8.2 IOMUX Controller (IOMUXC)

8.2.1 Overview

The IOMUX Controller (IOMUXC), together with the IOMUX, enables the IC to share one pad to several functional blocks. This sharing is done by multiplexing the pad's input and output signals.

Every module requires a specific pad setting (such as pull up or keeper), and for each pad, there are up to 8 muxing options (called ALT modes). The pad settings parameters are controlled by the IOMUXC.

The IOMUX consists only of combinatorial logic combined from several basic IOMUX cells. Each basic IOMUX cell handles only one pad signal's muxing.

Figure 8-1 illustrates the IOMUX/IOMUXC connectivity in the system.

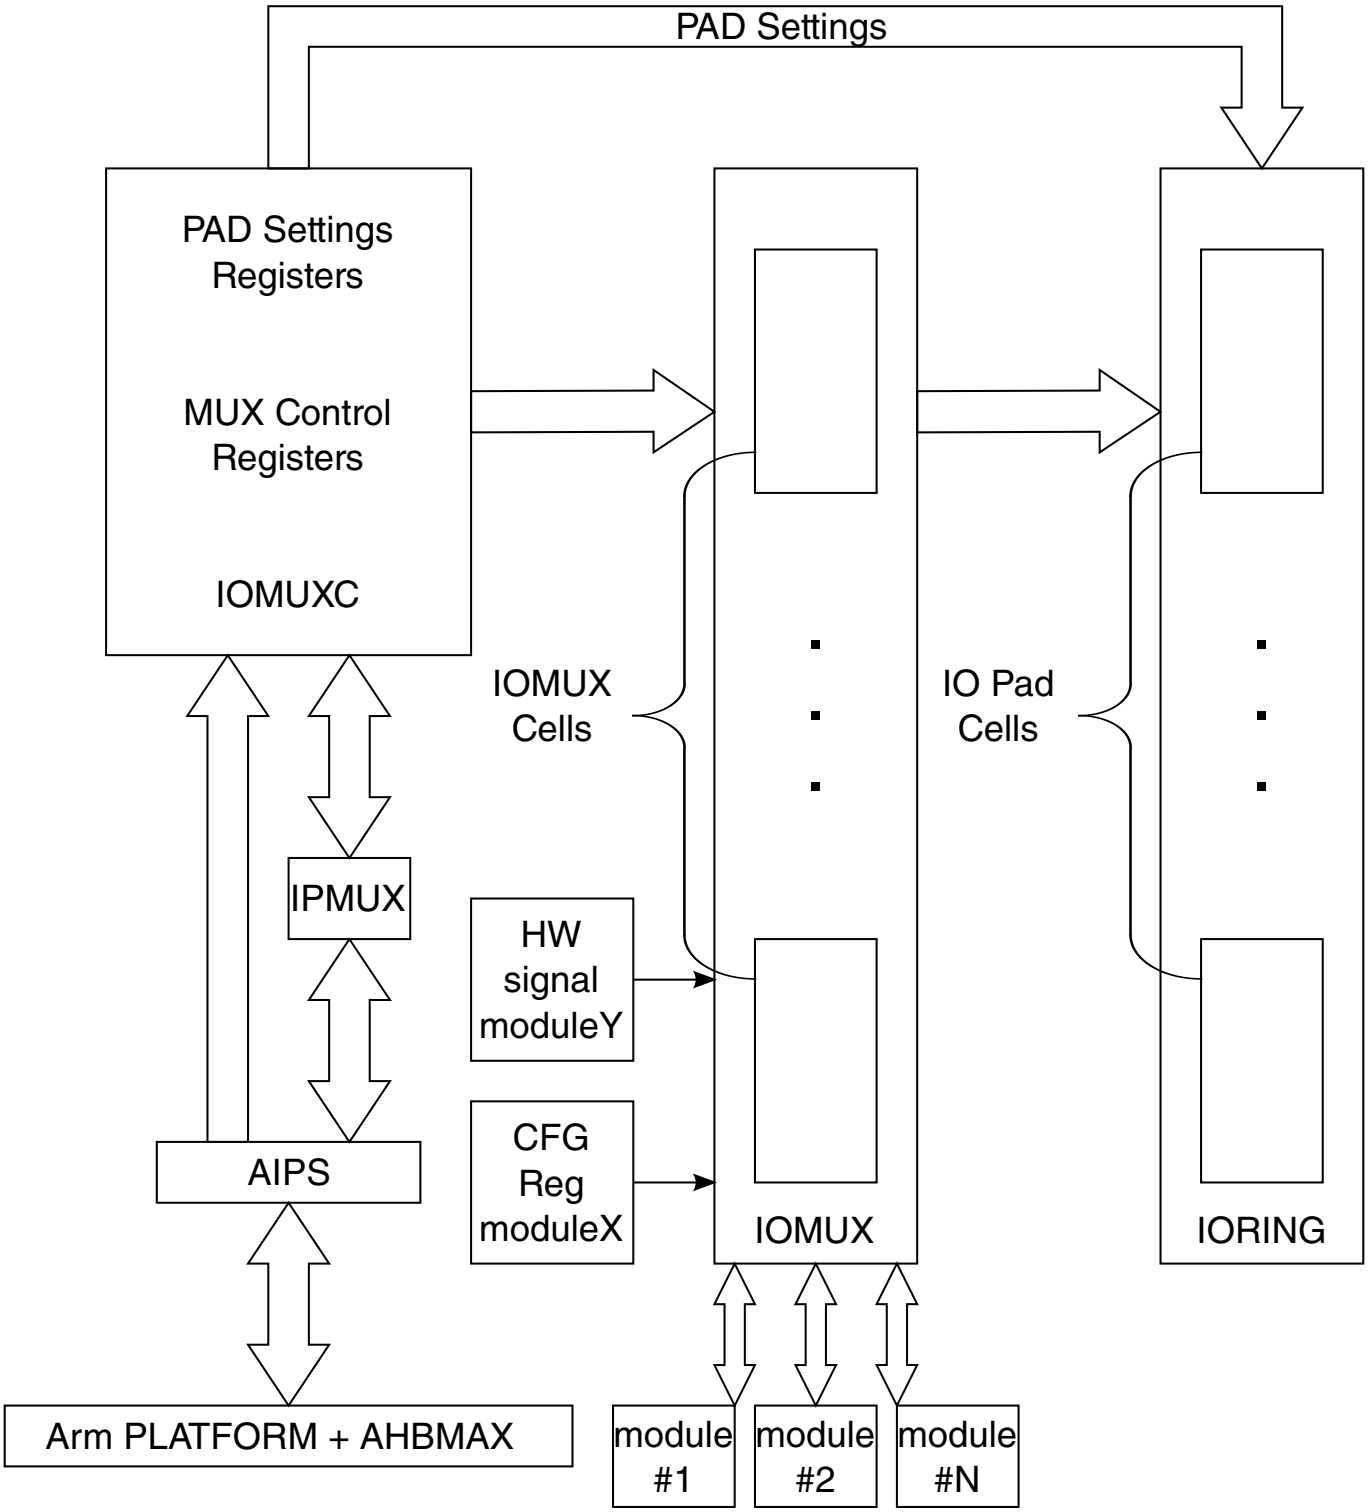

Figure 8-1. IOMUX SoC Level Block Diagram

8.2.1.1 Features

The IOMUXC features are:

- 32-bit software mux control registers (IOMUXC_SW_MUX_CTL_PAD_<PAD NAME> or IOMUXC_SW_MUX_CTL_GRP_<GROUP NAME>) to configure 1 of 8 alternate (ALT) MUX_MODE feilds of each pad or a predefined group of pads and to enable the forcing of an input path of the pad(s) (SION bit).
- 32-bit software pad control registers (IOMUXC_SW_PAD_CTL_PAD_<PAD_NAME> or IOMUXC_SW_PAD_CTL_GRP_<GROUP NAME>) to configure specific pad settings of each pad, or a predefined group of pads.
- 32-bit general purpose registers - several (GPR0 to GPR*n*) 32-bit registers according to SoC requirements for any usage.
- 32-bit input select control registers to control the input path to a module when more than one pad drives this module input.

Each SW MUX/PAD CTL IOMUXC register handles only one pad or one pad's group.

Only the minimum number of registers required by software are implemented by hardware. For example, if only ALT0 and ALT1 modes are used on Pad x then only one bit register will be generated as the MUX_MODE control field in the software mux control register of Pad x.

The software mux control registers may allow the forcing of pads to become input (input path enabled) regardless of the functional direction driven. This may be useful for loopback and GPIO data capture.

8.2.2 Clocks

The table found here describes the clock sources for IOMUXC.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 8-1. IOMUXC Clocks

Clock name	Clock Root	Description
ipt_clk_io		IO clock
ipg_clk_s	ipg_clk_root	Peripheral access clock

8.2.3 Functional description

This section provides a complete functional description of the block.

The IOMUXC consists of two sub-blocks:

- IOMUXC_REGISTERS includes all of the IOMUXC registers (see Features).
- IOMUXC_LOGIC includes all of the IOMUXC combinatorial logic (IP interface controls, address decoder, observability muxes).

The IOMUX consists of a number (about the number of pads in the SoC) of basic iomux_cell units. If only one functional mode is required for a specific pad, there is no need for IOMUX and the signals can be connected directly from the module to the I/O. The IOMUX cell is required whenever two or more functional modes are required for a specific pad or when one functional mode and the one test mode are required.

The basic iomux_cell design, which allows two levels of HW signal control (in ALT6 and ALT7 modes - ALT7 gets highest priority) is shown in Figure 8-2.

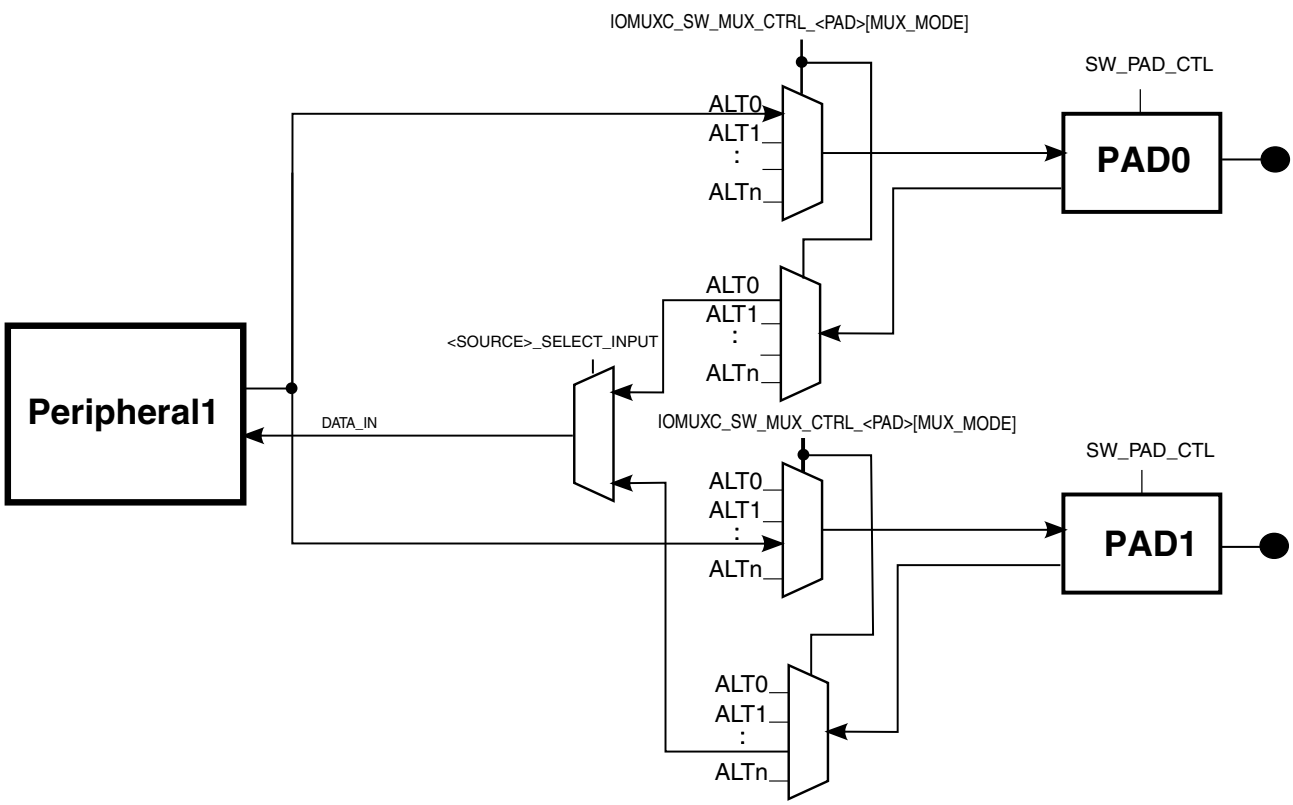

Figure 8-2. IOMUX Cell Block Diagram

8.2.3.1 ALT6 and ALT7 extended muxing modes

The ALT7 and ALT6 extended muxing modes allow any signal in the system (such as fuse, pad input, JTAG, or software register) to override any software configuration and to force the ALT6/ALT7 muxing mode.

It also allows an IOMUX software register to control a group of pads.

8.2.3.2 SW Loopback through SION bit

A limited option exists to override the default pad functionality and force the input path to be active (ipp_ibe==1'b1) regardless of the value driven by the corresponding module. This can be done by setting the SION (Software Input On) bit in the IOMUXC_SW_MUX_CTL register (when available) to "1".

Uses include:

- LoopBack - Module x drives the pad and also receives pad value as an input.
- GPIO Capture - Module x drives the pad and the value is captured by GPIO.

8.2.3.3 Daisy chain - multi pads driving same module input pin

In some cases, more than one pad may drive a single module input pin. Such cases require the addition of one more level of IOMUXing; all of these input signals are muxed, and a dedicated software controlled register controls the mux in order to select the required input path.

A module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programable via the IOMUXC_SW_MUX_CTL_<PAD> registers) and one for defining it as the input path (via the daisy chain registers).

This means that a module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programable via the IOMUXC_SW_MUX_CTL_<PAD> registers) and one for defining it as the input path (via the daisy chain registers). The daisy chain is illustrated in the figure below.

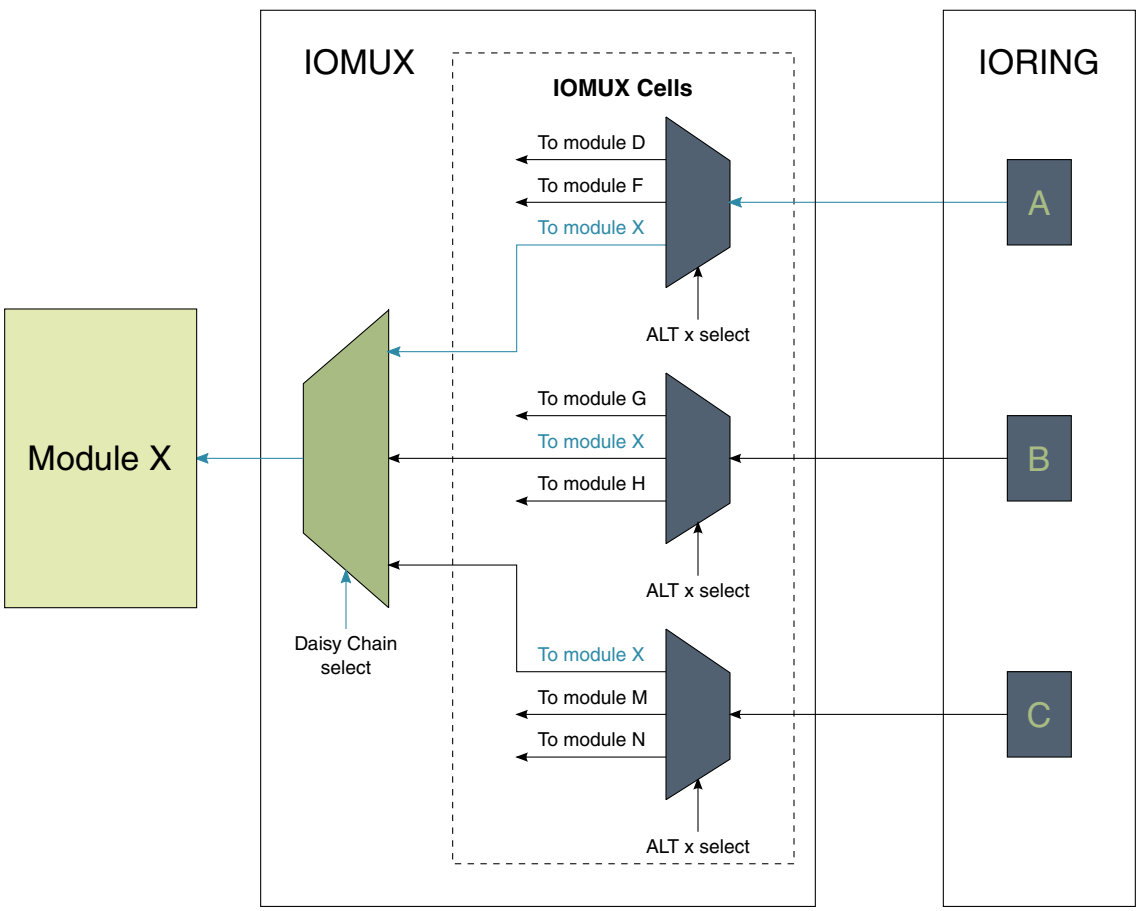

Figure 8-3. Daisy chain illustration

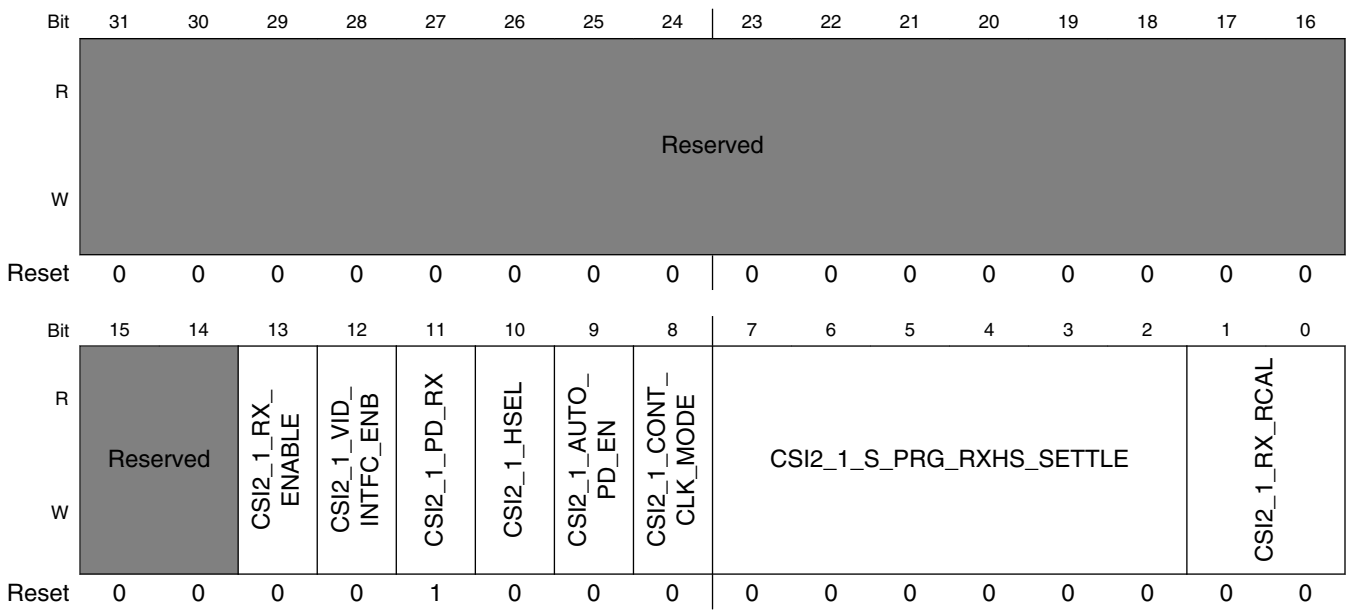
8.2.4.35 GPR34 General Purpose Register (IOMUXC_GPR_GPR34)

GPR Register

Address: 3034_0000h base + 88h offset = 3034_0088h



IOMUXC_GPR_GPR34 field descriptions

Field	Description
31–14 -	This field is reserved. Reserved
13 CSI2_1_RX_ENABLE	MIPI CSI2_1 Controller Receive Enable, active high. When deasserted, the RX controller will pause data reception at the next packet boundary. Since the CSI-2 protocol does not allow the Receiver to pause data, when rx_enable is deasserted the RX Controller still receives data from the RX DPHY but it does not forward the receive packets to the user interface but instead discards the received data. When rx_enable

Table continues on the next page...

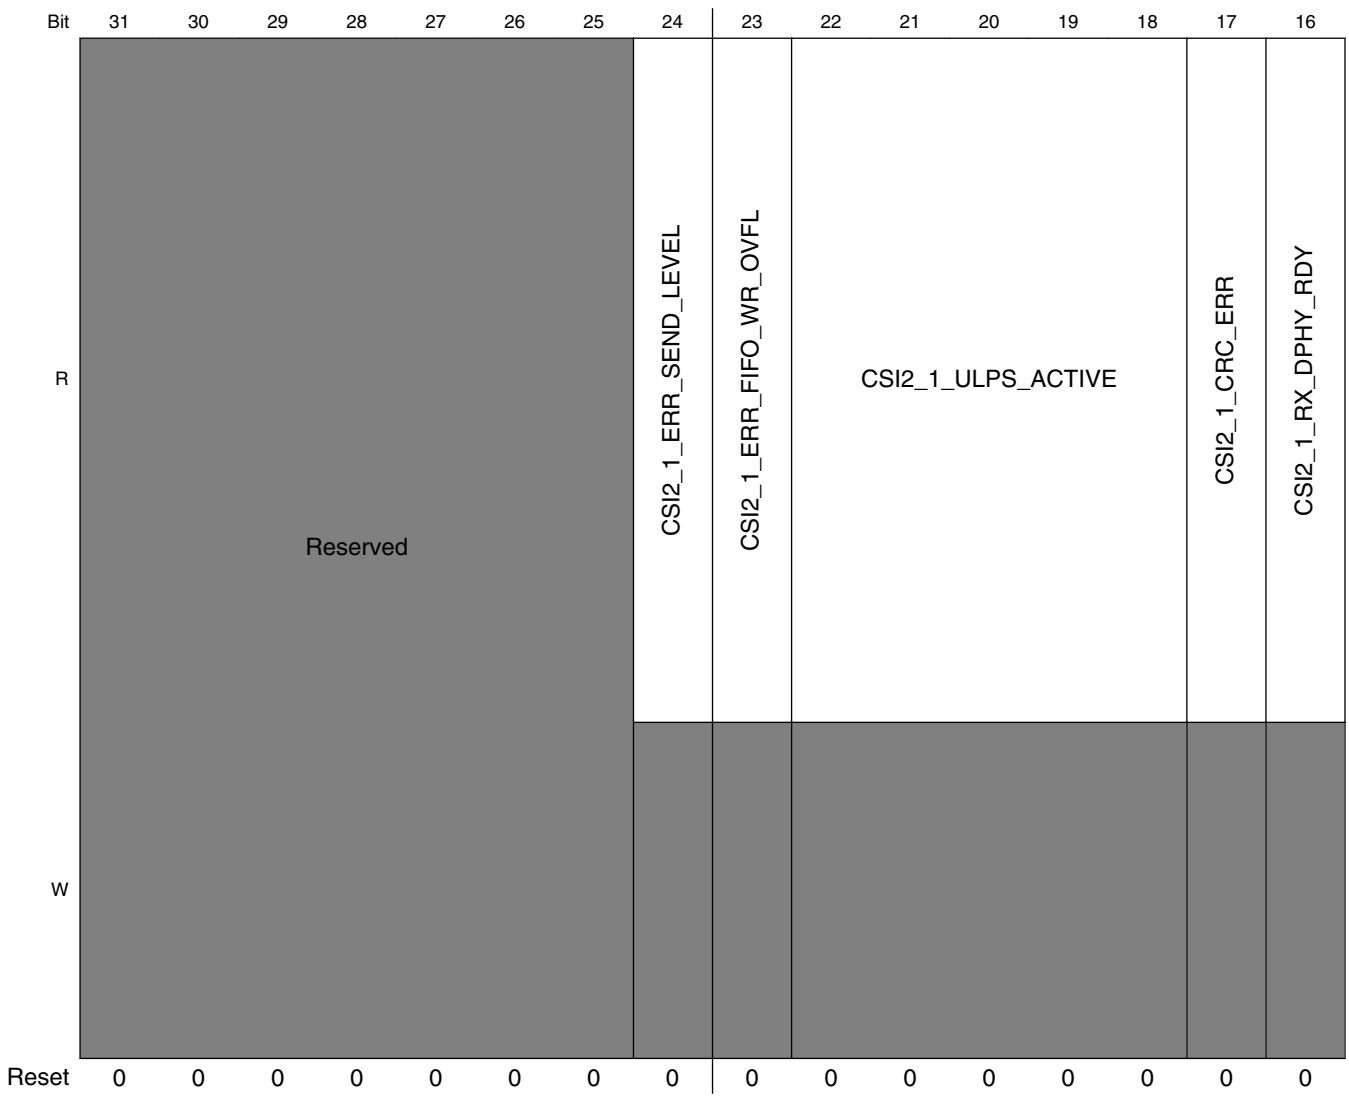
IOMUXC_GPR_GPR34 field descriptions (continued)

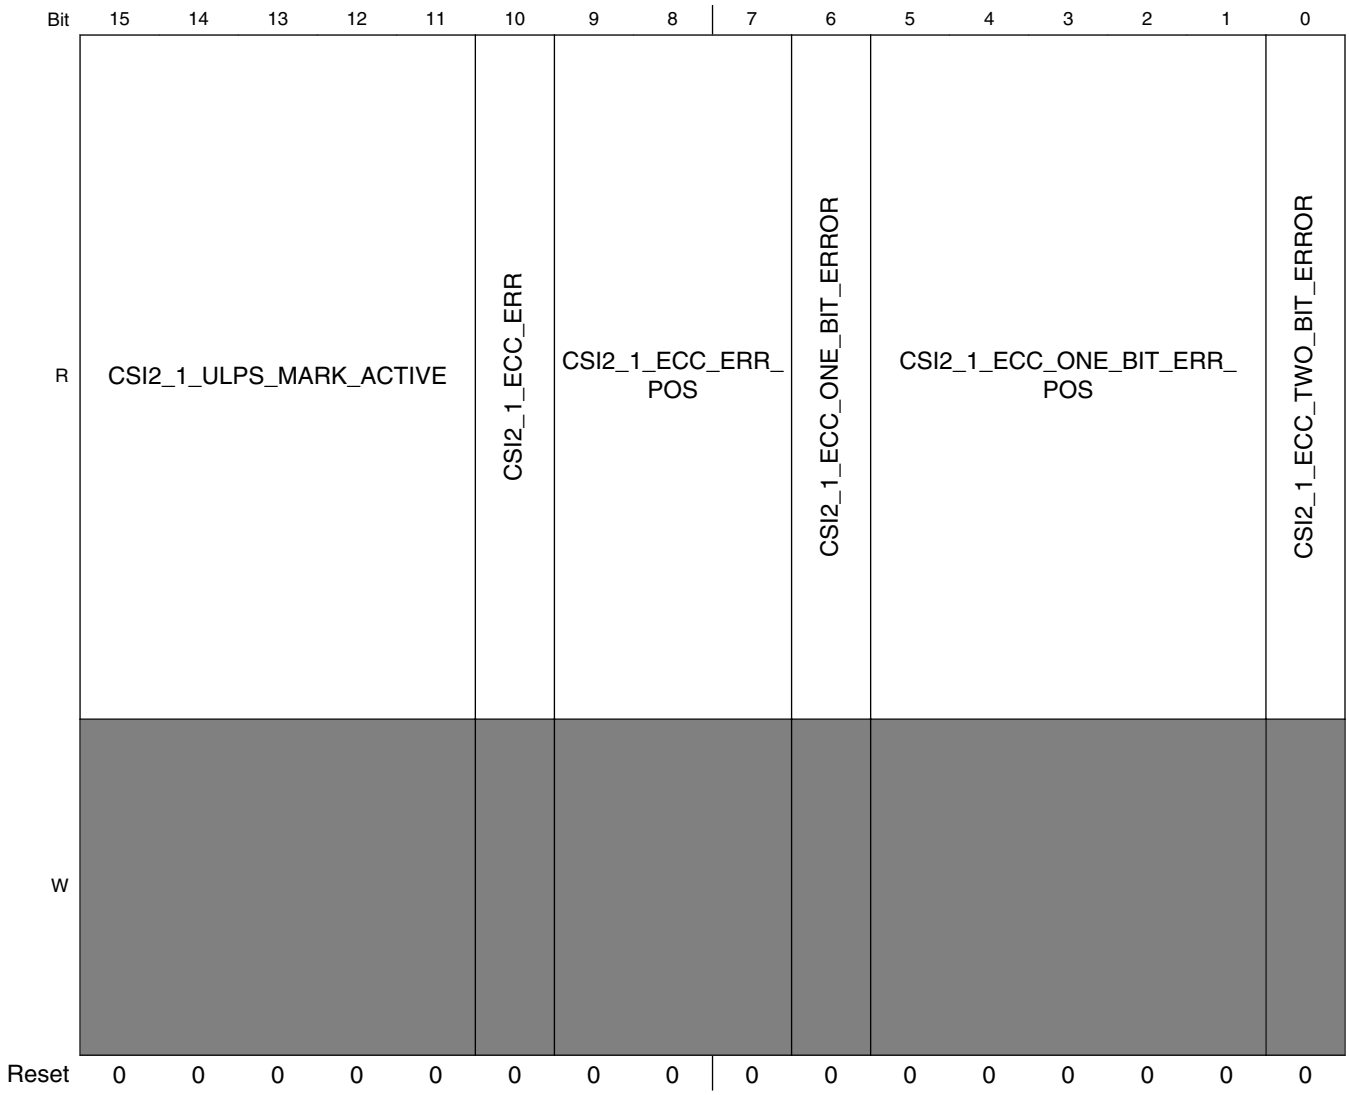
Field	Description
	is asserted, the RX controller will wait for the start of the next packet before allowing data to be sent out over the user interface.
12 CSI2_1_VID_INTFC_ENB	MIPI CSI2_1 controller video interface enable. 0 Disable 1 Enable
11 CSI2_1_PD_RX	MIPI CSI2_1 D-PHY Power Down input.When high, all blocks are powered down.
10 CSI2_1_HSEL	MIPI CSI2_1 D-PHY High Speed Select 0 1.0 Gbps operation 1 1.2 Gbps operation
9 CSI2_1_AUTO_PD_EN	MIPI CSI2_1 D-PHY Power down inactive lanes reported by CFG_NUM_LANES input bus. 0 Inactive lanes are powered up and driving LP11. 1 Inactive lanes are powered down.
8 CSI2_1_CONT_CLK_MODE	MIPI CSI2_1 D-PHY slave clock lane feature enable to maintain HS reception state during continuous clock mode operation. 0 Feature disable 1 Feature enabled
7–2 CSI2_1_S_PRG_RXHS_SETTLE	MIPI CSI2_1 D-PHY program T_HS_SETTLE bits. HS-RX waits for Time-out T_HS_SETTLE in order to neglect transition effects.
CSI2_1_RX_RCAL	MIPI CSI2_1 D-PHY On-chip termination control bits for manual calibration of HS-RX. 00 25% higher than mid-range. Highest impedance setting. 01 15% higher than mid-range. 10 Mid-range impedance setting. 11 25% lower than mid-range. Lowest impedance setting.

8.2.4.36 GPR35 General Purpose Register (IOMUXC_GPR_GPR35)

GPR Register

Address: 3034_0000h base + 8Ch offset = 3034_008Ch





IOMUXC_GPR_GPR35 field descriptions

Field	Description
31–25 -	This field is reserved. Reserved
24 CSI2_1_ERR_SEND_LEVEL	For MIPI CSI2_1 Controller, this flag indicates the video interface pixel fifo did not accumulate enough sample to trigger its send level setting before the end of an image data packet was detected. This flag would generally mean that the cfg_vid_p_fifo_send_level is set to high.
23 CSI2_1_ERR_FIFO_WR_OVFL	For MIPI CSI2_1 Controller, this flag indicates the video interface pixel fifo overflowed on a pixel write. This means the output video port is not removing pixels quickly enough to keep up with the input data rate. This flag would generally mean the clk_vid rate is too low.
22–18 CSI2_1_ULPS_ACTIVE	MIPI CSI2_1 Controller Receive Ultra Low Power State active. Bits assert high when corresponding clock or data lane is in ULPS mode. Bit [0] – Clock Lane Bit [1] – Data Lane 0 Bit [2] – Data Lane 1

Table continues on the next page...

IOMUXC_GPR_GPR35 field descriptions (continued)

Field	Description
	Bit [3] – Data Lane 2 Bit [4] – Data Lane 3
17 CSI2_1_CRC_ERR	MIPI CSI2_1 Controller CRC status. Asserts high when the CRC calculated on the received data does not match the CRC the transmitter sent at the end of the packet. Valid when the eop_out output asserts.
16 CSI2_1_RX_DPHY_RDY	MIPI CSI2_1 D-PHY ready status 0 Not ready 1 Ready
15–11 CSI2_1_ULPS_MARK_ACTIVE	MIPI CSI2_1 Controller Receive Ultra Low Power State Mark status. Bits assert high when corresponding clock or data lane has exited ULPS and entered Mark-1 state. Lanes will remain in Mark-1 state for a minimum of 1ms as per the MIPI DPHY specification. While in Mark-1 state, no other active, like High Speed data transmission, is allowed. Bit [0] – Clock Lane Bit [1] – Data Lane 0 Bit [2] – Data Lane 1 Bit [3] – Data Lane 2 Bit [4] – Data Lane 3
10 CSI2_1_ECC_ERR	MIPI CSI2_1: Error detected in the ECC bits. This signal is no longer supported.
9–7 CSI2_1_ECC_ERR_POS	MIPI CSI2_1: Position of the corrected single bit error in the packet header. Valid when pkt_hdr_valid is asserted high.
6 CSI2_1_ECC_ONE_BIT_ERROR	MIPI CSI2_1: Two packet header bit errors were detected and not corrected, active high and is valid when pkt_hdr_is high.
5–1 CSI2_1_ECC_ONE_BIT_ERR_POS	MIPI CSI2_1: Position of the corrected single bit error in the packet header. Valid when pkt_hdr_valid is asserted high.
0 CSI2_1_ECC_TWO_BIT_ERROR	MIPI CSI2_1: Two packet header bit errors were detected and not corrected, active high and is valid when pkt_hdr_is high.

