmitted immediately after a packet has been transmitted. Initiation of this pulse will be performed by software by setting a bit in the VFIR Control register.

The pulse is shown below.

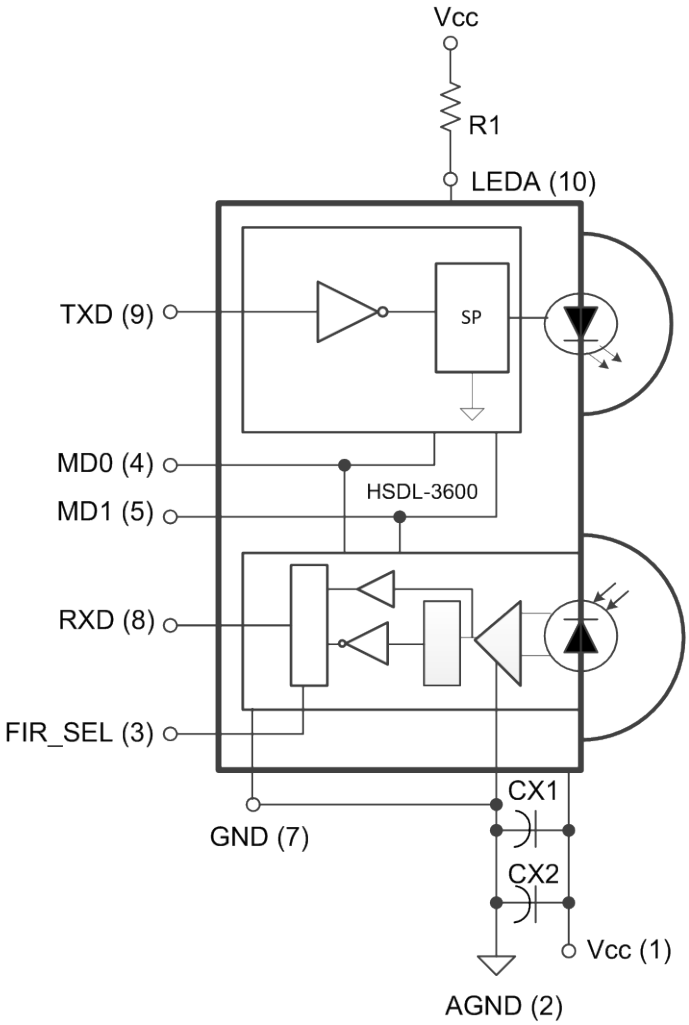
Figure 132: SIP



34.3.11.1 External Interface

The SIR/FIR/VFIR signals are muxed to the external transceiver. The transceiver has TX and RX pins, and may optionally have controls for receiver gain and transmitter power. This module provides the TX and RX pins, and each has a polarity control for compatibility with all vendors. Other transceiver pins are not directly supported, although they could be provided using GPIO signals. Refer to the drawing below for typical interface. TXD and RXD are VFIR module pins. MD and FIR_SEL pins would be GPIO. MD pins are for transmit power. FIR_SEL controls gain of receiver, and should be set to zero for SIR mode.

Figure 133: Typical Interface



34.4 UART Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

The Tegra K1 UART is based on the 16550 industry standard Universal Asynchronous Receiver/Transmitter (UART), with enhancements to support autobaud detection and End-of-Received Data timeout detection.

The UART supports a device clock of up to 72 MHz, for a maximum baud rate of 4.5 Megabits per second.

The THR, RBR and DLL registers all occupy the same address space.

- The Transmitter Holding Register (THR) is Write-Only, and can be accessed if the LSR.DLAB bit is clear.
- The Receiver Buffer Register (RBR) is Read-Only, and can be accessed if the LSR.DLAB bit is clear.
- The Divisor Latch LSByte Register (DLL) is Read/Write and can be accessed if the LSR.DLAB bit is set.

34.4.1 UART_THR_DLAB_0_0

UART Transmit Holding Register

Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	R/W	Reset	Description
7:0	RO	0x0	THR_A: Transmit holding register, holds the character to be transmitted by the UART. In FIFO mode, a write to this FIFO places the data at the end of the FIFO.
7:0	RO	X	RBR_A: Receive Buffer Register. Rx Data read from here.
7:0	RO	0x0	DLL_A: Divisor Latch LSB (low 8 bits of 16-bit Baud Divisor)

34.4.2 UART_IER_DLAB_0_0

The IER and DLH registers occupy the same address space, selected by the LSR.DLAB bit. The Interrupt Enable Register (IER) is selected if the LSR.DLAB bit is clear. The Divisor Latch MSByte register (DLM) is selected if the LSR.DLAB bit is set. The DLM register holds the upper 8 bits of the 16-bit Baud Divisor (16x).

UART Interrupt Enable por=0x00000000

RX_TIMEOUT occurs when data has been sitting in the Rx FIFO for more than 4 character times without being read because there is not enough data to reach the trigger level. Interrupt needed to handle this case so that all data is received in a timely manner. Note that this normally occurs at the end of an incoming data stream.

EORD (End of Receive Data) Interrupt occurs when the receiver detects that data stops coming in for more than 4 character times. This interrupt is useful for determining that the sending device has completed sending all its data. EORD timeout will not occur if the receiving data stream is stopped because of hardware handshaking.

To clear the EORD timeout interrupt you must DISABLE the EORD interrupt enable (IE_EORD).

Interrupt Enable and Divisor Latch MSByte Registers

Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx000000)

Bit	Reset	Description
5	0x0	IE_EORD: Interrupt Enable for End of Received Data 0 = DISABLE 1 = ENABLE
4	0x0	IE_RX_TIMEOUT: Interrupt Enable for Rx FIFO timeout 0 = DISABLE 1 = ENABLE
3	0x0	IE_MSI: Interrupt Enable for Modem Status Interrupt 0 = DISABLE 1 = ENABLE
2	0x0	IE_RXS: Interrupt Enable for Receiver Line Status Interrupt 0 = DISABLE 1 = ENABLE
1	0x0	IE_THR: Interrupt Enable for Transmitter Holding Register Empty interrupt 0 = DISABLE 1 = ENABLE
0	0x0	IE_RHR: Interrupt Enable for Received Data Interrupt 0 = DISABLE 1 = ENABLE

34.4.3 UART_IIR_FCR_0

The FCR and IIR registers occupy the same address space. The FIFO Control Register (FCR) is write-only. The Interrupt Identification Register (IIR) is read-only.

UART FIFO Control Register por=0x00000000

The DMA can run in one of two modes:

- If Mode0 is selected (NO_CHANGE), the Rx DMA request goes active whenever the Rx FIFO is not empty. Only single byte transactions can be performed in this mode. If the FIFO is not enabled, Mode0 MUST be used.
- If Mode1 is selected (CHANGE), the Rx DMA request goes active whenever the Rx FIFO trigger level is reached.

For best performance, always enable the FIFO and select DMA Mode 1.

For RX_TRIG, the FIFO_COUNT references the number of bytes in the receive FIFO.

For TX_TRIG, the FIFO_COUNT references the number of empty bytes in the transmit FIFO. For example, FIFO_COUNT_GREATER_16 means that there are at least 16 empty byte slots in the TX_FIFO.

UART Interrupt ID Register por=0x00000001

The Interrupt ID field indicates the current highest priority interrupt. If more than one interrupt is pending the one with the highest priority will be shown.

The table below shows the encoding. Priority flows from top (highest) to bottom (lowest).

Table 146 Interrupt ID Encoding

IIR[3:0]	Priority Level
0001	No interrupt
0110	Overrun Error, Parity Error, Framing Error, Break
0100	Receiver Data Available
1100	rx_timeout_intr
1000	eord_timeout_intr
0010	Transmitter Holding Register empty
0000	modem_status interrupt

UART FIFO Control and Interrupt Identification Registers

Offset: 0x8 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:6	X	EN_FIFO: FIFO Mode Status 0=16450 mode(no FIFO) 1 = 16550 mode (FIFO) 1 = MODE_16550 0 = MODE_16450
7:6	0x0	RX_TRIG: 0 = FIFO_COUNT_GREATER_1 1 = FIFO_COUNT_GREATER_4 2 = FIFO_COUNT_GREATER_8 3 = FIFO_COUNT_GREATER_16

Bit	Reset	Description
5:4	0x0	TX_TRIG: 0 = FIFO_COUNT_GREATER_16 1 = FIFO_COUNT_GREATER_8 2 = FIFO_COUNT_GREATER_4 3 = FIFO_COUNT_GREATER_1
3	X	IS_PRI2: Encoded Interrupt ID Refer to IIR[3:0] table above 0 = DISABLE 1 = ENABLE
3	0x0	DMA: 0:DMA_MODE_0 1:DMA_MODE_1 0 = NO_CHANGE 1 = CHANGE
2	X	IS_PRI1: Encoded Interrupt ID Refer to IIR[3:0] table above 0 = DISABLE 1 = ENABLE
2	0x0	TX_CLR: 1 = Clears the contents of the transmit FIFO and resets its counter logic to 0 (the transmit shift register is not cleared or altered). This bit returns to 0 after clearing the FIFOs. 0 = NO_CLEAR 1 = CLEAR
1	X	IS_PRI0: Encoded Interrupt ID Refer to IIR[3:0] table above 0 = DISABLE 1 = ENABLE
1	0x0	RX_CLR: 1 = Clears the contents of the receive FIFO and resets its counter logic to 0 (the receive shift register is not cleared or altered). This bit returns to 0 after clearing the FIFOs. 0 = NO_CLEAR 1 = CLEAR
0	X	IS_STA: Interrupt Pending if ZERO 0 = INTR_PEND 1 = NO_INTR_PEND
0	0x0	FCR_EN_FIFO: 1 = Enable the transmit and receive FIFOs. This bit should be enabled 0 = DISABLE 1 = ENABLE

34.4.4 UART_LCR_0

UART Line Control Register

Offset: 0xc │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7	0x0	DLAB: Divisor Latch Access Bit (set to allow programming of the DLH, DLM Divisors) 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
6	0x0	SET_B: Set BREAK condition -- Transmitter sends all zeroes to indicate BREAK 0 = NO_BREAK 1 = BREAK
5	0x0	SET_P: Set (force) parity to value in LCR [4] 0 = NO_PARITY 1 = PARITY
4	0x0	EVEN: Even parity format. There will always be an even number of 1s in the binary representation (PAR = 1) 0 = DISABLE 1 = ENABLE
3	0x0	PAR: 0 = No parity sent 0 = NO_PARITY 1 = PARITY
2	0x0	STOP: 0 = Transmit 1 stop bit 1 = Transmit 2 stop bits (receiver always checks for 1 stop bit) 0 = DISABLE 1 = ENABLE
1:0	0x0	WD_SIZE: 3=Word length of 8 0 = WORD_LENGTH_5 1 = WORD_LENGTH_6 2 = WORD_LENGTH_7 3 = WORD_LENGTH_8

34.4.5 UART_MCR_0

The RTS and CTS pins are used for hardware handshaking with an external serial device. RTS (Request-To-Send) informs the device that the UART is ready to accept data. CTS (Clear-To-Send) comes from the RTS of the external device and indicates that data can be sent.

The RTS pin can be controlled manually with the RTS bit in the MCR or automatically by setting the RTS_EN bit.

If RTS_EN is set, the RTS pin automatically removes the Request-To-Send when the FIFO reaches the trigger level.

If the CTS_EN bit is set, the UART transmitter stops transmitting when the Clear-To-Send input is taken away.

UART Modem Control Register

Offset: 0x10 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx0000000)

Bit	Reset	Description
6	0x0	RTS_EN: 1 = Enable RTS Hardware Flow Control 0 = DISABLE 1 = ENABLE

2	0x0	DRI: Change (Delta) in RI state detected 0 = DISABLE 1 = ENABLE
1	0x0	DDSR: Change (Delta) in DSR state detected 0 = DISABLE 1 = ENABLE
0	0x0	DCTS: Change (Delta) in CTS state detected 0 = DISABLE 1 = ENABLE

34.4.8 UART_SPR_0

UART Scratchpad Register

Offset: 0x1c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	SPR_A: Scratchpad register (not used internally)

34.4.9 UART_IRDA_CSR_0

Bits [7:6] control the infrared (SIR) encoding. If enabled, each zero bit is transmitted as a short IR pulse. No pulse is sent during idle or '1' data bits. The IR pulse can be either 3/16 or 4/16 of a normal bit time.

The low 4 bits control signal polarity and apply whether or not SIR coding is enabled.

UART IrDA Pulse Coding CSR Register

Offset: 0x20 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx00xx0000)

Bit	Reset	Description
7	0x0	SIR_A: 1 = Enable SIR coder 0 = Disable SIR coder 0 = DISABLE 1 = ENABLE
6	0x0	PWT_A: 0=3/16th Baud Pulse, 1=4/16 0 = BAUD_PULSE_3_14 1 = BAUD_PULSE_4_14
3	0x0	INVERT_RTS: Inverts the normally inactive high nRTS pin 0 = DISABLE 1 = ENABLE
2	0x0	INVERT_CTS: Inverts the normally inactive high nCTS pin 0 = DISABLE 1 = ENABLE
1	0x0	INVERT_TXD: Inverts the normally inactive high TXD pin 0 = DISABLE 1 = ENABLE
0	0x0	INVERT_RXD: Inverts the normally inactive high RXD pin 0 = DISABLE 1 = ENABLE

34.4.10 UART_RX_FIFO_CFG_0

Offset: 0x24 │ Read/Write: R/W │ Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx0x000001)

Bit	Reset	Description
7	0x0	EN_RX_FIFO_TRIG: Enable use of RX_FIFO_TRIG count (obsoletes RX_TRIG when enabled) 0 = DISABLE 1 = ENABLE
5:0	0x1	RX_FIFO_TRIG: Set RX_FIFO trigger level (any value 1 thru 32)

34.4.11 UART_MIE_0

UART Modem Interrupt Enable Register

Offset: 0x28 │ Read/Write: R/W │ Reset: 0x0000000f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx1111)

Bit	Reset	Description
3	0x1	DCD_INT_EN: Interrupt Enable for Change (Delta) in CD state detected 0 = DISABLE 1 = ENABLE
2	0x1	DRI_INT_EN: Interrupt Enable for Change (Delta) in RI state detected 0 = DISABLE 1 = ENABLE
1	0x1	DDSR_INT_EN: Interrupt Enable for Change (Delta) in DSR state detected 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
0	0x1	DCTS_INT_EN: Interrupt Enable for Change (Delta) in CTS state detected 0 = DISABLE 1 = ENABLE

34.4.12 UART_ASR_0

The UART has autobaud sensing logic that can measure the width of the start bit of incoming data to determine baud rate. For this to work, the incoming character must have its LSB set. A <cr> works well (0x0d). The logic uses the UART device clock to count how wide the start pulse is, and the BUSY bit is set when the sensing is complete. The value in {RX_RATE_SENSE_H,RX_RATE_SENSE_L} should be divided by 16 with Round-to-Nearest, and the resulting value loaded into the DLM,DLL register pair to set the Baud Clock to 16X the Baud Rate.

UART Auto Sense Baud Register

Offset: 0x3c │ Read/Write: R/W │ Reset: 0x00000000 (0b00xxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
31	0x0	VALID: This bit is set when the controller finishes counting the clocks between two successive clock edges after there is a write to ASR with don't care data. 0 = UN_SET 1 = SET
30	0x0	BUSY: This bit is set when there is a write to ASR and is reset when the controller finishes counting the clock edges between two successive clock edges. 0 = NO_BUSY 1 = BUSY
15:8	0x0	RX_RATE_SENSE_H: Shows bits [15:8] of the count of clock edges between two successive clock edges.
7:0	0x0	RX_RATE_SENSE_L: Shows bits [7:0] of the count of clock edges between two successive clock edges.