SW_MUX_CTL Register

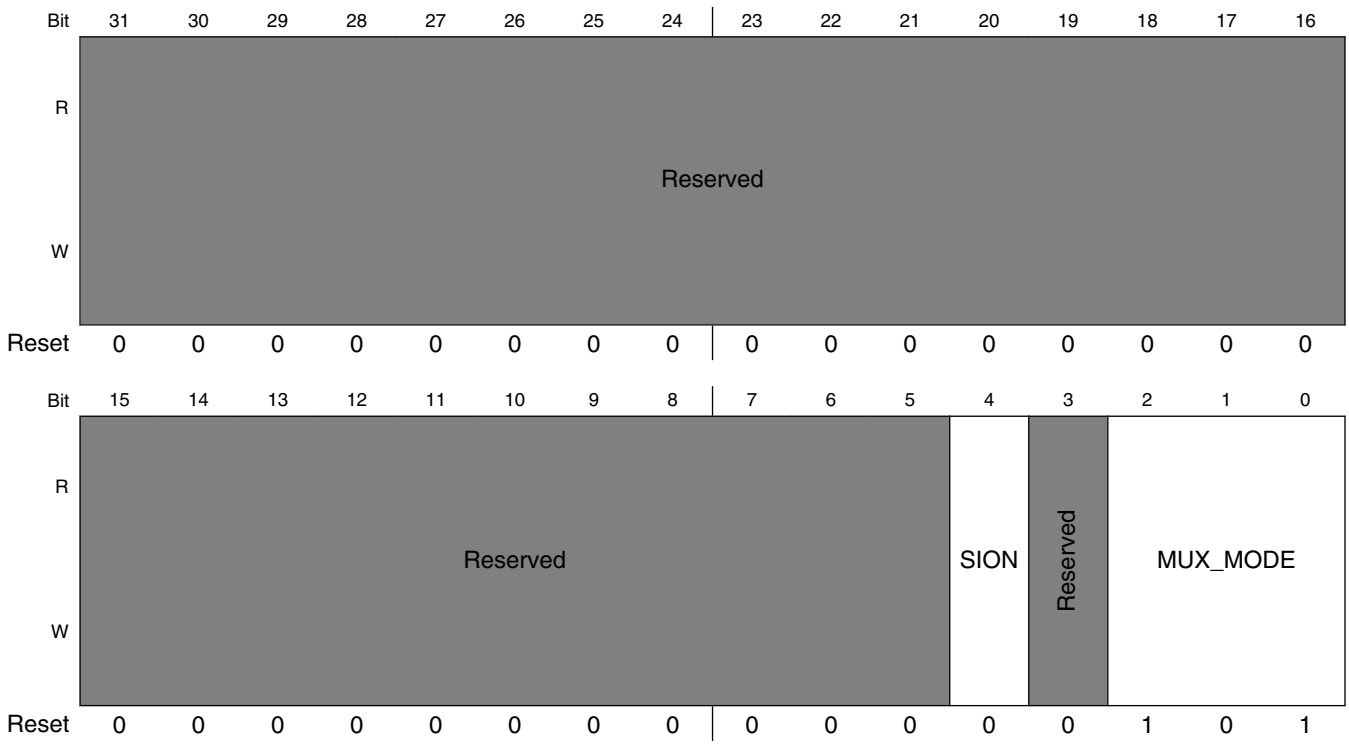
Address: 3033_0000h base + 100h offset = 3033_0100h



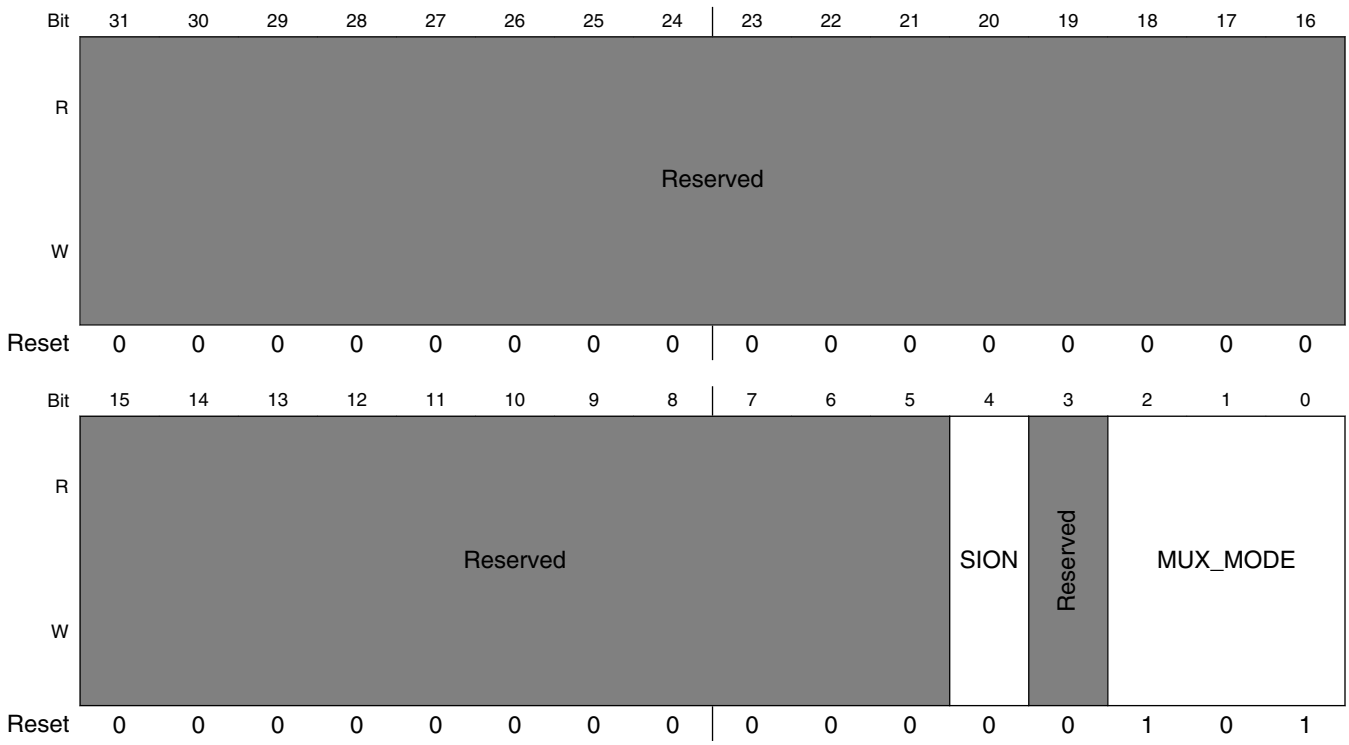
IOMUXC_SW_MUX_CTL_PAD_NAND_CE2_B field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field Force the select mux mode Input path no matter of MUX_MODE functionality 0 **SION_DISABLED** — Input Path of pad NAND_CE2_B is determined by functionality 1 **SION_ENABLED** — Force Input Path of pad NAND_CE2_B
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field Select 1 of 3 iomux modes to be used for pad: NAND_CE2_B 000 **ALT0_RAWNAND_CE2_B** — Select mux mode: ALT0 mux port: CE2_B of instance: RAWNAND 001 **ALT1_QSPI_B_SS0_B** — Select mux mode: ALT1 mux port: B_SS0_B of instance: QSPI 101 **ALT5_GPIO3_IO03** — Select mux mode: ALT5 mux port: IO03 of instance: GPIO3

8.2.5.61 SW_MUX_CTL_PAD_NAND_CE3_B SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_NAND_CE3_B)

SW_MUX_CTL Register

Address: 3033_0000h base + 104h offset = 3033_0104h



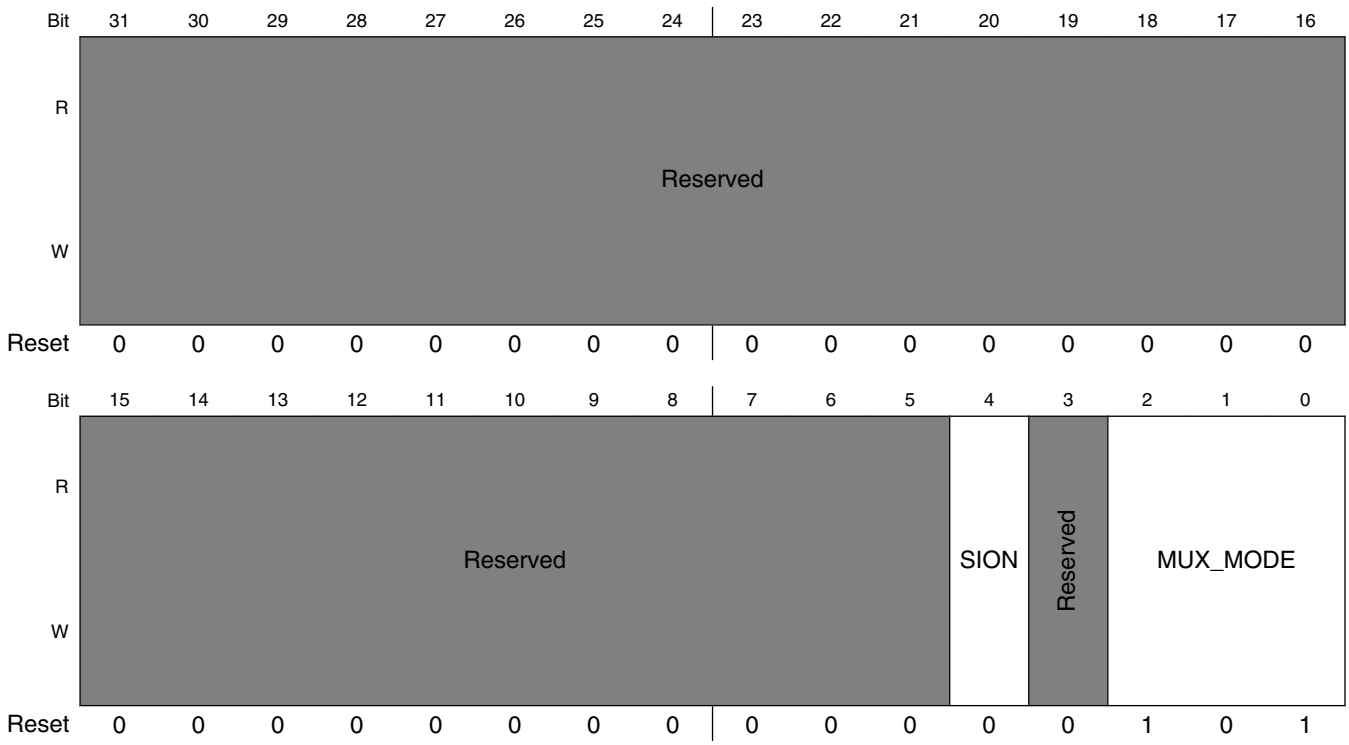
IOMUXC_SW_MUX_CTL_PAD_NAND_CE3_B field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field Force the select mux mode Input path no matter of MUX_MODE functionality 0 **SION_DISABLED** — Input Path of pad NAND_CE3_B is determined by functionality 1 **SION_ENABLED** — Force Input Path of pad NAND_CE3_B
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field Select 1 of 3 iomux modes to be used for pad: NAND_CE3_B 000 **ALT0_RAWNAND_CE3_B** — Select mux mode: ALT0 mux port: CE3_B of instance: RAWNAND 001 **ALT1_QSPI_B_SS1_B** — Select mux mode: ALT1 mux port: B_SS1_B of instance: QSPI 101 **ALT5_GPIO3_IO04** — Select mux mode: ALT5 mux port: IO04 of instance: GPIO3

8.2.5.62 SW_MUX_CTL_PAD_NAND_CLE SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_NAND_CLE)

SW_MUX_CTL Register

Address: 3033_0000h base + 108h offset = 3033_0108h



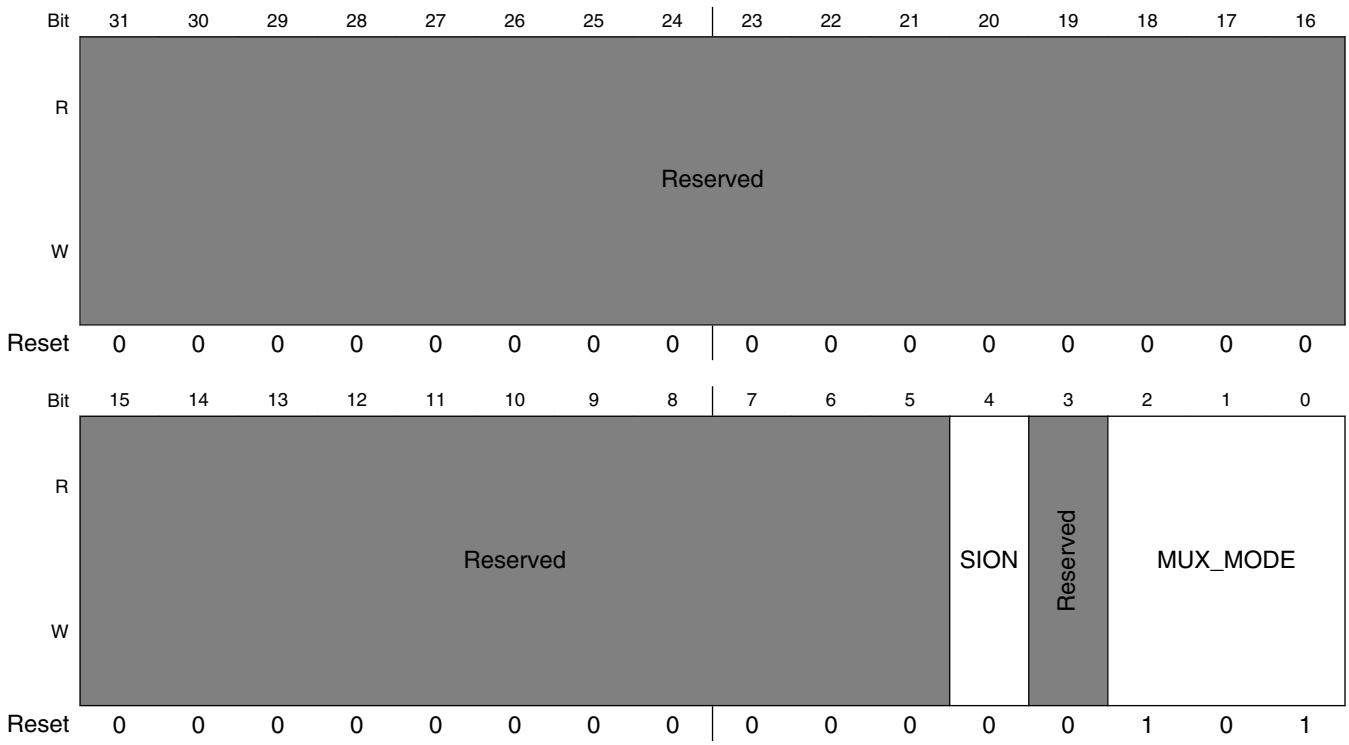
IOMUXC_SW_MUX_CTL_PAD_NAND_CLE field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field Force the select mux mode Input path no matter of MUX_MODE functionality 0 **SION_DISABLED** — Input Path of pad NAND_CLE is determined by functionality 1 **SION_ENABLED** — Force Input Path of pad NAND_CLE
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field Select 1 of 3 iomux modes to be used for pad: NAND_CLE 000 **ALT0_RAWNAND_CLE** — Select mux mode: ALT0 mux port: CLE of instance: RAWNAND 001 **ALT1_QSPI_B_SCLK** — Select mux mode: ALT1 mux port: B_SCLK of instance: QSPI 101 **ALT5_GPIO3_IO05** — Select mux mode: ALT5 mux port: IO05 of instance: GPIO3

8.2.5.63 SW_MUX_CTL_PAD_NAND_DATA00 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_NAND_DATA00)

SW_MUX_CTL Register

Address: 3033_0000h base + 10Ch offset = 3033_010Ch



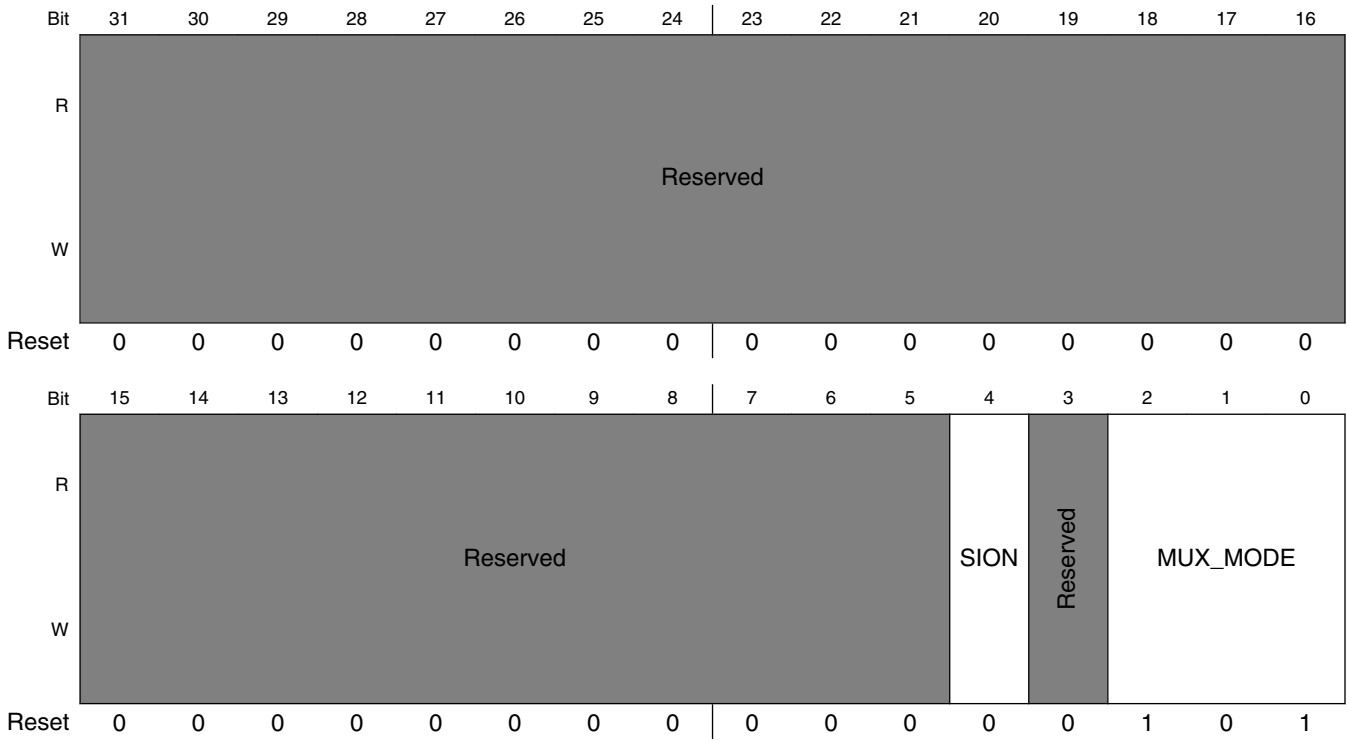
IOMUXC_SW_MUX_CTL_PAD_NAND_DATA00 field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field Force the select mux mode Input path no matter of MUX_MODE functionality 0 **SION_DISABLED** — Input Path of pad NAND_DATA00 is determined by functionality 1 **SION_ENABLED** — Force Input Path of pad NAND_DATA00
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field Select 1 of 3 iomux modes to be used for pad: NAND_DATA00 000 **ALT0_RAWNAND_DATA00** — Select mux mode: ALT0 mux port: DATA00 of instance: RAWNAND 001 **ALT1_QSPI_A_DATA0** — Select mux mode: ALT1 mux port: A_DATA0 of instance: QSPI 101 **ALT5_GPIO3_IO06** — Select mux mode: ALT5 mux port: IO06 of instance: GPIO3

8.2.5.64 SW_MUX_CTL_PAD_NAND_DATA01 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_NAND_DATA01)

SW_MUX_CTL Register

Address: 3033_0000h base + 110h offset = 3033_0110h



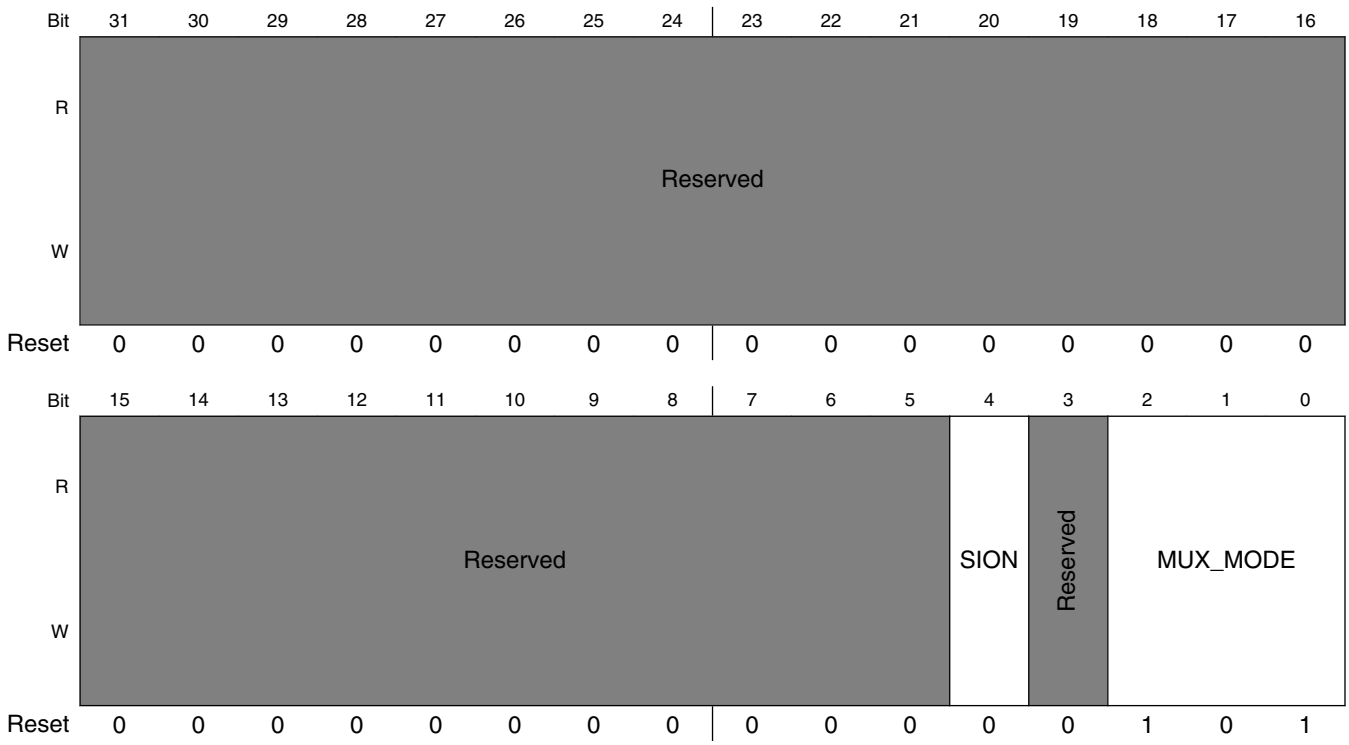
IOMUXC_SW_MUX_CTL_PAD_NAND_DATA01 field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field Force the select mux mode Input path no matter of MUX_MODE functionality 0 **SION_DISABLED** — Input Path of pad NAND_DATA01 is determined by functionality 1 **SION_ENABLED** — Force Input Path of pad NAND_DATA01
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field Select 1 of 3 iomux modes to be used for pad: NAND_DATA01 000 **ALT0_RAWNAND_DATA01** — Select mux mode: ALT0 mux port: DATA01 of instance: RAWNAND 001 **ALT1_QSPI_A_DATA1** — Select mux mode: ALT1 mux port: A_DATA1 of instance: QSPI 101 **ALT5_GPIO3_IO07** — Select mux mode: ALT5 mux port: IO07 of instance: GPIO3

8.2.5.65 SW_MUX_CTL_PAD_NAND_DATA02 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_NAND_DATA02)

SW_MUX_CTL Register

Address: 3033_0000h base + 114h offset = 3033_0114h



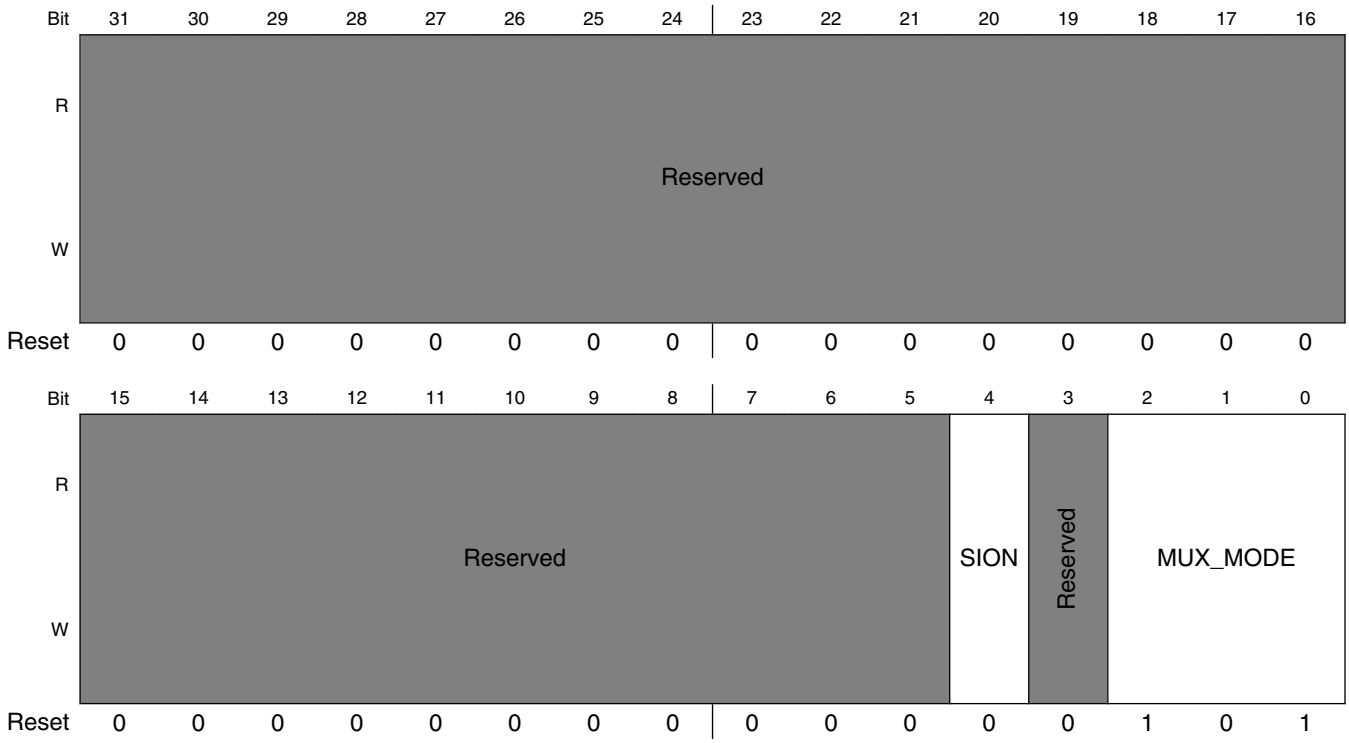
IOMUXC_SW_MUX_CTL_PAD_NAND_DATA02 field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field Force the select mux mode Input path no matter of MUX_MODE functionality 0 **SION_DISABLED** — Input Path of pad NAND_DATA02 is determined by functionality 1 **SION_ENABLED** — Force Input Path of pad NAND_DATA02
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field Select 1 of 3 iomux modes to be used for pad: NAND_DATA02 000 **ALT0_RAWNAND_DATA02** — Select mux mode: ALT0 mux port: DATA02 of instance: RAWNAND 001 **ALT1_QSPI_A_DATA2** — Select mux mode: ALT1 mux port: A_DATA2 of instance: QSPI 101 **ALT5_GPIO3_IO08** — Select mux mode: ALT5 mux port: IO08 of instance: GPIO3

8.2.5.66 SW_MUX_CTL_PAD_NAND_DATA03 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_NAND_DATA03)

SW_MUX_CTL Register

Address: 3033_0000h base + 118h offset = 3033_0118h



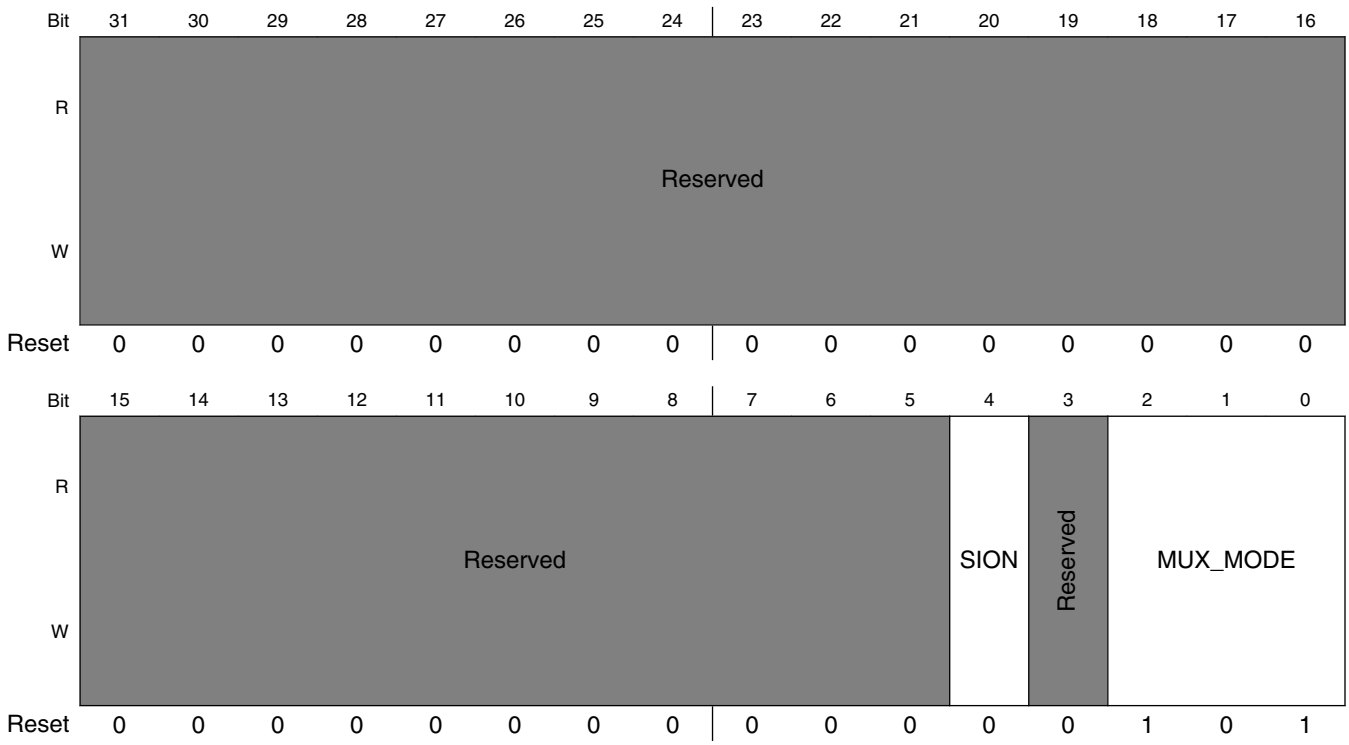
IOMUXC_SW_MUX_CTL_PAD_NAND_DATA03 field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field Force the select mux mode Input path no matter of MUX_MODE functionality 0 **SION_DISABLED** — Input Path of pad NAND_DATA03 is determined by functionality 1 **SION_ENABLED** — Force Input Path of pad NAND_DATA03
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field Select 1 of 3 iomux modes to be used for pad: NAND_DATA03 000 **ALT0_RAWNAND_DATA03** — Select mux mode: ALT0 mux port: DATA03 of instance: RAWNAND 001 **ALT1_QSPI_A_DATA3** — Select mux mode: ALT1 mux port: A_DATA3 of instance: QSPI 101 **ALT5_GPIO3_IO09** — Select mux mode: ALT5 mux port: IO09 of instance: GPIO3