34.5 VFIR Registers

34.5.1 VFIR_CTL_0

The VFIR Control register is used to:

- enable/disable entire IRDA module
- configure the controller in FIR mode or VFIR mode or SIR or UART mode
- configure either in Transmit mode or Receive mode
- invert the polarity of Tx or Rx line
- invert the polarity of Tx or Rx line
- enable/disable DMA
- know the attention levels of Transmit FIFO and Receive FIFO
- start a transmit or receive operation
- select the frequency
- clear the Transmitter FIFO/Receiver FIFO

VFIR Control Register

Offset: 0x0 | Read/Write: R/W | Reset: 0x00000020 (0b000xxxx0x000x000xx00000000100000)

Bit	Reset	Description
31	0x0	GLOBAL_ENABLE: 0 = Entire IRDA module is disabled 0 = DISABLE 1 = ENABLE
30	0x0	GO: Set to 1 to start transmit or receive operation, self-clearing 0 = STOP 1 = START
29	0x0	AUTO_RESTART: Set to 1 to restart another operation when previous is done 0 = STOP 1 = RE_START
24	0x0	FORCE_BAD_CRC: Debugging bit to force a CRC error 0 = DISABLE 1 = ENABLE
22	0x0	TX_FIFO_CLR: Clear the Transmitter FIFO 0 = DISABLE 1 = ENABLE
21:20	0x0	TX_ATN_LVL: 00: when not full 3 = slots_empty_12 2 = slots_empty_8 1 = slots_empty_4 0 = not_full
18	0x0	RX_FIFO_CLR: Clear the Receiver FIFO 0 = DISABLE 1 = ENABLE
17:16	0x0	RX_ATN_LVL: 00: when not empty 3 = slots_full_12 2 = slots_full_8 1 = slots_full_4 0 = not_empty
13	0x0	START_SIP: Self-clearing bit to initiate a Serial Ir Interaction Pulse.
12	0x0	EN_PULSECORR: Fixes single pulse errors caused by VFIR propagation effects. 0 = DISABLE 1 = ENABLE
11	0x0	DMA_EN: DMA Enable Allow requests to go to the APB_DMA controller. 0 = DISABLE 1 = ENABLE
10	0x0	TX_TERM: of outgoing frame, i.e., the calculated CRC will be sent, followed by the frame stop sequence. The interrupt will be generated if enabled. 0 = ABORT 1 = NORMAL
9	0x0	COUNT_ODATA: When enabled, the controller will end the frame when the Outgoing Frame Data Length (OFDL) count is reached. Use in conjunction with TX_Term above so controller will know when and how to end the frame. 0 = DISABLE 1 = ENABLE
8	0x0	FORCEBRK: break state (zero) regardless of what the transmitter is doing. 0 = TX_ENABLE 1 = TX_DISABLE

Bit	Reset	Description
7	0x0	NEGATE_RX: Invert polarity on incoming RX pin (applies to all modes) 0 = DISABLE 1 = ENABLE
6	0x0	NEGATE_TX: Invert polarity on outgoing TX pin (applies to all modes) 0 = DISABLE 1 = ENABLE
5:4	0x2	FREQUENCY: The 8 and 24 MHz clocks can be used to save power during transmits. The 72 MHz clock can be used in case the 48 MHz clock is not available due to system constraints. 0 = F8MHz 1 = F24MHz 2 = F48MHz 3= F72MHz
3	0x0	TRANSMIT: 0 = Receive (FIR/VFIR modes) 1 = TRANSMIT 0 = RECEIVE

34.5.2 VFIR_STS_0

The VFIR Status and Interrupt Identification register is used to get the following status:

- Transmitter/Receiver FIFO Trigger level status
- Transmitter/Receiver FIFO FULL/EMPTY status
- Transmitter/Receiver FIFO empty slots
- whether a Transmit or Receive operation is done or not
- whether End of Frame is received or not
- whether there is any CRC error in received data or not
- whether there is any error in the received data
- whether the controller is busy with transmitting/receiving the data
- whether the VFIR interrupt is generated or not. To generate the interrupt, the corresponding enable bit has to be set in the VFIR Interrupt Enable Register

VFIR Status and Interrupt Identification Register

Offset: 0x4 │ Read/Write: R/W │ Reset: 0xXXXXX0X0 (0bxxxxxxxxxxxxxxxxxxxx0xxx0x000000)

Bit	R/W	Reset	Description
31	RO	X	TX_FTRIG: Transmitter FIFO Trigger level Reached
30	RO	X	TX_FIFO_FULL: Transmitter FIFO is Full
29	RO	X	TX_FIFO_EMPTY: Transmitter FIFO is Empty
28:24	RO	X	TX_FIFO_EMPTY_COUNT: Number of empty slots (words) in the Tx FIFO. The FIFO is a shared Rx/Tx FIFO with a total of decimal 20 entries

Bit	R/W	Reset	Description
23	RO	X	RX_FTRIG: Receiver FIFO Trigger level Reached
22	RO	X	RX_FIFO_FULL: Receiver FIFO is Full
21	RO	X	RX_FIFO_EMPTY: Receiver FIFO is Empty
20:16	RO	X	RX_FIFO_FULL_COUNT: Number of words available to read in the Rx FIFO. The FIFO is a shared Rx/Tx FIFO with a total of decimal 20 entries
15	RO	X	INTR: Global VFIR interrupt (OR of all FIR/VFIR interrupts)
14	RO	X	BUSY: Transmitting or receiving data. It is clear when the controller is idle or transmits a Serial infrared Interaction Pulse (SIP)
11	RW	0x0	TX_UNDRN: break. This bit is cleared upon reading from the register.
7	RW	0x0	MISSED_PACKET: Another Rx arrived before the previous was serviced. Serviced is defined as clearing the Rx_EOF flag. This bit is cleared by writing a 1 to this bit.
6	RO	X	BITSYNC_LOCK: Debug status bit which indicates that receiver is Locked to incoming bitstream.
5	RW	0x0	RX_DETECT: Activity detected on Rx pin This bit is cleared by writing a 1 to this bit.
4	RW	0x0	RX_ERR: Receiver Error. This bit is set when an unexpected or illegal data has been received. This can be a break in transmission, illegal chip values or framing errors. This bit is cleared by writing a 1 to this bit.
3	RW	0x0	RX_FOVRN: Receiver FIFO overrun error occurred. This bit is cleared by writing a 1 to this bit.
2	RW	0x0	RX_CRC_ERR: CRC check on input data failed. This bit is cleared by writing a 1 to this bit.
1	RW	0x0	RX_EOF: Received End of Frame. Set when the last byte in frame is within the receiver FIFO. This bit is cleared by writing a 1 to this bit.
0	RW	0x0	DONE: Done flag. Set when controller completes a Transmit or Receive packet, even if the packet finished early due to errors. This bit is cleared by writing a 1 to this bit.

34.5.3 VFIR_IER_0

VFIR Interrupt Enable Register is used to generate a VFIR interrupt for different conditions. VFIR Interrupt bit is present in VFIR.

Status and Interrupt Identification Register

For example when the controller finishes the Transmitting/Receiving operation and if IE_DONE is set, then an interrupt is generated. Similar is the case for other bits in this register

VFIR Interrupt Enable Register

Offset: 0x8 │ Read/Write: R/W │ Reset: 0x00000000 (0b0xxxxxxx0xxxxxxxxxxx0xxx0x000000)

Bit	Reset	Description
31	0x0	IE_TX_FTRIG: Enable Interrupt on Transmitter FIFO Trigger level reached 0 = DISABLE 1 = ENABLE
23	0x0	IE_RX_FTRIG: Enable Interrupt on Receiver FIFO Trigger level reached 0 = DISABLE 1 = ENABLE
11	0x0	IE_TX_UNDRN: Transmit a break for the receiving side to abort reception. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
7	0x0	IE_MISSED_PACKET: Enable Interrupt for Missed Packet error 0 = DISABLE 1 = ENABLE
5	0x0	IE_RX_DETECT: Enable Interrupt on Activity on Rx Pin 0 = DISABLE 1 = ENABLE
4	0x0	IE_RX_ERR: Enable Interrupt on Receiver Error 0 = DISABLE 1 = ENABLE
3	0x0	IE_RX_FOVRN: Enable Interrupt on Receiver FIFO overrun 0 = DISABLE 1 = ENABLE
2	0x0	IE_RX_CRC: Enable Interrupt for input CRC check failure 0 = DISABLE 1 = ENABLE
1	0x0	IE_RX_EOF: Enable Interrupt for Received End of Frame 0 = DISABLE 1 = ENABLE
0	0x0	IE_DONE: Enable Interrupt for Done Status 0 = DISABLE 1 = ENABLE

34.5.4 VFIR_OFDL_0

VFIR Outgoing Frame Data Length is used to configure the number of bytes of data to be sent.

VFIR Outgoing Frame Data Length

Offset: 0xc │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0x0	OFDL: Set to the length in bytes of the outgoing frame. Length is calculated on the information field only (address, control and data fields only) without the CRC and flags. When in this mode, the amount of data transferred to the controller is counted and when the count is reached the controller finishes sending the frame in normal fashion by transmitting CRC field, STO flag and then the SIP.

34.5.5 VFIR_IFDL_0

VFIR Incoming Frame Data Length gives the information of the data received in bytes.

VFIR Incoming Frame Data Length

Offset: 0x10 │ Read/Write: RO │ Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	IFDL: Running length in bytes of the incoming data stream. At the end of frame reception when the Received End of Frame interrupt occurs, this register reflects the length of the information field received in that frame, not counting the CRC field and other flags. Resets on the start of next frame reception, when a new STA field has been detected.

34.5.6 VFIR_FIFO_0

The VFIR FIFO is a shared FIFO. It holds the data in Transmitter/Receiver mode.

VFIR.FIFO (VFIR FIFO)

Offset: 0x40 │ Read/Write: R/W │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DATA: Shared FIFO. When transmitting, this FIFO holds the data to be transmitted. When receiving, this FIFO holds the received data.

35.0 SERIAL PERIPHERAL INTERFACE (SPI) CONTROLLER

The Serial Peripheral Interface (SPI) controller is a serial communications link between the processor and on-chip/off-chip serial peripheral devices such as sensors, ADC/DAC devices, and Flash controllers. Tegra® K1 devices support both Master and Slave modes of SPI operation on this interface.

In this section:

- *Word* refers to 32-bit data in the TX or RX FIFO
- *Packet* refers to variable length data that is transmitted or received
  - In Unpacked Mode, packet size can be any length from 4 to 32 bits in Master mode or 8 to 32 bits in Slave mode
  - In Packed Mode, packet size can be 4, 8, 16, or 32 bits

35.1 Functionality

The Tegra K1 SPI Controller works as a Master/Slave on the SPI bus. It has independent transmit and receive FIFOs of 64 x 32 bits each. Software can program the controller to generate transactions of a required packet length on the SPI bus, where a transaction is a sequence of packets in either direction.

The controller supports either APB DMA or program transfer to read and write from the FIFOs as required. At the end of each transaction, an interrupt can be generated, if enabled. Software uses transmit and receive operations in combination with chip select (CS) control to generate commands on the SPI bus.

The interface consists of four signals: Chip Select/Slave Select (CS_N), Clock (SCLK), Master Data Out and Slave Data In (MOSI), and Master Data In and Slave Data Out (MISO).

Features

- Master and Slave functionality
  - Master: All transmission format modes are supported for both transmit and receive operations
  - Slave (transmits): Modes 1 and 3 are supported
  - Slave (receives): All modes are supported
- Independent Rx and Tx FIFOs
- FIFO depth of 64 x 32 bits
- Programmable bit lengths from 3 to 31 bits, resulting in packet sizes of 4 to 32 bits
- PIO or DMA Mode depending on packet size

  Options include Packed/Unpacked, Full-Duplex Mode, Both Enable Bit (x2 Mode), Both Enable Byte (x2 Mode), Bidirectional, Least Significant Bit, Least Significant Byte First (Endian-ness), software or hardware chip-select polarity selection
- Programmable clock phase and polarity
- Programmable delay between consecutive transfers
- Packed mode support for bit lengths of 3 (4-bit packet size), 7 (8-bit packet size), and 15 (16-bit packet size)
- Chip select (CS) can be controlled by software or can be generated automatically by hardware on packet boundaries
- Maximum 4-chip support with programmable CS polarity for each chip select
- DMA support
- Simultaneous receive and transmit operations supported
- The maximum frequency of the device clock is 50 MHz, so the maximum data rate is 50 Mbits/s

35.1.1 Transmission Format

Using the Mode field in the SPI Command1 Register, software sets one of the four modes in which the SPI controller works. The two bits of the Mode field specify the idle (inactive) state of SCLK before the chip select is asserted and the data transmitting/receiving edges of SCLK. Mode [1] determines the SCLK polarity. If the polarity is 0, then the SCLK signal is 0 when idle and transitions to 1 when data transfer starts. If the clock polarity is 1, then the SCLK signal is 1 when idle and transitions to 0 when data transfer starts. Mode [0] is the SCLK phase control bit. If the clock phase is 0, then the receiver latches the data on the first transition of SCLK from the idle state. If the clock phase is 1, then the receiver latches the data on the second transition of SCLK.

Modes supported by the SPI controller are:

- Master: All transmission format modes are supported both for transmitting and receiving
- Slave: Modes 1 and 3 are supported for transmitting
- Slave: All modes are supported for receiving

The following table defines the four modes for the SPI protocol.

Table 147: SPI Modes with Clock Polarity and Phase

SPI Mode	Clock Polarity	Clock Phase	SCLK Inactive State	Data Latch IN	Data Latch OUT
0	0	0	Low	Latched IN on the positive edge of clock	Latched OUT on the negative edge of clock
1	0	1	Low	Latched IN on the negative edge of clock	Latched OUT on the positive edge of clock
2	1	0	High	Latched IN on the negative edge of clock	Latched OUT on the positive edge of clock
3	1	1	High	Latched IN on the positive edge of clock	Latched OUT on the negative edge of clock

35.1.2 Modes of Operation

35.1.2.1 Master and Slave Modes

The SPI controller can be configured to operate as a Master or Slave. When the M/S bit in the SPI Command1 Register is set, Master mode is selected; when the M/S bit in the SPI Command1 Register is cleared, Slave mode is selected. Only the SPI Master can initiate a transaction.

In Master mode, data from the Tx FIFO is transmitted on the MOSI pin. The data from the slave is received on the MISO pin and sent to the Rx FIFO. The Master can simultaneously transmit and receive on MOSI and MISO in Full-Duplex Mode.

In Slave mode, once software enables the SPI controller by setting the PIO bit, it simply waits for the Master to initiate a transaction. Before the transaction begins, the slave logic continuously polls the CS input. When the Master asserts CS and SCLK is transmitted to the Slave, the Slave data is transmitted from the Tx FIFO on MISO and data from MOSI is received in the Rx FIFO. The Slave can also simultaneously transmit and receive on MOSI and MISO in Full-Duplex Mode.

Table 148: Master Mode Port Configuration

Name	Direction	Description
MOSI	Bidirectional	Output in Full-Duplex/Tx Mode Input in Both_Enable Rx Mode
MISO	Bidirectional	Input in Full-Duplex/Rx Mode
SCLK	Output	Output in Both_Enable TX Mode
CS_#x	Output	Slave select signal to x, where x is a number between 0 to 3

Table 149: Slave Mode Port Configuration

Name	Direction	Description
MISO	Bidirectional	Output in Full-Duplex/Tx Mode Input in Both_Enable Rx Mode
MOSI	Bidirectional	Input in Full-Duplex/Rx Mode Output in Both_Enable TX Mode
SCLK	Input	Synchronization clock received from the Master
CS_#	Input	Select signal

When the SPI controller is configured to interface with multiple slaves, the controller has one CS signal for each slave, up to a maximum of four slaves. During a transfer, the master asserts CS specified in the CS_SEL bits in SPI Command1 Register. There can be no more than one slave transmitting data during any particular transfer.

Known Limitations

In Slave Mode, the maximum block size supported by the SPI controller is 0xFFFB with packed mode and bit lengths of 8 or 16.

35.1.2.2 DMA and PIO Modes

PIO and DMA are the two main operational modes for the SPI controller. PIO mode is used when the number of packets to the transmitter or receiver is less than or equal to 64. DMA mode is used when the number of packets to the transmitter or receiver is greater than 64. In PIO or DMA mode, the SPI controller sends an interrupt to the processor at the end of each transfer. In this mode software configures the number of packets and number of bits in each packet to be transmitted/received. The limitation of PIO Mode is that it can be used only if the maximum number of packets that can be transferred is less than or equal to 64 packets (the FIFO depth is 64). If software wants to transmit/receive more than 64 packets in PIO Mode, it has to reconfigure the SPI controller every 64 packets.

To send/receive more than 64 packets, the SPI Controller can be configured in DMA mode (enabled by writing 1 to the DMA_EN bit in the SPI DMA Control Register). The SPI controller transmits or receives the number of packets as indicated by the BLOCK_SIZE field in the SPI Block Size Register. BLOCK_SIZE is a 16-bit field, so 2^{16} packets (amounting to 256 KB) can be transmitted/received in a single software configuration.

CS usage guideline: If a hardware-based CS is used, the CS goes to the inactive state after the transfer of packets as programmed in the BLOCK_SIZE register field is completed. If CS has to stay active in multiple consecutive transactions (for

example, the first transaction – Tx: 64 Packets; the second transaction – Rx: 128 Packets), then the software based CS has to be used (in hardware-based CS, CS goes to the inactive state after the completion of the first transaction).

35.1.2.3 Packed and Unpacked Modes

SPI communication can be carried out in Packed or Unpacked Mode. These are both present in DMA and PIO Modes.

- Packed Mode: In Packed Mode, data can be transmitted/received with each packet size equal to 4, 8, 16, or 32 bits. The PACKED field and BIT_LEN field in the DMA Command1 Register determine if the mode Packed or Unpacked and the length of each packet. If the BIT_LEN field is set to 03h, each packet is 4 bits long and each word in the Tx/Rx FIFO contains 8 such packets. Similarly, if BIT_LEN is 07h, the packet length is 8. If BIT_LEN is 0Fh, the packet length is 16. If BIT_LEN is 1Fh, the packet length is 32. In Packed Mode, if BIT_LEN is set to 03h and if the number of packets is set to a non-multiple of 4 (for example, 5), the last word in FIFO contains only the fifth packet with 4 valid bits; 28 extra invalid bits will be ignored by the controller for transmits and will contain invalid data for receives.
- Unpacked Mode: If BIT_LEN is set to 03h, then each word in the Tx/Rx FIFO has 4 bits with the remaining bits in each word being ignored. BIT_LEN can be any value from 3 to 31 in Unpacked Mode.

35.1.2.4 Bidirectional Mode

Bidirectional mode is selected when the BIDIR bit is set in the SPI Command1 Register. In this mode, the SPI controller uses only one serial data pin for the interface with external device(s). The M/S bit decides which pin to use. The MOSI pin becomes the serial data I/O (MOMI) pin for the Master Mode, and the MISO pin becomes serial data I/O (SISO) pin for the Slave Mode. The SPI controller does not use the MISO pin in Master Mode and the MOSI pin in Slave Mode.

Table 150: Bidirectional Mode Port Configuration for Master (M/S Bit Set)

Name	Direction	Description
MOSI > MOMI	Bidirectional	Data Output and Input to Slave(s)
MISO > --	--	--
SCLK	Output	Synchronization clock to all Slaves
CS	Output	Slave select signal to x, where x is a number from 0 to 3, inclusive

Table 151: Bidirectional Mode Port Configuration for Slave (M/S Bit Cleared)

Name	Direction	Description
MOSI > --	--	--
MISO > SISO	Bidirectional	Data Output and Input from Slave(s)
SCLK	Input	Synchronization clock
CS	Input	Select signal

35.1.2.5 Both Enable Byte and Bit Modes (SPI x2 Mode)

The Both Enable Byte Mode is selected when the BOTH_EN_BYTE bit is set in the SPI Command1 Register. In this mode, the SPI controller uses both data pins only for transmitting or only for receiving. When the BOTH_EN_BYTE register field is set to 1, the Tx and Rx bits decide whether to transmit or receive. When the Tx bit is set, the MOSI and MISO pins are used to transmit serial data from the Tx FIFO and Rx FIFO at the same time. When the Rx bit is set, the MISO and MOSI pins are used to receive serial data onto Tx FIFO and Rx FIFO at the same time.

Table 152: Both Enable Mode Port Configuration for Master (Tx Bit Set)

Name	Direction	Description
MOSI	Output	Data Output to Slave(s)
MISO	Output	Data Output to Slave(s)
SCLK	Output	Synchronization clock to all Slaves
CS_N_OUT	Output	Slave select signal to x, where x is a number from 0 to 3, inclusive

Table 153: Both Enable Mode Port Configuration for Slave (Rx Bit Set)

Name	Direction	Description
MOSI	Input	Data Input from Slave(s)
MISO	Input	Data Input from Slave(s)
SCLK	Input	Synchronization clock
CS_N	Input	Select signal

The Both Enable Bit Mode is selected when the BOTH_EN_BIT bit is set in the SPI Command1 Register. This feature is different from Both Enable Byte as follows: In Both Enable Byte Mode, a packet from the Tx FIFO is transmitted or received on the MOSI data line and a packet from the Rx FIFO is transmitted or received on the MISO data line. In Both Enable Bit Mode, a packet from the Tx FIFO is transmitted or received on both MOSI and MISO data lines. Even bits are transmitted or received on the MOSI data line and odd bits are transmitted or received on the MISO data line. This is the same in both Master and Slave Modes.

> **Note**: BOTH_EN_BYTE and BOTH_EN_BIT should not be set to 1 at the same time. BOTH_EN_BYTE or BOTH_EN_BIT should not be set to 1 when the BIDIR bit is set to 1.

35.1.2.6 En_LE_Bit and En_LE_Byte Modes

> **Note**: En_LE_Bit is Enable Little Endian Bit, and En_LE_Byte is Enable Little Endian Byte.

These two bits allow a data packet to be transmitted or received in Little Endian or Big Endian format. Once a data packet is read from the Tx FIFO, it undergoes a two-step pre-processing based on En_LE_Byte and En_LE_Bit.

> Step 1. In this step, En_LE_Byte configures whether a packet has to be arranged internally according to the Little Endian byte format or Big Endian byte format. For example, if a 2-byte packet is written into the FIFO by software as Byte 1,Byte 0, setting En_LE_Byte = 0 makes the SPI controller arrange the packet internally as Byte 0,Byte 1(Big

Endian format). If En_LE_Byte = 1, the SPI controller internally arranges the packet as Byte 1,Byte 0 (Little Endian format) before the packet is transmitted.

Step 2. In this step, the output of Step 1 is taken, and data is put on the MOSI/MISO line according to En_LE_Bit. If En_LE_Bit is set to 0, the most significant bit of the output of Step 1 is put on the MOSI/MISO line first. If En_LE_Bit is set to 1, the least significant bit of Step 1 output is put on the MOSI/MISO line.

These steps are illustrated in the following table.

Step 1	**FIFO Packet (MSB - LSB)**	**Byte**	**Output of Step 1**
	Byte 1, Byte 0	0	Byte 0, Byte 1
		1	Byte 1, Byte 0
Step 2	**Output of Step 1**	**Bit**	**Data Transmitted on MOSI (Right-most Bit Sent First)**
	Byte 0, Byte 1	0	Byte 1 (0), Byte 1 (1), …, Byte 0 (6), Byte 0 (7)
	Byte 0, Byte 1	1	Byte 0 (7), Byte 0 (6), …, Byte 1 (1), Byte 1 (0)
	Byte 1, Byte 0	0	Byte 0 (0), Byte 0 (1), …, Byte 1 (6), Byte 1 (7)
	Byte 1, Byte 0	1	Byte 1 (7), Byte 1 (6), …, Byte 0 (1), Byte 0 (0)

Similarly for Receive operations, the first packet received will be internally rearranged first based on En_LE_Bit, then the output of the previous step will be rearranged based on En_LE_Byte before writing the final packet into the Rx FIFO.

The following examples explain the effect of these two bits:

- Unpacked Mode
  - Tx: The following example shows how a 20-bit length packet from the FIFO is transmitted. The right-most bit in Column D in the table below is transmitted first. B.7-B.0 indicates that bit 0 is transmitted first followed by bit 1 until bit 7, which is transmitted last.

A	B	C	D
FIFO WORD: 20 (MSB) – 0 (LSB)	**En_LE_Bit**	**En_LE_Byte**	**Data Transmitted on MOSI/MISO Line**
	0	0	16, 17,18, 19, 20, B.8-B.15, B.0-B.7
	0	1	B.0-B.7, B.8-B.15, 16, 17, 18, 19, 20
	1	0	B.7-B.0, B.15-B.8, 20, 19, 18, 17, 16
	1	1	B.20-B.0

  - Rx: The following example shows how a 20-bit length packet from the FIFO is received. The right-most bit in Column D in the table below is received last on the MOSI/MISO lines. B.7-B.0 indicates that bit 7 is received first followed by bit 6 until bit 0, which is received last. B.20 – B.0 are always written into the FIFO after the En_LE_Byte and En_LE_Bit transformations.

A	B	C	D
FIFO WORD: 20 (MSB) – 0 (LSB)	**En_LE_Bit**	**En_LE_Byte**	**Data Received on MOSI/MISO Line**
	0	0	B.7-B.0, B.15-B.8, 20, 19, 18, 17, 16
	0	1	20, 19, 18,17, 16, B.15-B.8, B.7-B.0

A	B	C	D
FIFO WORD: 20 (MSB) – 0 (LSB)	**En_LE_Bit**	**En_LE_Byte**	**Data Received on MOSI/MISO Line**
	1	0	16, 17, 18, 19, 20, B.8-B.15, B.0-B.7
	1	1	B.0-B.20

- Packed Mode
  - Tx: The following example shows how 3 16-bit packets are transmitted. Column B indicates the valid packets to be transmitted. Because FIFO Word2 is not transmitted entirely, valid packets are only from B.15-B.0. In Column D, P1(0 -15) indicates Packet1 of Column B is transmitted, B.15 is transmitted first, and B.0 is transmitted last.

A	B: Valid Packets	B	C	D
FIFO WORD1: 31 (MSB) – 0 (LSB)	**P1(15-0), P0(15-0)**	**En_LE_Bit**	**En_LE_Byte**	**Data Transmitted on MOSI/MISO Line**
FIFO WORD2: 31 (MSB) – 0 (LSB)	**P2(15-0)**	0	0	P2(8-15), P2(0-7), P1(8-15), P1(0-7), P0(8-15), P0(0-7)
		0	1	P2(0-7), P2(8-15), P1(0-7), P1(8-15), P0(0-7), P0(8-15)
		1	0	P2(7-0), P2(15-8), P1(7-0), P1(15-8), P0(7-0), P0(15-8)
		1	1	P2(15-8), P2(7-0), P1(15-8), P1(7-0), P0(15-8), P0(7-0)

  - Rx: The following example shows how 3 16-bit packets are received. Column B indicates the valid received packets in the Rx FIFO. In column D, P1(0 -15) indicates Packet1 of Column B is received, B.0 is received first, and B.15 is received last.

A	B: Valid Packets	B	C	D
FIFO WORD1: 31 (MSB) – 0 (LSB)	**P1(15-0), P0(15-0)**	**En_LE_Bit**	**En_LE_Byte**	**Data Received on MOSI/MISO Line**
FIFO WORD2: 31 (MSB) – 0 (LSB)	**P2(15-0)**	0	0	P0(7-0), P0(15-8), P1(7-0), P1(15-8), P2(7-0), P2(15-8)
		0	1	P0(15-8), P0(7-0), P1(15-8), P1(7-0), P2(15-8), P2(7-0)
		1	0	P0(8-15), P0(0-7), P1(8-15), P1(0-7), P2(8-15), P2(0-7)
		1	1	P0(15-8), P0(7-0), P1(15-8), P1(7-0), P2(15-8), P2(7-0)

35.2 SPI Programming Guidelines

There are two basic modes of operation: DMA and PIO modes. It is required that software sets up all parameters in the SPI Command1 and Command2 registers, SPI CS Timing 1 and 2 registers, SPI FIFO Control/Status register, SPI DMA Control register, and SPI Block Size register before enabling the PIO bit in any of these modes.

35.2.1 DMA Mode

This mode is enabled by writing 1 to the DMA bit in the SPI DMA Control register. In this mode, the SPI controller transmits or receives the number of packets as indicated by the BLOCK_SIZE field in the SPI Block Size register.

If the PACKED bit is set and BIT_LEN is set to 7, then all FIFO words contain 4 packets to transfer (transmit or receive). Packets will be transferred as per the En_LE_Bit and En_LE_Byte bit configurations (see the En_LE_Bit and En_LE_Byte Modes section), with packet 0 in byte 0 of the FIFO and packet 3 in byte 3 of the FIFO.

In Unpacked Mode, if BIT_LEN is set to N, each packet will consist of (N + 1) bits. These bits will be transmitted/received in the Tx_FIFO/Rx_FIFO as per the En_LE_Bit and En_LE_Byte bit configurations (see the En_LE_Bit and En_LE_Byte Modes section). Any remaining bits in the FIFO will be ignored by the hardware. The maximum packet length is 32, which can be selected by setting BIT_LEN to 31. In this case, all data bits in the FIFO contain valid packet data.

A DMA request will be generated to APB_DMA in this mode depending on the setting of Tx_TRIG and Rx_TRIG. If transmits are enabled, setting Tx_TRIG to 00 will generate a Tx DMA request whenever the Tx FIFO has one word of space available (if not full). Setting Tx_TRIG to 01 will generate a Tx DMA request whenever the Tx FIFO has 4 words of space available. If receives are enabled, setting Rx_TRIG to 00 will generate an Rx DMA request whenever the Rx FIFO has one word of data available (is not empty). Setting Rx_TRIG to 01 will generate an Rx DMA request whenever the Rx FIFO has 4 words of data available.

35.2.2 PIO Mode

This mode is enabled by writing 1 to the PIO bit in the SPI Command1 register. In this mode, the SPI controller transmits/ receives as many packets as configured by software in the SPI Block Size Register.

PIO Mode has the same features as DMA Mode. The difference between PIO Mode and DMA Mode is that in PIO Mode, the maximum number of packets that can be transmitted or received is less than or equal to 64.

35.2.3 Interrupt Generation

The SPI controller generates an interrupt to the processor at the end of a transfer in PIO Mode or when an error is detected (both in PIO and DMA Modes) if the IE.TX or IE.RX bit in the SPI DMA Control register is enabled for transmit and receive modes of operation, respectively.

If IE.TX is enabled during transmits, an interrupt is generated whenever RDY or one of the FIFO status bits in the SPI FIFO Control/Status Register is set by the hardware. During transmits, when the SPI controller is configured as a Slave, if software/APB DMA cannot fill the transmit FIFO fast enough, hardware will set the Tx_FIFO_UNR bit and an underrun condition is generated. If software tries to write to a full Tx FIFO, hardware sets the Tx_FIFO_OVF bit as an indication that software attempted to overflow the Tx FIFO. Hardware makes sure that the overflowing data is never written to the Tx FIFO.

If IE.RX is enabled during receives, an interrupt is generated whenever RDY or one of the status bits in the SPI FIFO Control/Status Register is set by the hardware. During receives, when the SPI controller is configured as a Slave, if software/APB DMA cannot read the receive FIFO fast enough, hardware will set the Rx_FIFO_OVF bit and an overflow condition is generated. However, if software tries to read from an empty Rx FIFO, hardware sets the RXF_UNR bit as an indication that software attempted to underrun the Rx FIFO.

The interrupt can be cleared by writing a 1 to the source of the interrupt. If the interrupt is generated by assertion of RDY, then writing a 1 to the RDY bit clears the interrupt. If the interrupt is generated by assertion of Tx_FIFO_OVF, then writing a 1 to the TXF_OVF bit clears the interrupt. If the interrupt is generated by assertion of Rx_FIFO_UNR, then writing a 1 to RXF_UNR bit clears the interrupt.

> **Guideline for DMA Mode use cases**: In DMA Mode, if interrupts are enabled, the SPI software driver has to deal with 3 interrupts: one from the SPI controller and two from the Tx and Rx APB DMA channels. This might make it complicated for the driver and also stresses the system. In such cases, software can use the Rx DMA interrupt as the final one at which point all hardware activities can be assumed to be complete. But, in variable transfer lengths (continuous mode), software has to rely on the controller's interrupts.

35.2.4 Clock Initialization and Control

The SPI controller runs at 50 MHz at its interface to external SPI devices. The internal SPI controller clock (spi_clk) should run at the same frequency as the outgoing Interface Clock (Sclk_Out) in Master Mode. In Slave Mode, the internal SPI interface clock frequency has to be 50% greater than the external clock (Sclk_in).

The SPI clock is selected from different clock sources using a generic clock switch module. The clock switch module supports glitch-free switching of clock from one source to another. There are 4 clock sources:

- osc_clk
- pllP_out
- pllC_out
- pllM_out0

The selected clock is divided by an 8-bit value written in the divider register. The clock is then trimmed, and gated branches are generated for the SPI instances.

Note: The ratio between the slave core clock and the slave interface clock must be maintained between 1.5x and 4x. For example if the slave interface clock is running at 10 MHz, the slave core clock must not be less than 10x1.5 MHz and not greater than 10x4 MHz.