8.2.5.67 SW_MUX_CTL_PAD_NAND_DATA04 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_NAND_DATA04)

SW_MUX_CTL Register

Address: 3033_0000h base + 11Ch offset = 3033_011Ch



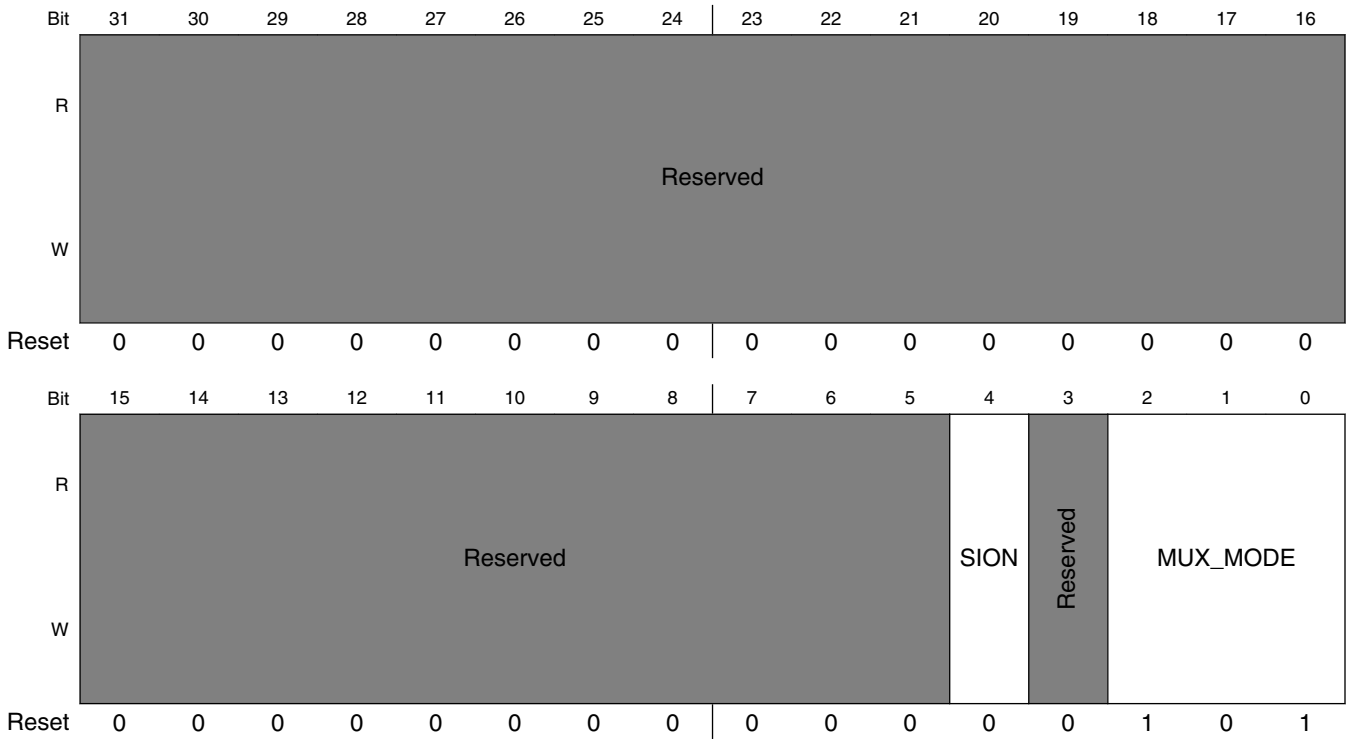
IOMUXC_SW_MUX_CTL_PAD_NAND_DATA04 field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field Force the select mux mode Input path no matter of MUX_MODE functionality 0 **SION_DISABLED** — Input Path of pad NAND_DATA04 is determined by functionality 1 **SION_ENABLED** — Force Input Path of pad NAND_DATA04
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field Select 1 of 3 iomux modes to be used for pad: NAND_DATA04 000 **ALT0_RAWNAND_DATA04** — Select mux mode: ALT0 mux port: DATA04 of instance: RAWNAND 001 **ALT1_QSPI_B_DATA0** — Select mux mode: ALT1 mux port: B_DATA0 of instance: QSPI 101 **ALT5_GPIO3_IO10** — Select mux mode: ALT5 mux port: IO10 of instance: GPIO3

8.2.5.68 SW_MUX_CTL_PAD_NAND_DATA05 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_NAND_DATA05)

SW_MUX_CTL Register

Address: 3033_0000h base + 120h offset = 3033_0120h



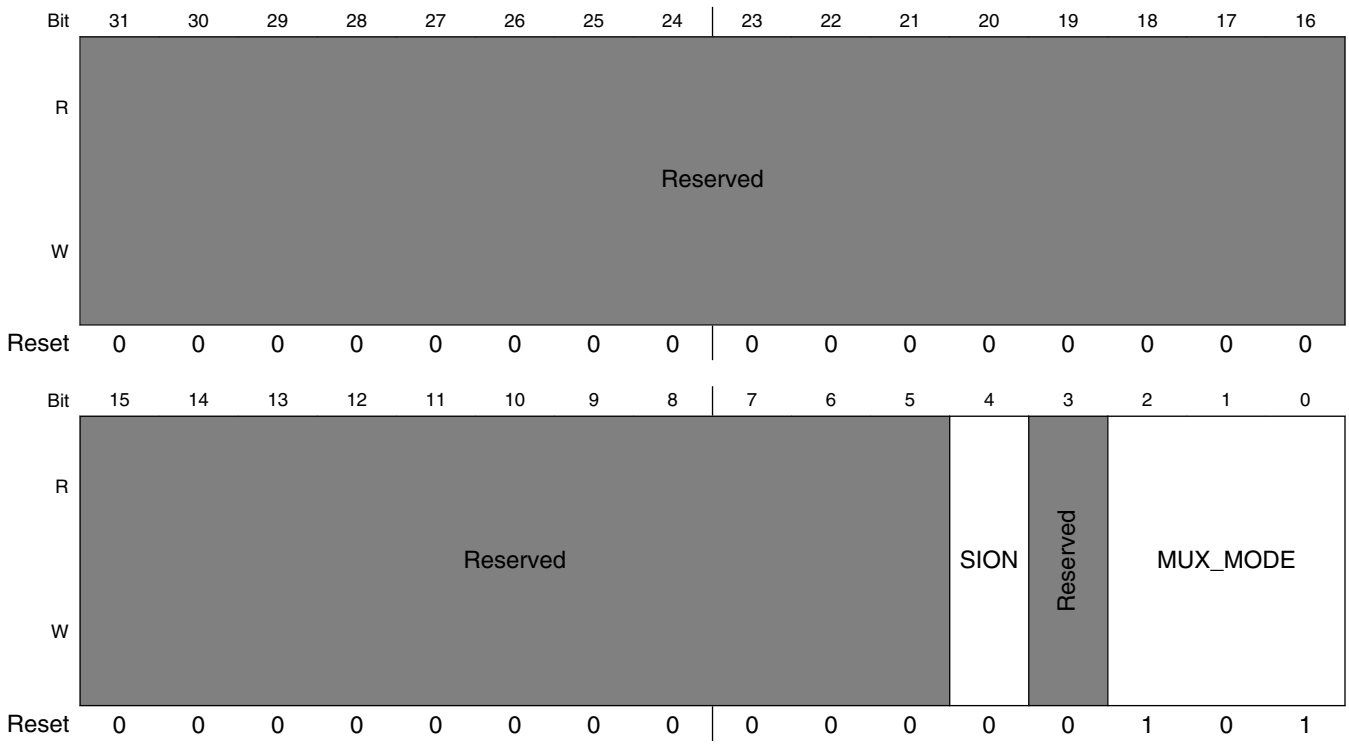
IOMUXC_SW_MUX_CTL_PAD_NAND_DATA05 field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field Force the select mux mode Input path no matter of MUX_MODE functionality 0 **SION_DISABLED** — Input Path of pad NAND_DATA05 is determined by functionality 1 **SION_ENABLED** — Force Input Path of pad NAND_DATA05
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field Select 1 of 3 iomux modes to be used for pad: NAND_DATA05 000 **ALT0_RAWNAND_DATA05** — Select mux mode: ALT0 mux port: DATA05 of instance: RAWNAND 001 **ALT1_QSPI_B_DATA1** — Select mux mode: ALT1 mux port: B_DATA1 of instance: QSPI 101 **ALT5_GPIO3_IO11** — Select mux mode: ALT5 mux port: IO11 of instance: GPIO3

8.2.5.69 SW_MUX_CTL_PAD_NAND_DATA06 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_NAND_DATA06)

SW_MUX_CTL Register

Address: 3033_0000h base + 124h offset = 3033_0124h



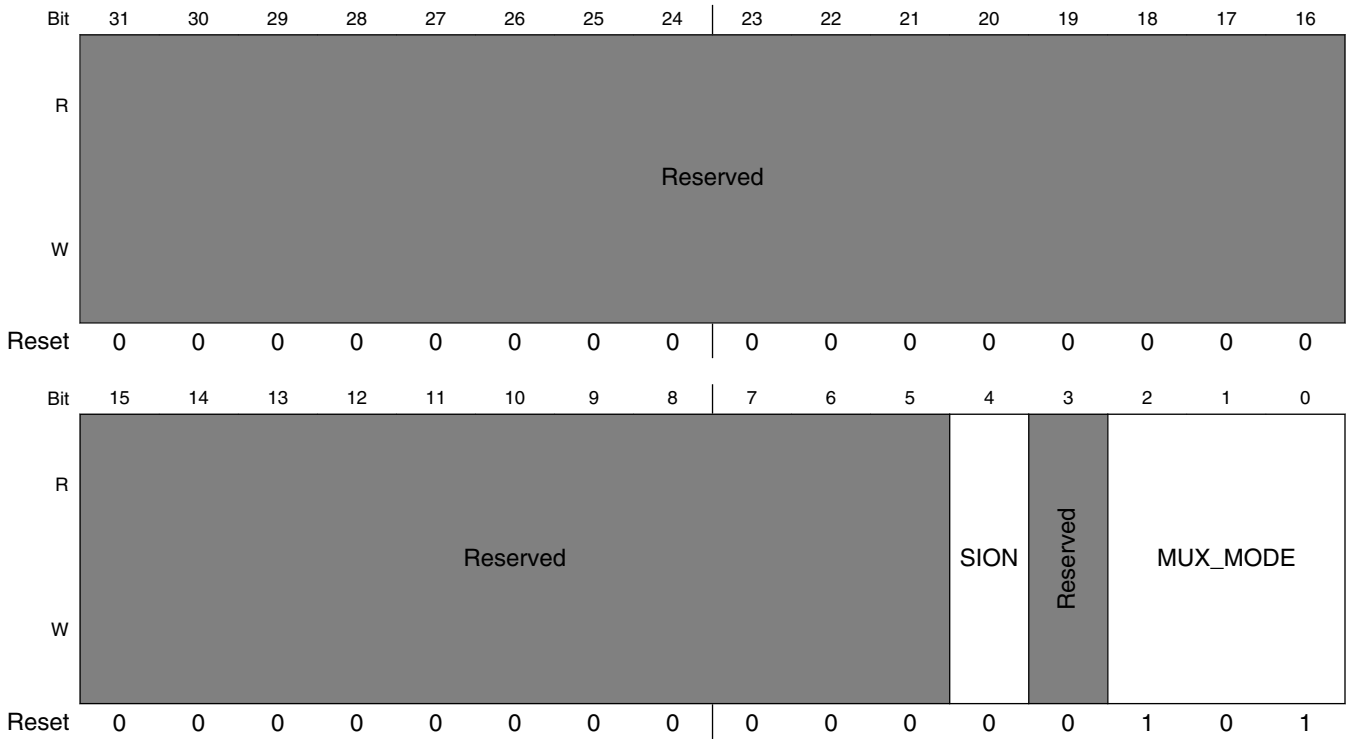
IOMUXC_SW_MUX_CTL_PAD_NAND_DATA06 field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field Force the select mux mode Input path no matter of MUX_MODE functionality 0 **SION_DISABLED** — Input Path of pad NAND_DATA06 is determined by functionality 1 **SION_ENABLED** — Force Input Path of pad NAND_DATA06
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field Select 1 of 3 iomux modes to be used for pad: NAND_DATA06 000 **ALT0_RAWNAND_DATA06** — Select mux mode: ALT0 mux port: DATA06 of instance: RAWNAND 001 **ALT1_QSPI_B_DATA2** — Select mux mode: ALT1 mux port: B_DATA2 of instance: QSPI 101 **ALT5_GPIO3_IO12** — Select mux mode: ALT5 mux port: IO12 of instance: GPIO3

8.2.5.70 SW_MUX_CTL_PAD_NAND_DATA07 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_NAND_DATA07)

SW_MUX_CTL Register

Address: 3033_0000h base + 128h offset = 3033_0128h



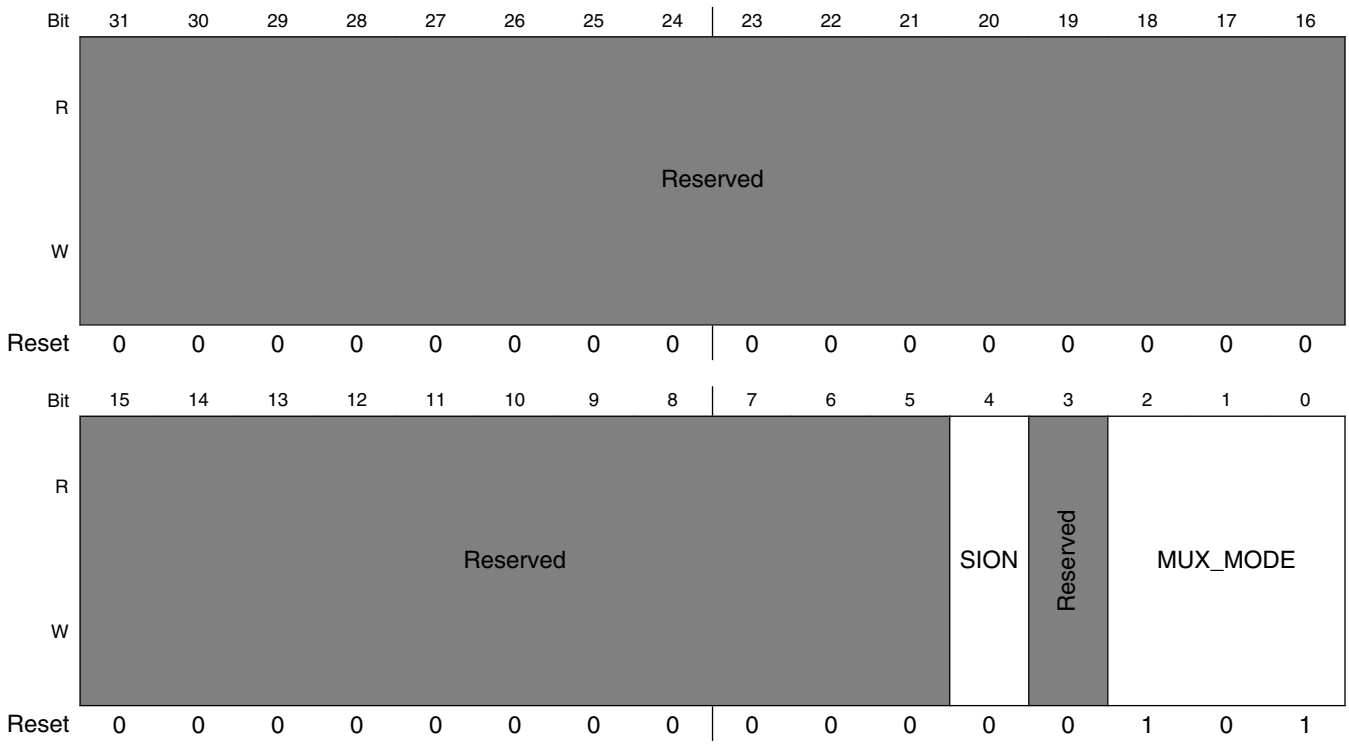
IOMUXC_SW_MUX_CTL_PAD_NAND_DATA07 field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field Force the select mux mode Input path no matter of MUX_MODE functionality 0 **SION_DISABLED** — Input Path of pad NAND_DATA07 is determined by functionality 1 **SION_ENABLED** — Force Input Path of pad NAND_DATA07
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field Select 1 of 3 iomux modes to be used for pad: NAND_DATA07 000 **ALT0_RAWNAND_DATA07** — Select mux mode: ALT0 mux port: DATA07 of instance: RAWNAND 001 **ALT1_QSPI_B_DATA3** — Select mux mode: ALT1 mux port: B_DATA3 of instance: QSPI 101 **ALT5_GPIO3_IO13** — Select mux mode: ALT5 mux port: IO13 of instance: GPIO3

8.2.5.71 SW_MUX_CTL_PAD_NAND_DQS SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_NAND_DQS)

SW_MUX_CTL Register

Address: 3033_0000h base + 12Ch offset = 3033_012Ch



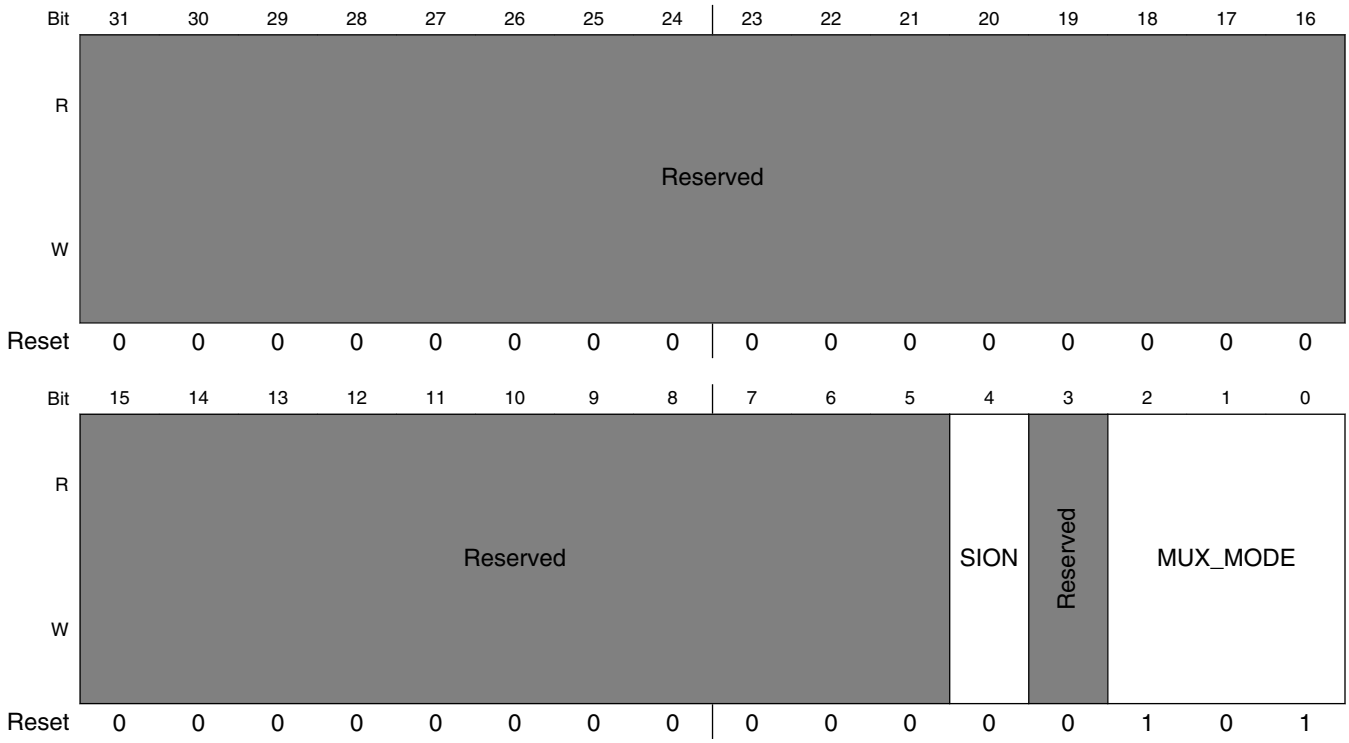
IOMUXC_SW_MUX_CTL_PAD_NAND_DQS field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field Force the select mux mode Input path no matter of MUX_MODE functionality 0 **SION_DISABLED** — Input Path of pad NAND_DQS is determined by functionality 1 **SION_ENABLED** — Force Input Path of pad NAND_DQS
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field Select 1 of 3 iomux modes to be used for pad: NAND_DQS 000 **ALT0_RAWNAND_DQS** — Select mux mode: ALT0 mux port: DQS of instance: RAWNAND 001 **ALT1_QSPI_A_DQS** — Select mux mode: ALT1 mux port: A_DQS of instance: QSPI 101 **ALT5_GPIO3_IO14** — Select mux mode: ALT5 mux port: IO14 of instance: GPIO3

8.2.5.72 SW_MUX_CTL_PAD_NAND_RE_B SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_NAND_RE_B)

SW_MUX_CTL Register

Address: 3033_0000h base + 130h offset = 3033_0130h



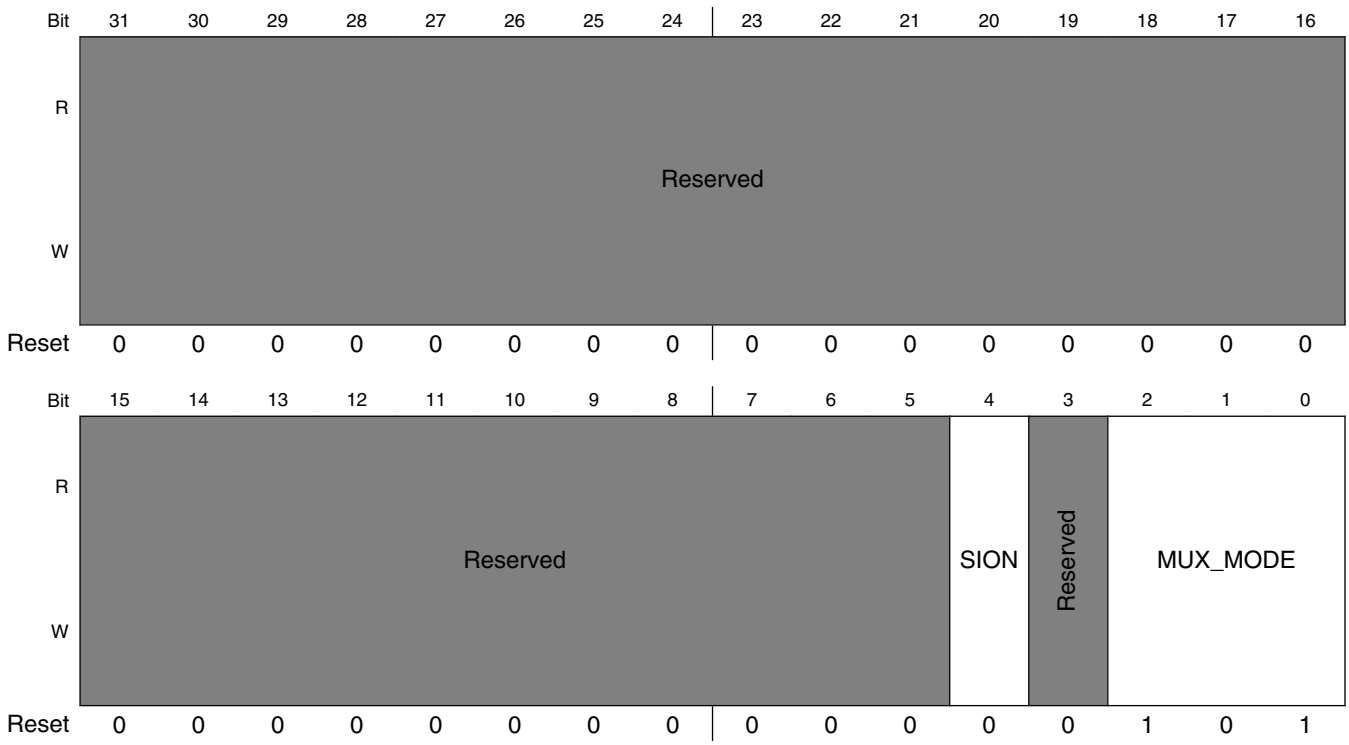
IOMUXC_SW_MUX_CTL_PAD_NAND_RE_B field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field Force the select mux mode Input path no matter of MUX_MODE functionality 0 **SION_DISABLED** — Input Path of pad NAND_RE_B is determined by functionality 1 **SION_ENABLED** — Force Input Path of pad NAND_RE_B
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field Select 1 of 3 iomux modes to be used for pad: NAND_RE_B 000 **ALT0_RAWNAND_RE_B** — Select mux mode: ALT0 mux port: RE_B of instance: RAWNAND 001 **ALT1_QSPI_B_DQS** — Select mux mode: ALT1 mux port: B_DQS of instance: QSPI 101 **ALT5_GPIO3_IO15** — Select mux mode: ALT5 mux port: IO15 of instance: GPIO3

8.2.5.73 SW_MUX_CTL_PAD_NAND_READY_B SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_NAND_READY_B)

SW_MUX_CTL Register

Address: 3033_0000h base + 134h offset = 3033_0134h



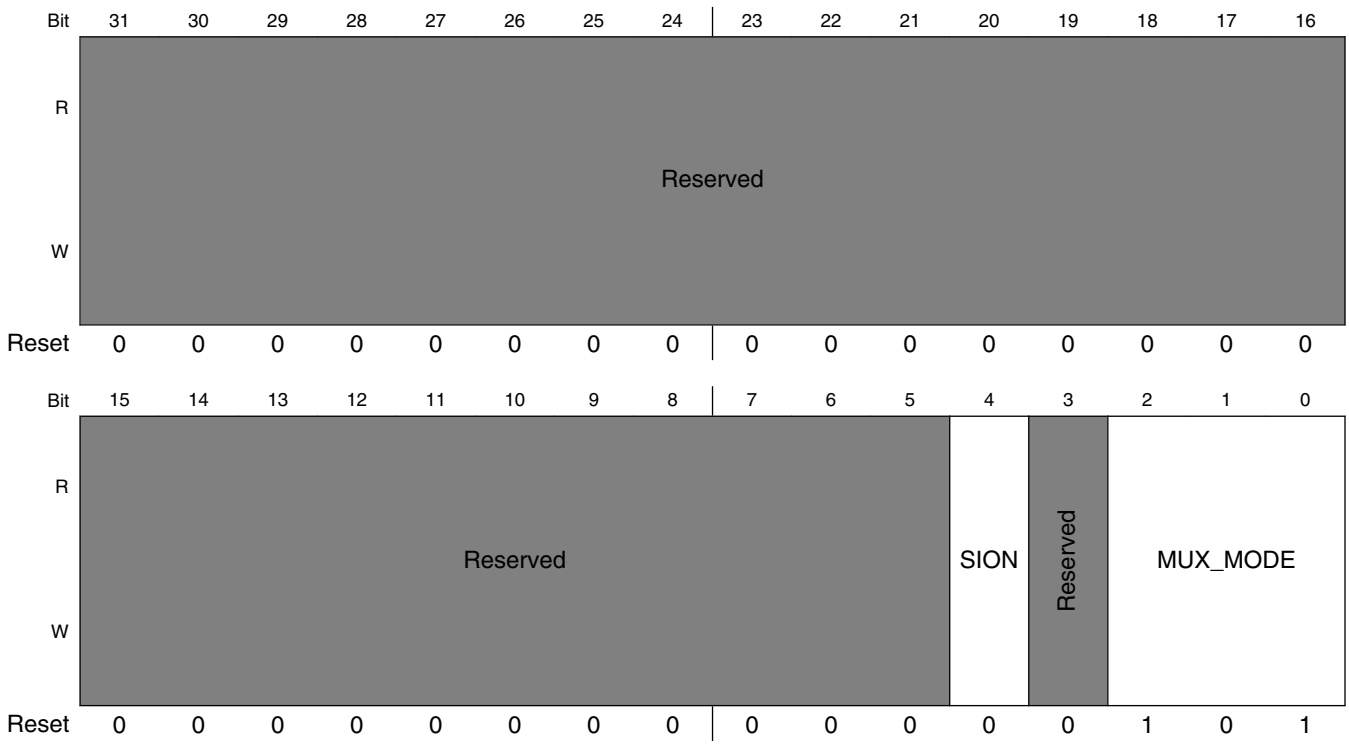
IOMUXC_SW_MUX_CTL_PAD_NAND_READY_B field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field Force the select mux mode Input path no matter of MUX_MODE functionality 0 **SION_DISABLED** — Input Path of pad NAND_READY_B is determined by functionality 1 **SION_ENABLED** — Force Input Path of pad NAND_READY_B
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field Select 1 of 2 iomux modes to be used for pad: NAND_READY_B 000 **ALT0_RAWNAND_READY_B** — Select mux mode: ALT0 mux port: READY_B of instance: RAWNAND 101 **ALT5_GPIO3_IO16** — Select mux mode: ALT5 mux port: IO16 of instance: GPIO3

8.2.5.74 SW_MUX_CTL_PAD_NAND_WE_B SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_NAND_WE_B)

SW_MUX_CTL Register

Address: 3033_0000h base + 138h offset = 3033_0138h



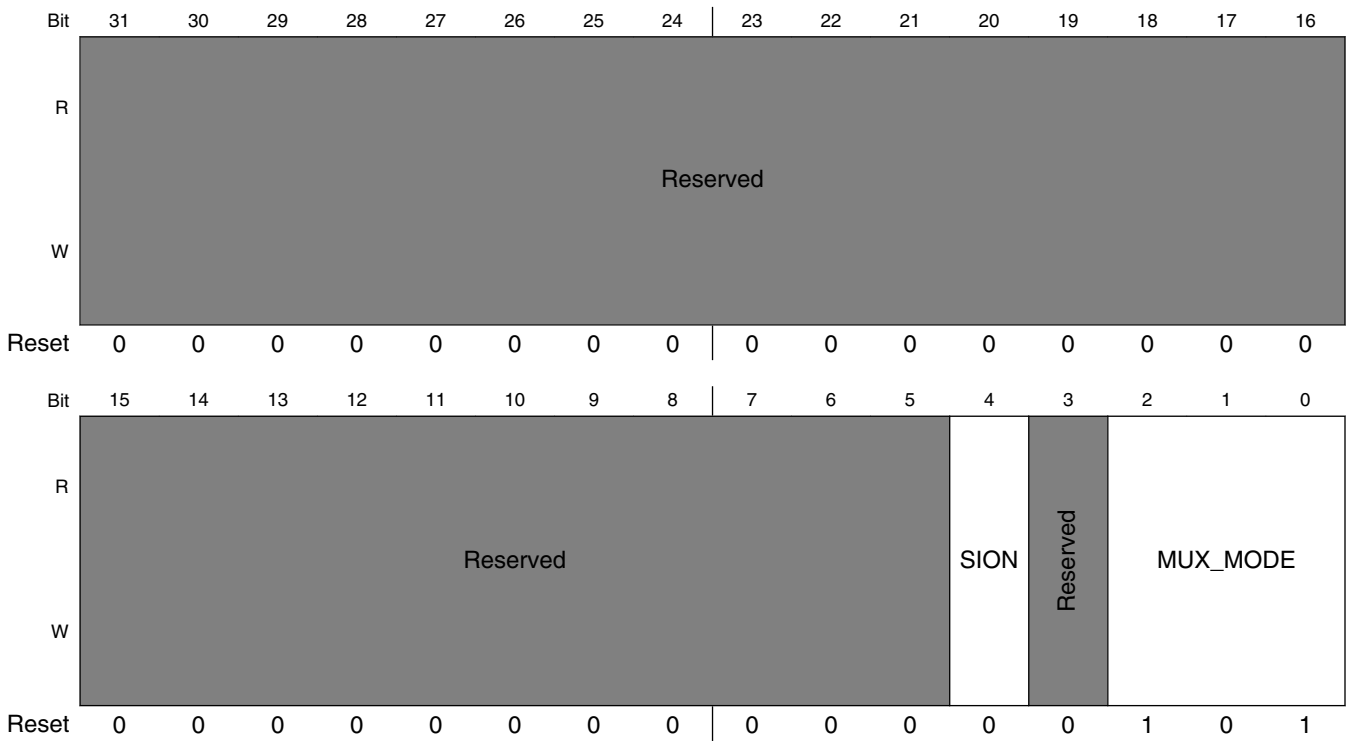
IOMUXC_SW_MUX_CTL_PAD_NAND_WE_B field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field Force the select mux mode Input path no matter of MUX_MODE functionality 0 **SION_DISABLED** — Input Path of pad NAND_WE_B is determined by functionality 1 **SION_ENABLED** — Force Input Path of pad NAND_WE_B
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field Select 1 of 2 iomux modes to be used for pad: NAND_WE_B 000 **ALT0_RAWNAND_WE_B** — Select mux mode: ALT0 mux port: WE_B of instance: RAWNAND 101 **ALT5_GPIO3_IO17** — Select mux mode: ALT5 mux port: IO17 of instance: GPIO3

8.2.5.75 SW_MUX_CTL_PAD_NAND_WP_B SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_NAND_WP_B)

SW_MUX_CTL Register

Address: 3033_0000h base + 13Ch offset = 3033_013Ch



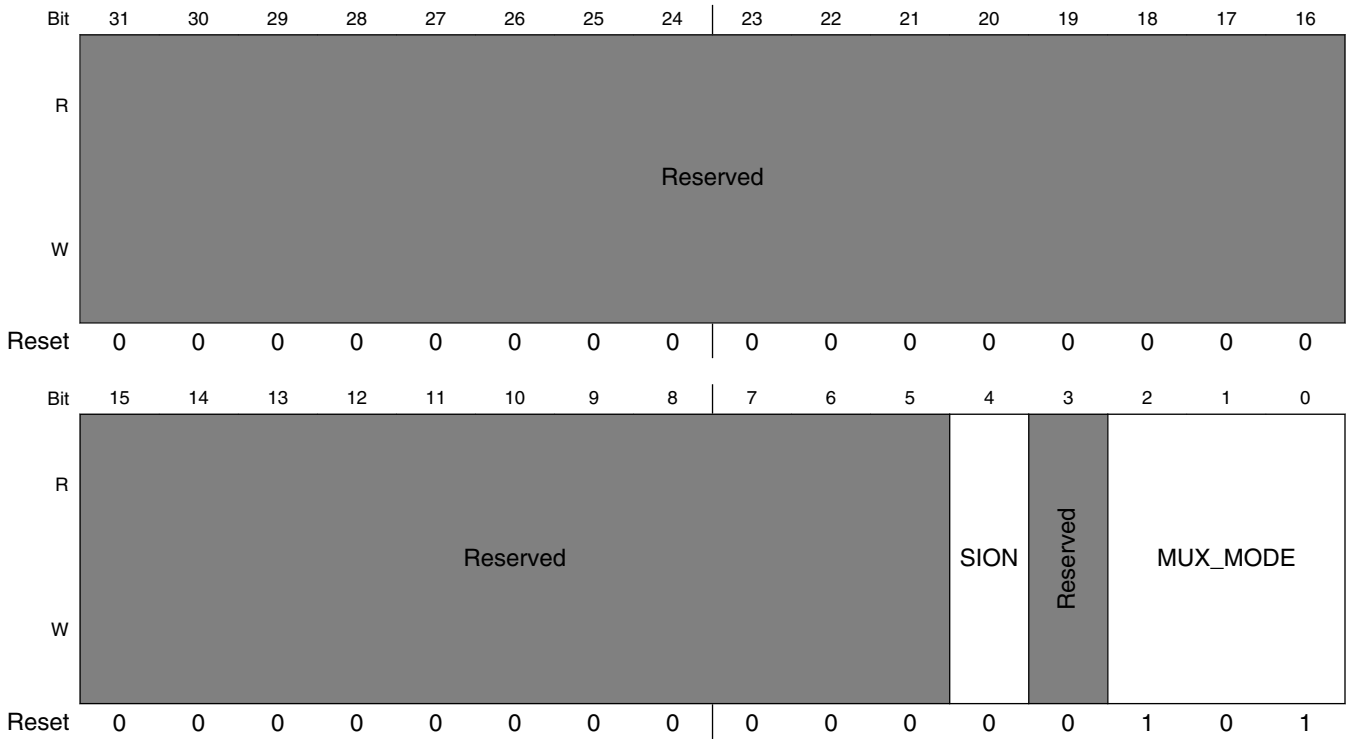
IOMUXC_SW_MUX_CTL_PAD_NAND_WP_B field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field Force the select mux mode Input path no matter of MUX_MODE functionality 0 **SION_DISABLED** — Input Path of pad NAND_WP_B is determined by functionality 1 **SION_ENABLED** — Force Input Path of pad NAND_WP_B
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field Select 1 of 2 iomux modes to be used for pad: NAND_WP_B 000 **ALT0_RAWNAND_WP_B** — Select mux mode: ALT0 mux port: WP_B of instance: RAWNAND 101 **ALT5_GPIO3_IO18** — Select mux mode: ALT5 mux port: IO18 of instance: GPIO3