The CLK_RST_CONTROLLER_CLK_OUT_ENB_H_0, CLK_RST_CONTROLLER_CLK_OUT_ENB_V_0, and CLK_RST_CONTROLLER_CLK_OUT_ENB_U_0 registers in the CAR (Clock and Reset) block contain the enable bits for the SPI controller. In addition, the clock source and divider registers (CLK_SOURCE_SBC1, CLK_SOURCE_SBC2, CLK_SOURCE_SBC3, CLK_SOURCE_SBC4, CLK_SOURCE_SBC5, and CLK_SOURCE_SBC6) contain the 2-bit field SBCx_CLK_SRC to determine the PLL clock source, while the SBCx_CLK_DIVISOR field determines the divide ratio.

See the Clock and Reset Controller section for more information on clock configuration.

Controller Reset

The SPI controller can be reset by writing 1 to SPI1 (bit 11) in the RST_DEVICES.H (0x6000:6008) register. Software needs to write a 0 to this bit to bring the SPI controller out of reset.

See the Clock and Reset Controller section for more information on SPI controller reset.

Slave Mode GPIO Synchronization

Because SPI does not support flow control, the GPIO is required to have the proper communication to avoid any clock loss from the Master. GPIO can be used in the following way for proper synchronization:

- SPI slave client software will write to the Config registers of the SPI controller and make the SPI slave ready.
- After that the slave client software will toggle GPIO to inform the Master that the Slave is ready.
- Then the SPI master sends SCLK to the slave device.

If there is no GPIO to tell the Master that the Slave is ready, there is a chance to lose clock/data.

Guidelines

This section provides guidelines for programming the SPI controller:

- Program all the required register fields (no particular order is required except for the PIO/DMA bit, which has to be programmed last):
  - Clock Mode
  - Packed/Unpacked Mode
  - Tx_EN/Rx_EN

- BOTH_EN_BYTE/BOTH_EN_BIT
- En_LE_Bit/En_LE_Byte
- BIT_LEN and BLOCK_SIZE values
- CS_SW_HW (software based or hardware based)
  - If CS_SW_HW is set, the value on CS_SW_VAL will be driven out.
  - When CS HW is used program the Setup & Hold Values in CS Timing Register.
- Program the DMA Trig values appropriately, if DMA Mode is used
- Enable interrupts if PIO Mode is used

- Lastly, program PIO or DMA to indicate the start of transfer.

Once software enables PIO/DMA, no required bits can be changed until the end of transfer except for PIO/DMA bit. Clearing the PIO/DMA bit will end the transaction. In case the SPI controller is configured to Receive Mode and software clears the PIO/DMA bit, then the partial data which the controller received until then will be written into the FIFO. This is true both for Master and Slave.

Do not enable conflicting features. For example, avoid enabling BOTH_EN_BIT (or) BOTH_EN_BYTE along with bidirectional (BIDIR) mode.

In Slave Mode after PIO or DMA is set, hardware first waits for the CS to go low by one of the 4 Masters. Then on reception of Sclk, transfer begins. If CS or Sclk is removed by the Master in the middle of a transfer, software must terminate the transaction by clearing the PIO/DMA bit. In case of Rx, hardware then writes the last received packet (incomplete packet) to the Rx FIFO. If software does not clear the PIO/DMA bit, the SPI controller will just keep waiting for the Sclk from the Master. If Sclk resumes later, the transaction continues from where it paused earlier.

If any error conditions occur, hardware will set the corresponding status bits in the SPI FIFO Control/Status register and stop the transfer. If IE is enabled, an interrupt is generated. Software has to clear the source of the interrupt by writing a 1 to it, after the completion of ISR.

Special Guidelines for Slave Mode

Software should not program the controller register when the interface clock is toggling. Software can disable the external clock input before programming the registers and then re-enable it once all the registers bits are programmed.

Error Conditions

When the SPI controller is configured as a Master, the following error scenarios can happen:

- Tx_FIFO overflow

  Tx_FIFO overflow happens when the CPU/APB_DMA writes into the Tx FIFO when it is full. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with the Tx_FIFO_OVF bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and the Tx_FIFO_OVF bit. To start a new transaction, software has to flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.
- Rx_FIFO overflow

  Rx_FIFO overflow happens when the CPU/APB_DMA writes into the Rx FIFO when it is full in BOTH_EN Mode. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with Rx_FIFO_OVF bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and the Rx_FIFO_OVF bit. To start a new transaction, software has to flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.
- Tx_FIFO underrun

Tx_FIFO underrun happens when the CPU/APB_DMA reads from the Tx FIFO when it is empty. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with the Tx_FIFO_UNR bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and the Tx_FIFO_UNR bit. To start a new transaction, software has to flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

- Rx_FIFO underrun

  Rx_FIFO underrun happens when the CPU/APB_DMA reads from the Rx FIFO in BOTH_EN Mode. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with the Rx_FIFO_UNR bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and the Rx_FIFO_UNR bit, along with the Interrupt bit. To start a new transaction, software has to flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

  Note: In Master Mode, all the errors above can happen only when the CPU/APB_DMA reads/writes an empty/full FIFO. The SPI controller will never write/read a full/empty FIFO. Instead the controller will pause (stops sending clocks to the slave with chip select being in an active state) whenever the FIFOs are full/empty.

When the SPI controller is configured as a Slave, the following error scenarios can happen:

- Tx_FIFO overflow

  Tx_FIFO overflow happens when the CPU/APB_DMA or the SPI controller writes into the Tx FIFO when it is full. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with Tx_FIFO_OVF bit in the status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and Tx_FIFO_OVF bit. To start a new transaction, software has to disable the Master from sending clocks and then flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

- Rx_FIFO overflow

  Rx_FIFO overflow happens when the CPU/APB_DMA or the SPI controller writes into Rx FIFO when it is full in BOTH_EN Mode. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with Rx_FIFO_OVF bit in the status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and Rx_FIFO_OVF bit along with the Interrupt bit. To start a new transaction, software has to disable the Master from sending clocks and flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

- Tx_FIFO underrun

  Tx_FIFO underrun happens when the CPU/APB_DMA or the SPI controller reads from Tx FIFO when it is empty. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with the TX_FIFO_UNR bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and TX_FIFO_UNR bit along with the Interrupt bit. To start a new transaction, software has to disable the Master from sending clocks and flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

- Rx_FIFO underrun

  Rx_FIFO underrun happens when the CPU/APB_DMA or the SPI controller reads from the Rx FIFO in BOTH_EN Mode. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with the RX_FIFO_UNR bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and RX_FIFO_UNR bit along with the Interrupt bit. To start a new transaction, software has to disable the Master from sending clocks and flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

- CS_inactive

When the SPI controller is configured as a Slave and cs_active between packets is set, if an external Master deasserts the chip select in the middle of a transaction, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and sets the CS_INACTIVE bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the CS_INACTIVE bit. To start a new transaction, software has to disable the Master from sending clocks and flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

It is software's responsibility to read the data that is left out of the RX FIFO for CS inactive. For example, if the interrupt trigger is set for 4 words, and external master has taken the CS off in between the transfer, and, at that point of time, the RX FIFO has only 2 words, it is software's responsibility to read out those 2 words or flush the FIFO.

- Frame_End

  When the SPI controller is configured as a Slave and DMA-continuous and cs_active between packets is set, if an external Master stops sending clocks for more than slave_idle_clock_count programmed in the register, the SPI controller will end the transaction by setting the DMA bit to 0, and sets the FRAME_END bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the FRAME_END bit along with the Interrupt bit. To start a new transaction, software has to disable the Master from sending clocks and flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register. If the Master resumes the clk within "slave_idle_clock_count", the SPI controller will also pause and resume the transaction whenever ext_clk is available.

Programming Trimmers

The 3 programmable trimmers in the SPI controller are used only in Master Mode:

- SPI-Tx trimmer

  This trimmer is used in Master Tx mode to adjust/center the outgoing data with respect to the outgoing clock.

- SPI-Rx trimmer

  This trimmer is used in Master Rx mode to delay the loopback clock to the Rx shift registers. This trimmer is used to adjust the Master SCLK with respect to the SPI slave device's Tx data.

- SPI-Spare Control Register Byte1

  This 3-bit trimmer controls the internal timing of the Master mode Rx datapath. This trimmer along with the SPI Rx trimmer may be set independently to adjust the loopback clock delay. This trimmer adjusts the programmable delay on the u_spi_slave_rx* flops in inbound paths. These are half cycle paths, and delays have been added to increase Setup margin on these paths.

- The SPI controller has a programmable delay chain with a 3-tap delay chain. The 3 taps use 100D, 100D, and 60D and are programmed as follows:
  - 000: Bypass through each mux: will see 3 muxes in path
  - 001: 60D
  - 010: 100D
  - 100: 100D
  - 011: 60D + 100D
  - 110: 100D + 100D
  - 101: 100D+60D
  - 111: 100D+100D+60D
- Spare cells used as control for these delay taps:
  - (u_spi1_shift_padmacro/spi_spare_control_byte1_in_reg_2_,
  - u_spi1_shift_padmacro/spi_spare_control_byte1_in_reg_1_,

- u_spi1_shift_padmacro/spi_spare_control_byte1_in_reg_0_)

35.3 SPI Controller Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

There are six sets of the SPI controller registers, one for each of the six SPI controllers. The register descriptions below give the offset of each register within its SPI controller’s address range. See the Address Map section for the starting address of each SPI controller.

35.3.1 SPI_COMMAND1

SPI Command1 Register

This register is used to set the bit length and to select the transfer mode.

Chip Select can also be selected to be in hardware mode as software mode with both active high and active low polarities to support devices with varying CS polarities.

Offset: 0x0 │ Read/Write: R/W │ Reset: 0x43d00000 (0b01000011110100000000xxxxx000000)

Bit	Reset	Description
31	0x0	PIO: Program 1 after all the other bits in the SPI_COMMAND2 and SPI_COMMAND1 registers are programmed to start the transfer. Hardware clears this bit automatically after the transfer is done. Clearing of this bit by software will stop the shifter and latch the partial data into the buffer (in Receive Mode). 0 = STOP (default) 1 = GO
30	0x1	M/S: Master/Slave mode select. 0 = Slave Mode (external clock) 1 = Master Mode (internal clock) (default)
29:28	0x0	MODE: The SPI interface clock mode has to be programmed according to the device with which it is communicating. 0 = Mode 0 (default) 1 = Mode 1 2 = Mode 2 3 = Mode 3 Master: All modes are supported both for Tx and Rx. Slave: Modes 1and 3 are supported for Tx Slave: All modes are supported for Rx.
27:26	0x0	CS_SEL: In Master Mode, these bits are programmed to select a slave in the multi-slave environment. 0 = Selects CS0 (default) 1 = Selects CS1 2 = Selects CS2 3 = Selects CS3
25	0x1	CS_POL_INACTIVE#3: In Master or Slave Mode, the inactive value of the external device’s cs value, which is connected to CS3, needs to be programmed. 1 = CS3 Inactive value of External device is high, 0 = CS3 Inactive value of External device is low 0 = LOW 1 = HIGH (default)
24	0x1	CS_POL_INACTIVE#2: In Master or Slave Mode, the inactive value of the external device’s cs value, which is connected to CS2, needs to be programmed, 1 = CS2 Inactive value of External device is high, 0 = CS2 Inactive value of External device is low 0 = LOW 1 = HIGH (default)
23	0x1	CS_POL_INACTIVE#1: In Master or Slave Mode, the inactive value of the external device’s cs value, which is connected to CS1, needs to be programmed. 1 = CS1 Inactive value of

Bit	Reset	Description
		External device is high, 0 = CS1 Inactive value of External device is low 0 = LOW 1 = HIGH (default)
22	0x1	CS_POL_INACTIVE#0: In Master or Slave Mode, the inactive value of the external device's cs value, which is connected to CS0, needs to be programmed. 1 = CS0 Inactive value of External device is high, 0 = CS0 Inactive value of External device is low 0 = LOW 1 = HIGH (default)
21	0x0	CS_SW_HW: Software control of the SPI_CS signal in Master Mode. In Slave Mode, this bit need not be programmed. 1 = CS controlled by software; 0 = CS controlled by hardware 0 = SPI _CS#(CS_SEL) is driven to the active state during packet transfers by the hardware (default) 1 = SPI _CS#(CS_SEL) is driven with the value in the CS_SW_VAL bit
20	0x1	CS_SW_VAL: CS signal value in Master Mode. In Slave Mode, this bit need not be programmed. If CS_SW_HW is 1, then the value in CS_SW_VAL is driven out on CS. If CS_SW_HW is 0, then this bit has no effect. 0 = CS is LOW 1 = CS is HIGH (default)
19:18	0x0	IDLE.SDA: Inactive data signal format. Controls the output enable of the SDA line when the controller is inactive and not doing data transfers. 0 = Drive low. (Master Mode) (default) 1 = Drive high. (Master Mode) 2 = External Pull Down. (Slave Mode) 3 = External Pull high. (Slave Mode)
17	0x0	BIDIR: Bidirectional Transfer Control Bit: This bit enables the bidirectional mode of the transfer. 0 = Normal Mode (default) 1 = Bidirectional Mode
16	0x0	En_LE_Bit: 1 = Enable Little Endian Bit. 0 = Disable Little Endian Bit 0 = LAST 1 = FIRST
15	0x0	En_LE_Byte: 1 = Enable Little Endian Byte. 0 = Disable Little Endian Byte 0 = LAST 1 = FIRST
14	0x0	BOTH_EN_BIT (x2 Mode): Both MISO and MOSI can also be used to transmit or receive at the same time when this bit is set. Even bits from the Tx FIFO packet are transmitted/received on MOSI, and Odd bits from the Tx FIFO packet are transmitted/received on MISO. Refer to the Both Enable Byte and Bit Modes (SPI x2 Mode) section for more information. 0 = Normal Mode (default) 1 = Transmit/Receive on both MISO and MOSI at the same time when the Tx_EN and Rx_EN bits are set
13	0x0	BOTH_EN_BYTE (x2 Mode): The 2 FIFOs can also be used to transmit or receive at the same time when this bit is set. Refer to the Both Enable Byte and Bit Modes (SPI x2 Mode) section for more information. **Note**: the BIDIR bit has to be 0 before this bit is set. 0 = Normal Mode (default) 1 = Transmit/Receive on both MISO and MOSI at the same time when the Tx_EN and Rx_EN bits are set
12	0x0	Rx_EN: Receive enable. Setting this bit to 1 enables the controller to receive the data. 0 = DISABLE (default) 1 = ENABLE
11	0x0	Tx_EN: Transmit enable. Setting this bit to 1 enables the controller to transmit the data. 0 = DISABLE (default) 1 = ENABLE
10:6	N/A	Reserved for future use. Always write zeros.

Bit	Reset	Description
5	0x0	PACKED: Packed mode enable bit.. 0 = Unpacked Mode (default) 1 = Packed Mode. This is only valid if the BIT_LEN field is set to either 3 (4-bit transfer), 7 (8-bit transfer), 15 (16-bit transfer), or 31 (32-bit transfer).
4:0	0x0	BIT_LEN: This field is used during PIO and DMA transfers. It represents the number of bits transmitted/received in either Packed or Unpacked Mode. The minimum bit length in Master Mode is 4 and the minimum length in Slave Mode is 1 byte (BIT_LEN = 7). The default is 0. 3 = 4-bit transfer N = N+1-bit transfer 31 = 32-bit transfer

35.3.2 SPI_COMMAND2

SPI Command2 Register

Offset: 0x4 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxx000000000000)

Bit	Reset	Description
31:12	N/A	Reserved for future use. Always write zeros.
11:6	0x0	Tx_Clk_TAP_DELAY: Delays the clock going out to the external device with these tap values. Useful only in Master Mode.
5:0	0x0	Rx_Clk_TAP_DELAY: Delays the clock coming in from the external device with these tap values. Useful only in Master Mode.

35.3.3 SPI_CS_TIM1

SPI CS Timing1 Register

Offset: 0x8 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:28	0x0	CS_SETUP_TIME#3: Specifies the setup time of the chip select to the data being transmitted or received on CS#3 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
27:24	0x0	CS_HOLD_ TIME#3: Specifies the hold time of the chip select to the data being transmitted or received on CS#3 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
23:20	0x0	CS_SETUP_ TIME#2: Specifies the setup time of the chip select to the data being transmitted or received on CS#2 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
19:16	0x0	CS_HOLD_ TIME#2: Specifies the hold time of the chip select to the data being transmitted or received on CS#2 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
15:12	0x0	CS_SETUP_ TIME#1: Specifies the setup time of the chip select to the data being transmitted or received on CS#1 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.

Bit	Reset	Description
11:8	0x0	CS_HOLD_ TIME#1: Specifies the hold time of the chip select to the data being transmitted or received on CS#1 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
7:4	0x0	CS_SETUP_ TIME#0: Specifies the setup time of the chip select to the data being transmitted or received on CS#0 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
3:0	0x0	CS_HOLD_ TIME#0: Specifies the hold time of the chip select to the data being transmitted or received on CS#0 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.

35.3.4 SPI_CS_TIM2

SPI CS Timing2 Register

Offset: 0xc │ Read/Write: R/W │ Reset: 0x20202020 (0bxx100000xx100000xx100000xx100000)

Bit	Reset	Description
31:30	N/A	Reserved for future use. Always write zeros.
29	0x1	CS_ACTIVE_BETWEEN_PACKETS#3: Specifies if CS stays active between two packets on CS#3 1 = CS active between two packets (default) 0 = CS inactive between two packets
28:24	0x0	CYCLES_BETWEEN_PACKETS#3: Specifies the number of cycles between two packets in the PIO/DMA Mode for communication on CS#3. The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
23:22	N/A	Reserved for future use. Always write zeros.
21	0x1	CS_ACTIVE_BETWEEN_PACKETS#2: Specifies if CS stays active between two packets on CS#2 1 = CS active between two packets (default) 0 = CS inactive between two packets
20:16	0x0	CYCLES_BETWEEN_PACKETS#2: Specifies the number of cycles between two packets in the PIO/DMA Mode for communication on CS#2. The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
15:14	N/A	Reserved for future use. Always write zeros.
13	0x1	CS_ACTIVE_BETWEEN_PACKETS#1: Specifies if CS stays active between two packets on CS#1 1 = CS active between two packets (default) 0 = CS inactive between two packets
12:8	0x0	CYCLES_BETWEEN_PACKETS#1: Specifies the number of cycles between two packets in the PIO/DMA Mode for communication on CS#1. The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
7:6	N/A	Reserved for future use. Always write zeros.
5	0x1	CS_ACTIVE_BETWEEN_PACKETS#0: Specifies if CS stays active between two packets on CS#0

Bit	Reset	Description
		1 = CS active between two packets (default) 0 = CS inactive between two packets
4:0	0x0	CYCLES_BETWEEN_PACKETS#0: Specifies the number of cycles between two packets in the PIO/DMA Mode for communication on CS#0. The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.

35.3.5 SPI_TRANS_STATUS

SPI TRANSFER Status Register

Read this register for the status of the transfer.

Offset: 0x10 │ Read/Write: R/W │ Reset: 0x00ff0000 (0bx0xxxxx11111111xxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
31	N/A		Reserved for future use. Always write zeros.
30	RW	0x0	RDY: Ready bit. This bit is set to 1 at the end of every transfer, and an interrupt is also generated if the corresponding interrupt enable is set in PIO/DMA Mode. Software writes a 1 to clear it. The interrupt is also cleared when this bit is cleared. 0 = NOT_READY (default) 1 = READY
29:24	N/A		Reserved for future use. Always write zeros.
23:16	RW	0xff	SLV_IDLE_COUNT: Slave Continuous Mode. If Sclk is not received for this number of cycles, then Slave Continuous mode is terminated, and the status bit FRAME_END is set. The default is 255 (8'hff).
15:0	RO	X	BLOCK_COUNT: Counts the number of packets in a transaction (Tx or Rx) in DMA/PIO Mode. In DMA Continuous Mode, this field gives the number of packets only if the number of packet is less than 2^{16}.

35.3.6 SPI_FIFO_STATUS

SPI Control/Status FIFO Status Register

SPI STATUS register: Read this register to know the status of the transfer. Error bit is set whenever we encounter Errors such as Underflow/Overflow

Offset: 0x14 │ Read/Write: R/W │ Reset: 0x00400005 (0b00xxxxxxxxxxxxxx00xxxxx00000xxxx)

Bit	R/W	Reset	Description
31	RW	0x0	CS_INACTIVE: When the SPI is in Slave Mode, if CS is deasserted, this bit is set to indicate an error and the received number of bits is written in the Rx FIFO. An interrupt is generated if IE.Tx or IE.Rx is set. The default is 0.
30	RW	0x0	FRAME_END: When the SPI is in Slave Continuous mode, if Sclk is not received for the number of clocks specified in the SLV_IDLE_COUNT field, the continuous mode is terminated and this status bit is set. The default is 0.
29:23	RO	X	RX_FIFO_FULL_COUNT: Indicates the number of slots in the receive FIFO remaining before the FIFO is empty. This field is used by software for debugging purposes.
22:16	RO	X	TX_FIFO_EMPTY_COUNT: Indicates the number of slots in the transmit FIFO remaining before the FIFO is full. This field is used by software for debugging purposes.
15	RW	0x0	RX_FIFO_FLUSH: Software writes a 1 to this bit to flush the Rx FIFO. This bit reads as 1 when the flush operation is in progress and returns to 0 when it is finished. 0 = NOP (default) 1 = FLUSH

Bit	R/W	Reset	Description
14	RW	0x0	TX_FIFO_FLUSH: Software writes a 1 to this bit to flush the Tx FIFO. This bit reads as 1 when the flush operation is in progress and returns to 0 when it is finished. 0 = NOP (default) 1 = FLUSH
13:9	N/A		Reserved for future use. Always write zeros.
8	RW	0x0	ERR: Will be set to 1 by hardware when errors such as underflow/overflow occur. Software writes a 1 to clear the flag. 0 = OK (default) 1 = ERROR
7	RW	0x0	TX_FIFO_OVF: TX FIFO Overflow. This bit is set to 1 whenever the SPI controller or software tries to write to a full Tx FIFO. An interrupt is generated if the interrupt enable is set for transmit operations (IE.TX in the SPI_DMA_CTL register). Software writes a 1 to clear this bit. 0 = OK (default) 1 = ERROR
6	RW	0x0	TX_FIFO_UNR: TX FIFO Underrun. This bit is set to 1 whenever the SPI controller or software tries to read from an empty Tx FIFO. An interrupt is generated if the interrupt enable is set for transmit operations (IE.TXC in the SPI_DMA_CTL register). Software writes a 1 to clear this bit. 0 = OK (default) 1 = ERROR
5	RW	0x0	RX_FIFO_OVF: RX FIFO Overflow. This bit is set to 1 whenever the SPI controller or software tries to write into a full Rx FIFO. An interrupt is generated if the interrupt enable is set for receive operations (IE.RXC in the SPI_DMA_CTL register). Software writes a 1 to clear this bit. 0 = OK (default) 1 = ERROR
4	RW	0x0	RX_FIFO_UNR: RX FIFO Underrun. This bit is set to1 whenever the SPI controller or software tries to read from an empty Rx FIFO. An interrupt is generated if the interrupt enable is set for receive operations (IE.RXC in the SPI_DMA_CTL register). Software writes a 1 to clear this bit. 0 = OK (default) 1 = ERROR
3	RO	X	TX_FIFO_FULL: TX FIFO Full Status. Hardware sets this bit to 1 if the Tx FIFO is full; otherwise this bit is 0. The Tx FIFO is empty at power on reset (POR). 0 = NOT_FULL (default) 1 = FULL
2	RO	X	TX_FIFO_EMPTY: TX FIFO Empty Status. Hardware sets this bit to 1 if the Tx FIFO is empty; otherwise this bit is 0. The Tx FIFO is empty at POR. 0 = NOT_EMPTY 1 = EMPTY (default)
1	RO	X	RX_FIFO_FULL: RX FIFO Full Status. Hardware sets this bit to 1 if the Rx FIFO is full; otherwise this bit is 0. The Rx FIFO is empty at POR. 0 = NOT_FULL (default) 1 = FULL
0	RO	X	RX_FIFO_EMPTY: RX FIFO Empty Status. Hardware sets this bit to 1 if the Rx FIFO is empty; otherwise this bit is 0. The Rx FIFO is empty at POR. 0 = NOT_EMPTY 1 = EMPTY (default)

35.3.7 SPI_TX_DATA

SPI Transmit Data Register

Offset: 0x18 │ Read/Write: RO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description

31:0	X	SPI_Tx_DATA. Transmit Data. This register holds the last data that was transmitted by the SPI controller.

35.3.8 SPI_RX_DATA

SPI Receive Data Register

Offset: 0x1c │ Read/Write: RO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	SPI_Rx_DATA. Receive Data. This register holds the last data that was received by the SPI controller.

35.3.9 SPI_DMA_CTL

SPI DMA Control Register

SPI DMA Control Register: Used in the DMA transfers. We can set trigger levels in this register

Offset: 0x20 │ Read/Write: R/W │ Reset: 0x00000000 (0b0000xxxxxxx00xx00xxxxxxxxxxxxxxx)

Bit	Reset	Description
31	0x0	DMA: Enable DMA Mode transfer. Software writes a 1 to this bit to start a transfer in the DMA mode. All fields in the SPI_COMMAND1 and SPI_DMA_CTL register must be set before writing a 1 to this bit. This bit is cleared by the SPI controller after all packets have been transferred as indicated by the DMA_BLOCK_SIZE field. Clearing this bit by software will stop the shifter and latch the partial data into buffer. 0 = DMA Mode is disabled (default) 1 = DMA Mode is enabled
30	0x0	CONT: Enable Continuous Mode transfer. 0 = Continuous Mode is disabled (default) 1 = Continuous Mode is enabled
29	0x0	IE.RX: Interrupt enable on receive completion. 0 = Disable interrupt generation for receives (default) 1 = Enable interrupt generation at the end of a receive transfer
28	0x0	IE.TX: Interrupt enable on transmit completion. 0 = Disable interrupt generation for transmits (default) 1 = Enable interrupt generation at the end of a transmit transfer
27:21	N/A	Reserved for future use. Always write zeros.
20:19	0x0	RX_TRIG: Receive FIFO trigger level. 00: 1 word. DMA trigger is asserted whenever there is at least 1 packet in the RX FIFO. (default) 01: 4 words. DMA trigger is asserted when there are at least 4 packets in the RX FIFO. 10: 8 words. DMA trigger is asserted when there are at least 8 packets in the RX FIFO. 11: 16 words. DMA trigger is asserted when there are at least 16 packets in the RX FIFO. (Presently, the APB DMA does not support this trigger level.)
18:17	N/A	Reserved for future use. Always write zeros.
16:15	0x0	TX_TRIG: Transmit FIFO trigger level. 00: 1 word. DMA trigger is asserted whenever there is space for at least 1 packet in the TX FIFO. (default) 01: 4 words. DMA trigger is asserted when there is space for at least 4 packets in the TX FIFO. 10: 8 words. DMA trigger is asserted when there is space for at least 8 packets in the TX FIFO. 11: 16 words. DMA trigger is asserted when there is space for at least 16 packets in the TX FIFO. (Presently, the APB DMA does not support this trigger level.)

35.3.10 SPI_DMA_BLK

SPI Block Size Register

Offset: 0x24 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
31:16	N/A	Reserved for future use.
15:0	0x0	BLOCK_SIZE: Size of data block to be transferred in PIO/DMA Mode. The default is 0. In DMA Mode, the maximum number of 32-bit packets that can be transferred is 2^{16} = 65536. In PIO Mode, the maximum number of 32-bit packets that can be transferred is 64 (FIFO depth). The Block Size has to be programmed 1 packet lower than intended; for example, a value of 3 indicates 4 packets are to be transferred.

35.3.11 SPI_FIFO1

SPI TX FIFO Register

Offset: 0x108 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	SPI Tx_FIFO. Tx FIFO.

35.3.12 SPI_FIFO2

SPI RX FIFO Register

Offset: 0x188 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	SPI Rx_FIFO. Rx FIFO.

35.3.13 SPI_SPARE_CTLR

SPI Spare Control Register

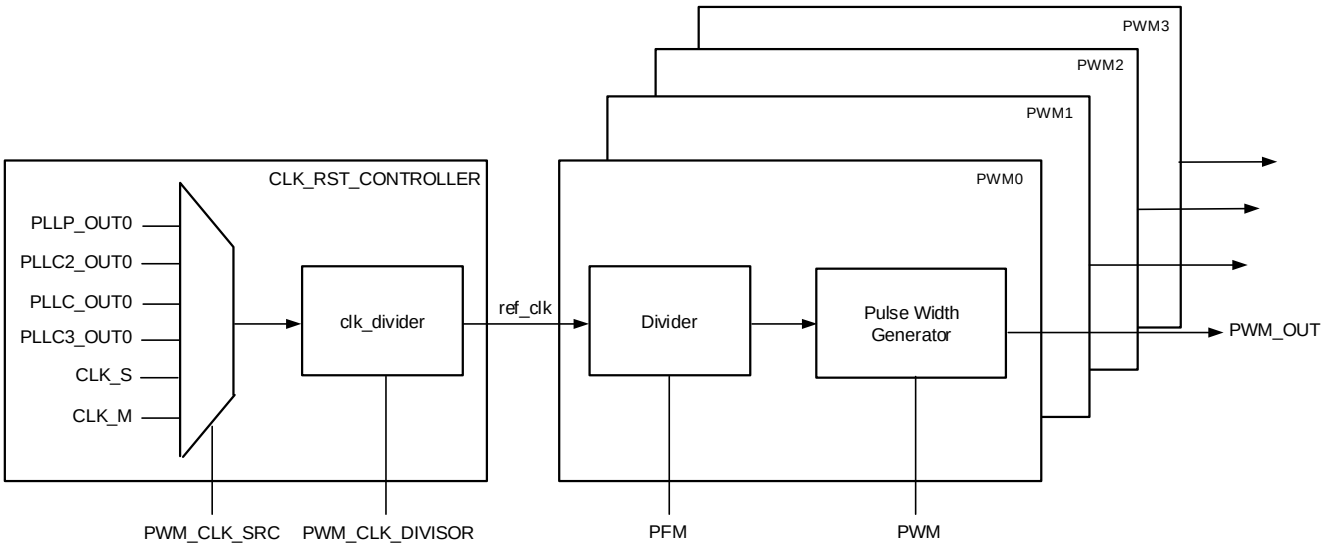
Offset: 0x18c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:11	0x0	Reserved for future use, always write zero.
10:8	0x0	SPI_SPARE_CONTROL_REGISTER_BYTE2. Program these bits with Rx_Clk_TAP_DELAY in the COMMAND2 register to adjust the clock delay on internal registers. Useful in Master Mode only.
7:0	0x0	Reserved for future use, always write zero.

36.0 PWM CONTROLLER

The Pulse Width Modulator (PWM) controller is a four channel frequency divider whose pulse width varies. Each channel has a programmable frequency divider and a programmable pulse width generator.

Figure 134: PWM Controller Block Diagram



Fpwm_out= Fref_clk / (PFM+1) / 256

Frequency division is a 13-bit programmable value, and pulse division is an 8-bit value.

The PWM controller runs off a device clock, which is programmed in the Clock and Reset controller, and can be any frequency up to the device clock maximum speed of 48 MHz.

The device clock frequency is always subject to a minimum divide by 256 to generate the PWM output frequency, and may also be subdivided to slow it down further based on the programmable value locally.

There is an APB interface that interfaces the register logic to the APB bus.

The PWM controller contains four independently programmable pulse width modulators. Each generated pulse has an n/256 duty cycle. PWM signals are useful for LCD contrast and brightness control, VCO-generated clocks and other analog voltage references where high precision is not required.

36.1 Functionality

There are four PWM controllers on four individual pins on the chip. The pinmux corresponding to these are SDC primary pin groups. For the four PWM controllers there are four corresponding registers:

- PWM_CSR0
- PWM_CSR1
- PWM_CSR2
- PWM_CSR3

Each PWM controller must be enabled (bit [31]) to be operational. Pulse Width [23:16] determines the output pulse width and must be programmed appropriately. Pulse Width [30:24] is not used and must be 0. Frequency Divider [12:0] determines the Divided clock.

36.2 PWM Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

36.2.1 PWM_CONTROLLER_PWM_CSR_0_0

PWM Output-0 Configuration Control Register

Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0b0000000000000000xxx0000000000000)

Bit	Reset	Description
31	0x0	ENB: Enable Pulse width modulator 0 = DISABLE 1 = ENABLE
30:16	0x0	PWM_0: pulse width that needs to be programmed. 0=Always low. 1=1/256 Pulse high. 2=2/256 Pulse high. N=N/256 Pulse high
12:0	0x0	PFM_0: Frequency divider that needs to be programmed.