8.2.5.76 SW_MUX_CTL_PAD_SAI5_RXFS SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_SAI5_RXFS)

SW_MUX_CTL Register

Address: 3033_0000h base + 140h offset = 3033_0140h



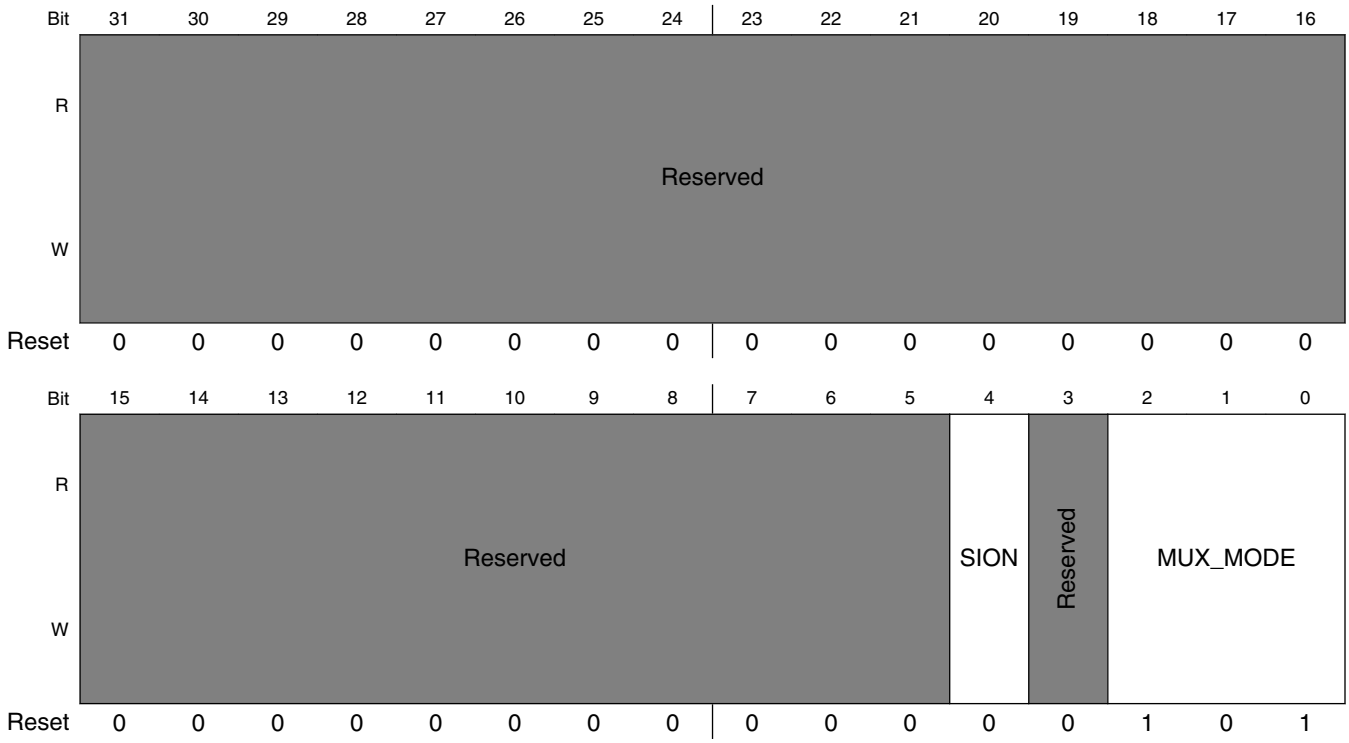
IOMUXC_SW_MUX_CTL_PAD_SAI5_RXFS field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field Force the select mux mode Input path no matter of MUX_MODE functionality 0 **SION_DISABLED** — Input Path of pad SAI5_RXFS is determined by functionality 1 **SION_ENABLED** — Force Input Path of pad SAI5_RXFS
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field Select 1 of 3 iomux modes to be used for pad: SAI5_RXFS 000 **ALT0_SAI5_RX_SYNC** — Select mux mode: ALT0 mux port: RX_SYNC of instance: SAI5 001 **ALT1_SAI1_TX_DATA0** — Select mux mode: ALT1 mux port: TX_DATA0 of instance: SAI1 101 **ALT5_GPIO3_IO19** — Select mux mode: ALT5 mux port: IO19 of instance: GPIO3

8.2.5.77 SW_MUX_CTL_PAD_SAI5_RXC SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_SAI5_RXC)

SW_MUX_CTL Register

Address: 3033_0000h base + 144h offset = 3033_0144h



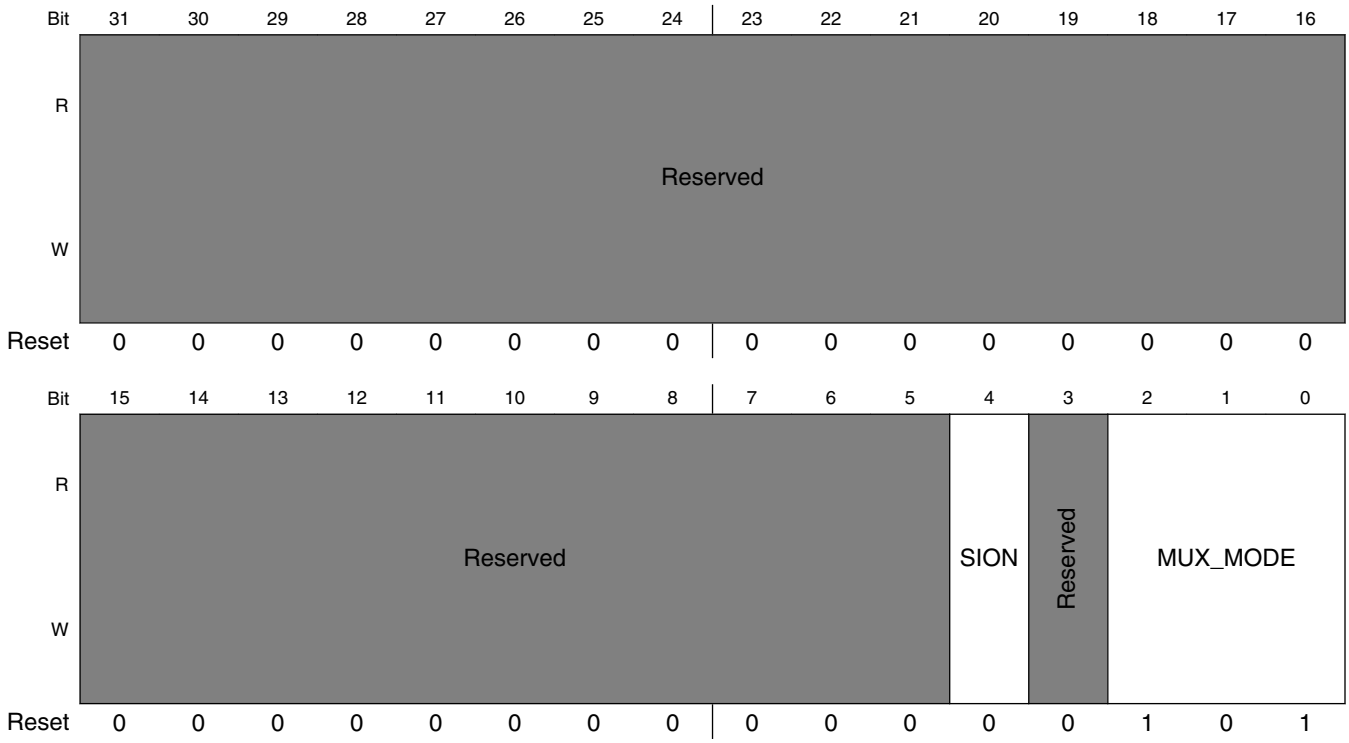
IOMUXC_SW_MUX_CTL_PAD_SAI5_RXC field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field Force the select mux mode Input path no matter of MUX_MODE functionality 0 **SION_DISABLED** — Input Path of pad SAI5_RXC is determined by functionality 1 **SION_ENABLED** — Force Input Path of pad SAI5_RXC
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field Select 1 of 3 iomux modes to be used for pad: SAI5_RXC 000 **ALT0_SAI5_RX_BCLK** — Select mux mode: ALT0 mux port: RX_BCLK of instance: SAI5 001 **ALT1_SAI1_TX_DATA1** — Select mux mode: ALT1 mux port: TX_DATA1 of instance: SAI1 101 **ALT5_GPIO3_IO20** — Select mux mode: ALT5 mux port: IO20 of instance: GPIO3

8.2.5.78 SW_MUX_CTL_PAD_SAI5_RXD0 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_SAI5_RXD0)

SW_MUX_CTL Register

Address: 3033_0000h base + 148h offset = 3033_0148h



IOMUXC_SW_MUX_CTL_PAD_SAI5_RXD0 field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field Force the select mux mode Input path no matter of MUX_MODE functionality 0 **SION_DISABLED** — Input Path of pad SAI5_RXD0 is determined by functionality 1 **SION_ENABLED** — Force Input Path of pad SAI5_RXD0
3 -	This field is reserved. Reserved

8.3 General Purpose Input/Output (GPIO)

8.3.1 Overview

The GPIO general-purpose input/output peripheral provides dedicated general-purpose pins that can be configured as either inputs or outputs.

When configured as an output, it is possible to write to an internal register to control the state driven on the output pin. When configured as an input, it is possible to detect the state of the input by reading the state of an internal register. In addition, the GPIO peripheral can produce CORE interrupts.

The GPIO is one of the blocks controlling the IOMUX of the chip.

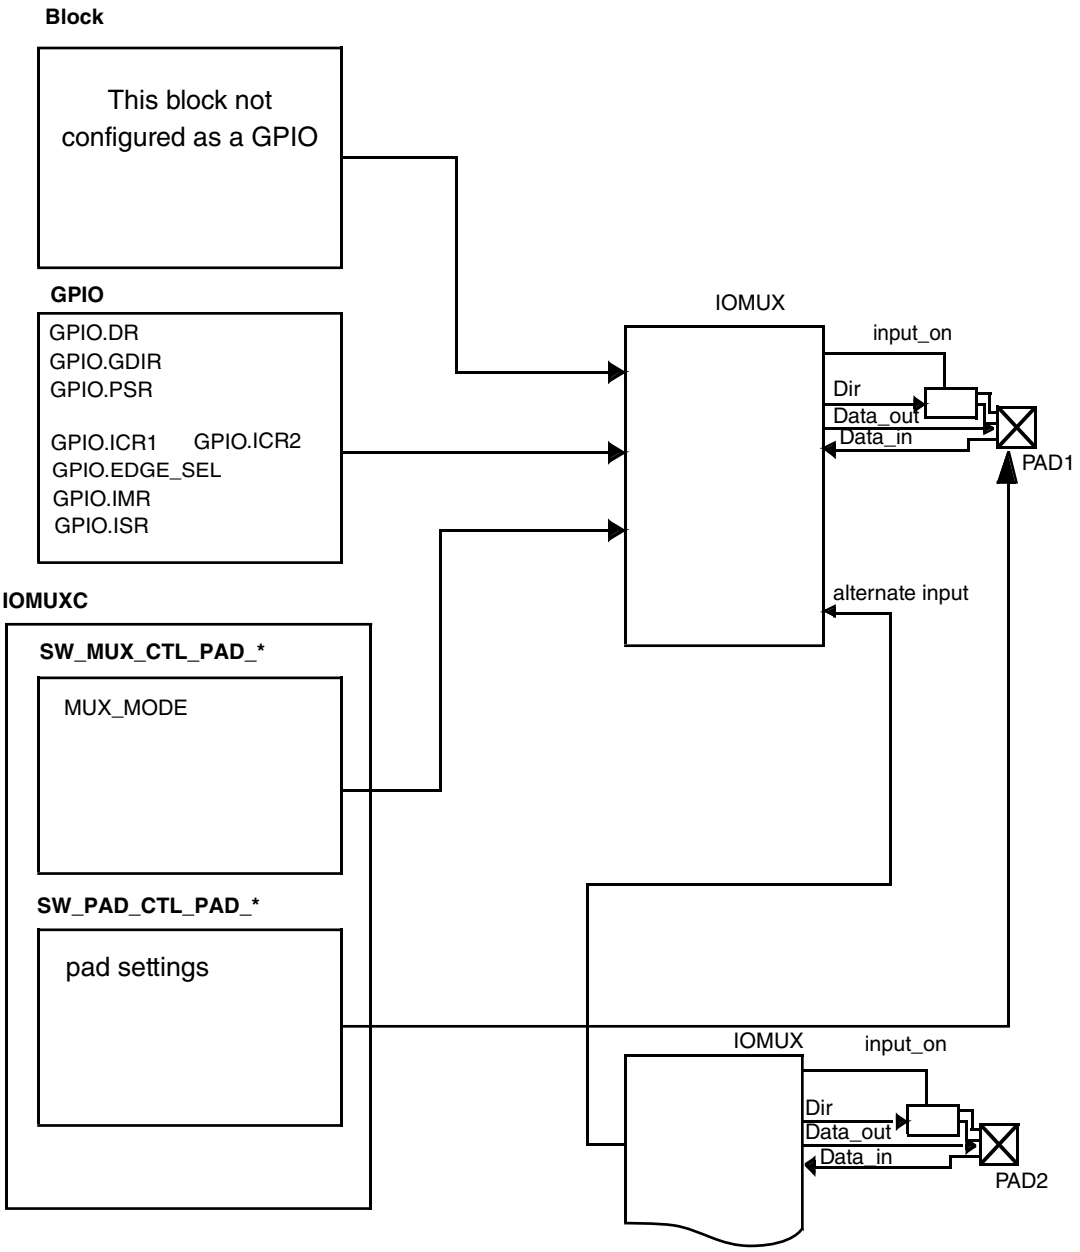

Figure 8-4. Chip IOMUX Scheme

The GPIO functionality is provided through eight registers, an edge-detect circuit, and interrupt generation logic.

The eight registers are:

- Data register (GPIO_DR)
- GPIO direction register (GPIO_GDIR)
- Pad sample register (GPIO_PSR)
- Interrupt control registers (GPIO_ICR1, GPIO_ICR2)

- Edge select register (GPIO_EDGE_SEL)
- Interrupt mask register (GPIO_IMR)
- Interrupt status register (GPIO_ISR)

These registers are described in detail in GPIO Memory Map/Register Definition.

Each GPIO input has a dedicated edge-detect circuit which can be configured through software to detect rising edges, falling edges, logic low-levels or logic high-levels on the input signals. The outputs of the edge detect circuits are optionally masked by setting the corresponding bit in the interrupt mask register (GPIO_IMR). These qualified outputs are OR'ed together to generate two one-bit interrupt lines:

- Combined interrupt indication for GPIOx signals 0 - 15
- Combined interrupt indication for GPIOx signals 16 - 31

In addition, GPIO1 provides visibility to each of its 8 low order interrupt sources (i.e. GPIO1 interrupt n, for n = 0 – 7). However, individual interrupt indications from other GPIOx are not available.

The GPIO edge detection is described further in Interrupt Control Unit.

The GPIO's overall functionality is described further in GPIO Functional Description.

8.3.1.1 Block Diagram

The GPIO subsystem contains multiple GPIO blocks, which can generate and control up to 32 signals for general purpose.

A block diagram of the GPIO is shown in Figure 8-5

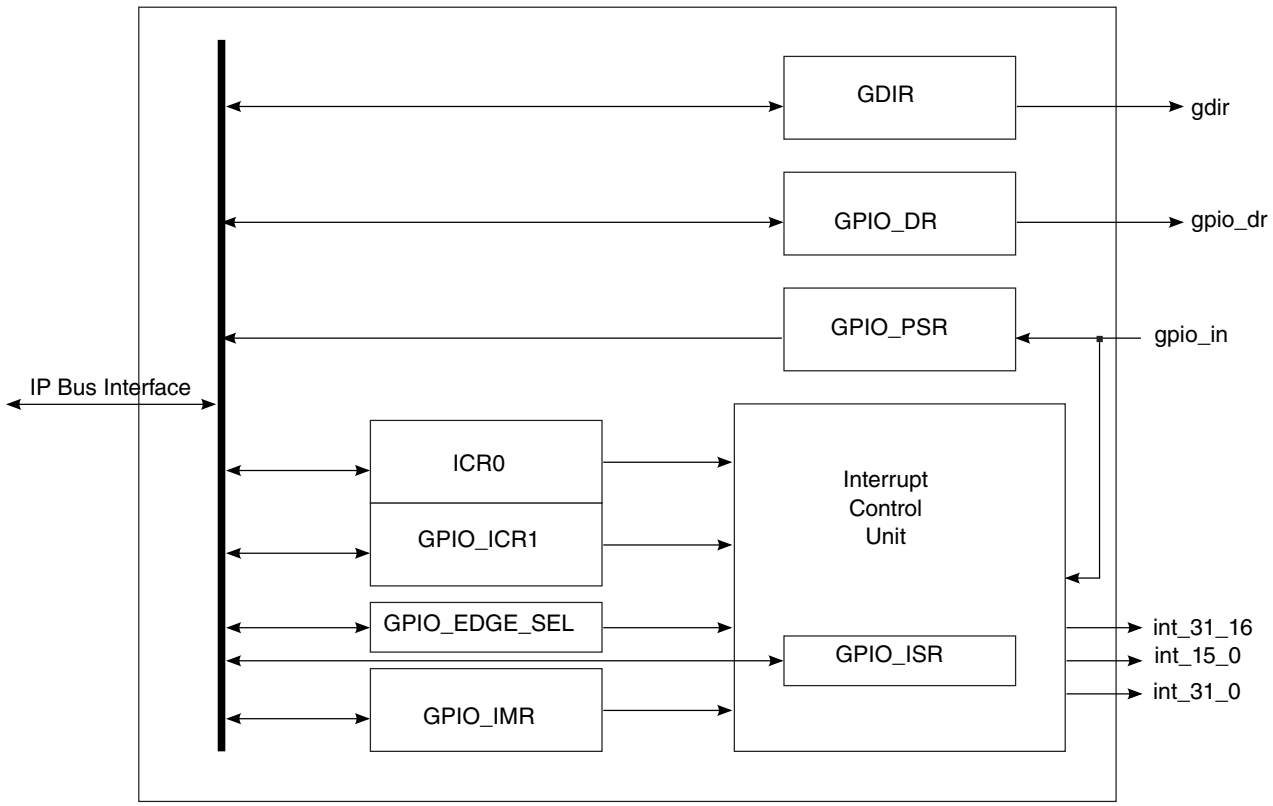

Figure 8-5. GPIO Block Diagram

8.3.1.2 Features

The GPIO includes the following features:

- General purpose input/output logic capabilities:
  - Drives specific data to output using the data register (GPIO_DR)
  - Controls the direction of the signal using the GPIO direction register (GPIO_GDIR)
  - Enables the core to sample the status of the corresponding inputs by reading the pad sample register (GPIO_PSR).
- GPIO interrupt capabilities:
  - Supports up to 32 interrupts
  - Identifies interrupt edges
  - Generates three active-high interrupts to the SoC interrupt controller

8.3.2 Clocks

The table found here describes the clock sources for GPIO.

Please see the clock controller Module for clock setting, configuration and gating information.

Table 8-2. GPIO Clocks

Clock name	Clock Root	Description
ipg_clk_s	ipg_clk_root	Peripheral access clock

8.3.3 GPIO Functional Description

This section provides a complete functional description of the block.

8.3.3.1 GPIO Function

A GPIO signal can operate as a general-purpose input/output when the IOMUX is set to GPIO mode. Each GPIO signal may be independently configured as either an input or an output using the GPIO direction register (GPIO_GDIR).

When configured as an output (GPIO_GDIR bit = 1), the value in the data bit in the GPIO data register (GPIO_DR) is driven on the corresponding GPIO line. When a signal is configured as an input (GPIO_GDIR bit = 0), the state of the input can be read from the corresponding GPIO_PSR bit.

8.3.3.2 GPIO Programming

8.3.3.2.1 GPIO Read Mode

The programming sequence for reading input signals should be as follows:

1. Configure IOMUX to select GPIO mode (Via IOMUX Controller (IOMUXC)).
2. Configure GPIO direction register to input (GPIO_GDIR[GDIR] set to 0b).
3. Read value from data reg*ister*/pad status register.

A pseudocode description to read [input3:input0] values is as follows:

```
// SET INPUTS TO GPIO MODE.
write sw_mux_ctl_<input0>_<input1>_<input2>_<input3>, 32'h00000000
// SET GDIR TO INPUT.
write GDIR[31:4,input3_bit, input2_bit, input1_bit, input0_bit,] 32'hxxxxxxx0
// READ INPUT VALUE FROM DR.
read DR
// READ INPUT VALUE FROM PSR.
read PSR
```

NOTE

While the GPIO direction is set to input (GPIO_GDIR = 0), a read access to GPIO_DR does not return GPIO_DR data. Instead, it returns the GPIO_PSR data, which is the corresponding input signal value.

8.3.3.2.2 GPIO Write Mode

The programming sequence for driving output signals should be as follows:

1. Configure IOMUX to select GPIO mode (Via IOMUXC), also enable SION if need to read loopback pad value through PSR
2. Configure GPIO direction register to output (GPIO_GDIR[GDIR] set to 1b).
3. Write value to data register (GPIO_DR).

A pseudocode description to drive 4'b0101 on [output3:output0] is as follows:

```
// SET PADS TO GPIO MODE VIA IOMUX.
write sw_mux_ctl_pad_<output[0-3]>.mux_mode, <GPIO_MUX_MODE>
// Enable loopback so we can capture pad value into PSR in output mode
write sw_mux_ctl_pad_<output[0-3]>.sion, 1
// SET GDIR=1 TO OUTPUT BITS.
write GDIR[31:4,output3_bit,output2_bit, output1_bit, output0_bit,] 32'hxxxxxxxF
// WRITE OUTPUT VALUE=4'b0101 TO DR.
write DR, 32'hxxxxxxx5
// READ OUTPUT VALUE FROM PSR ONLY.
read_cmp PSR, 32'hxxxxxxx5
```

8.3.3.3 Interrupt Control Unit

In addition to the general-purpose input/output function, the edge-detect logic in the GPIO peripheral reflects whether a transition has occurred on a given GPIO signal that is configured as an input (GDIR bit = 0). The interrupt control registers (GPIO_ICR1 and GPIO_ICR2) may be used to independently configure the interrupt condition of each input signal (low-to-high transition, high-to-low transition, low, or high). For information about GPIO_ICR1 and GPIO_ICR2 settings, see GPIO Memory Map/Register Definition.

The interrupt control unit is built of 32 interrupt control subunits, where each subunit handles a single interrupt line.

8.3.4 GPIO Memory Map/Register Definition

There are eight 32-bit GPIO registers. All registers are accessible from the IP interface. Only 32-bit access is supported.

The GPIO memory map is shown in the following table.

GPIO memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3020_0000	GPIO data register (GPIO1_DR)	32	R/W	0000_0000h	8.3.4.1/ 1808
3020_0004	GPIO direction register (GPIO1_GDIR)	32	R/W	0000_0000h	8.3.4.2/ 1809
3020_0008	GPIO pad status register (GPIO1_PSR)	32	R	0000_0000h	8.3.4.3/ 1809
3020_000C	GPIO interrupt configuration register1 (GPIO1_ICR1)	32	R/W	0000_0000h	8.3.4.4/ 1810
3020_0010	GPIO interrupt configuration register2 (GPIO1_ICR2)	32	R/W	0000_0000h	8.3.4.5/ 1814
3020_0014	GPIO interrupt mask register (GPIO1_IMR)	32	R/W	0000_0000h	8.3.4.6/ 1817
3020_0018	GPIO interrupt status register (GPIO1_ISR)	32	w1c	0000_0000h	8.3.4.7/ 1818
3020_001C	GPIO edge select register (GPIO1_EDGE_SEL)	32	R/W	0000_0000h	8.3.4.8/ 1819
3021_0000	GPIO data register (GPIO2_DR)	32	R/W	0000_0000h	8.3.4.1/ 1808
3021_0004	GPIO direction register (GPIO2_GDIR)	32	R/W	0000_0000h	8.3.4.2/ 1809
3021_0008	GPIO pad status register (GPIO2_PSR)	32	R	0000_0000h	8.3.4.3/ 1809
3021_000C	GPIO interrupt configuration register1 (GPIO2_ICR1)	32	R/W	0000_0000h	8.3.4.4/ 1810
3021_0010	GPIO interrupt configuration register2 (GPIO2_ICR2)	32	R/W	0000_0000h	8.3.4.5/ 1814
3021_0014	GPIO interrupt mask register (GPIO2_IMR)	32	R/W	0000_0000h	8.3.4.6/ 1817
3021_0018	GPIO interrupt status register (GPIO2_ISR)	32	w1c	0000_0000h	8.3.4.7/ 1818
3021_001C	GPIO edge select register (GPIO2_EDGE_SEL)	32	R/W	0000_0000h	8.3.4.8/ 1819

GPIO memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3022_0000	GPIO data register (GPIO3_DR)	32	R/W	0000_0000h	8.3.4.1/ 1808
3022_0004	GPIO direction register (GPIO3_GDIR)	32	R/W	0000_0000h	8.3.4.2/ 1809

8.3.4.1 GPIO data register (GPIOx_DR)

The 32-bit GPIO_DR register stores data that is ready to be driven to the output lines. If the IOMUXC is in GPIO mode and a given GPIO direction bit is set, then the corresponding DR bit is driven to the output. If a given GPIO direction bit is cleared, then a read of GPIO_DR reflects the value of the corresponding signal.Two wait states are required in read access for synchronization.

The results of a read of a DR bit depends on the IOMUXC input mode settings and the corresponding GDIR bit as follows:

- If GDIR[*n*] is set and IOMUXC input mode is GPIO, then reading DR[*n*] returns the contents of DR[*n*].
- If GDIR[*n*] is cleared and IOMUXC input mode is GPIO, then reading DR[*n*] returns the corresponding input signal's value.
- If GDIR[*n*] is set and IOMUXC input mode is not GPIO, then reading DR[*n*] returns the contents of DR[*n*].
- If GDIR[*n*] is cleared and IOMUXC input mode is not GPIO, then reading DR[*n*] always returns zero.

GPIOx_DR field descriptions

Field	Description
DR	Data bits. This register defines the value of the GPIO output when the signal is configured as an output (GDIR[n]=1). Writes to this register are stored in a register. Reading GPIO_DR returns the value stored in the register if the signal is configured as an output (GDIR[n]=1), or the input signal's value if configured as an input (GDIR[n]=0). **NOTE:** The I/O multiplexer must be configured to GPIO mode for the GPIO_DR value to connect with the signal. Reading the data register with the input path disabled always returns a zero value.

8.3.4.2 GPIO direction register (GPIOx_GDIR)

GPIO_GDIR functions as direction control when the IOMUXC is in GPIO mode. Each bit specifies the direction of a one-bit signal. The mapping of each DIR bit to a corresponding SoC signal is determined by the SoC's pin assignment and the IOMUX table. For more details consult the IOMUXC chapter.

GPIOx_GDIR field descriptions

Field	Description
GDIR	GPIO direction bits. Bit n of this register defines the direction of the GPIO[n] signal. **NOTE:** GPIO_GDIR affects only the direction of the I/O signal when the corresponding bit in the I/O MUX is configured for GPIO. 0 **INPUT** — GPIO is configured as input. 1 **OUTPUT** — GPIO is configured as output.

8.3.4.3 GPIO pad status register (GPIOx_PSR)

GPIO_PSR is a read-only register. Each bit stores the value of the corresponding input signal (as configured in the IOMUX). This register is clocked with the ipg_clk_s clock, meaning that the input signal is sampled only when accessing this location. Two wait states are required any time this register is accessed for synchronization.

Field	Description
5–4 ICR18	Interrupt configuration 2 fields. This register controls the active condition of the interrupt function for GPIO interrupt 18. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 **LOW_LEVEL** — Interrupt n is low-level sensitive. 01 **HIGH_LEVEL** — Interrupt n is high-level sensitive. 10 **RISING_EDGE** — Interrupt n is rising-edge sensitive. 11 **FALLING_EDGE** — Interrupt n is falling-edge sensitive.
3–2 ICR17	Interrupt configuration 2 fields. This register controls the active condition of the interrupt function for GPIO interrupt 17. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 **LOW_LEVEL** — Interrupt n is low-level sensitive. 01 **HIGH_LEVEL** — Interrupt n is high-level sensitive. 10 **RISING_EDGE** — Interrupt n is rising-edge sensitive. 11 **FALLING_EDGE** — Interrupt n is falling-edge sensitive.
ICR16	Interrupt configuration 2 fields. This register controls the active condition of the interrupt function for GPIO interrupt 16. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 **LOW_LEVEL** — Interrupt n is low-level sensitive. 01 **HIGH_LEVEL** — Interrupt n is high-level sensitive. 10 **RISING_EDGE** — Interrupt n is rising-edge sensitive. 11 **FALLING_EDGE** — Interrupt n is falling-edge sensitive.

8.3.4.6 GPIO interrupt mask register (GPIOx_IMR)

GPIO_IMR contains masking bits for each interrupt line.

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	IMR

GPIOx_IMR field descriptions

Field	Description
IMR	Interrupt Mask bits. This register is used to enable or disable the interrupt function on each of the 32 GPIO signals. Settings:

GPIOx_IMR field descriptions (continued)

Field	Description
	Bit IMR[n] (n=0...31) controls interrupt n as follows: 0 **MASKED** — Interrupt n is disabled. 1 **UNMASKED** — Interrupt n is enabled.

8.3.4.7 GPIO interrupt status register (GPIOx_ISR)

The GPIO_ISR functions as an interrupt status indicator. Each bit indicates whether an interrupt condition has been met for the corresponding input signal. When an interrupt condition is met (as determined by the corresponding interrupt condition register field), the corresponding bit in this register is set. Two wait states are required in read access for synchronization. One wait state is required for reset.

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	ISR																															
W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPIOx_ISR field descriptions

Field	Description
ISR	Interrupt status bits - Bit n of this register is asserted (active high) when the active condition (as determined by the corresponding ICR bit) is detected on the GPIO input and is waiting for service. The value of this register is independent of the value in GPIO_IMR. When the active condition has been detected, the corresponding bit remains set until cleared by software. Status flags are cleared by writing a 1 to the corresponding bit position.

8.3.4.8 GPIO edge select register (GPIOx_EDGE_SEL)

GPIO_EDGE_SEL may be used to override the ICR registers' configuration. If the GPIO_EDGE_SEL bit is set, then a rising edge or falling edge in the corresponding signal generates an interrupt. This register provides backward compatibility. On reset all bits are cleared (ICR is not overridden).

Address: Base address + 1Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	GPIO_EDGE_SEL																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPIOx_EDGE_SEL field descriptions

Field	Description
GPIO_EDGE_SEL	Edge select. When GPIO_EDGE_SEL[*n*] is set, the GPIO disregards the ICR[*n*] setting, and detects any edge on the corresponding input signal.

Chapter 9
External Memory

9.1 External Memory Overview

9.1.1 External Memory Overview

9.1.1.1 DRAM Interface

The chip has a single 16/32-bit DRAM controller.

The DRAM controller and PHY are licensed from SNPS. The key features of the DRAM controller and PHY include:

- LPDDR4-3200 in POP BGA package
- LPDDR4-3200, DDR4-2400, and DDR3L-1600 in Non-POP BGA package
- 32/16-bit DRAM interface
- 800MHz 128-bit AXI bus
- Up to 8GB of memory capacity
- Support various low power modes, clock and power gated operations, that are defined for i.MX 8M Quad. In addition, it shall be able to place the external DRAM into and out of its self-refresh mode as requested by different low-power operating modes

9.1.1.2 eSD/eMMC/SDIO Support

The chip has two Ultra Secured Digital Host Controller (uSDHC) modules for the SD/eMMC interface. It provides the interface between the host system and SD/SDIO/MMC cards. The key features include:

- Supports SD/SDIO standard, up to version 3.0
- Supports MMC standard, up to version 5.1
- Supports 3.3V and 1.8V operation, but does not support 1.2V operation

- Supports 1-bit / 4-bit SD and SDIO modes, 1-bit / 4-bit / 8-bit MMC modes
  - Up to 400 Mbps of data transfer for SDIO cards using 4 parallel data lines in SDR mode
  - Up to 800 Mbps of data transfer for SDIO card using 4 parallel data lines in DDR mode
  - Up to 400 Mbps of data transfer for SDXC cards using 4 parallel data lines in SDR mode
  - Up to 800 Mbps of data transfer for SDXC card using 4 parallel data lines in DDR mode
  - Up to 1600 Mbps of data transfer for MMC cards using 8 parallel data lines in SDR mode
  - Up to 3200 Mbps of data transfer for MMC cards using 8 parallel data lines in DDR mode
- One uSDHC controller (SD1) can support up to 8-bit interface, the other controller (SD2) can only support up to 4-bit interface.