36.2.2 PWM_CONTROLLER_PWM_CSR_1_0

PWM Output-1 Configuration Control Register

Offset: 0x10 | Read/Write: R/W | Reset: 0x00000000 (0b0000000000000000xxx0000000000000)

Bit	Reset	Description
31	0x0	ENB: Enable pulse width modulator 0 = DISABLE 1 = ENABLE
30:16	0x0	PWM_0: pulse width that needs to be programmed. 0=Always low. 1=1/256 Pulse high. 2=2/256 Pulse high. N=N/256 Pulse high
12:0	0x0	PFM_1: Frequency divider that needs to be programmed.

36.2.3 PWM_CONTROLLER_PWM_CSR_2_0

PWM Output-2 Configuration Control Register

Offset: 0x20 | Read/Write: R/W | Reset: 0x00000000 (0b0000000000000000xxx0000000000000)

Bit	Reset	Description
31	0x0	ENB: Enable pulse width modulator 0 = DISABLE 1 = ENABLE
30:16	0x0	PWM_0: Pulse width that needs to be programmed. 0=Always low. 1=1/256 Pulse high 2=2/256 Pulse high N=N/256 Pulse high
12:0	0x0	PFM_2: Frequency divider that needs to be programmed.

36.2.4 PWM_CONTROLLER_PWM_CSR_3_0

PWM Output-3 Configuration Control Register

Offset: 0x30 | Read/Write: R/W | Reset: 0x00000000 (0b0000000000000000xxx0000000000000)

Bit	Reset	Description
31	0x0	ENB: Enable pulse width modulator 0 = DISABLE 1 = ENABLE
30:16	0x0	PWM_0: Pulse width that needs to be programmed 0=Always low 1=1/256 Pulse high 2=2/256 Pulse high N=N/256 Pulse high
12:0	0x0	PFM_3: Frequency divider that needs to be programmed.

[THIS PAGE INTENTIONALLY LEFT BLANK]

37.0 THERMAL SENSOR AND THERMAL THROTTLING CONTROLLER

37.1 Thermal Throttling Controller (SOC_THERM)

The goals of the thermal throttling controller include:

- Thermal sensing: Access, capture and processing data from thermal sensors which are located in multiple locations around the SOC.
- Thermal throttling: Providing a means of reducing the chip performance to manage power consumption in response to thermal events. Provide support for several possible software and hardware throttling mechanisms.
- External OC Alarm Slowdown: Providing a means of reducing chip performance to manage power consumption on detecting over-current alarms from outside the Tegra® K1 SOC. Examples of such OC alarms include “AC power unplug” event, PMIC over-current, battery over-current, radio power amplifier over-current events. Some events require the system to be throttled to lower power/performance within latencies that cannot be handled by software alone.
- Throttling in a di/dt safe manner: Providing hardware support to ensure that throttling in response to over-temperature and over-current events happens in a di/dt safe manner. The support is implemented in the SOC_THERM (for pulse skipper) and in CAR (for PLL slowdown).

The intention of this section is not to provide a full programmer’s guide, but solely to document the register interface to allow better understanding of NVIDIA provided drivers.

37.2 Thermal Sensor

Thermal and voltage sensors are used to constantly monitor the temperature and voltage on the chip. Sensors are placed across the die to gauge the temperature of the whole chip. The TSensor module:

- Generates interrupt to software to lower temperature via DVFS, on reaching a certain thermal/voltage threshold
- Generates a signal to the CAR block to reduce CPU frequency by half, on reaching a certain thermal/voltage threshold
- Generates a signal to the PMC when temperature reaches dangerously high levels to reset the chip and sets a flag in PMC

37.3 Programming Guidelines

37.3.1 Boot-Time Initialization

At boot time, software needs to:

1. Program thermal thresholds. Thresholds for heavy hardware throttling and THERMTRIP should be in fuses.
2. Program CPU block activity weights.
3. Configure thermal and EDP throttling.
4. Initialize throttle settings.
5. Program lock registers to lock contents of important registers.
6. Initialize, set up, and train PLLs for clocking.
7. Enable thermal and EDP throttling.

37.3.2 LP1 Mode

Software should make sure that there is no active hardware throttling when entering LP1 mode.

On LP1 entry, the CPU_PWR_GOOD signal from the PMC to SOC_THERM is deasserted and the FCCPLEX is not throttled. Software needs to reprogram throttle vectors because the system generally runs at a lower frequency in this mode. It is not necessary to reprogram locked registers for transitioning into or out of LP1.

37.3.3 LP0 Mode

Software should disable throttling before entering LP0 mode to ensure that there is no ongoing hardware throttling and both PLL and pulse skippers are completely under software control.

Software needs to restore all control registers, thresholds, and throttle settings when exiting from LP0 mode. The exception to this is THERMTRIP_CTL which is handled by the boot ROM.

37.3.4 PLL Hardware Controller Sequences

Software needs to follow certain sequences when configuring the CPU PLL because the SOC_THERM can throttle the PLL.

37.3.4.1 PLLx Start-up Sequence

1. When PLLx is first enabled, software has full control. The default value of PLLx_ENABLE_SWCTL=1. The default hardware controller state is SEQ_OFF.
2. Software programs the relevant CAR registers to enable and train the PLL using the software bypass path.
3. Software programs default values to the PLLX_SW_RAMP_CFG registers.
4. Software programs PLLx_ENABLE_SWCTL=0 to relinquish software control of PLLx.

37.3.4.2 Software Use of the PLLx Hardware Controller

Software can use the PLLx Hardware Controller to ramp the PLLx in normal DVFS frequency change scenarios. Software has to use the following sequence to ramp the PLL using the hardware controller:

1. Check that the clock to the device is enabled via the CLK_OUT_ENB_L/H/U CAR registers.
2. Program software copies for DYNRAMP_STEPA, DYNRAMP_STEPB, NDIV_NEW, NDIV, and RAMP_MODE to the appropriate values.
3. Trigger the ramp by setting PLLx_SEQ_TRIGGER=1. If a ramp is already ongoing, the new values take effect after the current ramp is complete.
4. Software can monitor the PLLx_HW_CTRL_STATUS register to know the current ramp status and poll for SW_RAMP_DONE. In general, software uses this to determine if a corresponding voltage change is needed after the frequency change.
5. When SW_RAMP_DONE is asserted, software needs to clear PLLx_SEQ_TRIGGER.

37.3.4.3 Programming Sequence When Hardware Throttling is Engaged

Hardware throttling takes precedence, so the following sequence should hold even when software is trying to change frequency.

1. SOC_THERM_throttlectl asserts soc_therm2car_pllx_throttle_en=1.
   - The CAR asserts car2pllx_hw_throttle_en=1.
   - If PLLx_SW_OVERRIDE==0, then the internal hw_throttle_en signal is asserted.
2. SOC_THERM_throttlectl drives the dynamic ramp interface to the CAR for the intended target frequency.
3. SOC_THERM_throttlectl asserts either soc_therm2car_pllx_fast_mode or soc_therm2car_pllx_slow_mode.

4. SOC_THERM_throttlectl asserts soc_therm2car_pllx_seq_en=1.
   - The CAR asserts car2pllx_seq_en=1.
   - The programmed values are latched to their hardware copy, and a ramp sequence is started based on the selected mode.
   - If at this time, a ramp is already ongoing, then the new values take effect after the current ramp completes.
5. PLLx asserts PLL_LOCK=1 when the ramp is complete. This causes the sequencer to return to the SEQ_OFF state and assert pllx2car_ramp_done=1.
6. The CAR asserts car2soc_therm_pllx_ramp_done=1. This completes ramp and handshake with SOC_THERM_throttlectl. PLLx is now locked to the target frequency.
7. SOC_THERM_throttlectl can initiate a new ramp (using a different target frequency and mode) after this point.

37.3.4.4 Sequence when both Hardware and Software Try to Program the PLL

Hardware throttling is given precedence over software when ramping PLLx. This is done by providing a separate set of registers (labeled hardware copy in the block diagram) and separate set of ramp control signals. Hardware uses the hw_throttle_en and hw_seq_trigger signals while software uses the PLLx_SEQ_TRIGGER signal to start a new ramp. If hw_throttle_en==1, then the hardware throttle values are muxed into the PLL.

Note that there is no mechanism to stop and restart a sequence in the middle of a ramp. So if software has managed to start a ramp (in slow or fast mode), hardware throttling begins only after the current ramp is done. Hardware throttling has to tolerate this latency. The latency can be reduced if software uses a combination of fast and slow modes for this ramp.

37.3.4.5 Sequence when Software is Changing PLLs for a new PLLx VCO Range

If the target frequency chosen by SW DVFS is outside the current PLLx VCO range, then software first selects a different PLL, re-locks PLLx to the new range, and then switches back to PLLx.

For Outbound Path (Reprogramming PLLx to New Range):

Typically, software switches either to PLLP/2 (200 MHz) or PLLP (400 MHz) clock. To avoid di/dt issues with this switch, software should first do a dynamic ramp down to VCOmin (it can be fast ramp) and then switch to PLLP.

For Inbound Path (Switching Back to PLLx After Re-Locking to New Range):

Similarly, when the new VCO range is programmed, switching directly to the new target frequency may also be a di./dt event. To avoid di/dt problems, software should first switch to VCOmin of new range and dynamically ramp up to the target frequency.

The following sequence covers these cases:

1. Switch to the new PLL:
   - Program CAR PLLx registers to ramp down to VCOmin.
   - Set PLLx_ENABLE_SWCTL=1. This disables the PLLx hardware controller.
   - PLLx latches in the new settings using the software bypass path. PLLx switches to the new settings when the ongoing ramp (if any) is completed.
2. Software reads the status registers to check when the ramp is complete.
3. Use existing software ↔ CAR↔ PLLx path to disable PLLx.
4. Re-program PLLx.
   - Software programs PLL to VCOmin.
5. Switch back to PLLx.
   - Then dynamic ramp up to target – 80% fast, 20% slow.

6. Enable the hardware sequencer (see Enabling and Disabling the Hardware Sequencer). PLLx_ENABLE_SWCTL=0. Hardware cannot ramp PLLx until this step is done.

At this point, the PLLx can start ramping to the new frequency. If a hardware throttling event has occurred at the time when controller is enabled, the hardware values are used to ramp the PLLx.

37.3.4.6 Sequence when Software Wants to Switch PLLs

At low frequencies, software may choose to switch the clock source for a unit to a different PLL. In this case, software does not necessarily turn PLLx (or the hardware controller) OFF to ensure a fast response time when the clock source is switched back to PLLx. However, this presents a problem for hardware throttling because SOC_THERM does not have visibility of the clock source switch. In this case, SOC_THERM_throttlectl may continue to try and throttle PLLx. Since PLLx is enabled, this may cause PLLx to ramp to the throttled value. However, since it is not feeding into any unit, the ramp does not have any effect on the unit frequency. Other than wasting power, this does not have any problematic effect on the unit operation.

It is also useful if software can communicate to the SOC_THERM_throttlectl block when it switches PLLs. If SOC_THERM_throttlectl has this information and still requires throttling, then it will use only pulse skipping instead of trying to ramp the PLLx. The throttle sequencer configuration register DISABLE_PLLx_THROTTLE field can be used for this purpose.

When software wants to switch back to PLLx, it is likely that PLLx is not at the same frequency when software had switched clock sources. In this case, software has two options:

1. Use Software Override Mode**:** When software wants to switch back, it asserts the PLLx_SW_OVERRIDE bit so that hardware throttling is disabled. It can then choose either to program new values or use existing ones. In either case, software needs to set PLLx_SEQ_TRIGGER=1 to make sure these values take effect. The sequence is as follows:
   a. Set PLLx_SW_OVERRIDE=1.
   b. (optional) Program the PLLx_SW_CFG registers with target frequency values.
   c. Set PLLx_SEQ_TRIGGER=1.
   d. Wait for SW_RAMP_STATUS=1
      - If PLLx is currently in the middle of a hardware ramp, then SW_RAMP_STATUS is asserted after the software values have taken effect.
   e. Switch the clock source to PLLx.
2. Use Software Bypass Path: In this case, software disables the hardware controller and programs PLLx to a target frequency through the default CAR registers. It switches the clock source to PLLx when this ramp is complete. Note that software still has to go through the “disable hardware controller sequence”.

37.3.4.7 RAMP_DONE Response to Software

The RAMP_DONE signal indicates the completion of the dynamic ramp and serves as an acknowledgement that the corresponding ramp settings were successfully applied. It is possible that software updates the PLLx configuration registers, but before it can begin its ramp, a hardware throttle event occurs that results in PLLx being ramped to a different configuration. In this case, the RAMP_DONE ack from this (i.e., hardware) ramp should not serve as the ack for software because a different configuration was used.

A separate SW_RAMP_DONE signal solves this problem. PLLx_HW_CTRL keeps track of the source of the current PLL configuration and asserts the corresponding ramp_done signal when the ramp is complete.

37.3.4.8 Enabling and Disabling the Hardware Sequencer

Enabling the Hardware Controller

1. Software enables and trains PLLx for initial start-up. Software programs default values to the PLLx_SW_CFG register.

2. Software sets PLLx_ENABLE_SWCTL=0 to relinquish control to the hardware sequencer. Either software or hardware can now start a ramp sequence if required.

Disabling the Hardware Controller

There are two possibilities:

1. Software disables the Hardware controller because it wants to take control of PLLx:
    a. Read PLLx_HW_CTRL_STATUS to know the current status of the sequencer.
    b. Set PLLx_ENABLE_SWCTL=1. This enables the software bypass path and disables the hardware controller.
    c. If PLLx is in the middle of a ramp, the software bypass values take effect after the current ramp completes.

Note that software does not need to wait or read any status for this.

2. Software wants to turn the PLLx OFF:
    a. Read PLLx_HW_CTRL_STATUS to know the current status of the sequencer. Wait for RAMP_DONE=1 and hardware controller to go to SEQ_OFF state.
    b. Set PLLx_IDDQ_MODE=1 to turn OFF PLLx. This disables the dynamic ramp sequencer FSM.

When software wants to turn PLLx back on, it has to follow the sequence described in the PLLx Start-up Sequence subsection.

37.4 TSensor Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

All SOC_THERM registers are in the APB address space. Refer to the Address Map section for the base addresses.

37.4.1 SOC_THERM_THERMCTL_LEVEL0_GROUP_CPU_0

Offset: 0x0 │ Read/Write: R/W │ Reset: 0x0000000X (0bxxxxxxx00000000000000000000xx)

Bit	R/W	Reset	Description
24:17	RW	0x0	UP_THRESH: Threshold value for thermal sensor. Signed field for temperatures from -127ºC to +127ºC

38.0 AUDIO-VIDEO PROCESSOR (AVP)

38.1 Overview

The AVP, or Audio-Video Processor, is an ARM7™ based processor sub-system used to:

- Manage the initial stages of boot
- Control and assist the hardware audio decoding blocks, BSEA and VCP2
- Control and assist the hardware video decoder, VDE

It can control the system and has access to the entire memory map (except for the PCIe® controller, GPU aperture, and CPU internal hardware).

The AVP has 256 Kbytes of local RAM, known as IRAM, for local code and data. IRAM is very low latency to the AVP, typically single cycle, and is also low power. Critical code and data should be stored in IRAM for the best performance and lowest power.

The AVP has access to DRAM either through an 8KB unified cache, or through an uncached memory aperture.

38.2 Address Map

Refer to the *Address Map* section of this document for the address map details.

38.3 Cache Controller

Refer to the *AVP Cache Controller* section of this document for the details of the cache controller.

38.4 Interrupts

Interrupts are controlled for the AVP by the system interrupt controller. Refer to the *Interrupt Controller* section of this document. All system interrupts are available to be routed to the AVP.

38.5 IRAM and Crossbar Bus

IRAM is configured as four contiguous banks of 64 Kilobytes of RAM. Each of these banks is accessible over a crossbar bus architecture, so that simultaneous access is possible to each bank from the crossbar masters.

The masters on the crossbar bus are:

- The ARM7 core
- The CPU complex over the AXI to ARM7 bridge
- The VCP2 audio acceleration block
- The UCQ interface of the VDE and BSEA
- The AHB bus interface

38.6 AVP Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

Arbitration for the various resources on the crossbar bus can be configured via the Arbitration Priority registers. Each crossbar master can be assigned a priority for each crossbar resource so that the resource controller can evaluate the latency needs for each master and complete the requests in the most efficient manner.

It is important that each master is assigned a different priority for each resource. If any two priorities are the same the hardware will override the settings with "safe" values, which may not be what the programmer has intended. So when updating the priorities, you should program all of the priority registers at the same time (one for each master).

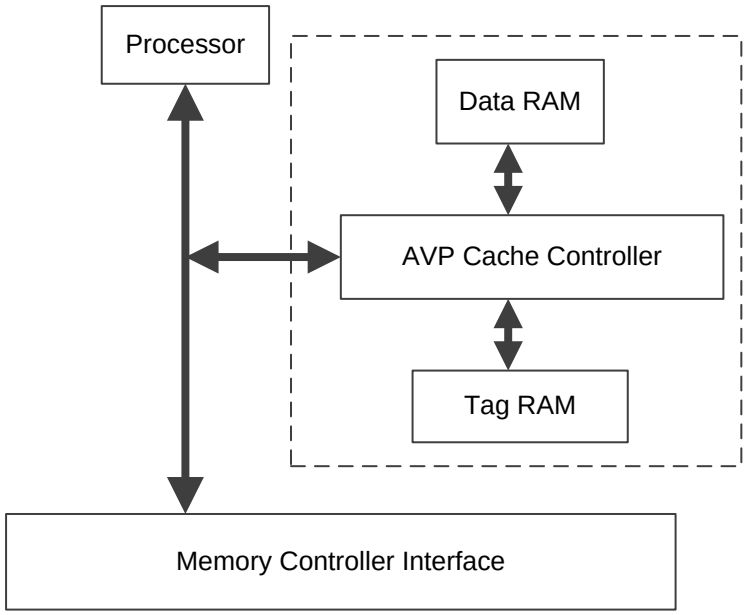
39.0 AVP CACHE CONTROLLER

39.1 Overview

The AVP Cache Controller is used to cache both instructions and data stored in main memory for the ARM7™ processor. It provides cached and uncached accesses to memory for the AVP. Cacheable and uncacheable address ranges are determined by descriptors associated with linear segments of addresses. Memory Controller read and write efficiency is increased through use of read and write buffers, respectively. Refer also to the Audio-Video Processor (AVP) section of this document.

The following diagram shows a high-level view of the AVP Cache Controller.

Figure 135: Cache Controller Overview



39.2 Features

- Four-way set associative cache
- 32 KB cache size
- 32-byte cache line size
- 32 segment descriptors
- Atomic updates for arbitrary sets of descriptors in the MMU

39.3 Address Space

The AVP cache handles addresses in one of the following ranges (statically defined by the global address map):

- A window corresponding to most of the external memory, [0x40:2G[. The exception vectors are located in [0, 0x40[.
- A window corresponding to the GART [GART_BASE, GART_BASE + GART_SIZE[. Refer to the Address Map section for the GART address range.
- A window corresponding to the register interface

All other addresses are routed towards the crossbar and the rest of the system; they are ignored by the AVP cache. Address decode and data return multiplexing are not part of the AVP cache but of a global address decoder.

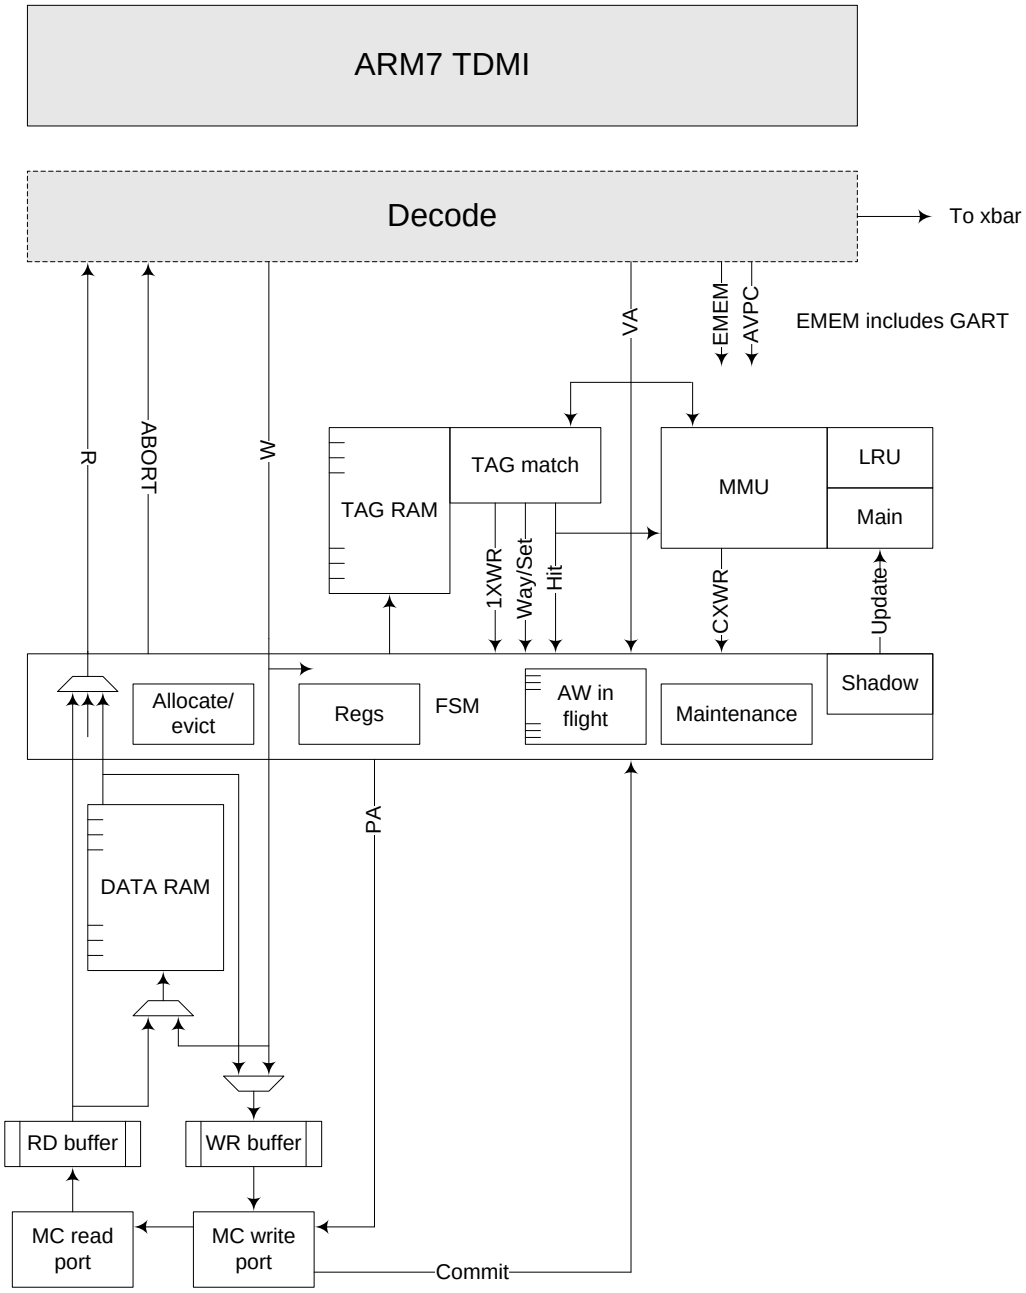
39.4 Reference Block Decomposition

The main blocks inside the AVP cache are:

- Read buffer
- Write buffer
- Tag and Data RAM
- MMU
- Tag check logic
- A main control FSM

The next figure shows a reference decomposition of AVP cache in functional blocks. The grey blocks are not part of the AVP Cache Controller.

Figure 136: AVP Cache Reference Functional Decomposition



39.5 Memory Management Unit

The Memory Management Unit (MMU) associates each memory address in the EMEM address range (MC and GART) with a set of attributes. The set of attributes is defined by a bitmap with the following fields:

- C: Cacheable, indicates that the corresponding address may be stored in the cache
- X: eXecute, indicates that the corresponding address is allowed to be the target of an instruction fetch
- R: indicates that the corresponding address is allowed to be the target of a read data access
- W: indicates that the corresponding address is allowed to be the target of a write data access

An access that is not identified as being allowed results in an abort and the characteristics of the aborted transaction captured. The exact transaction parameters captured are:

- Type of access (X, R, or W)
- Target address
- Sequential or Initial
- Width of access (8, 16, or 32 bits)
- Associated segment descriptor (including an identification for the default descriptor and for multiple segments)

39.5.1 Segment Descriptors

The memory attributes are defined as constant on contiguous segments of the address space. The segments are aligned on cache line boundaries, with each segment defined by:

- The set of attributes associated with the segment: C, X, R, W
- The start address of the segment (the LSBs are not stored)
- The stop address of the segment (the LSBs are not stored)

An address matches a segment descriptor if $Start[31:5] \leq Address[31:5] \leq Stop[31:5]$ so that a descriptor with Stop less than Start never matches any address. This is why there is no explicit valid bit, but the hardware maintains a bitmap of valid descriptors so as to avoid matching invalid descriptors.

39.5.2 Atomic Update of Segment Descriptors

Correct software operation requires the capability to perform atomic updates of multiple segment descriptors. Atomic operations are cumbersome for software, instead a simple hardware context switch approach is implemented. Note that the atomic update described below is the only way to update a segment descriptor; that is, there is no direct way to modify a descriptor stored in the main descriptor table.

The MMU contains a shadow table of segment descriptors and an associated bitmap of update flags, one per table position. When triggered, hardware copies from the shadow table to the main table the set of descriptors identified in the bitmap. No MMU match is performed until the update is complete, backpressuring the ARM7™ bus, if needed. At the end of the copy operation, all update flags must be cleared.

At any update trigger, even if the update bitmap is empty, the Least Recently Used Table Lookaside Buffer (LRU TLB) is invalidated.

39.6 Access to Memory

39.6.1 Read Buffer

The Tegra® K1 AVP cache introduces a read buffer that captures the full memory atom returned by the memory controller. Subsequent linear accesses can hit in the read buffer, increasing both performance and efficiency.

The operation of the read buffer is (almost) transparent for software by using the following buffer flushing conditions:

- The read buffer is flushed for any external memory data read access that is not sequential with the previous external memory data read access in the current scan direction. In particular, this precludes:
  - Using any byte in the buffer more than once (this avoids problems with algorithms that poll on an uncached address)
  - Non-contiguous accesses in the buffer
- Any write that overlaps with the read buffer
- Any locked access
- Any change of any interrupt
- Any change inside the MMU that might impact any memory attribute
- Any cache line eviction
- If a time-to-live timer expires, the timer is started at the time the read buffer is initialized and restarted at each hit in the buffer
- When explicitly triggered by a control bit

39.6.2 Write Merging Buffer

The AVP cache introduces a write buffer that captures up to 256 bits corresponding to a cache line for better performance and efficiency. The operation of the write buffer is transparent for software by using the following buffer flushing conditions:

- The write buffer is flushed for any external memory data write access that is not sequential with the previous external memory data write access in the current scan direction. In particular, this precludes:
  - Using any byte in the buffer more than once (this avoids problems with algorithms that poll on an uncached address, ensuring all changes will be observed in external memory)
  - Non-contiguous accesses in the buffer
- Any read that overlaps with the write buffer
- Only MC atoms with at least one valid byte in them are forwarded to the MC. If more than one MC atom is valid, they are sent coalesced to the MC.
- Any locked access
- Any change of any interrupt
- Any change inside the MMU that might impact any memory attribute
- If a time-to-live timer expires, the timer is started at the time the write buffer is initialized and restarted at each hit in the buffer.
- When explicitly triggered by a control bit

Note: The write buffer is not used when any non-blocking cache operation is active.

39.7 Cache Maintenance

The Cache Maintenance Control (CMC) block provides visibility of the cache operation to software; it allows software-controlled maintenance operations. Caches maintain a lot of state information, so direct manipulation of registers or memory records inside the cache is risky. In general, hardware provides higher level primitives that are safe to use with a minimal software involvement.

The general primitive operation in the CMC works like this:

- A set of registers is programmed detailing the action to be performed
- A specific register access triggers a hardware state machine that performs the action
- Hardware explicitly signals completion of the action
- External access to involved registers before completion of the action might result in undefined behavior

The following maintenance operations are supported in the CMC:

- Clean line: if the line is dirty write the line to main memory, mark the line as clean
- Invalidate line: mark the line as invalid, this is done without checking the dirty bits associated with the line
- Clean and invalidate line: if the line is dirty, write the line to main memory, and mark the line as invalid
- Clean ways, invalidate ways, clean and invalidate ways: same as above but applied on all lines in a set of ways identified by a bitmap. Invalidate ways is useful at reset; clean and clean and invalidate are useful for coherency, especially before a suspend to memory

39.8 Initializing the AVP Cache Controller

To initialize the AVP cache controller:

1) Write INIT to the AVP_CACHE_MMU_CMD_0 register.

2) Write AVP_CACHE_MMU_FALLBACK_ENTRY_0 with the following bit settings:

- CACHED = DISABLE
- EXE_ENA = ENABLE
- RD_ENA = ENABLE
- WR_ENA = ENABLE

3) Initialize the AVP_CACHE_MMU_SHADOW_ENTRY_0 registers using the sequence described in the AVP_CACHE_MMU_SHADOW_ENTRY_0 register description.

4) Invalidate the cache:

- Write 0x1 to AVP_CACHE_INT_CLEAR_0.
- Write AVP_CACHE_MAINT_2_0 with the following bits:
  - OPCODE = INVALID_WAY
  - WAY_BITMAP = DEFAULT_MASK
- Poll AVP_CACHE_INT_RAW_EVENT_0 until bit 0 goes high
- Write AVP_CACHE_INT_CLEAR with the value read from AVP_CACHE_INT_RAW_EVENT_0

5) Enable the cache by writing AVP_CACHE_CONFIG_0 with the following bits:

- ENABLE_CACHE = TRUE
- TAG_CHECK_ABORT_ON_ERROR = 1

39.9 AVP Cache Controller Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

39.9.1 AVP_CACHE_CONFIG_0

Offset: 0x0 | Read/Write: R/W | Reset: 0x80004000 (0b1xxxxxxxxxxxxxx00100000000xx0000) | Default: 0x00000001

Bit	Reset	SW Default	Description
31	0x1	_NONE_	OBS_BUS_EN: Enable clocking of the OBS_BUS capture register. This has a default value of TRUE to allow monitoring things before registers can be programmed. 0 = FALSE 1 = TRUE
16	FALSE	_NONE_	DISABLE_SAMELINE: enable the feature that when consecutive reads are within the same cache line, reading TAG RAM can be avoided to save power. 0 = FALSE 1 = TRUE
15	0x0	_NONE_	TAG_CHECK_CLR_ERROR
14	0x1	_NONE_	TAG_CHECK_ABORT_ON_ERROR
13	0x0	_NONE_	FULL_LINE_DIRTY: TRUE: if a word of a cache line is dirty, assume the full line is dirty and write out 256 bits. Do not write out just 128 bits if all dirty words fall within the same 128 bits. This bit is really only there to check out how much power is really saved by this feature. 0 = FALSE 1 = TRUE
12	0x0	_NONE_	ENABLE_HANG_DETECT: TRUE: when the request state machine doesn't return to idle within a specific number of cycles, the cache generates an ABORT to the ARM7. This is useful for debugging. 0 = FALSE 1 = TRUE
11	0x0	_NONE_	DISABLE_RB: TRUE: all uncached reads are from external memory. The 'cached' 128-bit read buffer is not used. Asserting this bit when the read buffer is active will immediately invalidate it. 0 = FALSE 1 = TRUE
10	0x0	_NONE_	DISABLE_WB: TRUE: don't gather sequential writes in the write buffer. Always write them immediately to external memory. Asserting this bit while the write buffer is active, will immediately flush its contents. 0 = FALSE 1 = TRUE
9:8	PARALLEL	_NONE_	MMU_TAG_MODE: Determines when the cache will check the TAG RAM and the MMU. PARALLEL: when a request comes in, both TAG and MMU lookup's are done right away. This results in the fastest operation. The result that comes up first is used. When both results come in at the same time, the MMU values are used. TAG_FIRST: look up the MMU first. Only look up MMU when that the TAG lookup results in a MISS MMU_FIRST: look up the MMU first. Only look up TAG when the segment is cached. NOTE: in PARALLEL and TAG_FIRST mode, lookups are kicked off for all ARM requests, even if they don't fall inside the GART or the EMEM address space, so they will consume more power than MMU_FIRST. In case the ARM is running most of its code from IRAM (which are often the most power sensitive use cases), it is better to use MMU_FIRST and take a 1 cycle performance penalty for cache hits. 0 = PARALLEL 1 = TAG_FIRST 2 = MMU_FIRST
7	0x0	_NONE_	ENABLE_INTERRUPT: 0 = FALSE

Bit	Reset	SW Default	Description
			1 = TRUE
6	0x0	_NONE_	NEVER_ALLOCATE: TRUE: when there's a cacheable access that results in a cache miss, no new line is allocated. The access is treated as an uncached access instead. The effect is similar to locking all the ways of a cache (see LOCK_BITMAP). 0 = FALSE 1 = TRUE
3	0x0	_NONE_	FORCE_WRITE_THROUGH: FALSE: cached writes are Write Back - Write Allocate. TRUE: cached writes are Write Through. When the memory location is already in the cache, the data will be written both to external memory and to the cache line. The line will not be marked dirty. When the memory location is not in the cache, the write will be treated as an uncached write. 0 = FALSE 1 = TRUE
2	0x0	_NONE_	DISABLE_RANDOM_ALLOC: FALSE: an LSFR is used to randomize the way that will be allocated next. TRUE: the LSFR is strapped to zero. This may be useful for testing purposes to remove an element of randomness. 0 = FALSE 1 = TRUE
1	0x0	_NONE_	ENABLE_SKEW_ASSOC: ENABLE: enable skewed associativity when calculating the indices of the different tag rams. This can avoid some pathological cache collision cases. DISABLE: no skewed associativity. The tag indices are taken straight from the transaction address. Note: DO NOT ENABLE. 0 = FALSE 1 = TRUE
0	0x0	TRUE	ENABLE_CACHE: TRUE: activates the cache. Memory requests inside the GART or EMEM address space are cached depending on the outcome of the MMU. FALSE: cache is inactive. All memory requests that fall inside the GART or EMEM address space are sent directly to external memory. The MMU is not checked at all when the cache is disabled (and does not have to be initialized). Read buffer and write buffer optimizations are performed. 0 = FALSE 1 = TRUE

39.9.2 AVP_CACHE_LOCK_0

Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
3:0	0x0	LOCK_BITMAP: When bit is set to 1, the corresponding way is locked and never considered for cache line replacement.