9.1.1.3 Raw NAND Support

The Raw NAND Flash controller consists of three components:

- GPMI as the NAND controller pin interface
- APBH_DMA as the DMA engine that drives the GPMI module
- BCH as the 62-bit error correction hardware engine with an AXI bus master and a private connection to GPMI.

The Raw NAND Flash controller support following key features:

- 8-bit NAND FLASH, up to 4 devices supported by 4 chip-selects and 1 ganged ready/busy
- ONFI 2.x complaint, synchronous clock rate of up to 100 MHz with data rate of up to 200 MB/s
- Support ONFI NAND for Micron and Hynix and Toggle NAND for Toshiba and Samsung
- BCH62 for ECC, up to 200MB/s

9.1.1.4 Quad SPI Interface

There is one Quad Serial Peripheral Interface (QuadSPI) block that acts as an interface to one or two external serial flash devices, each with up to four bidirectional data lines. The key features include:

- Each channel can be configured as 1/2/4-bit operation
- Support both dual-channel or single-channel operation

- Support both SDR mode and DDR mode
- Support up to 80MHz SDR Mode and 50MHz DDR Mode

9.2 DRC Performance Monitor (DRC_PERF_MON)

9.2.1 Introduction

This section provides an introduction to the DDR performance monitor.

9.2.2 Functional description

The main functions of the DDR Performance Monitor include:

- Monitor the performance signals provided by DDR controller
- Sample the MRR read data (LPDDR4) or MPR read data (DDR4) after DDR controller issues an Mode register read command

9.2.2.1 Performance Counter

This module contain a number of counters. One of them is a special counter which counts "time". The rest of them are used for signal monitoring.

The special counter (COUNTER0) will be "cleared" when COUNTER0_CTRL[counter_0_clear] is set. It will start to increment if COUNTER0_CTRL[counter_0_enable] is set to high. This counter will overflow when the value reaches 0xFFFF_FFFF. Once this happens, all the counters will lock and an interrupt will be generated.

The counters 1-3 used for signal monitoring operates the same way as the special counter. They will be cleared when counter_n_clear is high, and become active when both counter_0 and counter_n are enabled and not overflowing. When active, counter_n will increase if the monitored signal is high.

The signal being monitored can be selected from the below list via counter_n_csv:

- WAQ_COUNT_0[3:0]: the number of used positions in the write queue FIFO
- WAQ_POP_0: one write granted by port arbiter
- RAQ_WCOUNT_0[3:0]: number of used positions in the read queue
- RAQ_POP_0: one read granted by port arbiter
- LPR_CREDIT_CNT[6:0]: number of available low priority read CAM slots free

- HPR_CREDIT_CNT[6:0]: number of available high priority read CAM slots free
- WR_CREDIT_CNT[6:0]: number of available write CAM slots free
- stat_ddrc_reg_selfref_type[1:0] self-refresh status and type:
  - 00 - not in self refresh
  - 11 - self-refresh by automatic
  - 10 - caused by SW/HW interface
- perf_hif_rd: asserts for every read command to the DDRC
- perf_hif_wr: asserts for every write command to the DDRC
- perf_hif_rmw: asserts for every read modify write to the DDRC
- perf_hif_hi_pri_rd: asserts for every high priority read
- perf_hpr_req_with_nocredit: asserts when there is a high priority read request not served due to no available credit
- perf_hpr_xact_when_critical: asserts for every high priority read transaction that is scheduled when the high priority queue is in critical state
- perf_lpr_req_with_nocredit: asserts when there is a low priority read request not served due to no available credit
- perf_lpr_xact_when_critical: asserts for every low priority read transaction that is scheduled when the low priority queue is in critical state
- perf_wr_xact_when_critical: asserts for every write transaction that is scheduled when the write queue is in critical state
- perf_dfi_rd_data_cycles: assert for every read data cycle
- perf_dfi_wr_data_cycles: assert for every write data cycle
- perf_rdwr_transitions: assert for every read->write or write->read transition
- perf_op_is_precharge: assert for every precharge command issued
- perf_op_is_activate: assert for every active command issued
- perf_op_is_load_mode: assert for every MRW or MRR command issued
- perf_op_is_mwr: assert for every masked write command issued
- perf_op_is_rd: assert for every read command issued
- perf_op_is_rd_activate: assert for every read active issued
- perf_op_is_refresh: assert for every refresh command issued
- perf_op_is_wr: assert for every write command issued
- perf_raw_hazard: asserts for every read-after-write collision that happens in the controller

9.2.2.2 Mode register read

DDR performance monitor will sample MRR read data (LPDDR4) or MPR read data (DDR4) after DDRC issues a mode register command.

Serial mode and parallel mode are supported for DDR4 MPR read and it can be selected via MRR_0_DATA[mrr_mode_sel].

9.2.3 Memory Map and register definition

This section includes the DRC_PERF_MON module memory map and detailed descriptions of all registers.

9.3 DDR Controller (DDRC)

9.3.1 Introduction

The DDRC (DDR Controller) is a very low power, high efficiency, low-latency and high performance memory controller for interfacing DDR based memories.

The following types of SDRAMs are supported by the DDRC:

- DDR4
- LP-DDR4

9.3.1.1 Block diagram

The following shows the block diagram for the DDR Controller.

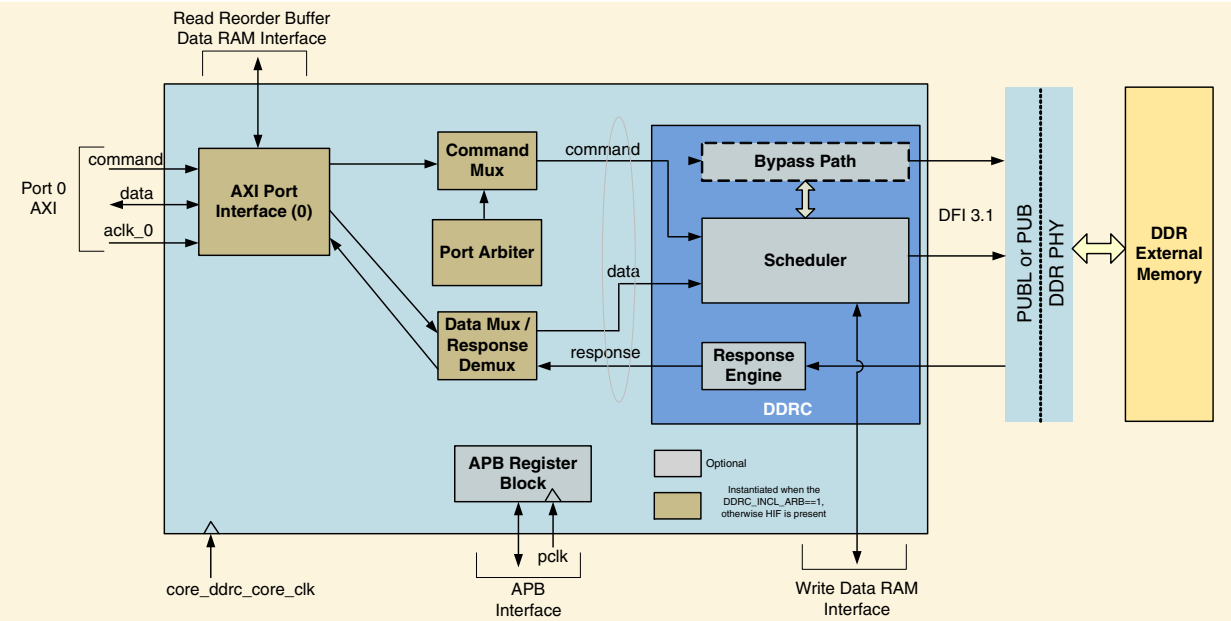

Figure 9-1. DDRC block diagram

The PUB /PUBL is the PHY Utility Block is an adaption layer between the controller and the PHY handling control function.

9.3.1.2 Features

The DDRC includes the following features:

- Direct software request control or programmable internal control for ZQ short calibration cycles
- Support for ZQ long calibration after self-refresh exit
- Direct software request control or programmable internal control for ZQ calibration cycles
- Support for ZQ Reset feature through software
- Dynamic scheduling to optimize bandwidth and latency
- Read and write buffers in fully associative CAMs, 32 each
- Delayed writes for optimum performance on SDRAM data bus
- Out of order execution of commands maximises the SDRAM efficiency
- Hardware configurable and software programmable Quality of Service (QoS) support:

    - Support for three traffic classes on read commands—high priority reads, variable priority reads and low priority reads
    - Support for two traffic classes on write commands—normal priority writes and variable priority writes
    - Support for port urgent and port throttling control
- Programmable SDRAM parameters
- Supports BL16 burst length
- Supports 1,2 memory ranks
- Control options to avoid starvation of lower priorities
- Guaranteed coherency for write-after-read (WAR) and read-after-write (RAW) hazards
- Write combine to allow multiple writes to the same address to be combined into a single write to SDRAM; supported for same starting address
- Paging policy selectable by configuration registers as any of the following:
    - Leave pages open after accesses, or
    - Close page when there are no further accesses available in the controller for that page, or
    - Auto-precharge with each access, with an optimization for page-close mode which leaves the page open after a flush for read-write and write-read collision cases
- Supports automatic SDRAM power-down entry and exit caused by lack of transaction arrival for programmable time
- Supports automatic Clock Stop entry and exit caused by lack of transaction arrival
- Supports automatic DDRC low power mode operation caused by lack of transaction arrival for programmable time via Hardware Low Power Interface
- Supports self-refresh entry and exit as follows:
    - Supports automatic self-refresh entry and exit caused by lack of transaction arrival for programmable time
    - Support for self-refresh entry and exit under software control
    - Support for self-refresh entry and exit using dedicated DDRC hardware low power interface control (similar to the AMBA 3 AXI protocol low power control interface)
- Support for dynamically changing clock frequency while in self-refresh:
    - DDR4 DLL-off mode supported
    - Shadow timing registers provided to allow fast frequency changing
- Support for explicit SDRAM mode register updates under software control
- Flexible address mapper logic to allow application specific mapping of row, column, bank, and rank bits
- Programmable support for 1T or 2T timing
- User-selectable refresh control options:
    - Controller-generated auto-refreshes at programmable average intervals

    - In multi-rank designs, an offset can be applied to each rank's refresh timer to allow rank refreshes to expire at different times (this can increase efficiency by allowing traffic to continue to other ranks while a given rank is being refreshed)
    - Ability to group up to 8 controller-generated refreshes together to be issued consecutively (this reduces the frequency of page closings, increasing overall efficiency)
    - When controller-generated refreshes are grouped, some refreshes can be issued speculatively when the controller is idle for a programmable period of time
    - Ability to disable controller-generated auto-refreshes
    - Ability to issue a refresh through direct software request
    - When LP-DDR4 is used, user-selectable ability to perform per-bank refreshes rather than all-banks refreshes
    - When DDR4 is used, fine granularity refresh can be selected
- DDR4 protocol up to DDR4-3200 speed grade (1:2 frequency ratio mode) and DDR4-2133 speed grade (1:1 frequency ratio mode) are supported by the DDRC. The following features are supported:
    - Data Bus Inversion (DBI)
    - Geardown mode may be programmed where allowed by memory and PHY specification (not supported for 1:1 frequency ratio mode)
    - Maximum power saving mode
    - Multi-purpose register (MPR) reads and writes
    - Per DRAM addressability
    - Fine granularity refresh
    - Cyclic redundancy check (CRC) with retry (not supported for 1:1 frequency ratio mode)
    - Command/address latency
    - Programmable Preamble (not supported for 1:1 frequency ratio mode)
    - 3DS with up to 8 logical ranks/DDR4-2666
- Supports Dual Data Channel, also called "Shared AC", with a common address and command bus

9.3.2 Functional description

The DDRC converts system bus transactions into memory commands on the DFI interface that are compliant with the DDR protocols. The DDRC supports both memory components and DIMMs(Dual in-line Memory Module).

Please see the block diagram at Block diagram.

The main components of the block are:

- **AXI Port Interface (XPI) block**: This block provides the interface to the application ports. It provides bus protocol handling, data buffering and reordering for read data, data bus size conversion (upsizing or downsizing), and memory burst address alignment. Read data is stored in a SRAM, read re-order buffer and returned in order, to the AXI ports. The SRAM may be instantiated as embedded memory external to the DDRC or be implemented as flops within the DDRC.
- **Port Arbiter (PA) block**: This block provides latency sensitive, priority based arbitration between the addresses issued by the XPIs (by the ports).
- **DDR Controller (DDRC) block**: This block contains a logical CAM (Content Addressable Memory), which can be synthesized using standard cells. This holds information on the commands, which is used by the scheduling algorithms to optimally schedule commands to be sent to the PHY, based on priority, bank/rank status and DDR timing constraints. A bypass path is also provided (optionally).
- **APB Register Block**: This block contains the software accessible registers.

The details on DDRC are as follows:

- Write data is stored in DDRC until its associated command is issued to the PHY.
- Read data is handled by the response engine in the DDRC and is returned in the order of scheduled read commands on the HIF.
- ECC handling is an optional function which is handled by logic modules within the DDRC in the write data path and in the response engine.

1:1 and 1:2 frequency ratios are terms used for the frequency ratio between the DDRC clock (core_ddrc_core_clk) and the memory clock.

When MEMC_PROG_FREQ_RATIO = 1 the parameter MEMC_FREQ_RATIO is tied to 2 and the HIF data bus is four times the memory data width.

The register MSTR.frequency_ratio controls whether the controller operates in 1:1 frequency ratio mode or 1:2 frequency ratio mode. When MSTR.frequency_ratio is programmed to 1 the DDRC clock rate is the same as the memory clock rate (referred to as SDR, single data rate) i.e. 1:1 frequency ratio mode. When MSTR.frequency_ratio is programmed to 0 the DDRC clock rate is one half the memory clock rate (referred to as HDR, half data rate) i.e. 1:2 frequency ratio mode.

When MEMC_PROG_FREQ_RATIO = 0 the parameter MEMC_FREQ_RATIO controls whether the controller operates in 1:1 frequency ratio mode or 1:2 frequency ratio mode. When MEMC_FREQ_RATIO=1 the DDRC clock rate is the same as the memory clock rate (referred to as SDR, single data rate) i.e. 1:1 frequency ratio mode. The HIF data bus is twice the memory data width. When MEMC_FREQ_RATIO=2 the DDRC clock rate is one half the memory clock rate (referred to as HDR, half data rate), that is, 1:2 frequency ratio mode. The HIF data bus is four times the memory data width

In the case of 1:1 frequency ratio mode, the DDRC and PHY operate at the same clock frequency and are referred to as a ‘matched frequency system’ in the DFI Specification.

For example if MEMC_PROG_FREQ_RATIO=1, in 1:1 frequency ratio mode, if the memory data width is 32 bits and the memory clock rate is 400 MHz or 800 Mbps, the HIF data bus would be 128 bits wide and only the lower half of the dfi bus is utilized. The DDRC clock rate would be 400 MHz. If the frequency ratio mode is changed to 1:2, the HIF data bus would be 128 bits wide and all of the dfi data bus is utilized. The DDRC clock rate would be 200 MHz.

For example if MEMC_PROG_FREQ_RATIO=0, in 1:1 frequency mode, if the memory data width is 32 bits and the memory clock rate is 400 MHz or 800 Mbps, the HIF data bus would be 64 bits wide and all of the dfi data bus is utilized. The DDRC clock rate would be 400 MHz. If the frequency mode is changed to 1:2, the HIF data bus would be 128 bits wide and all of the dfi data bus is utilized. The DDRC clock rate would be 200 MHz.

The terms “DFI clock” and “DFI PHY clock” are used in this document in accordance with the DFI specification:

- The DFI clock is the clock on which the DFI interface runs. It is the core_ddrc_core_clk.
- The DFI PHY clock is the SDRAM clock. In 1:1 frequency ratio, this has the same frequency as the DFI clock. In 1:2 frequency ratio, this has twice the frequency of the DFI clock.

9.3.2.1 AXI Port Interface (XPI)

The AXI protocol is burst-based with read and write request channels that specify the host ID for the request, start byte address, burst length, burst size, and burst type. This information is processed by the interface and is used subsequently by the DDRC.

The XPI interfaces the AXI application port to the DDRC and performs the following main functions:

- Read address generation
- Write address generation
- Read data generation
- Read data and response generation
- Write response generation

The XPI converts AXI bursts into read and write requests, which are forwarded to the Port Arbiter (PA). In the opposite direction, the XPI converts the responses from the DDRC into appropriate AXI responses.

The interface between XPI and PA is same as HIF (but with independent channels for read and write commands). Each AXI port can be independently configured to operate with a clock that is synchronous or asynchronous to the memory controller clock.

The AXI Specification requires that transactions must not cross a 4K address boundary. AXI compliant masters must meet this requirement. However, if a master does not comply with this AXI protocol requirement, the user can relax this restriction in the DDRC and set the boundary between 4K and 4G using the hardware parameter DDRC_AXI_ADDR_BOUNDARY.

9.3.2.1.1 Read Address Channel

The AXI read address channel has the following features:

- The read transaction can be of any length up to 256 for incremental bursts, 16 for wrapping bursts.
- The burst types supported are incremental and wrapping.
- The burst start address can be unaligned to the AXI data width boundaries
- The size of the burst can be less than the full width of the AXI data bus (also known as sub-sized transfers).

The signals on the read address channel are registered into the XPI in accordance with the AXI valid/ready handshaking protocol and are synchronous with the AXI clock (aclk).

Read requests are accepted if the request can be written into the Read Address Queue (RAQ). This is used to store all the read address requests. If DDRC_XPI_USE2RAQ_n is set to 0, there is single address queue on a given port. If DDRC_XPI_USE2RAQ_n is set to 1, there are two address queues on a given port, named Blue and Red address queues. Clock domain crossing from aclk to DDRC clock (core_ddrc_core_clk) is performed in the RAQ block. The depth of the RAQ can be configured to suit the system requirements of the user.

After registering the read address channel by the RAQ, the following operations are performed:

- Generation of new read requests is based on alignment (derived from AXI address and size), burst lengths (derived from AXI length and memory burst length), and

burst type (derived from AXI incremental or wrapping). Each AXI burst is divided into packets of length equal to the memory burst length (BL2, BL4, BL8, BL16).
- Generation of new HIF address in the case of unaligned burst and burst expansion. A burst is aligned to the memory burst boundary when:
  - A(R|W)ADDR[X]=0 if BL2
  - A(R|W)ADDR[1+X:X]=0 if BL4
  - A(R|W)ADDR[2+X:X]=0 if BL8 or
  - A(R|W)ADDR[3+X:X]=0 if BL16, Where, X is log2 of the number of data bytes in the SDRAM interface. Therefore,
  - If MEMC_DRAM_DATA_WIDTH = 8, X = 0
  - If MEMC_DRAM_DATA_WIDTH = 16, X = 1
  - If MEMC_DRAM_DATA_WIDTH = 32, X = 2 and so on

In case of an unaligned burst, the first read request is unaligned and the remaining read requests are aligned.

In general, realignment to a memory burst boundary potentially causes some data beats to be discarded (affecting bandwidth) and potentially introduces additional latency on the read data and response channel.

The arready output is defaulted to logic one and remains in logic one unless the RAQ becomes full or a WRAP burst is requested (arready is low on the next cycle after a WRAP burst is accepted). The read transaction is popped from the RAQ when it is not empty.

The XPI handles the generation of the token which is used by the DDRC for identifying the read command and corresponding data.

9.3.2.1.2 Write Address Channel

Write Address Queue (WAQ) is used to store all the addresses for write requests from a given port. There is a single queue for all AXI IDs from a given port. The write address channel behavior is similar to the read address channel.

The depth of the WAQ can be configured to suit the system requirements of the user. Write address and read address channels are independent and the ordering between the write and read requests may not be preserved.

To preserve the sequence, a higher-level protocol needs to wait for read/write response before sending the next transaction.

Transactions across the ports are independent and can be issued in any order.

The write command is not forwarded to the DDRC until the write data is collected and the strobes are evaluated.

9.3.2.1.3 Wrap Burst Expansion

A WRAP burst may be expanded by the XPI into multiple SDRAM transactions. This is also true for cases where WRAP bursts, which could be accommodated by a single transaction on the SDRAM interface. A WRAP burst is expanded into a single SDRAM transaction only in particular cases as highlighted in the tables below.

NOTE

SDRAM burst length 16 is not supported by XPI in this case. If the burst length is programmed to 16, XPI uses the value 8.

Table 9-1. MEMC_BURST_LENGTH 16 Wrap Expansion

Direction	Port Data Width	(SDRAM BurstLength8&&Quarter Burst) || (SDRAM Burst Length4&&Half Burst)|| (SDRAM BurstLength4&&Quarter Burst)	(SDRAM Burst Length16&&Quarter Burst)|| (SDRAM Burst Length8&&Half Burst)|| (SDRAM Burst Length4&& Full Burst)	(SDRAM Burst Length16&&Half Burst)|| (SDRAM Burst Length8&&Full Burst)	SDRAM Burst Length16&&Full Burst
Read	Native-Sized	N/A	Single	Single	Single
	Up-Sized	Single(onlyif araddris alignedtotheHIF burst)	Single	Single	Single
	Down-Sized	N/A	N/A	Single	Single
Write	Native-Sized	N/A	Multiple	Multiple	Single
	Up-Sized	Multiple	Multiple	Multiple	Single(onlyif awaddrisalignedtotheHIF burst)
	Down-Sized	N/A	N/A	Multiple	Single

In the tables, full burst is when:

DDR_bytes = AXI_bytes, half burst is when DDR_bytes = 2*AXI_bytes and quarter burst is when DDR_bytes = 4*AXI_bytes.

Where, DDR_bytes refers to the number of bytes transferred in a DDR burst: MSTR.burst_rdwr*2*MEMC_DRAM_DATA_WIDTH/8

AXI_bytes refers to the number of bytes transferred in an AXI burst: 2(ALEN +1)*(DDRC_PORT_DW_n/8)

As an example, in a natural-size port, with MEMC_FREQ_RATIO=1 and MEMC_BURST_LENGTH=16, when the SDRAM burst length is programmed to 8 (Burst length of 16), ALEN 7 results in a full burst.

9.3.2.1.4 Read Data and Response Channel

The XPI handles the common response interface to the DDRC to process the read data from the memory.

AXI read data and response channel has a single data storage queue (RDQ - Read Data Queue) with two clocks—AXI clock for reading and DDRC clock for writing.

Data from different IDs are stored in the same queue and are returned in the order of read address acceptance. You can configure the depth of the queue independently for each port.

The FSM handling the AXI handshake as well as the FIFO push and pop has the following features:

- Based on the information stored, filter the dummy beats
- Based on the signal hif_rdata_last, generate the rlast

The controller provides an OKAY response for the each read, except for exclusive read transactions. The DDRC provides an EXOKAY response.

SLVERR respinse may be returned for the read transactions (both normal and exclusive) for the following cases:

- ECC uncorrected error detected at the DFI
- On-chip parity address or data error
- InvalidLPDDR4 row address
- Transaction has been poisoned

NOTE

SLVERR has the highest priority.

9.3.2.1.4.1 Read Reorder Buffer

The read data can be returned from the DDRC in a different order from which the read commands are forwarded from the XPI. (due to the re-ordering of read commands in the DDRC to maximize SDRAM bandwidth).A read reorder buffer is implemented in each port to reorder the read data for that port to the same order as the order of the AXI read commands.

The read reorder buffer SRAM holds the same number of entries as the read CAM and each entry holds the read data corresponding to a DDR command. Storage for the reorder buffer can be implemented internally in the DDRC or implemented externally to the DDRC as embedded SRAM and accessed through an External RAM Interface. In either case, the control circuits for the read reorder SRAM are clocked by the DDRC clock (and not AXI clock). If implemented as embedded SRAM, a two-port SRAM is required.

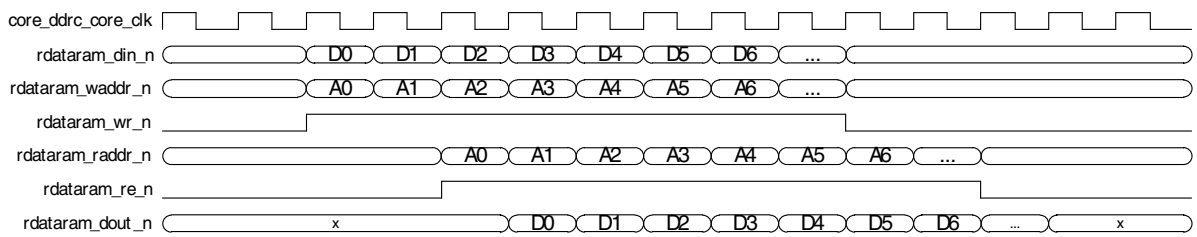

Figure 9-2. read Reorder Buffer Data RAM Interface Timing

The AXI protocol allows the read data for transactions of different IDs to be interleaved. To reduce potential delays where read data for one ID is blocked waiting for data associated with another ID, the read reorder buffer is organized as number of virtual channels (See the figure below). The Read Reorder Virtual Channel is a mechanism to allow independent read data reordering between multiple groups of AXI IDs.

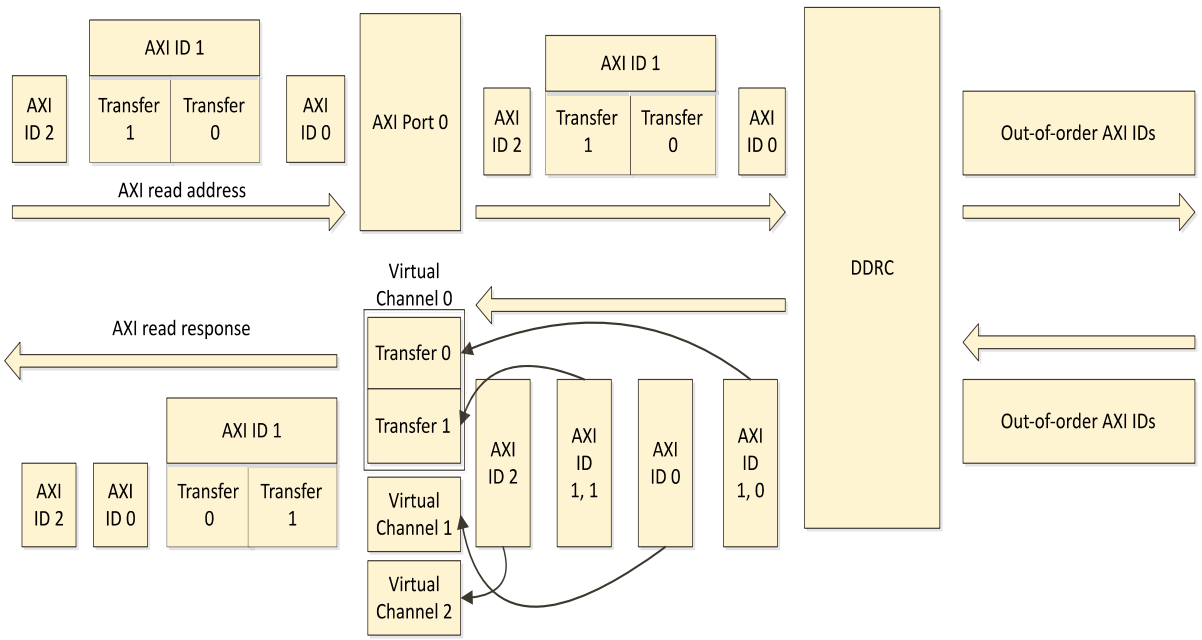

Figure 9-3. RRB Configured with Three Virtual Channels

9.3.2.1.5 Write data Channel

The AXI write data channel has a data storage queue (WDQ - Write Data Queue) with the following clocks:

- AXI clock (aclk_n) for writing and
- DDRC clock (core_ddrc_core_clk) for reading

This queue is used for the clock domain crossing between the AXI clock domain and the controller clock domain and acts as a registering layer in the case of a synchronous interface.

At the output of WDQ, some beats of a write data packet can be masked depending on alignment, burst size and burst length.

Write data from each port is forwarded to the DDRC, which forwards the data to a common data storage.

9.3.2.1.6 Data Width Conversion

The XPI performs the data width conversion between the data width at the AXI interface and internal HIF data width. The AXI data width can be set by the hardware parameter DDRC_PORT_DW.

Both data width down-conversion (where the AXI data bus is wider than the internal HIF data-bus width) and data width up-conversion (where the AXI data bus is narrower than the internal HIF data-bus width) are supported.

If no data width conversion is performed, port is referred as Native-sized:

DDRC_PORT_DW_n = 2 * MEMC_DRAM_DATA_WIDTH if MEMC_FREQ_RATIO = 1

DDRC_PORT_DW_n = 4 * MEMC_DRAM_DATA_WIDTH if MEMC_FREQ_RATIO = 2

When data width up conversion is performed, port is referred as Up-sized:

DDRC_PORT_DW_n < 2 * MEMC_DRAM_DATA_WIDTH if MEMC_FREQ_RATIO = 1

DDRC_PORT_DW_n < 4 * MEMC_DRAM_DATA_WIDTH if MEMC_FREQ_RATIO = 2

When data width down conversion is performed, port is referred as Down-sized:

DDRC_PORT_DW_n > 2 * MEMC_DRAM_DATA_WIDTH if MEMC_FREQ_RATIO = 1

DDRC_PORT_DW_n > 4 * MEMC_DRAM_DATA_WIDTH if MEMC_FREQ_RATIO = 2

The only exception is when Shared-AC with data channel interleaving is used, where Native-sized port is equivalent to a Down-sized port (1:2 ratio) in Single Channel configuration.

The width of the queues, Write Data Queue (WDQ) and Read Data Queue (RDQ) are always set to the wider data width. In the case of data width down-conversion, these queues are set to the width of the AXI data bus. In the case of data width up-conversion, these queues are set to the width of the internal HIF data-bus width

9.3.2.1.7 Write Response Channel

The write response is generated once the last beat of write data, for a given AXI burst, is accepted by the DDRC. The write response queue can be instantiated with configurable depth which is set by the hardware parameter DDRC_AXI_WRQD_n.

The write response generation makes use of the result of the exclusive access monitor. For a write transaction, the response is always returned as OKAY. For an exclusive write transaction, the response can be returned as OKAY or EXOKAY.

SLVERR response may be returned in the following cases:

- Invalid LPDDR4 row address
- On-chip parity address or data error
- Transaction has been poisoned

NOTE

SLVERR has the highest priority

9.3.2.1.8 Exclusive Access

The DDRC supports the AXI Exclusive Access feature. This feature is enabled using the hardware parameter DDRC_EXCL_ACCESS. This parameter defines the number of addresses the DDRC can monitor.

All exclusive read transactions have an EXOKAY response (except in the case of an ECC uncorrectable error). Successful exclusive write accesses have an EXOKAY response, unsuccessful exclusive write accesses return an OKAY response. If an exclusive write fails, the data mask for the exclusive write is forced low so the data is not written.

One address range per AXI ID is monitored for exclusivity. Therefore, if a master does not complete the write portion of an exclusive operation, a subsequent exclusive read to the same ID changes the address that is being monitored for exclusivity.

Once an exclusive access monitor for a given address is enabled, all write transactions are monitored for violation, regardless of the originating port. In other words, the violation check operates across the ports.

The exclusive access monitor compares the exclusive write transaction address, size, length, ID and port number against the exclusive read transaction address, size, length, ID and port number, and only accepts an exclusive write when these parameters match. Otherwise, the exclusive write is considered as fail.

If the EXCL_ACCESS parameter is configured to support no (0) exclusive accesses, the DDRC behaves like an AXI slave that does not support exclusive accesses. Therefore, all exclusive accesses return OKAY responses.

In some cases SLVERR response may be returned for exclusive access transactions. For more information about this, see **“Read Data and Response Channel”** and **“Write Response Channel”**.

NOTE

- The read response SLVERR is generated for an exclusive read transaction for ECC configurations, when ECC is enabled and an uncorrectable error is detected. The master, upon receiving a SLVERR to an exclusive read command should not complete the exclusive operation by sending an exclusive write command. If it does, the DDRC monitors return EXOKAY if there is no violation.
- The maximum number of bytes that are monitored as a region per address cannot exceed 128 bytes. The AXI exclusive transaction length must always be a power of two.
- When all the monitors are active, further exclusive read should not be issued. If this happens, one of the active monitors is evicted using a round robin control and new exclusive read is accepted. The selection of the monitor to be evicted is based on a pointer which rotates across all the locations when a new exclusive read is received.

9.3.2.1.8.1 Dual Channel considerations

In dual channel configurations, Shared AC and LPDDR4 dual channel, a second set of monitors is instantiated for the second channel. This means that the total number of exclusive monitors is doubled.

This has the following implications:

- Maximum number of monitored locations is equal to DDRC_EXCL_ACCESS*2 (DDRC_EXCL_ACCESS locations per data channel).
- If a master issues two Exclusive Read accesses to the same ARID to different channels (for example, channel 0 first, followed by channel 1, without issuing Exclusive Write access in between), channel 0 monitor for this ID is not evicted immediately and channel 1 monitor starts monitoring for the same ID.

According to AXI protocol, the maximum transfer size for exclusive accesses is 128 bytes. For correct functionality, an exclusive access transfer must not be interleaved across two data channels, that is, one EXA transfer goes to one channel only.

The following are the possible ways to achieve this requirement:

- The channel select bit of the address map (ADDRMAP0.addrmap_dch_bit0) can be programmed at or above the 128 byte boundary. For

MEMC_DRAM_DATA_WIDTH=16, this boundary corresponds to HIF[6] or addrmap_dch_bit0=4. For MEMC_DRAM_DATA_WIDTH=32, this boundary corresponds to HIF[5] or addrmap_dch_bit0=3.

- If the required channel interleaving boundary is less than 128 bytes, then the size of all EXA transfers must be constrained to be less or equal to the interleaving boundary.

9.3.2.1.9 Software Coherency for AXI Ports

The section “Address Collision Handling” describes how the DDRC handles in-order execution of commands to the same address.

For the commands issued at the AXI port, the logic in the DDRC protects against all types of software coherency hazards when the AXI master waits for write (read) response before sending the next same address read (same address write) or vice versa.

Some special AXI masters expect an ordering relationship between the reads and writes when the opposite direction transactions are sent without waiting for the previous response. For these special cases, additional logic should be instantiated in the XPI to enforce the order of acceptance within the reads and writes between the AXI and HIF interfaces at the DDRC. This logic is included by setting of the hardware parameter DDRC_RDWR_ORDERED_n and enabled by the register PCFGR_n.rdwr_ordered_en. When this feature is enabled and read and write transactions are presented at the same cycle, the pre-arbiter gives precedence to read transactions, incrementing the write transaction order token by 1 with respect to the read transaction order token. For example, if the last order token issued was equal to 0, then the read order token will be equal to 1 and the write order token will be equal to 2.

9.3.2.1.10 Transaction Poisoning

Sideband signals arpoison/awpoison, render an AXI transaction (read or write) invalid and the DDRC signals that AXI transaction poisoning has occurred. The input signal must be asserted coinciding with the associated AXI transaction. If a write is poisoned, all of its strobes are de-asserted, making the write effectively transparent to the memory. If a read is poisoned, the command is issued to the DDR memory and all the read data beats are overwritten and returned as zeros.

The DDRC may be programmed to signal that an AXI transaction poisoning has occurred by setting an interrupt or by driving the AXI SLVERR response for that transaction response. The AXI Poison Configuration Register POISONCFG (see DDRC_REGS Registers) is used to define whether an interrupt and/or AXI SLVERR is generated when an AXI transaction poisoning has occurred. There is separate control for read and write

transactions. The port specific AXI Poison status register is asserted whenever an AXI transaction is poisoned on that port. There is a separate status for read and write transactions. The interrupt and status register is cleared by the register POISONCFG.rd_poison_intr_clr/POISONCFG.wr_poison_intr_clr. Interrupt status is stored in the AXI Poison Status register POISONSTAT (see DDRC_REGS Registers onpage 464). This register is a mirror in the APB clock domain of the actual interrupts, so status is updated with 2 or 3 pclk cycles of delay depending on the CDC logic.

An external block is expected to drive these new sideband signals depending on the access security requirements on transaction by transaction basis. Therefore, this feature replaces the need to implement ARM Trustzone.

9.3.2.1.11 AXI Data Channel Interleaving

A given AXI port (XPI) can access both data channels and low granularity interleaving between the two data channels is possible by mapping a suitable LSB address bit which is at the memory burst boundary. In that case, for example, a long AXI burst can be expanded to HIF commands so that back to back accesses are to alternating data channels. This setting achieves the highest efficiency possible from a single AXI port.

On the read data path, data order - based on AXI ordering rules - has to be preserved within each channel and between both channels. The read reorder buffer reorders the data coming from a given channel. The data ordered from both channels is then reordered by the data channel reorder logic. Thus two separate data SRAMs are instantiated, one for each channel, whose outputs are combined to provide a single wide AXI read data channel.

By setting the correct system mapping, one port can be set to access one data channel and another port can be set to access the other data channel. This configuration saves logic area in XPI block.

9.3.2.2 AHB Port Interface

The AHB slave port interface consists of an A2X block and XPI block as described in “AXI Port Interface (XPI)”. The A2X block converts the AHB slave port transactions into AXI equivalent transactions before forwarding them to the XPI, where the transactions are finally broken down into HIF packets and sent to the Port Arbiter (PA).

9.3.2.2.1 A2X

The A2X controls the following features of the AHB Slave port interface.

9.3.2.2.1.1 Split Mode

The split mode of the AHB slave port can be set by the parameter DDRC_AHB_SPLIT_MODE_n. Split response is used to control the AHB bus for efficiency and coherency on a multi-master split capable port. This is especially for AHB read transactions where the master is split once the NSEQ address is captured. When the DDRC fetches the read data for split transaction, the AHB interface slave port is free to receive a transaction for another master. The maximum number of splits (simultaneous) is equal to the number of AHB masters configured for the port. Once data is retrieved for a particular master, the master that is split is recalled.

For AHB write, the transaction may be split depending on the write response mode. For more information about this, see **"Write Response Mode"**.

In non-split mode, a single master controls the AHB interface slave port until its transaction completes, unless it is early burst terminated before completion. In the case of a read, the port output hready_resp is deasserted after the NSEQ phase of the transaction and asserted again during the data phase of each beat once the read data is available. When operated in this mode, every read transaction holds the bus for the amount of data beats requested plus at least the read idle latency time of the DDRC. For this reason, nonsplit AHB configuration has a negative impact on the performance of the port when compared with the split configurations.

9.3.2.2.1.2 Write Response mode

There are three AHB write response modes namely non-bufferable, bufferable, or dynamic write response modes. These modes can be programmed (per port) by the parameter DDRC_AHB_WRITE_RESP_MODE_n.

In non-bufferable mode, the hready_resp for the data phase of the last write beat for a defined length AHB burst is not asserted until the A2X logic receives confirmation from XPI (through bresp_n) that the last data beat is accepted by the DDRC. When the port operates in non-split mode, hready_resp remains low until this event occurs. When the port operates in split mode, the master whose write transaction is on the bus is split on either the last write data beat or if hready_resp has been driven low for DDRC_AHB_HREADY_LOW_PERIOD_n cycles (whichever occurs latter), and then recalled when that beat is accepted by the DDRC. For an undefined length INCRs, hready_resp for the data phase of each beat is not asserted until the A2X logic receives

confirmation that each beat is accepted by the DDRC. This indicates performance degradation for long undefined INCR writes when compared with the bufferable equivalent.

In bufferable mode, the logic does not wait for this last beat of write data to be accepted by the DDRC. Instead, hready_resp on the AHB port interface is asserted for the data phase of this beat once the AHB port of the DDRC can accept it. If operating in split mode, a split is generated if the hready_resp is driven low for greater than DDRC_AHB_HREADY_LOW_PERIOD_n cycles.

In dynamic mode, the transactions can be either bufferable or non-bufferable depending on the value of hprot according to the AMBA AHB Specification for the individual AHB transactions, where hprot[2]=1'b0 is non-bufferable and hprot[2]=1'b1 is bufferable.

9.3.2.2.1.3 Error Response

The AHB port only returns an error response on hresp_n for a data beat that has an uncorrectable ECC error. For this to occur, the DDRC should be configured to enable ECC logic. For more information about this, see "Read-Modify-Write (RMW) Generation".

9.3.2.2.1.4 Early Burst Termination (EBT)

A defined length write transaction that is early burst terminated by another transaction has its remaining write data beats masked during memory access. When the early burst terminated master returns, only the remaining write data beats that are masked after the initial EBT are sent to the memory. This EBT of defined length write transactions causes multiple memory accesses. The non-bufferable response for the single defined length transaction that is split into multiple memory access is given only after all memory accesses are completed.

Any defined length read transaction must return to retrieve all its data if early burst terminated. Any undefined length INCR read transaction has all remaining data beats that are not retrieved by a master, up to the read prefetch beats set by the pin hincr_arlen_n, flushed internally in the DDRC.

9.3.2.2.1.5 AHB Lite mode

The parameter DDRC_AHB_LITE_MODE_n is used to set an AHB port to operate in AHB Lite mode. This means that the port can be connected only to a single master and responds to AHB read and nonbufferable write transactions by driving hready_resp low (as opposed to split responses). This simplifies the AHB master/arbiter system connected to an AHB Lite port.

9.3.2.2.1.6 Endian conversion

The A2X provides endian mapping from the AHB port to the XPI with respect to the transaction size. This section outlines the key features of the A2X endian mapping.

The key features of endian conversion are as follows:

- Register: The functionality is enabled by PCFGC_n.ahb_endianness (see DDRC_MP Registers)
- Endian transformations supported:
  - Little Endian (LE)
  - Big Endian-32 (BE-32) invariant
  - Big Endian-A (BE-A) address invariant

9.3.2.2.2 Write Streaming

For AHB write streaming, the write data buffer parameter DDRC_AHB_WDQD should be set to a size that can support enough write data beats from the first valid AHB write beat. So, the transaction on the AHB slave interface port to time the first beat is accepted by the DDRC, signified by asserting the DDRCs hif_wdata_valid and hif_wdata_stall outputs.

9.3.2.2.3 Read Streaming

For non-split configurations, it is not possible to stream different transaction due to the nature of the AHB protocol, as we cannot get the address of the next AHB transaction to access memory until the read data for the current transaction has completed. We can stream within a transaction from the time the first read beat is available until the last read beat of the same transaction.

For split capable configurations, depending on the number of masters and arbitration scheme used accessing a port and the type of AHB transaction used, it is possible to stream reads after the initial read latency delay from the first AHB transaction.

9.3.2.2.4 XPI

The XPI used in conjunction with the A2X provides features to complete the overall AHB slave port solution. These features include data width conversion from the AHB port data width to the internal data width used by the PA and DDRC, which is twice the width of the SDRAM data interface in case of 1:1 clock frequency ratio and four times the width of the SDRAM data interface in case of 1:2 clock frequency ratio.

Each AHB port can be independently configured to operate with a clock that is synchronous or asynchronous to the memory controller clock.This clock crossing logic is done within the XPI.

ECC is supported for configurations with AHB port interfaces.

9.3.2.2.5 Software Coherency For AHB Ports

Coherency of read after write (RAW) and write after read (WAR) to the same address is always guaranteed. For more information about this, see “Software Coherency for AXI Ports” and “Address Collision Handling”.

9.3.2.3 Host Interface (HIF)

HIF is an internal interface when the DDRC is configured to include a multi port arbiter (the hardware parameter DDRC_INCL_ARB is set to 1). In this case, the AXI Port Interface and/or Port Arbiter handle all signals on this interface, effectively acting as the SoC core.

Read, write, as well as write data are received through the HIF. Following the receipt and acceptance of a write the DDRC requests write data from the interface. The interface subsequently provides the independently timed write data in the requested order (which matches the order in which requests are made to the DDRC). See “Dual HIF Functionality” for further details on Dual HIF functionality. Both read and write requests can be reordered later, before being output on the DFI interface.

Requests to the DDRC are throttled in two ways:

- A credit mechanism that ensures that buffer space is available for any request the SoC core makes to the DDRC, prior to the request being made.
- An independent stall mechanism that throttles requests when address collisions take place or if entering self-refresh through the software self-refresh or hardware low power self-refresh.

Data is handled separately. The DDRC throttles data by potentially waiting after it receives a write before requesting the associated data. If there is collision, then the throttling lasts until the collision is cleared in the DDRC. Once write data is requested, it is always accepted by the DDRC.

Read data is sent to the host via a common response interface. For more information about this, see “Common Response”.

This section describes the following about the HIF:

- “Dual HIF Functionality”
- “Credit Mechanism”
- “Read Requests”
- “Write Requests and Data”
- “Read-Modify-Write Requests”
- “Common Response”

9.3.2.3.1 Dual HIF functionality

Dual HIF functionality is as follows:

- Converts HIF single command channel into separate HIF command channel for Read and Write commands.
- Read/Write Arbitration is not performed by the PA
- Dual HIF functionality is supported only if the DDRC is configured to support a multi port arbiter (DDRC_INCL_ARB=1).
- Dual HIF functionality is supported only if the DDRC is configured to include the logic to optimize timing over scheduling efficiency (MEMC_OPT_TIMING=1).
- Dual HIF functionality continues to guarantee coherency for write-after-read (WAR) and read-afterwrite (RAW) hazards. Also, if a Read and Write/ to the same address are taken at the same time (both hif_rcmd_stall=0 and hif_wcmd_stall=0), the Write/ is performed first.

The table provides the details of the signals modified by the DDRC_DUAL_HIF parameter.

Table 9-2. Comparison of Signals Modified by DDRC_DUAL_HIF Parameter

DDRC_DUAL_HIF=0 Single HIFCommand Channel	DDRC_DUAL_HIF=1 [1] Separate HIF Command Channels One for Reads (*_rd) One for Writes/ (*_wr)
hif_cmd_valid	hif_rcmd_valid hif_wcmd_valid
hif_cmd_type	hif_rcmd_type hif_wcmd_type

Table continues on the next page...

Table 9-2. Comparison of Signals Modified by DDRC_DUAL_HIF Parameter (continued)

hif_cmd_addr	hif_rcmd_addr hif_wcmd_addr
hif_cmd_pri	hif_rcmd_prihif_wcmd_pri
hif_cmd_token	hif_rcmd_token hif_wcmd_token
hif_cmd_token	hif_rcmd_length hif_wcmd_length
hif_cmd_wdata_ptr	hif_rcmd_wdata_ptr hif_wcmd_wdata_ptr
hif_cmd_autopre	hif_rcmd_autopre hif_wcmd_autopre
hif_cmd_stall	hif_rcmd_stall hif_wcmd_stall

NOTE

1. As DDRC_DUAL_HIF=1 is only possible if DDRC_INCL_ARB=1, the right hand column refers to internal signals within the DDRC. It is provided for debug purposes only.

NOTE

The databook uses DDRC_DUAL_HIF=0 notation.

If you are using DDRC_DUAL_HIF=1, the internal signals should be interpreted in the following way:

- hif_cmd_valid refers to hif_rcmd_valid and/or hif_wcmd_valid.
- hif_cmd_stall refers to hif_rcmd_stall and/or hif_wcmd_stall and so on.

9.3.2.3.2 Credit Mechanism

The DDRC employs a credit mechanism to ensure that buffers do not overflow. The interface making the request to the DDRC, can only request commands for which it has been granted “credits” to issue.

Credits are tracked seperately for the following three command types:

- High Priority read(HPR)
- Low Prioroity rad(LPR)
- Write

Credits are counted for each command type independently according to the following rules:

- Initially the interface has zero credits.

- The interface logic must include counters to track the number of credits granted by the DDRC and decremented due to commands issued by the interface logic to the DDRC. The interface logic must have separate credit counters for each individual command type.
- Following the de-assertion of reset to the DDRC, credits are issued to the interface for each command type. A given credit count increments every time the DDRC issues a credit, indicated by the assertion of the appropriate *_credit signal on the rising edge of core_ddrc_core_clk. The credit counting logic implemented externally to the DDRC must run on the same clock.
- When the credit count is greater than zero, the interface can issue requests of that type to the DDRC. Each time a request is issued to the DDRC, the associated credit count is decremented.
- When DDRC_VPRW_EN is set to 1, the arbiter or the host can send Variable Priority Read (VPR) and Variable Priority Write (VPW) commands.
- VPR commands do not have a pre-allocated storage resource in the Read CAM (unlike HPR commands). VPR commands share the same resource with the LPR commands. As far as the credit mechanism is concerned, the VPR commands are counted in the LPR credit bucket.
- Similarly, VPW commands do not have a per-allocated storage resource in the Write CAM. VPW commands share the same resource with the Normal Write commands. As far as credit mechanism is concerned, the VPW commands are counted in the WR credit bucket.

The signals related to the credit request interface are:

- hif_cmd_valid
- hif_cmd_type
- hif_cmd_pri
- hif_lpr_credit
- hif_hpr_credit
- hif_wr_credit
- hif_cmd_stall

9.3.2.3.3 Clear Requests

When the LPR or HPR credit count is greater than zero, the interface can issue read requests to the DDRC accordingly.

A command is issued to the DDRC by asserting hif_cmd_valid on the rising edge of the clock. All read request fields must be driven to the appropriate values at the same time. These fields are:

- **hif_cmd_type**: specifies the request type as follows:

- ‘00’ indicates a write request
- ‘01’ indicates a read request
- ‘11’ is not supported

- **hif_cmd_pri**:
  - In HIF-only configurations (DDRC_INCL_ARB=0) where DDRC_VPRW_EN is set to 0, this signal is 1-bit wide. A ‘1’ indicates the read request is high priority. ‘0’ indicates the read request is low priority. This field is meaningless for write commands.
  - In Arbiter configurations (DDRC_INCL_ARB=1) or in HIF-only configurations (DDRC_INCL_ARB=0) where DDRC_VPRW_EN is set to 1, this signal is 2-bit wide.

  The encoding for Read is:

  - 2’b00 - LPR
  - 2’b01 - VPR
  - 2’b10 - HPR
  - 2’b11 - Reserved

  VPR commands are sent only in configurations with DDRC_VPRW_EN=1

- **hif_cmd_addr**: indicates the address for the read. Each word on the HIF (equivalent to 2 DDR words for 1:1 mode configurations (MEMC_FREQ_RATIO=1), or 4 DDR words for 1:2 mode configurations (MEMC_FREQ_RATIO=2)) is uniquely addressable.
- **hif_cmd_length**, is 2 bits if MEMC_BURST_LENGTH=16, 1 bit otherwise.

  Note the following:

  - For MEMC_BURST_LENGTH = 16, a normal read is 16 SDRAM words

  If MEMC_BURST_LENGTH=16:

  - 2’b11 -> Partial (Quarter) Read
  - 2’b10 -> Partial (Half) Read
  - 2'b00 -> Full Read

  Otherwise:

  - 1’b1 -> Partial (Half) Read
  - 1’b0 -> Full Read

In each case, a partial (half) read is half the length of a normal full read (where a word is the amount of data transferred on one edge of the DQS to the SDRAM in a fully configured system.) If MEMC_BURST_LENGTH=16, Partial (Quarter) Read is possible and is quarter the length of a normal full read. This field is meaningless for write or commands.

- **hif_cmd_token**: a bit field that is presented with the read command and is returned with the read response. As the responses may be presented out-of-order, the token is the identifier that indicates the read for which data is being returned on the response side. Therefore, multiple reads with the same token must never be pending in the DDRC simultaneously, as the responses would be indecipherable. Common uses for this field include identifying the requestor and serializing the response data. This field is meaningless for write or commands.

9.3.2.3.3.1 Valid And Stall

the requests by asserting hif_cmd_stall. For any cycle in which hif_cmd_stall is asserted on the rising edge of the clock, the hif_cmd_valid and all other associated request signals are ignored by the DDRC. When this happens, the interface must hold the request on the interface for another cycle and must not yet decrement the associated credit counter. When the DDRC de-asserts hif_cmd_stall on the rising edge of the clock, the request is accepted and the interface can then de-assert hif_cmd_valid or it can issue the next read, write or request (credits allowing).

The DDRC asserts hif_cmd_stall for any of the following conditions:

1. Software driven self-refresh entry requests.This is to ensure that DDRC is empty when memories are in self-refresh. For more information about this, see “Power Saving Features”.
2. Successful DDRC hardware low power entry requests to self-refresh. This is to ensure that DDRC is empty when memories are in self-refresh. For more information about this, see “Power Saving Features”.
3. Address collisions in the DDRC, where flow control is applied to prevent further commands from entering the DDRC. For more information about this, see “Address Collision Handling".
4. In the event of the Write CAM being full and no corresponding data for any of the write command has yet arrived.
5. Setting DBG1.dis_hif=1, causes hif_cmd_stall to be asserted.

NOTE

If Dual HIF functionality is enabled (DDRC_DUAL_HIF=1), hif_rcmd_stall/hif_wcmd_stall is asserted as follows:

- Conditions (1), (2), (3), and (5) cause both hif_rcmd_stall and hif_wcmd_stall to assert at the same time.
- Condition (4) only affects hif_wcmd_stall.

9.3.2.3.4 Write Requests And Data

When the WR credit count is greater than zero, the interface can issue write requests to the DDRC accordingly. A command is issued to the DDRC by asserting hif_cmd_valid on the rising edge of the clock.

All write request fields must be driven to the appropriate values at the same time. These fields are:

- **hif_cmd_type**: specifies the request type as follows:
  - '00' indicates a write request
  - '01' indicates a read request
  - '11' is not supported
- **hif_cmd_pri**: specifies the priority of the write request
  - In HIF-only configurations (DDRC_INCL_ARB=0) where DDRC_VPRW_EN is set to 0, this signal is 1-bit wide. This field is meaningless for write commands.
  - In Arbiter configurations (DDRC_INCL_ARB=1) or in HIF-only configurations (DDRC_INCL_ARB=0) where DDRC_VPRW_EN is set to 1, this signal is 2-bit wide.

  The encoding for Write is:

  - 2'b00 - NPW (Normal Priority Writes)
  - 2'b01 - VPW (Variable Priority Writes)
  - 2'b10 - Reserved
  - 2'b11 - Reserved

  VPW commands are sent only in configurations where DDRC_VPRW_EN=1
- **hif_cmd_addr**: indicates the address for the write or . Each word on the HIF (hif_wdata/hif_rdata_data) is uniquely addressable. For 1:1 frequency ratio mode configurations each 2 DDR words on the DQ bus are uniquely addressable via hif_cmd_addr. In 1:2 frequency ratio mode configurations every 4 DDR words are uniquely addressable.
- **hif_cmd_wdata_ptr**: a pointer into the requestor's own buffers that can be used to subsequently retrieve the write data. Once a write or request is accepted, this pointer is returned to the interface to retrieve the associated write data. (This field is not required, as requests are always accepted in order; the interface can choose to FIFO these pointers internally and ignore this field.)

The stall mechanism for write or requests is identical to that for read requests as explained in the section “Valid and Stall”.

Writes have three phases of operation: a write command, a write data pointer return, and finally write data provided to the DDRC. The write command phase indicates to the DDRC that a write transfer is required. The write data pointer return phase indicates to the SoC core that the DDRC is ready to receive the write data. The write data phase provides the write data to the DDRC.

In all these three phases, the transactions must follow the same order. The data pointer is returned in the same order in which the command is sent. The write data must also be sent in the same order. The DDRC can perform re-ordering to the commands later, before sending them on the DFI interface, to make efficient use of the SDRAM bandwidth.

9.3.2.3.4.1 Write Data Pointer Return

Following the acceptance of a write or request, the DDRC then returns the write data pointer to the interface logic to retrieve the associated write data. This is done by asserting hif_wdata_ptr_valid on the rising edge of clock. In the same cycle, hif_wdata_ptr indicates the value of the write data pointer. This is same as a pointer that is presented to the DDRC as hif_cmd_wdata_ptr during the write command phase.

There is no mechanism for stalling the acceptance of the write data pointer from the DDRC; the interface logic must present write data for every cycle in which hif_wdata_ptr_valid is asserted by the DDRC. The mechanism to throttle hif_wdata_ptr_valid assertions is for the interface to throttle write or requests presented to the DDRC.

There is no required timing between a write or command presented to the DDRC, and the same pointer is returned as hif_wdata_ptr. Multiple pointers can also be presented to the DDRC with multiple requests before the first is returned to the interface. The order of the pointers returned matches the order of the requests presented to the DDRC.

9.3.2.3.4.2 Write Data

After a write data pointer is returned to the interface logic, the interface logic must retrieve the associated data and present it to the DDRC. Data presented to the DDRC has no required timing relationship to the transfer of the write pointer on the interface. The data, however, must be returned in the same order that the pointers are presented to the interface (same order in which the original requests are made).

The write data can be throttled using hif_wdata_stall signal. The write data is accepted by the DDRC when hif_wdata_valid is detected high and hif_wdata_stall is detected low at the same positive edge of the clock. The signal hif_wdata_stall is asserted by the DDRC during a RMW operation. When the DDRC writes the read data for the RMW operation into the write data SRAM, it blocks the SoC core interface from sending any write data during those cycles by asserting this signal.

The write data SRAM can be implemented internally as synthesized flip-flops or implemented externally to the DDRC as embedded SRAM using DDRC_WDATA_EXTRAM parameter.

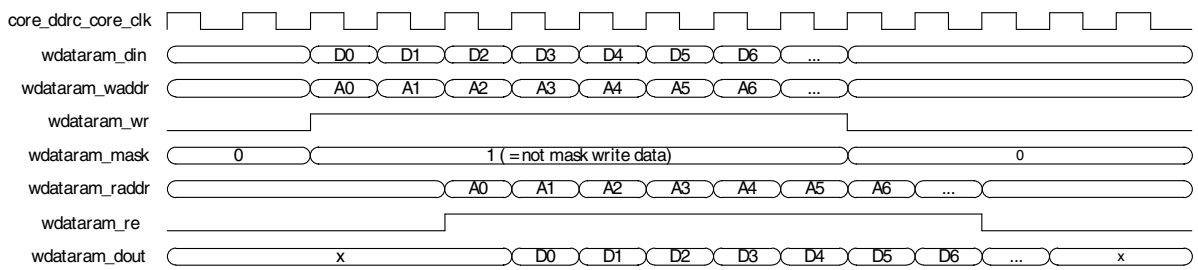

Figure 9-4. Write Data RAM Interface Timing

9.3.2.3.4.2.1 Write Data for the DDRC in BL16 Mode (MEMC_BURST_LENGTH = 16)

Write data is presented to the DDRC with the assertion of hif_wdata_valid. Each request can have one to eight data phases. hif_wdata_valid must be asserted for each data phase and hif_wdata_end must be asserted on the last data phase. hif_wdata is the data. Both hif_wdata_end and hif_wdata are valid only when hif_wdata_valid is '1'.

A normal write or RMW command has eight clocks of data associated with it. In this case, hif_wdata_end must be asserted on the eighth data phase. If the SoC core has less than 8 cycles of write data for a write command, it can choose to send 1, 2, 3, 4, 5, 6 or 7 cycles of data, and hif_wdata_end must be asserted in the appropriate last data phase - these are referred to as Partial Writes. In this case, the DDRC has all the data that it requires 7, 6, 5, 4, 3, 2 or 1 clock cycles earlier than in case of a full write. For these partial writes, the DDRC's behavior is dependent on whether DDRC_PARTIAL_WR is enabled or not:

- DDRC_PARTIAL_WR=0: DDRC still issues the number of SDRAM bursts on the DDR interface that it would issue for a normal (full) write, but masks the unused data phases.
- DDRC_PARTIAL_WR=1: DDRC issues the minimum number of SDRAM bursts on the DDRC interface, depending on the number of HIF write data beats and the HIF address alignment with respect to the SDRAM column address, because SDRAM writes must be sent aligned with BL. This may be smaller than that for a full write.

This analysis assumes 1:1 frequency ratio mode. For 1:2 frequency ratio mode, the number of data beats of the write data on the HIF is halved, so each request has one to four data phases. A Partial Write will have less than four data phases.

9.3.2.3.5 Common Response

The Common Response Interface returns data from the DDRC to the SoC core in response to read requests. The following signals are associated with this functionality:

- hif_rdata_valid
- hif_rdata_end
- hif_rdata_token
- hif_rdata_data

9.3.2.3.5.1 Response Data Ordering

Read data is returned on the HIF in the same order in which it is received from the PHY on the DFI interface. It is independent of whether the read address is aligned or unaligned. For information on how unaligned addresses are handled, see “Sequential/ Interleaved Operations”. For data lane mapping examples where the addresses are aligned, see “Data Lane Mapping Examples”.

9.3.2.3.5.2 Common Response Interface Example

The figure below shows a pair of read requests. The first request is to address A0 with token T0 and length 0. The second request is to A1 with token T1 and length 1. The second read data is returned before the first read data. The DDRC can determine that this sequence is possible due to the state of the open pages and other actions going on in the memories. This improves overall memory bandwidth utilization. The response token indicates which read's data is being provided. Once started, read data for a given token always completes for that token before the next token's read data is returned. The

hif_rdata_valid signal indicates valid data is on the bus and the hif_rdata_end signal indicates that the last data packet is being transmitted. The hif_rdata_valid can deassert in the middle of returning read data for one or more cycles, so hif_rdata_valid must be monitored to validate each cycle of returning read data.

NOTE

Block A: If hif_cmd_length is 1’b1 for this request, 1 cycle of read data comes back and the END signal is asserted in the same cycle.

Block B: If hif_cmd_length is 1’b0 for this request, 2 cycles of read data comes back and the END signal is asserted in the second cycle.

For MEMC_BURST_LENGTH=16, DFI 1:1 configurations, the following is applicable for Block A and Block B in the above figure:

Block A: If hif_cmd_length is 2’b10 for this request, 4 cycle of read data comes back and the END signal is asserted in the fourth cycle.

Block B: If hif_cmd_length is 2’b00 for this request, 8 cycles of read data comes back and the END signal is asserted in the 8th cycle.

9.3.2.3.5.3 LPDDR4 6Gb/12Gb and hif_rdata_addr_err

For LPDDR4 configurations, there is an extra output for DDRC, named hif_rdata_addr_err. This is asserted only in cases where LPDDR4 6Gb/12Gb (ADDRMAP6.lpddr4_6gb_12gb_24gb == 2'b01 or 2'b10) device density is used and the requested address for a read is not valid (when both row address bits MSB and MSB-1 are high). In these cases, DDRC performs a dummy read by changing the physical address to a valid one (row[MSB:MSB-1] changes from 2'b11 to 2'b10). The returned data is masked to 0 and hif_rdata_addr_err is asserted along with the relevant hif_rdata_valid/hif_rdata_token.

9.3.2.4 DFI Interface

The DDRC contains a DFI MC (Memory Controller) interface, which is used to connect to a DFIcompliant PHY, and to transfer address, control and data to the PHY. The DDRC interfaces to a PUB, PUBL, or PUBM2 block which acts as the DFI PHY interface. You can get more information about the DFI interface from the following specifications:

- DDR PHY Interface (DFI) Specification, Revision 3.1 (Preliminary), 21 March 2014 and
- DDR PHY Interface (DFI) Specification, Preliminary DFI 4.0 Specification - Addendum to DFI 3.1, 2 April 2014

The DFI interface is sub-divided into the following interface groups:

- Control Interface
- Write Data Interface
- Read Data Interface
- Update Interface
- Status Interface
- Training Interface (PHY-independent mode supported by the DDRC)
- Low Power Control Interface

9.3.2.4.1 1:1 Frequency Ratio Mode Considerations

The DDRC, including its DFI interface, runs at the single data rate (SDR) clock (referred to as 1:1 frequency ratio mode in the DFI Specification), so all DFI command and address signals are equal in width to the equivalent DDR SDRAM signals. DFI data signals are twice the width of the equivalent DDR SDRAM signals. The DDRC runs with an SDR clock and the PHY operates the SDR to DDR rate conversion on the data buses. In 1:1 frequency ratio mode, core_ddrc_core_clk and CK/CK# run at the same SDR clock frequency.

9.3.2.4.2 1:2 Frequency Ratio Mode Considerations

The DDRC, including its DFI interface runs at the half data rate (HDR) clock (referred to as 1:2 frequency ratio mode in the DFI Specification), so all DFI command and address signals are twice the width of the equivalent DDR SDRAM signals. DFI data signals are four times the width of the equivalent DDR SDRAM signals. The DDRC operates with an HDR clock. The PHY handles HDR-to-SDR conversion on the address bus to memory and HDR/DDR conversion on the data buses. In 1:2 frequency ratio mode, core_ddrc_core_clk runs at half the frequency of CK/CK#.

For DFI command and address signals in DFI 1:2, the DFI protocol refers to phase 0 (_p0)and phase 1 (_p1) but there are no such *_p0 and *_p1 signals in the DDRC. Instead, the lower half of the bits corresponds to phase 0 and the upper half of the bits corresponds to phase 1. For example, in a 4-rank system in DFI 1:2, dfi_cs[7:0] is the case. dfi_cs[3:0] corresponds to dfi_cs_p0 and dfi_cs[7:4] corresponds to dfi_cs_p1.

Similarly, for DFI write data signals in DFI 1:2, the DFI protocol refers to phase 0 (_p0) and phase 1 (_p1). But, there are no such *_p0 and *_p1 signals in the DDRC. Instead, the lower half of the bits correspond to phase 0 and the upper half of the bits correspond to phase 1.

Consider the following examples:

- In system that has 16 bits of SDRAM in DFI 1:2, dfi_wrdata[63:0] is the case. dfi_wrdata[31:0] corresponds to dfi_wrdata_p0 and dfi_wrdata[63:32] corresponds to dfi_wrdata_p1. Similarly, dfi_wrdata_en[3:0] is the case. dfi_wrdata_en[1:0] corresponds to dfi_wrdata_en_p0 and dfi_wrdata_en[3:2] corresponds to dfi_wrdata_en_p1. Similarly, dfi_wrdata_mask[7:0] is the case. dfi_wrdata_mask[3:0] corresponds to dfi_wrdata_mask_p0 and dfi_wrdata_mask[7:4] corresponds to dfi_wrdata_mask_p1.
- In system that has 32 bits of SDRAM in DFI 1:2, dfi_wrdata[127:0] is the case. dfi_wrdata[63:0] corresponds to dfi_wrdata_p0 and dfi_wrdata[127:64] corresponds to dfi_wrdata_p1. Similarly, dfi_wrdata_en[7:0] is the case. dfi_wrdata_en[3:0] corresponds to dfi_wrdata_en_p0 and dfi_wrdata_en[7:4] corresponds to dfi_wrdata_en_p1. Similarly, dfi_wrdata_mask[15:0] is the case. dfi_wrdata_mask[7:0] corresponds to dfi_wrdata_mask_p0 and dfi_wrdata_mask[15:8] corresponds to dfi_wrdata_mask_p1.

Similarly, for dfi_rddata_en in DFI 1:2, the DFI protocol refers to phase 0 (_p0) and phase 1 (_p1). But, there are no such *_p0 and *_p1 signals in the DDRC. Instead, the lower half of the bits correspond to phase 0 and the upper half of the bits correspond to phase 1.

Consider the following examples:

- In system that has 16 bits of SDRAM in DFI 1:2, dfi_rddata_en[3:0] is the case. dfi_rddata_en[1:0] corresponds to dfi_rddata_en_p0 and dfi_rddata_en[3:2] corresponds to dfi_rddata_en_p1.
- In system that has 32 bits of SDRAM in DFI 1:2, dfi_rddata_en[7:0] is the case. dfi_rddata_en[3:0] corresponds to dfi_rddata_en_p0 and dfi_rddata_en[7:4] corresponds to dfi_rddata_en_p1.

For dfi_rddata_valid/dfi_rddata/dfi_rddata_dbi signals in DFI 1:2, the DFI protocol refers to word 0 (_w0) and word 1 (_w1). But, there are no such *_w0 and *_w1 signals in the DDRC. Instead, the lower half of the bits correspond to word 0 and the upper half of the bits correspond to word 1.