39.9.3 AVP_CACHE_SIZE_0

Hardcoded value that indicates the number of ways.

Offset: 0xc | Read/Write: RO | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
1:0	X	MAX_WAY_INDEX: Number of ways – 1. So 0 -> 1 way, 1 -> 2 ways, etc. This field is hardcoded to value 3, indicating a 4-way cache.

39.9.4 AVP_CACHE_LFSR_0

Offset: 0x10 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	STATUS: For cache line selection during cache line fills, the cache uses a LFSR to determine the next way (in case there are no unallocated ways for that particular line.) This field contains the current status of the LFSR pseudo random generator. It gets updated for each cache fill operation. Only useful for debugging.

39.9.5 AVP_CACHE_TAG_STATUS_0

Offset: 0x14 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:5	X	CONFLICT_ADDR: Physical address for which a TAG_CHECK_ERROR was generated.
0	X	TAG_CHECK_ERROR: When asserted, there was a cache tag lookup with a hit for more than 1 way for the same tag address. This would be an internal error that is never supposed to happen.

39.9.6 AVP_CACHE_CLKEN_OVERRIDE_0

Offset: 0x18 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	CLK_GATED	RD_MCCIF_CLKEN_OVR: This overrides the clock gating of the memory read block that is used by the cache. This bit should always be set to CLK_GATED to ensure MCCIF clock shutdown when the cache is idle. 0 = CLK_GATED 1 = CLK_ALWAYS_ON
0	CLK_GATED	WR_MCCIF_CLKEN_OVR: This overrides the clock gating of the memory write block that's used by the cache. This bit should always be set to CLK_GATED to ensure MCCIF clock shutdown when the cache is idle. 0 = CLK_GATED 1 = CLK_ALWAYS_ON

39.9.7 AVP_CACHE_MAINT_0_0

Offset: 0x20 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	ADDR: Address field used for maintenance operations that require an address. Depending on the kind of operation, the semantics of this field may be a physical address in external memory (e.g., CLEAN_PHY and INVALID_PHY) or it may be the address of a line. For other operations, such as CLEAN_WAY, it is not used at all. This register needs to be written before the actual maintenance operation is executed by writing to MAINT_2.

39.9.8 AVP_CACHE_MAINT_1_0

Offset: 0x24 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DATA: Data field used for maintenance operations that require a data parameter.

39.9.9 AVP_CACHE_MAINT_2_0

All maintenance requests are blocking operations: new request from the ARM7 will stall until the maintenance operation has completed, so the ARM does not need to monitor the MAINTENANCE_DONE bit to ensure that everything has completed. For all *_WAY operations, this can result in seriously long stalls. In cases where latency is important (e.g., for interrupts), *_WAY

maintenance operations should be avoided. *_PHY or *_LINE maintenance operations should be used instead. The decision to use *_PHY or *_LINE will depend on the size physical memory buffer that needs to be cleaned or invalidated from the cache. For very large physical buffers or when the full cache needs to be cleaned or invalidated, software should simply loop over all lines in all ways and run the *_LINE command on each of them. When a small physical buffer needs to be cleaned and/or invalidated from the cache, it is more effective to use *_PHY commands.

Offset: 0x28 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxx000000000000)

Bit	Reset	Description
11:8	0x0	WAY_BITMAP: Select which the ways on which the *_WAY maintenance operations will work. One bit for each way.
7:0	NOP	OPCODE: 0 = NOP : No operation. after any op is executed, the field should be reset to NOP. 1 = CLEAN_PHY : Clean by physical address. This operation checks that the physical address stored in MAINT_0.ADDRESS is currently stored in the cache and will write its modified contents back to external memory. The cache line is not invalidated. 2 = INVALID_PHY : Invalidate by physical address. If the cache line was dirty, the contents are NOT first written to external memory. 3 = CLEAN_INVALID_PHY : Clean AND invalidate by physical address. CLEAN_PHY followed by INVALID_PHY. 9 = CLEAN_LINE : Clean 1 line in the cache. The line to be cleaned is taken from the MAINT_0.ADDRESS field and of the format { WAY_NR, LINE_NR }. 10 = INVALID_LINE : Invalidate 1 line in the cache. 11 = CLEAN_INVALID_LINE : Clean and invalidate 1 line in the cache. 17 = CLEAN_WAY : Clean all the lines of all the ways that are selected in the WAY_BITMAP field. 18 = INVALID_WAY : Invalidate all the lines of all the ways that are selected in the WAY_BITMAP field. 19 = CLEAN_INVALID_WAY : Clean AND invalidate all the lines of all the ways that are selected in the WAY_BITMAP field.

39.9.10 AVP_CACHE_INT_MASK_0

Offset: 0x40 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	MAINTENANCE_ERROR: Enable interrupt for MAINTENANCE_ERROR
0	0x0	MAINTENANCE_DONE: Enable interrupt for MAINTENANCE_DONE

39.9.11 AVP_CACHE_INT_CLEAR_0

Offset: 0x44 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	MAINTENANCE_ERROR: Clear both RAW_EVENT and INT_STATUS
0	0x0	MAINTENANCE_DONE: Clear both RAW_EVENT and INT_STATUS

39.9.12 AVP_CACHE_INT_RAW_EVENT_0

Offset: 0x48 | Read/Write: RO | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
1	X	MAINTENANCE_ERROR: Raw event for MAINTENANCE_ERROR. Raised when a MAINTENANCE operation was no successful. Usually because an incorrect OPCODE was written to the MAINT_2 register. When this bit is asserted, MAINTENANCE_DONE is not asserted.
0	X	MAINTENANCE_DONE: Raw event for MAINTENANCE_DONE. Raised when a MAINTENANCE operation has successfully completed.

39.9.13 AVP_CACHE_INT_STATUS_0

Offset: 0x4c | Read/Write: RO | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
1	X	MAINTENANCE_ERROR: Interrupt status (masked) for MAINTENANCE_ERROR
0	X	MAINTENANCE_DONE: Interrupt status (masked) for MAINTENANCE_DONE

39.9.14 AVP_CACHE_RB_CFG_0

Offset: 0x80 | Read/Write: R/W | Reset: 0x00000100 (0bxxxxxxxxxxxxxxxxxxxxxxx0100000000)

Bit	Reset	Description
9:0	0x100	TTL_TIMER_MAX: Time to live counter for uncached memory reads in the read buffer. This timer starts as soon as data from an external memory read has arrived in the read buffer. When this counter expires, the data in the read buffer is marked in valid. A value of 0 disables the TTL timer. It does NOT disable the read buffer! Use CONFIG.DISABLE_RB to disable the read buffering instead.

39.9.15 AVP_CACHE_WB_CFG_0

Offset: 0x84 | Read/Write: R/W | Reset: 0x00000100 (0bxxxxxxxxxxxxxxxxxxxxxxx0100000000)

Bit	Reset	Description
9:0	0x100	TTL_TIMER_MAX: Time to live counter for uncached memory writes in the write coalescing buffer. This time starts as soon as the first uncached write data is received from the ARM. When the timer expires, the contents of the write buffer are written to external memory. (There are many other events that may result in the write buffer being flushed to memory, such as non-sequential writes, RAW hazards, etc.) A value of 0 disables the TTL timer. It does NOT disable the write buffer. Use CONFIG.DISABLE_WB to disable write buffering instead.

39.9.16 AVP_CACHE_MMU_FALLBACK_ENTRY_0

Offset: 0xa0 | Read/Write: R/W | Reset: 0x0000000e (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx1110)

Bit	Reset	Description
3	ENABLE	WR_ENA: 0 = DISABLE 1 = ENABLE
2	ENABLE	RD_ENA: 0 = DISABLE 1 = ENABLE
1	ENABLE	EXE_ENA: 0 = DISABLE 1 = ENABLE
0	DISABLE	CACHED: 0 = DISABLE 1 = ENABLE

39.9.17 AVP_CACHE_MMU_SHADOW_COPY_MASK_0_0

Offset: 0xa4 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	MASK

39.9.18 AVP_CACHE_MMU_CFG_0

Offset: 0xac | Read/Write: R/W | Reset: 0x000000X7 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0111)

Bit	Reset	Description
5	X	CLR_ABORT: 0: NOP 1: Clean the abort statistics. (See ABORT_MODE-STORE_FIRST)
4	X	ABORT_MODE: STORE_FIRST: store the stats of the first MMU abort. Later aborts do not overwrite the first one as long as the abort statistics have not been cleared. STORE_LAST: always store the statistics of the latest abort. 0 = STORE_FIRST 1 = STORE_LAST
3	DISABLE	SEG_CHECK_ALL_ENTRIES: DISABLE: stop doing the lookup as soon as an entry is found that matches. This is the fastest and preferred way, but it will not detect a MMU entry overlap error if those overlapping entries are not part of the same group of 4. ENABLE: all lookups will go through all entries in the MMU. This will impact performance, but is guaranteed to flag overlapping address ranges between MMU entries. 0 = DISABLE 1 = ENABLE
2	ENABLE	TLB_ENA: Enable MMU TLB lookup optimization 0 = DISABLE 1 = ENABLE
1	ENABLE	SEQ_ENA: Enable MMU sequential access optimization 0 = DISABLE 1 = ENABLE
0	ENABLE	BLOCK_MAIN_ENTRY_WR: Enable writing directly into the active MMU entries instead of going through the shadow entries first and doing a block copy. 0 = DISABLE 1 = ENABLE

39.9.19 AVP_CACHE_MMU_CMD_0

Offset: 0xb0 | Read/Write: R/W | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
1:0	X	CMD: 0 = NOP 1 = INIT 2 = COPY_SHADOW

39.9.20 AVP_CACHE_MMU_ABORT_STAT_0

Offset: 0xb4 | Read/Write: RO | Reset: 0x00XX0XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
21	X	PROT: 0 = FALSE 1 = TRUE
20	X	SEQ: 0 = FALSE 1 = TRUE
19:18	X	SIZE
17:16	X	TYPE: 0 = EXE 1 = RD 2 = WR

Bit	Reset	Description
8:4	X	ENTRY
3	X	OVERLAP: 0 = FALSE 1 = TRUE
2:0	X	UNIT: 0 = NONE 1 = CACHE 2 = SEQ 3 = TLB 4 = SEG 5 = FALLBACK

39.9.21 AVP_CACHE_MMU_ABORT_ADDR_0

Offset: 0xb8 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	ADDR

39.9.22 AVP_CACHE_MMU_ACTIVE_ENTRIES_0_0

Offset: 0xbc | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	ENTRIES

39.9.23 AVP_CACHE_MMU_SHADOW_ENTRY_0

How to program the MMU entries:

The full MMU table should be updated atomically. The procedure to do this is as follows:

- Write all new entries in the MMU_SHADOW_ENTRY table
- For each of the entries in the shadow table that need to be copied, set the corresponding bit in the MMU_SHADOW_COPY_MASK register
- Issue the COPY_SHADOW command via the MMU_CMD register.

MMU_SHADOW_ENTRY addresses are mapped as follows: for each MMU entry, there are 4 32-bit words reserved, so to get the base pointer of an entry, you need to take the address of MMU_SHADOW_ENTRY_0 + (entry_nr * 16).

From there, the following offsets apply:

- 32-bit word 0: MIN_ADDR
- 32-bit word 1: MAX_ADDR
- 32-bit word 2: CXRW attributes

This is an array of 128 identical register entries; the register fields below apply to each entry.

Offset: 0x400..0x5ff | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
Word 0		
31:5	X	MIN_ADDR
Word 1		
31:5	X	MAX_ADDR
Word 2		
3	X	WR_ENA: 0 = DISABLE 1 = ENABLE
2	X	RD_ENA: 0 = DISABLE 1 = ENABLE
1	X	EXE_ENA: 0 = DISABLE 1 = ENABLE
0	X	CACHED: 0 = DISABLE 1 = ENABLE

39.9.24 AVP_CACHE_MMU_MAIN_ENTRY_0

This is an array of 128 identical register entries; the register fields below apply to each entry.

Offset: 0x800..0x9ff | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
Word 0		
31:5	X	MIN_ADDR
Word 1		
31:5	X	MAX_ADDR
Word 2		
3	X	WR_ENA: 0 = DISABLE 1 = ENABLE
2	X	RD_ENA: 0 = DISABLE 1 = ENABLE
1	X	EXE_ENA: 0 = DISABLE 1 = ENABLE
0	X	CACHED: 0 = DISABLE 1 = ENABLE

Notice

The information provided in this specification is believed to be accurate and reliable as of the date provided. However, NVIDIA Corporation (“NVIDIA”) does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information. NVIDIA shall have no liability for the consequences or use of such information or for any infringement of patents or other rights of third parties that may result from its use. This publication supersedes and replaces all other specifications for the product that may have been previously supplied.

NVIDIA reserves the right to make corrections, modifications, enhancements, improvements, and other changes to this specification, at any time and/or to discontinue any product or service without notice. Customer should obtain the latest relevant specification before placing orders and should verify that such information is current and complete.

NVIDIA products are sold subject to the NVIDIA standard terms and conditions of sale supplied at the time of order acknowledgement, unless otherwise agreed in an individual sales agreement signed by authorized representatives of NVIDIA and customer. NVIDIA hereby expressly objects to applying any customer general terms and conditions with regard to the purchase of the NVIDIA product referenced in this specification.

NVIDIA products are not designed, authorized or warranted to be suitable for use in medical, military, aircraft, space or life support equipment, nor in applications where failure or malfunction of the NVIDIA product can reasonably be expected to result in personal injury, death or property or environmental damage. NVIDIA accepts no liability for inclusion and/or use of NVIDIA products in such equipment or applications and therefore such inclusion and/or use is at customer’s own risk.

NVIDIA makes no representation or warranty that products based on these specifications will be suitable for any specified use without further testing or modification. Testing of all parameters of each product is not necessarily performed by NVIDIA. It is customer’s sole responsibility to ensure the product is suitable and fit for the application planned by customer and to do the necessary testing for the application in order to avoid a default of the application or the product. Weaknesses in customer’s product designs may affect the quality and reliability of the NVIDIA product and may result in additional or different conditions and/or requirements beyond those contained in this specification. NVIDIA does not accept any liability related to any default, damage, costs or problem which may be based on or attributable to: (i) the use of the NVIDIA product in any manner that is contrary to this specification, or (ii) customer product designs.

No license, either express or implied, is granted under any NVIDIA patent right, copyright, or other NVIDIA intellectual property right under this specification. Information published by NVIDIA regarding third-party products or services does not constitute a license from NVIDIA to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property rights of the third party, or a license from NVIDIA under the patents or other intellectual property rights of NVIDIA.