Consider the following examples:

- In system that has 16 bits of SDRAM in DFI 1:2, dfi_rddata[63:0] is the case. dfi_rddata[31:0] corresponds to dfi_rddata_w0 and dfi_rddata[63:32] corresponds to dfi_rddata_w1. Similarly, dfi_rddata_valid[3:0] is the case. dfi_rddata_valid[1:0] corresponds to dfi_rddata_valid_w0 and dfi_rddata_valid[3:2] corresponds to dfi_rddata_valid_w1. Similarly, dfi_rddata_dbi[7:0] is the case. dfi_rddata_dbi[3:0] corresponds to dfi_rddata_dbi_w0 and dfi_rddata_dbi[7:4] corresponds to dfi_rddata_dbi_w1.
- In system that has 32 bits of SDRAM in DFI 1:2, dfi_rddata[127:0] is the case. dfi_rddata[63:0] corresponds to dfi_rddata_w0 and dfi_rddata[127:64] corresponds to dfi_rddata_w1. Similarly, dfi_rddata_valid[7:0] is the case. dfi_rddata_valid[3:0] corresponds to dfi_rddata_valid_w0 and dfi_rddata_valid[7:4] corresponds to dfi_rddata_valid_w1. Similarly, dfi_rddata_dbi[15:0] is the case. dfi_rddata_dbi[7:0] corresponds to dfi_rddata_dbi_w0 and dfi_rddata_dbi[15:8] corresponds to dfi_rddata_dbi_w1.

9.3.2.4.3 DFI Write/Read Data to SDRAM Conversion

This conversion is performed in the PHY, and therefore PHY-Specific. The following details are applicable only to Synopsys DDR PHYs; other PHYs may differ from this.

The DFI data (both read and write) should contain data for multiple byte lanes and for multiple data beats (2 in 1:1 mode, 4 in 1:2 mode). The DFI Specification does not explicitly state how this data should be packed within dfi_rddata and dfi_wrdata. The Synopsys DDR PHYs and the DDRC DFI interfaces are designed with the assumption that the data is ordered by beat and then (within each beat) by byte.

For example, for a 2-byte configuration (16 bits of SDRAM) in 1:2 mode, the DFI data order is as follows (from MSB to LSB):

[byte1-beat3, byte0-beat3, byte1-beat2, byte0-beat2, byte1-beat1, byte0-beat1, byte1-beat0, byte0-beat0]

Therefore, the PHY sends the data it receives out to the memory in the following way:

- In beat 0, the data from dfi_wrdata[15:0] are sent on DQ[15:0]
- In beat 1, the data from dfi_wrdata[31:16] are sent on DQ[15:0]

- In beat 2, the data from dfi_wrdata[47:32] are sent on DQ[15:0]
- In beat 3, the data from dfi_wrdata[63:48] are sent on DQ[15:0]

Similarly, for a 2-byte configuration (16 bits of SDRAM) in 1:1 mode, the DFI data order is as follows (from MSB to LSB):

[byte1-beat1, byte0-beat1, byte1-beat0, byte0-beat0]

Therefore, the PHY sends the data it receives out to the memory in the following way:

- In beat 0, the data from dfi_wrdata[15:0] are sent on DQ[15:0]
- In beat 1, the data from dfi_wrdata[31:16] are sent on DQ[15:0]

Similarly, for a 4-byte configuration with 32 bits of SDRAM in 1:2 mode, the DFI data order is as follows (from MSB to LSB):

[byte3-beat3, byte2-beat3, byte1-beat3, byte0-beat3, byte3-beat2, byte2-beat2, byte1-beat2, byte0- beat2, byte3-beat1, byte2-beat1, byte1-beat1, byte0-beat1, byte3-beat0, byte2-beat0, byte1-beat0, byte0-beat0]

Therefore, the PHY sends the data it receives out to the memory in the following way:

- In beat 0, the data from dfi_wrdata[31:0] are sent on DQ[31:0]
- In beat 1, the data from dfi_wrdata[63:32] are sent on DQ[31:0]
- In beat 2, the data from dfi_wrdata[95:64] are sent on DQ[31:0]
- In beat 3, the data from dfi_wrdata[127:96] are sent on DQ[31:0]

Similarly, for a 4-byte configuration (32 bits of SDRAM) in 1:1 mode, the DFI data order is as follows (from MSB to LSB):

[byte3-beat1, byte2-beat1, byte1-beat1, byte0-beat1, byte3-beat0, byte2-beat0, byte1-beat0, byte0-beat0]

Therefore, the PHY sends the data it receives out to the memory in the following way:

- In beat 0, the data from dfi_wrdata[31:0] are sent on DQ[31:0]
- In beat 1, the data from dfi_wrdata[63:32] are sent on DQ[31:0]

For more information, see the addressing example in Figure A-1. Similar ordering is true for dfi_wrdata_en/dfi_wrdata_mask and dfi_rddata_en/dfi_rddata/dfi_rddata_valid/ dfi_rddata_dbi.

NOTE

- If dfi_rddata data slice independence is enabled (DDRC_DFI_RDDATA_PER_BYTE=1), the logic assumes the DDR PHY ordering on bytes/beats for dfi_rddata_valid/dfi_rddata/dfi_rddata_dbi.

9.3.2.4.4 Control Interface

The control interface is a reflection of the SDRAM control interface including address, bank, chip select, row strobe, column strobe, write enable, clock enable and ODT control, as applicable for the memory technology. This interface consists of the following signals:

- dfi_address (width of this signal depends on configuration - 20 bits if 18 bits if MEMC_DDR4 = 1; otherwise 16 bits)
- dfi_bank
- dfi_cas_n
- dfi_cke
- dfi_cs
- dfi_odt
- dfi_ras_n
- dfi_reset_n (this signal only exists if MEMC_DDR4 = 1)
- dfi_we_n
- dfi_bg (this signal only exists if MEMC_DDR4=1)
- dfi_act_n (this signal only exists if MEMC_DDR4 = 1)

For more information about the above signals, refer to “Signal Descriptions”.

9.3.2.4.5 Write Data Interface

The write data interface handles the transmission of write data across the DFI interface. The DFI Specification defines signals and timing relationships. This interface consists of the following signals:

- dfi_wrdata
- dfi_wrdata_en
- dfi_wrdata_mask

For more information about the above signals, refer to “Signal Descriptions”. The timing of this interface is user-configurable, to support all DFI-compliant PHYs through the DFITMG0.dfi_tphy_wrlat and DFITMG0.dfi_tphy_wrdata register (see DDRC_REGS Registers). For DFI 1:2, DFITMG0.dfi_wrdata_use_dfi_phy_clk determines whether DFITMG0.dfi_tphy_wrlat and DFITMG0.dfi_tphy_wrdata are in terms of SDR or HDR clock cycles. If HDR, timing for dfi_wrdata* generation for write commands on phase 0/ phase 1 are the same and dfi_wrdata* signals are aligned to HDR clock. If SDR, timing for dfi_wrdata* generation for write commands on phase 0/phase 1 are treated separately and dfi_wrdata* signals are not guaranteed to be aligned to HDR clock. Check your PHY requirements for correct programming.

In DDR4 configurations (when MEMC_DDR4 is set) or LPDDR4 configurations (when MEMC_LPDDR4 is set), the signal dfi_wrdata_mask can act as Write DBI signal depending on the user programming of the SDRAM mode register. For more information on DBI, see “Data Bus Inversion (DBI)”.

Also, as per JEDEC Specification, the polarity of dfi_wrdata_mask is inverted when using DDR4 memories (if MSTR.ddr4 = 1). Therefore, for DDR4, if a bit of dfi_wrdata_mask is ‘0’, the corresponding byte is masked.

9.3.2.4.5.1 Support for dfi_wrdata_cs/dfi_rddata_cs Signals (DFI 3.1)

There is an optional support for dfi_wrdata_cs and dfi_rddata_cs signals by setting parameter DDRC_DFI_DATA_CS_EN=1. This is a new feature introduced in DFI 3.0, which also applies to DFI 3.1. Enable this feature only if your PHY supports it. These signals are only supported for configurations with MEMC_NUM_RANKS>1. The polarity of these signals is defined by DFIMISC.dfi_data_cs_polarity.

The signal dfi_wrdata_cs is driven as follows:

- dfi_wrdata_cs is driven according to the relevant chip select tphy_wrcslat DFI PHY clock cycles after any command that generates dfi_wrdata. This includes a write, and in DDR4, a PDA (write). It is guaranteed to remain at this value for a minimum of tphy_wrcsgap plus the time for the write data (usually MSTR.burst_rdwr).

  Similarly, for dfi_rddata_c:

- dfi_rddata_cs is driven according to the relevant chip select tphy_rdcslat DFI PHY clock cycles after any command that generates dfi_rddata. This includes a Read, in LPDDR4, a MRR and in DDR4, a MPR (read). It is guaranteed to remain at this value for a minimum of tphy_rdcsgap plus the time for the read data (usually MSTR.burst_rdwr).

The table outlines the DFI timing value and the equivalent register in the DDRC.

Table 9-3. DFI timing values for dfi_wrdata_cs/dfi_rddata_cs

DFI Timing Value	DDRC Register
$t_{phy\_wrcslat}$	DFITMG2.dfi_tphy_wrcslat
$t_{phy\_wrcsgap}$	RANKCTL.diff_rank_wr_gap [1] [2]
$t_{phy\_rdcslat}$	DFITMG2.dfi_tphy_rdcslat
$t_{phy\_rdcsgap}$	RANKCTL.diff_rank_rd_gap[1] [2]

NOTE

1. For configurations with MEMC_FREQ_RATIO=2, this register is in terms of DFI clocks (controller clocks), while tphy_wrcsgap is in terms of DFI PHY clocks.
2. If using DDR4-LRDIMM, refer to TWRWR and TRDRD timing requirements in JEDEC DDR4 Data Buffer (DDR4DB01) Specification.

9.3.2.4.6 Read Data Interface

The read data interface handles the return of read data across the DFI interface. The DFI Specification defines signals and timing relationships. This interface consists of the following signals:

- dfi_rddata
- dfi_rddata_en
- dfi_rddata_valid
- dfi_rddata_dbi (this input signal exists only if MEMC_DDR4=1)

For more information about the above signals, refer to “Signal Descriptions”. The timing of this interface is user-configurable, to support all DFI-compliant PHYs via the DFITMG0.t_rddata_en register.

For DFI 1:2, DFITMG0.dfi_rddata_use_dfi_phy_clk determines whether DFITMG0.dfi_t_rddata_en is in terms of SDR or HDR clock cycles. If HDR, timing for dfi_rddata_en generation for read commands on phase 0/phase 1 is the same and dfi_rddata* signals are aligned to HDR clock. If SDR, timing for dfi_rddata* generation for read commands on phase 0/phase 1 are treated separately and dfi_rddata* signals are not guaranteed to be aligned to HDR clock. Check your PHY requirements for correct programming.

In DDR4 configurations (when MEMC_DDR4 is set), the signal dfi_rddata_dbi is the read DBI signal. For more information on DBI, see “Data Bus Inversion (DBI)”.

The DDRC has been verified with the Synopsys PHYs. It assumes that the DFI parameter tphy_rdlat does not exceed 48 cycles. For mDDR using BL2, it assumes that the DFI parameter tphy_rdlat does not exceed 26 cycles. For both cases, it also assumes that the DFI parameter trddata_en does not exceed the SDRAM read latency (RL).

9.3.2.4.7 Update Interface

During system operation, the system may require updates to internal settings to compensate for environmental conditions. To ensure that updates do not interfere with signals on the SDRAM interface, the DFI interface supports update modes where the DFI read, write, and control interface are suspended from normal activity. The DFI Specification defines both MC-initiated and PHY-initiated updates.

9.3.2.4.7.1 MC-initiated Updates

This interface consists of the following signals:

- dfi_ctrlupd_req
- dfi_ctrlupd_ack
- dfi_ctrlupd_ack2

For more information about the above signals, refer to “Signal Descriptions”.

MC-initiated updates can be acknowledged or ignored by the PHY. DFI MC-initiated updates are performed periodically by DDRC.

9.3.2.4.7.2 PHY-initiated Updates

This interface consists of the following signals:

- dfi_phyupd_req
- dfi_phyupd_type
- dfi_phyupd_ack

For more information about the above signals, see “Signal Descriptions”.

For more details, see “DFI PHY-initiated Update Request”.

9.3.2.4.8 Status Interface

The DFI interface requires status information for initialization and clock control to the SDRAM devices. These signals are used to convey information between the MC and PHY. This interface consists of the following signals:

- dfi_init_start
- dfi_init_complete
- dfi_frequency
- dfi_dram_clk_disable
- dfi_alert_n (this signal replaces dfi_parity_error.

The DDRC does not support the following signals (defined as optional in the DFI Specification):

- dfi_data_byte_disable
- dfi_freq_ratio

9.3.2.4.8.1 Initialization

The dfi_init_start signal is used to trigger the PHY initialization by setting it to 1. It is driven by the DDRC through the APB interface with the DFIMISC.dfi_init_start read-write register field. The signal dfi_init_complete indicates that the PHY has completed its initialization. This information can be read/polled by the DDRC through the APB interface with the DFISTAT.dfi_init_complete read-only register field.

9.3.2.4.8.2 Clock Disabling

The dfi_dram_clk_disable signal depends on setting of PWRCTL.en_dfi_dram_clk_disable (see DDRC_REGS Registers). For more information about this, see “Assertion of dfi_dram_clk_disable”.

9.3.2.4.8.3 Frequency Change

The interface consists of three signals:

- dfi_init_start: Output from the controller to the PHY
- dfi_init_complete: Output from the PHY to the controller
- dfi_frequency: Output from the controller to the PHY

The procedure is as follows:

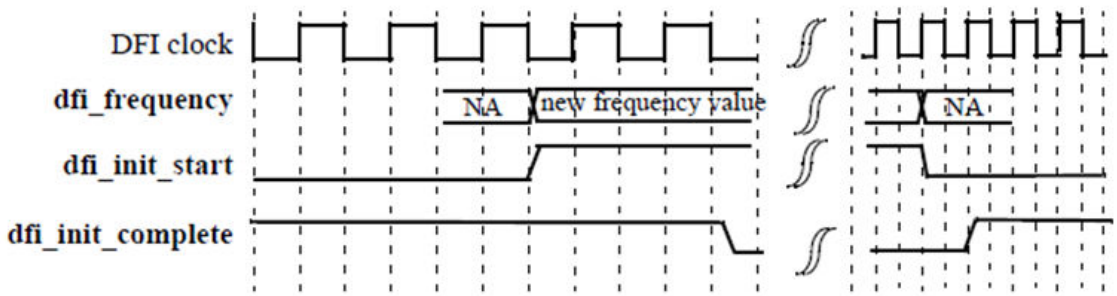

Figure 9-5. Frequency Change

dfi_frequency indicates the operating frequency of the system. This signal should change only at initialization, during a DFI frequency change operation, or other times that the system defines.This signal should be constant during normal operation.The number of supported frequencies and the mapping of signal values to clock frequencies are defined by the PHY, system, or both. For timing, the dfi_frequency signal must be set to a legal value and remain unchanged when dfi_init_start is asserted.The dfi_frequency signal can change any time when dfi_init_start is low and should be ignored at this time.

The behavior of the dfi_init_start signal is dependent on the dfi_init_complete signal.

If the PHY accepts the frequency change request, it must deassert the dfi_init_complete signal within tinit_start cycles of the dfi_init_start assertion. The MC continues to hold the dfi_init_start signal asserted until the clock frequency change has been completed. The de-assertion should be used by the PHY to reinitialize on the new clock frequency.

If the frequency change is not acknowledged (the dfi_init_complete signal remains asserted), the dfi_init_start signal must de-assert after tinit_start cycles. This requirement needs to be handled by the system as dfi_init_start is programmed through the software.

9.3.2.4.9 DFI Training Interface

The additional functions of SDRAM memories allow accurate alignment of critical timing signals. The DFI Specification version 2.1.1 accounts for these functions by providing a DFI training interface.

The DFI Specification defines the following operating modes for the training interface for write leveling, and read leveling:

- No Support
- MC Evaluation (not supported by the DDRC)

- PHY Evaluation
- PHY Independent

  These modes define whether the MC or PHY, or neither, maintains the responsibility for managing the programming of the delay lines and evaluating the response.

  The DFI training interface enables write and read leveling functions in a DFI-compliant PHY.

  In DDRC, the following modes are supported:

- “No Support and PHY Independent Mode”

While interfacing to the DDR PHY, the training is initiated by the PHY Utility Block (PUB) present in the PHY, and PHY independent training mode is used.

9.3.2.4.9.1 No Support and PHY Independent Mode

To enable the No Support and PHY independent mode, the PHY must drive the following signals to “11”:

- dfi_rdlvl_mode
- dfi_rdlvl_gate_mode
- dfi_wrlvl_mode

The above signals are inputs from the DFI-compliant PHY. For these modes, any other DFI Training signals which are outputs can be ignored while any other DFI Training signals that are inputs must be tied to all zeros.

Training is then performed automatically by the PHY, without any intervention from the DDRC. The PUB or PUBL block (part of the PHY) performs all required MRS commands to move the SDRAM to the correct state for each training stage.

If you are using a non-Synopsys PHY that supports PHY independent training mode, DDRC may have to perform these MRS commands.

However, DDRC has no knowledge on when the PHY is ready to execute each training stage, so this must be controlled by the user. For more information on mode register writes, see “Mode Register Write".

9.3.2.4.10 Low Power interface

In a DDR memory subsystem, it is advantageous to place the PHY in a low power state when the DDRC has knowledge that the memory subsystem remains idle for a period of time. Depending on the state of the system, the DDRC communicates state information to the PHY allowing the PHY to enter the appropriate power saving state. This interface consists of signals that are used to inform the PHY of a low power mode opportunity, as well as how quickly the DDRC requires the PHY to resume normal operation. This interface consists of the following signals:

- dfi_lp_req
- dfi_lp_wakeup
- dfi_lp_ack Software control is provided in DFILPCFG0/DFILPCFG1 registers (see DDRC_REGS Registers on page 464) for the following:
- This is an optional interface for a DFI-compliant PHY. The interface signals always exist in the DDRC. But the software can enable this interface in self-refresh and/or power-down and/or deep power-down mode and/or maximum power saving mode - DFILPCFG0.dfi_lp_en_pd, DFILPCFG0.dfi_lp_en_sr, DFILPCFG0.dfi_lp_en_dpd and DFILPCFG1.dfi_lp_en_mpsm respectively.
- Software control over what is driven on dfi_lp_wakeup signal (and its associated timing) in selfrefresh or power-down or deep power-down or maximum power saving mode - DFILPCFG0.dfi_lp_wakeup_pd, DFILPCFG0.dfi_lp_wakeup_sr, DFILPCFG0.dfi_lp_wakeup_dpd and DFILPCFG1.dfi_lp_wakeup_mpsm respectively.
- The timing of this DFI low power interface - DFILPCFG0.dfi_tlp_resp.
- ctl_idle output pin is a sideband signal (not specified in DFI) supported by certain Synopsys PHYs to trigger the PHY's Anti-Aging feature. This is driven the same as dfi_lp_req if enabled via software (DFIMISC.ctl_idle_en=1 and DFI Low Power Interface is also enabled via DFILPCFG0/DFILPCFG1). If configured for Shared AC, dfi_lp_req signal of both data channels must be asserted for ctl_idle to be asserted.

For more information, see "Power Saving Features".

9.3.2.4.11 PHY Master Interface

This interface consists of the following signals:

- dfi_phymstr_req
- dfi_phymstr_cs_state
- dfi_phymstr_state_sel
- dfi_phymstr_type
- dfi_phymstr_ack

For more information about the above signals, see "Signal Descriptions".

For more information about PHY Master interface, see “PHY Master Interface”.

9.3.2.5 APB Interface

The DDRC provides a dedicated APB 3.0 bus interface that is used to access the DDRC software programmable registers. The DDRC converts APB reads and writes into accesses to the internal register file. The APB data width is fixed to 32 bits for compatibility reasons with the DDR PHYs. The APB address width is 12 bits.

All APB interface signals (p*) are synchronous to pclk. pclk can be asynchronous to the core_ddrc_core_clk if the configuration parameter DDRC_P_ASYNC_EN is set. However, pclk frequency must be the same or less than the core_ddrc_core_clk frequency.

9.3.2.5.1 Register Classes

There are three classes of registers in the DDRC:

- Dynamic Registers
- Quasi Dynamic Registers
- Static Registers

Dynamic registers can be written at any time during operation.

Static registers can be written only when the controller is in reset.

Quasi dynamic registers can be written when the controller is in reset and some specific conditions outside reset. To write them, SWCTL.sw_done (see DDRC_REGS Registers on page 464) has to be set to 0 at the beginning of the programming sequence and set back to 1 at the end. After that, SWSTAT.sw_done_ack has to be polled for acknowledge.

9.3.3 Memory Map and register definition

This section includes the DDRC module memory map and detailed descriptions of all registers.

9.3.3.1 DDRC register descriptions

9.3.3.1.1 DDRC memory map

DDRC base address: 0h

Offset	Register	Width (In bits)	Access	Reset value
0h	Master Register0 (MSTR)	32	RW	0304_0001h
4h	Operating Mode Status Register (STAT)	32	RO	0000_0000h

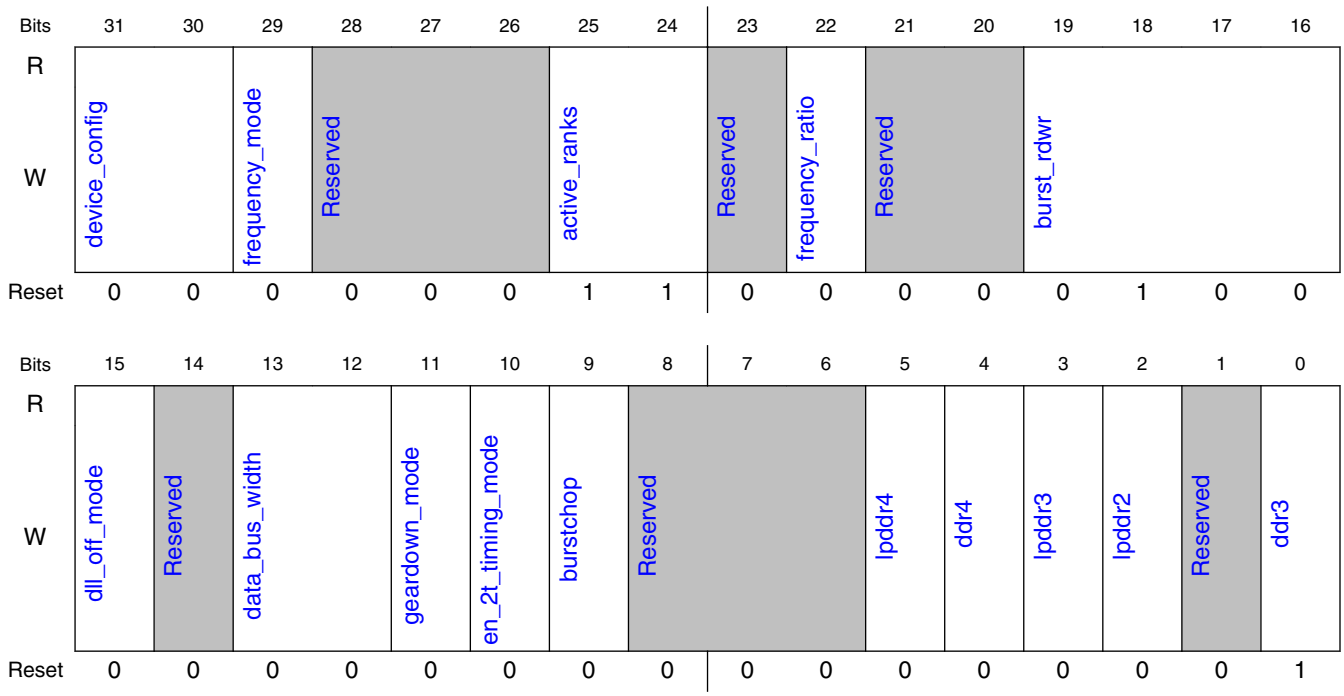
9.3.3.1.2 Master Register0 (MSTR)

9.3.3.1.2.1 Offset

Register	Offset
MSTR	0h

9.3.3.1.2.2 Diagram



9.3.3.1.2.3 Fields

Field	Function
31-30 device_config	Indicates the configuration of the device used in the system. 00b - x4 device 01b - x8 device 10b - x16 device 11b - x32 device
29 frequency_mode	Choose which registers are used. 0b - Original Registers 1b - Shadow Registers
28-26 —	Reserved
25-24 active_ranks	Only present for multi-rank configurations. Each bit represents one rank. For two-rank configurations, only bits[25:24] are present. • 1 - populated • 0 - unpopulated LSB is the lowest rank number. For 2 ranks following combinations are legal • 01 - One rank • 11 - Two ranks • Others- Reserved For 4 ranks following combinations are legal:

Table continues on the next page...

Field	Function
	• 0001 - One rank • 0011 - Two ranks • 1111 - Four ranks •
23 —	Reserved
22 frequency_ratio	Selects the Frequency Ratio 0b - 1:2 Mode 1b - 1:1 Mode
21-20 —	Reserved
19-16 burst_rdwr	SDRAM burst length used All other values are reserved. This controls the burst size used to access the SDRAM. This must match the burst length mode register setting in the SDRAM. (For BC4/8 on-the-fly mode of DDR3 and DDR4, set this field to 0x0100) Burst length of 2 is not supported with AXI ports when MEMC_BURST_LENGTH is 8. Burst length of 2 is only supported when the controller is operating in 1:1 frequency mode 0001b - Burst length of 2 (only supported for mDDR) 0010b - Burst length of 4 0100b - Burst length of 8 1000b - Burst length of 16 (only supported for mDDR, LPDDR2, and LPDDR4)
15 dll_off_mode	Set to 1 when the DDRC and DRAM has to be put in DLL-off mode for low frequency operation. Set to 0 to put DDRC and DRAM in DLL-on mode for normal frequency operation. If DDR4 CRC/parity retry is enabled (CRCPARCTL1.crc_parity_retry_enable = 1), dll_off_mode is not supported, and this bit must be set to '0'.
14 —	Reserved
13-12 data_bus_width	Selects proportion of DQ bus width that is used by the SDRAM - 00 - Full DQ bus width to SDRAM - 01 - Half DQ bus width to SDRAM - 10 - Quarter DQ bus width to SDRAM - 11 - Reserved Note that half bus width mode is only supported when the SDRAM bus width is a multiple of 16, and quarter bus width mode is only supported when the SDRAM bus width is a multiple of 32 and the configuration parameter MEMC_QBUS_SUPPORT is set. Bus width refers to DQ bus width (excluding any ECC width).
11 geardown_mode	1 indicates put the DRAM in geardown mode (2N) and 0 indicates put the DRAM in normal mode (1N). This register can be changed, only when the Controller is in self-refresh mode. This signal must be set the same value as MR3 bit A3. Note: Geardown mode is not supported if the configuration parameter MEMC_CMD_RTN2IDLE is set Note: Geardown mode is not supported if the configuration parameter DDRC_SHARED_AC is set (in Shared-AC mode) and the register value is don't care
10 en_2t_timing_mode	If 1, then DDRC uses 2T timing. Otherwise, uses 1T timing. In 2T timing, all command signals (except chip select) are held for 2 clocks on the SDRAM bus. Chip select is asserted on the second cycle of the command Note: 2T timing is not supported in LPDDR2/LPDDR3/LPDDR4 mode Note: 2T timing is not supported if the configuration parameter MEMC_CMD_RTN2IDLE is set Note: 2T timing is not supported in DDR4 geardown mode. Note: 2T timing is not supported in Shared-AC dual channel mode and the register value is don't care.
9 burstchop	When set, enable burst-chop (BC4 or 8 on-the-fly) in DDR3/DDR4. Burst Chop for Reads is exercised only in HIF configurations (DDRC_INCL_ARB not set) and if in full bus width mode (MSTR.data_bus_width = 00) and if MEMC_BURST_LENGTH=8 or 16. Burst Chop for Writes is exercised only if Partial Writes enabled (DDRC_PARTIAL_WR=1) and if CRC is disabled (CRCPARCTL1.crc_enable = 0). If DDR4 CRC/parity retry is enabled (CRCPARCTL1.crc_parity_retry_enable = 1), burst chop is not supported, and this bit must be set to '0'. BC4 (fixed) mode is not supported.
8-6	Reserved

Table continues on the next page...

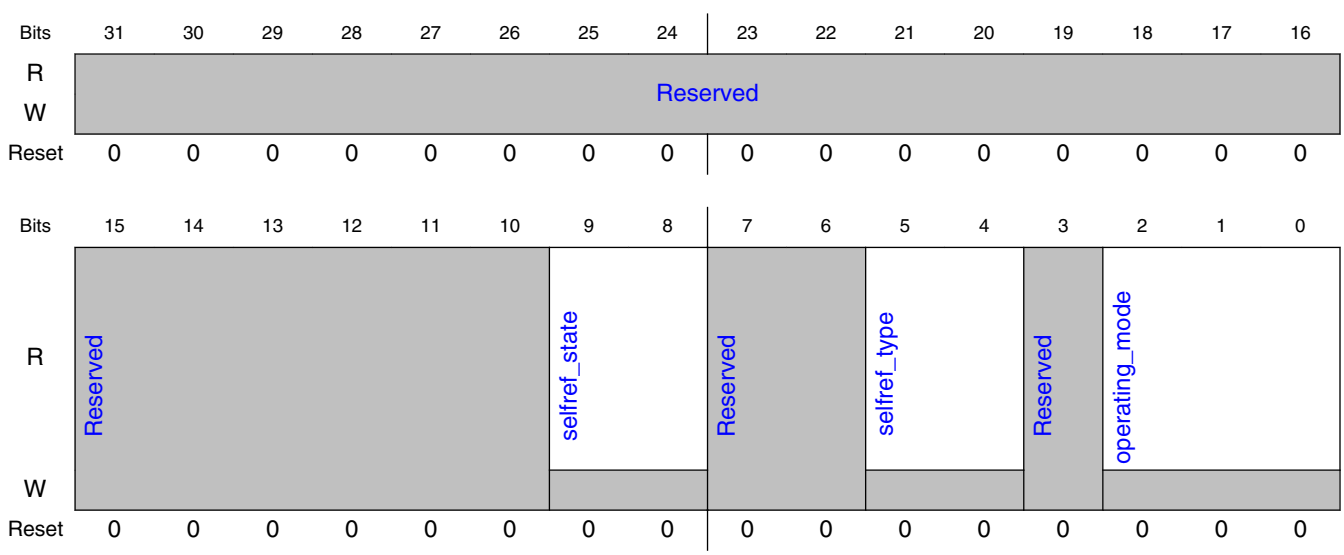
Field	Function
—	
5 lpddr4	Select LPDDR4 SDRAM - 1 - LPDDR4 SDRAM device in use. - 0 - non-LPDDR4 device in use Present only in designs configured to support LPDDR4.
4 ddr4	Select DDR4 SDRAM - 1 - DDR4 SDRAM device in use. - 0 - non-DDR4 device in use Present only in designs configured to support DDR4.
3 lpddr3	Select LPDDR3 SDRAM - 1 - LPDDR3 SDRAM device in use. - 0 - non-LPDDR3 device in use Present only in designs configured to support LPDDR3.
2 lpddr2	Select LPDDR2 SDRAM - 1 - LPDDR2 SDRAM device in use. - 0 - non-LPDDR2 device in use Present only in designs configured to support LPDDR2.
1 —	Reserved
0 ddr3	Select DDR3 SDRAM - 1 - DDR3 SDRAM device in use - 0 - non-DDR3 SDRAM device in use Only present in designs that support DDR3.

9.3.3.1.3 Operating Mode Status Register (STAT)

9.3.3.1.3.1 Offset

Register	Offset
STAT	4h

9.3.3.1.3.2 Diagram



9.3.3.1.3.3 Fields

Field	Function
31-10 —	Reserved
9-8 selfref_state	Self refresh state. This indicates self refresh or self refresh power down state for LPDDR4. This register is used for frequency change and MRR/MRW access during self refresh. 00b - SDRAM is not in Self Refresh. 01b - Self refresh 1 10b - Self refresh power down 11b - Self refresh
7-6 —	Reserved
5-4 selfref_type	Flags if Self Refresh (except LPDDR4) or SR-Powerdown (LPDDR4) is entered and if it was under Automatic Self Refresh control only or not. 00b - SDRAM is not in Self Refresh (except LPDDR4) or SR-Powerdown (LPDDR4). If retry is enabled by CRCPARCTRL1.crc_parity_retry_enable, this also indicates SRE command is still in parity error window or retry is in-progress. 10b - SDRAM is in Self Refresh (except LPDDR4) or SR-Powerdown (LPDDR4), which was not caused solely under Automatic Self Refresh control. It could have been caused by Hardware Low Power Interface and/or Software (reg_ddrc_selfref_sw). If retry is enabled, this guarantees SRE command is executed correctly without parity 11b - SDRAM is in Self Refresh (except LPDDR4) or SR-Powerdown (LPDDR4), which was caused by Automatic Self Refresh only. If retry is enabled, this guarantees SRE command is executed correctly without parity error.
3 —	Reserved
2-0 operating_mode	Operating mode This is 3-bits wide in configurations with mDDR/LPDDR2/LPDDR3/LPDDR4/DDR4 support and 2-bits in all other configurations. Non-mDDR/LPDDR2/LPDDR3/LPDDR4 and non-DDR4 designs: • 00 - Init • 01 - Normal • 10 - Power-down • 11 - Self refresh mDDR/LPDDR2/LPDDR3 or DDR4 designs: • 000 - Init • 001 - Normal • 010 - Power-down • 011 - Self refresh • 1XX - Deep power-down / Maximum Power Saving Mode LPDDR4 designs: • 000 - Init • 001 - Normal • 010 - Power-down • 011 - Self refresh / Self refresh power-down

Field	Function
31-17 —	Reserved
16 alt_addrmap_en	Enable Alternative Address Map 0b - Disable Alternative Address Map 1b - Enable Alternative Address Map
15-2 —	Reserved
1-0 rank_tmgreg_sel	rank_tmgreg_sel Indicates which register set is used for each rank. Each bit represents one rank. (LSB is the lowest rank number.)

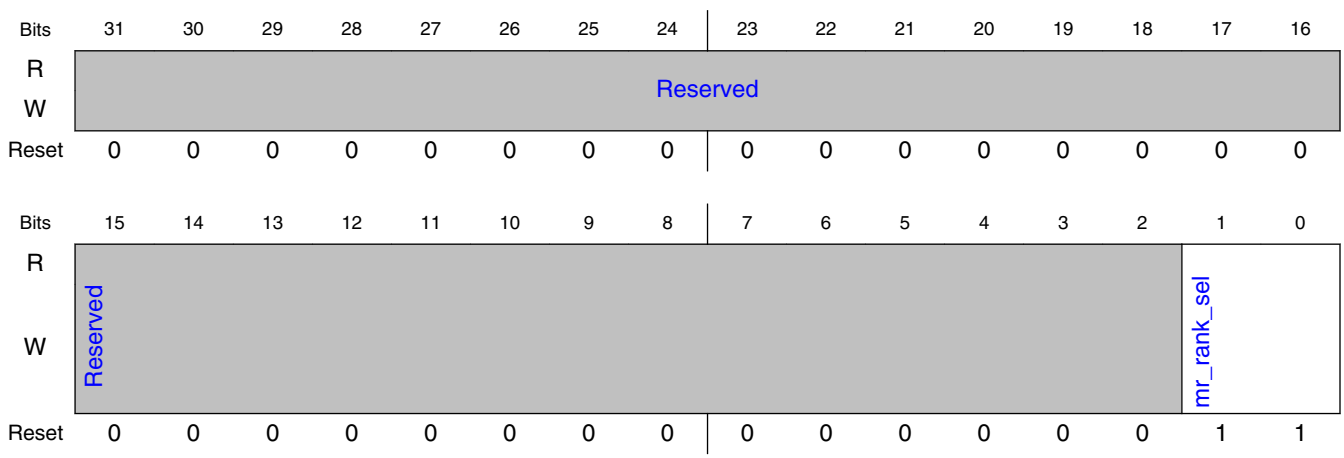
Field	Function
	NOTE: Only some of timing registers in DRAMTMGx are duplicated as MRAMTMGx for MRAM and its width is expanded for MRAM. This register can switch the duplicate registers, otherwise use DRAMTMGx. This register is only for DDR4 ST-MRAM rank, otherwise must be set to 0. This register must be set up while the Controller is in reset. 00b - USE DRAMTMGx registers for the rank 01b - USE MRAMTMGx registers for the rank

9.3.3.1.5 Operating Mode Status Register (MRCTRL3)

9.3.3.1.5.1 Offset

Register	Offset
MRCTRL3	Ch

9.3.3.1.5.2 Diagram



9.3.3.1.5.3 Fields

Field	Function
31-2 —	Reserved
1-0 mr_rank_sel	mr_rank_sel Controls which rank is accessed by MRCTRL0.mr_wr.

Field	Function
	Normally, it is desired to access all ranks, so all bits should be set to 1. However, for multi-rank UDIMMs/ RDIMMs/LRDIMMs which implement address mirroring, it may be necessary to access ranks individually. Examples (assume uMCTL2 is configured for 8 ranks): • 0x01 - select rank 0 only • 0x02 - select rank 1 only • 0x05 - select ranks 0 and 2

9.3.3.1.6 Mode Register Read/Write Control Register 0. (MRCTRL0)

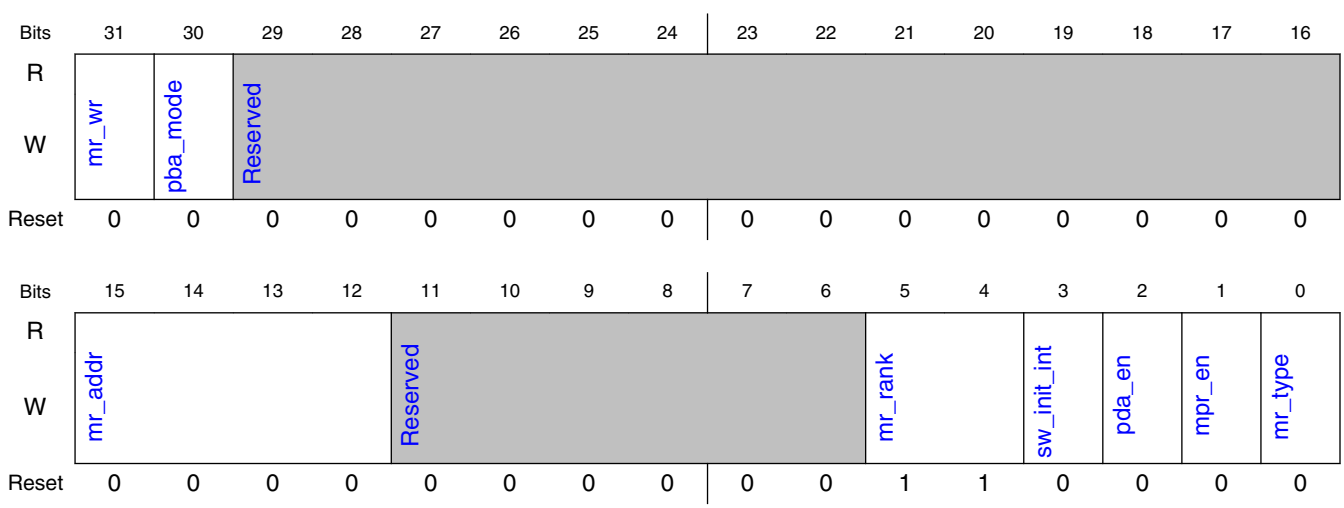
9.3.3.1.6.1 Offset

Register	Offset
MRCTRL0	10h

9.3.3.1.6.2 Function

Mode Register Read/Write Control Register 0. Note: Do not enable more than one of the following fields simultaneously: - sw_init_int - pda_en - mpr_en

9.3.3.1.6.3 Diagram



9.3.3.1.6.4 Fields

Field	Function
31 mr_wr	Setting this register bit to 1 triggers a mode register read or write operation. When the MR operation is complete, the DDRC automatically clears this bit. The other register fields of this register must be written in a separate APB transaction, before setting this mr_wr bit. It is recommended NOT to set this signal if in Init, Deep power-down or MPSM operating modes.
30 pba_mode	Indicates whether PBA access is executed. When setting this bit to 1 along with setting pda_en to 1, DDRC initiates PBA access instead of PDA access. - 0 - Per DRAM Addressability mode - 1 - Per Buffer Addressability mode The completion of PBA access is confirmed by MRSTAT.pda_done in the same way as PDA.
29-16 —	Reserved
15-12 mr_addr	Address of the mode register that is to be written to. Don't Care for LPDDR2/LPDDR3/LPDDR4 (see MRCTRL1.mr_data for mode register addressing in LPDDR2/LPDDR3/LPDDR4) This signal is also used for writing to control words of the register chip on RDIMMs/LRDIMMs. In that case, it corresponds to the bank address bits sent to the RDIMM/LRDIMM In case of DDR4, the bit[3:2] corresponds to the bank group bits. Therefore, the bit[3] as well as the bit[2:0] must be set to an appropriate value which is considered both the Address Mirroring of UDIMMs/RDIMMs/LRDIMMs and the Output Inversion of RDIMMs/LRDIMMs. 0000b - MR0 0001b - MR1 0010b - MR2 0011b - MR3 0100b - MR4 0101b - MR5 0110b - MR6 0111b - MR7
11-6 —	Reserved
5-4 mr_rank	Controls which rank is accessed by MRCTRL0.mr_wr. Normally, it is desired to access all ranks, so all bits should be set to 1. However, for multi-rank UDIMMs/RDIMMs/LRDIMMs which implement address mirroring, it may be necessary to access ranks individually. Examples (assume DDRC is configured for 4 ranks): 0x1 - select rank 0 only 0x2 - select rank 1 only 0x5 - select ranks 0 and 2 0xA - select ranks 1 and 3 0xF - select ranks 0, 1, 2 and 3
3 sw_init_int	Indicates whether Software intervention is allowed via MRCTRL0/MRCTRL1 before automatic SDRAM initialization routine or not. For DDR4, this bit can be used to initialize the DDR4 RCD (MR7) before automatic SDRAM initialization. For LPDDR4, this bit can be used to program additional mode registers before automatic SDRAM initialization if necessary. In LPDDR4 independent channel mode, note that this must be programmed to both channels beforehand. Note that this must be cleared to 0 after completing Software operation. Otherwise, SDRAM initialization routine will not re-start. 0b - Software intervention is not allowed 1b - Software intervention is allowed
2 pda_en	Indicates whether the mode register operation is MRS in PDA mode or not. Note that when pba_mode=1, PBA access is initiated instead of PDA access. 0b - MRS 1b - MRS in Per DRAM Addressability
1 mpr_en	Indicates whether the mode register operation is MRS or WR/RD for MPR (only supported for DDR4). 0b - MRS 1b - WR/RD for MPR
0 mr_type	Indicates whether the mode register operation is read or write. Only used for LPDDR2/LPDDR3/LPDDR4/DDR4.

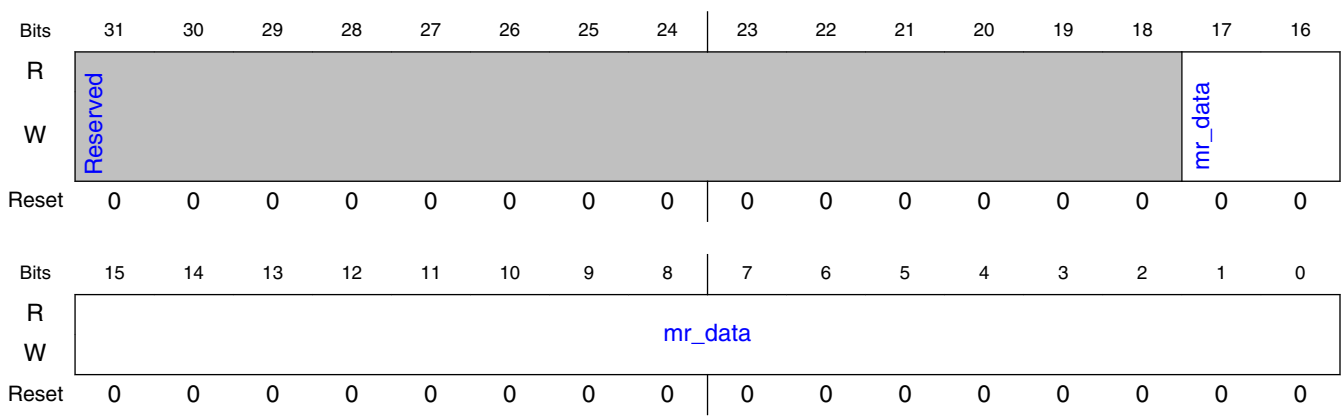
Field	Function
	0b - Write 1b - Read

9.3.3.1.7 Mode Register Read/Write Control Register 1 (MRCTRL1)

9.3.3.1.7.1 Offset

Register	Offset
MRCTRL1	14h

9.3.3.1.7.2 Diagram



9.3.3.1.7.3 Fields

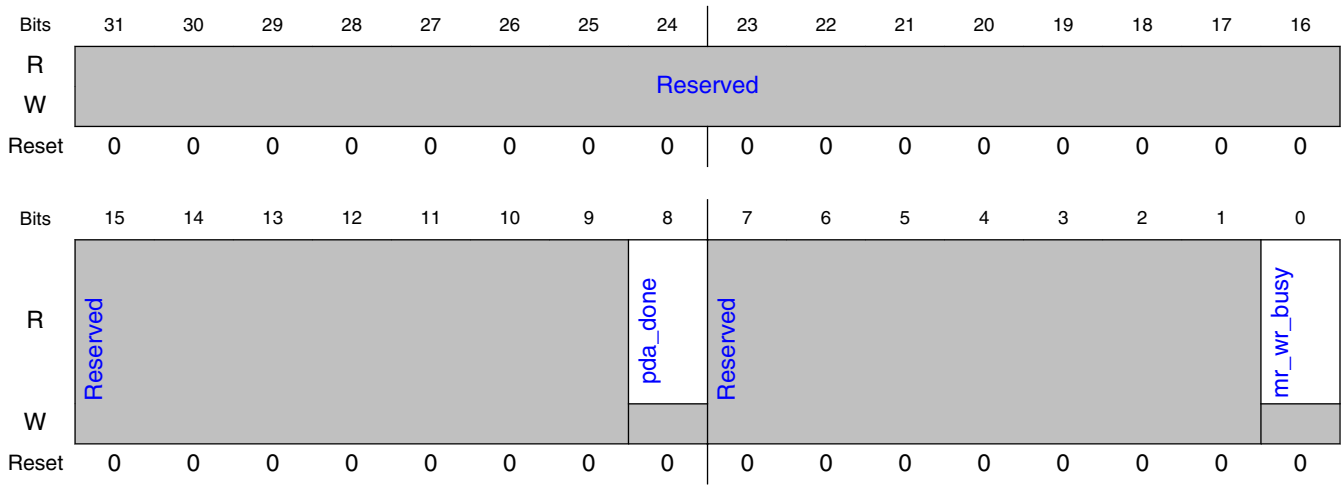
Field	Function
31-18 —	Reserved
17-0 mr_data	Mode register write data for all non-LPDDR2/non-LPDDR3/non-LPDDR4 modes. For LPDDR2/LPDDR3/LPDDR4, MRCTRL1[15:0] are interpreted as [15:8] MR Address [7:0] MR data for writes, don't care for reads. This is 18-bits wide in configurations with DDR4 support and 16-bits in all other configurations.

9.3.3.1.8 Mode Register Read/Write Status Register (MRSTAT)

9.3.3.1.8.1 Offset

Register	Offset
MRSTAT	18h

9.3.3.1.8.2 Diagram



9.3.3.1.8.3 Fields

Field	Function
31-9 —	Reserved
8 pda_done	The SoC core may initiate a MR write operation in PDA/PBA mode only if this signal is low. This signal goes high when three consecutive MRS commands related to the PDA/PBA mode are issued to the SDRAM. This signal goes low when MRCTRL0.pda_en becomes 0. Therefore, it is recommended to write MRCTRL0.pda_en to 0 after this signal goes high in order to prepare to perform PDA operation next time 0b - Indicates that mode register write operation related to PDA/PBA is in progress or has not started yet. 1b - Indicates that mode register write operation related to PDA/PBA has competed.
7-1 —	Reserved
0 mr_wr_busy	The SoC core may initiate a MR write operation only if this signal is low. This signal goes high in the clock after the DDRC accepts the MRW/MRR request. It goes low when the MRW/MRR command is issued to the SDRAM. It is recommended not to perform MRW/MRR commands when 'MRSTAT.mr_wr_busy' is high. 0b - Indicates that the SoC core can initiate a mode register write operation 1b - Indicates that mode register write operation is in progress

R W	mr_device_sel															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

9.3.3.1.9.3 Fields

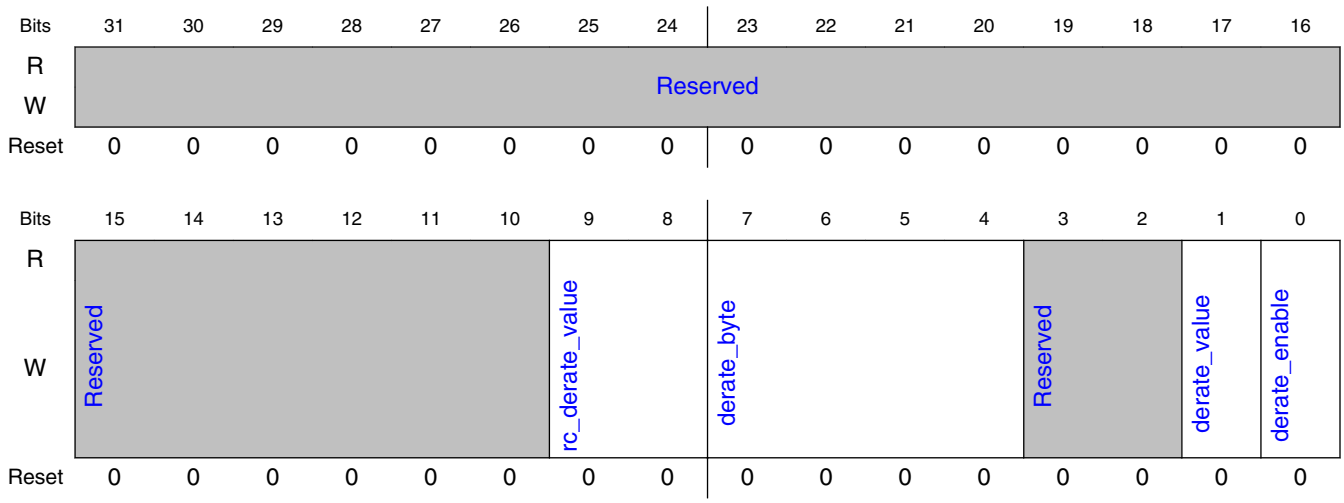
Field	Function
31-0 mr_device_sel	Indicates the device(s) to be selected during the MRS that happens in PDA mode. Each bit is associated with one device. For example, bit[0] corresponds to Device 0, bit[1] to Device 1 etc. A '1' should be programmed to indicate that the MRS command should be applied to that device. A '0' indicates that the MRS commands should be skipped for that device.

9.3.3.1.10 Temperature Derate Enable Register (DERATEEN)

9.3.3.1.10.1 Offset

Register	Offset
DERATEEN	20h

9.3.3.1.10.2 Diagram



9.3.3.1.10.3 Fields

Field	Function
31-10 —	Reserved
9-8 rc_derate_value	Derate value of tRC for LPDDR4. Present only in designs configured to support LPDDR4. The required number of cycles for derating can be determined by dividing 3.75ns by the core_ddrc_core_clk period, and rounding up the next integer. 00b - Derating uses +1 01b - Derating uses +2 10b - Derating uses +3 11b - Derating uses +4
7-4 derate_byte	Derate byte Present only in designs configured to support LPDDR2/LPDDR3/LPDDR4 Indicates which byte of the MRR data is used for derating. The maximum valid value depends on MEMC_DRAM_TOTAL_DATA_WIDTH.
3-2 —	Reserved
1 derate_value	Derate value. Present only in designs configured to support LPDDR2/LPDDR3/LPDDR4 Set to 0 for all LPDDR2 speed grades as derating value of +1.875 ns is less than a core_ddrc_core_clk period. For LPDDR3/4, if the period of core_ddrc_core_clk is less than 1.875ns, this register field should be set to 1; otherwise it should be set to 0. 0b - Derating uses +1 1b - Derating uses +2
0 derate_enable	Enables derating. Present only in designs configured to support LPDDR2/LPDDR3/LPDDR4. This field must be set to '0' for non-LPDDR2/LPDDR3/LPDDR4 mode. 0b - Timing parameter derating is disabled 1b - Timing parameter derating is enabled using MR4 read value.

9.3.3.1.11 Temperature Derate Interval Register (DERATEINT)

9.3.3.1.11.1 Offset

Register	Offset
DERATEINT	24h

9.3.3.1.11.3 Fields

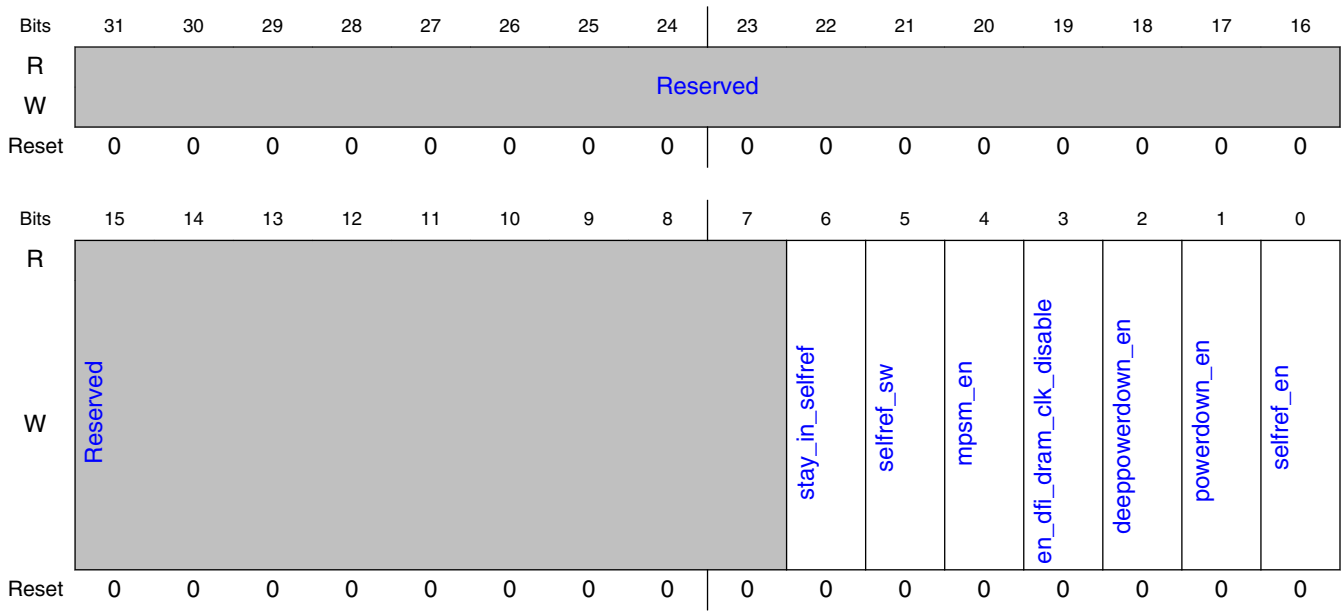
Field	Function
31-0 mr4_read_interval	Interval between two MR4 reads, used to derate the timing parameters. Present only in designs configured to support LPDDR2/LPDDR3/LPDDR4. This register must not be set to zero. Unit: DFI clock cycle.

9.3.3.1.12 Low Power Control Register (PWRCTL)

9.3.3.1.12.1 Offset

Register	Offset
PWRCTL	30h

9.3.3.1.12.2 Diagram



9.3.3.1.12.3 Fields

Field	Function
31-7 —	Reserved
6 stay_in_selfref	Self refresh state is an intermediate state to enter to Self refresh power down state or exit Self refresh power down state for LPDDR4. This register controls transition from the Self refresh state. - 1 - Prohibit transition from Self refresh state - 0 - Allow transition from Self refresh state 0b - 1b -
5 selfref_sw	A value of 1 to this register causes system to move to Self Refresh state immediately, as long as it is not in INIT or DPD/MPSM operating_mode. This is referred to as Software Entry/Exit to Self Refresh. 0b - Software Exit from Self Refresh 1b - Software Entry to Self Refresh
4 mpsm_en	When this is 1, the DDRC puts the SDRAM into maximum power saving mode when the transaction store is empty. This register must be reset to '0' to bring DDRC out of maximum power saving mode. Present only in designs configured to support DDR4. For non-DDR4, this register should not be set to 1. Note that MPSM is not supported when using a DDR PHY, if the PHY parameter DDRC_AC_CS_USE is disabled, as the MPSM exit sequence requires the chip-select signal to toggle. FOR PERFORMANCE ONLY.
3 en_dfi_dram_clk_disable	Enable the assertion of dfi_dram_clk_disable whenever a clock is not required by the SDRAM. If set to 0, dfi_dram_clk_disable is never asserted. Assertion of dfi_dram_clk_disable is as follows: In DDR2/DDR3, can only be asserted in Self Refresh. In DDR4, can be asserted in following: in Self Refresh in Maximum Power Saving Mode In mDDR/LPDDR2/LPDDR3, can be asserted in following: in Self Refresh in Power Down in Deep Power Down during Normal operation (Clock Stop) In LPDDR4, can be asserted in following: in Self Refresh Power Down in Power Down during Normal operation (Clock Stop)
2 deeppowerdown_en	When this is 1, DDRC puts the SDRAM into deep power-down mode when the transaction store is empty. This register must be reset to '0' to bring DDRC out of deep power-down mode. Controller performs automatic SDRAM initialization on deep power-down exit. Present only in designs configured to support

Table continues on the next page...

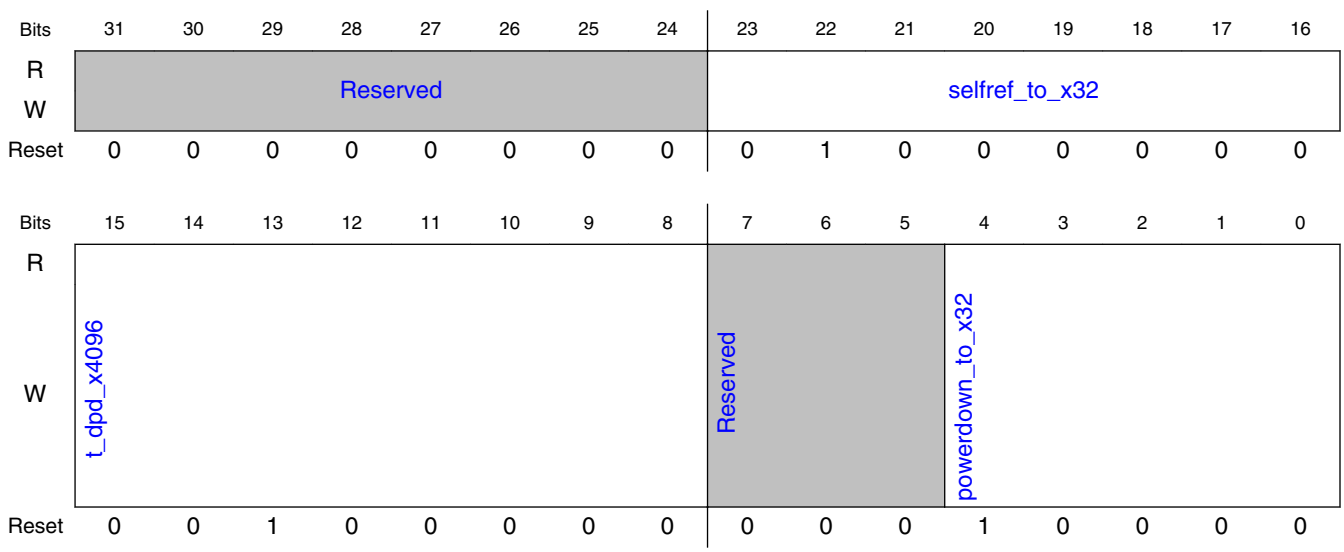
Field	Function
	mDDR or LPDDR2 or LPDDR3. For non-mDDR/non-LPDDR2/non-LPDDR3, this register should not be set to 1. FOR PERFORMANCE ONLY.
1 powerdown_en	If true then the DDRC goes into power-down after a programmable number of cycles "maximum idle clocks before power down" (PWRTMG.powerdown_to_x32). This register bit may be re-programmed during the course of normal operation.
0 selfref_en	If true then the DDRC puts the SDRAM into Self Refresh after a programmable number of cycles "maximum idle clocks before Self Refresh (PWRTMG.selfref_to_x32)". This register bit may be re-programmed during the course of normal operation.

9.3.3.1.13 Low Power Timing Register (PWRTMG)

9.3.3.1.13.1 Offset

Register	Offset
PWRTMG	34h

9.3.3.1.13.2 Diagram



9.3.3.1.13.3 Fields

Field	Function
31-24 —	Reserved

Table continues on the next page...

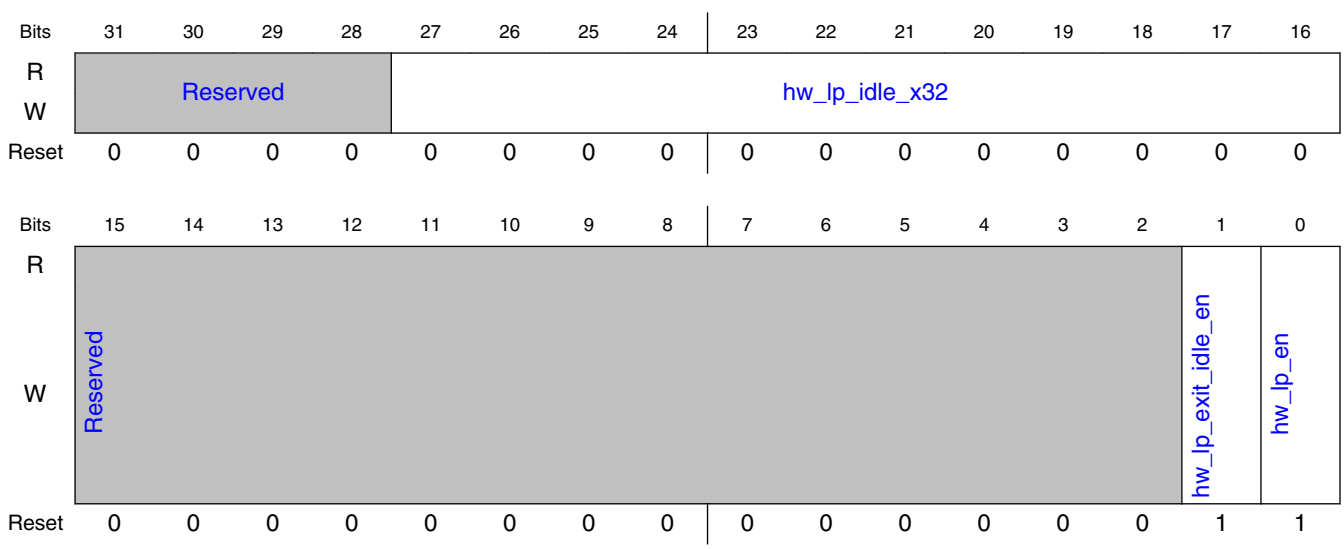
Field	Function
23-16 selfref_to_x32	After this many clocks of the DDRC command channel being idle the DDRC automatically puts the SDRAM into Self Refresh. The DDRC command channel is considered idle when there are no HIF commands outstanding. This must be enabled in the PWRCTL.selfref_en. Unit: Multiples of 32 DFI clocks. FOR PERFORMANCE ONLY.
15-8 t_dpd_x4096	Minimum deep power-down time. For mDDR, value from the JEDEC specification is 0 as mDDR exits from deep power-down mode immediately after PWRCTL.deeppowerdown_en is de-asserted. For LPDDR2/LPDDR3, value from the JEDEC specification is 500us. Unit: Multiples of 4096 DFI clocks. Present only in designs configured to support mDDR, LPDDR2 or LPDDR3. FOR PERFORMANCE ONLY.
7-5 —	Reserved
4-0 powerdown_to_x32	After this many clocks of the DDRC command channel being idle the DDRC automatically puts the SDRAM into power-down. The DDRC command channel is considered idle when there are no HIF commands outstanding. This must be enabled in the PWRCTL.powerdown_en. Unit: Multiples of 32 DFI clocks FOR PERFORMANCE ONLY.

9.3.3.1.14 Hardware Low Power Control Register (HWLPCTL)

9.3.3.1.14.1 Offset

Register	Offset
HWLPCTL	38h

9.3.3.1.14.2 Diagram



9.3.3.1.14.3 Fields

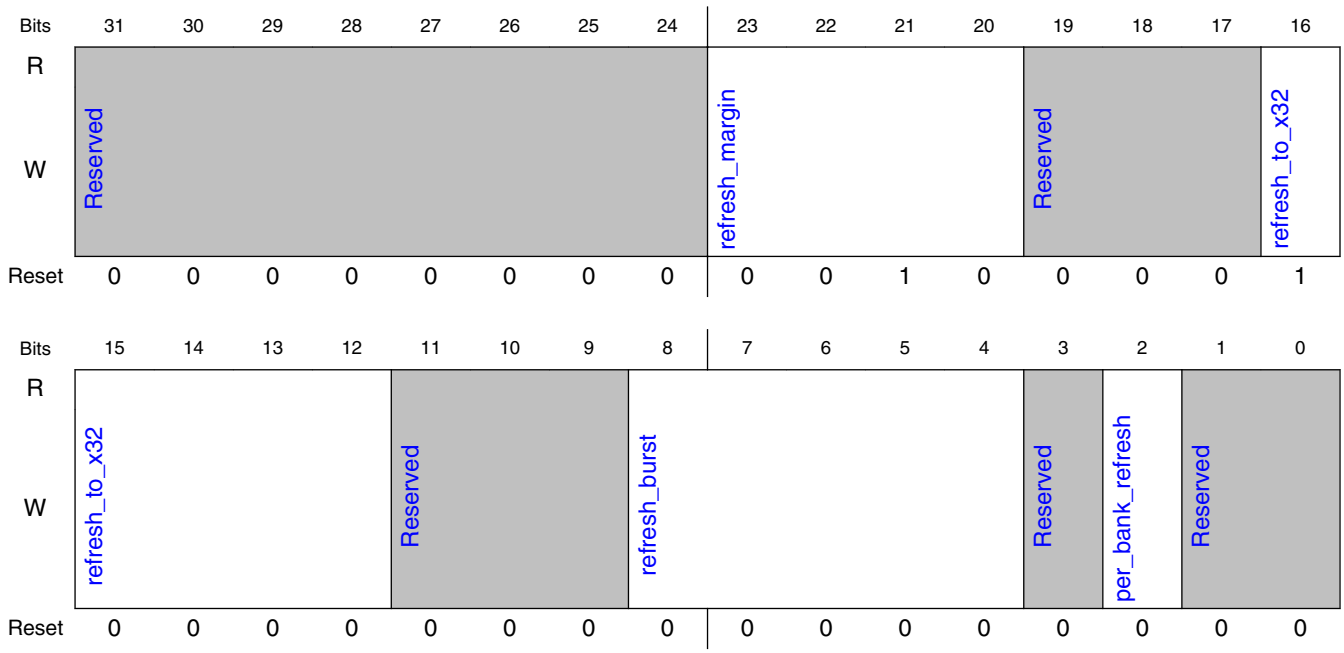
Field	Function
31-28 —	Reserved
27-16 hw_lp_idle_x32	Hardware idle period. The cactive_ddrc output is driven low if the DDRC command channel is idle for hw_lp_idle * 32 cycles if not in INIT or DPD/MPSM operating_mode. The DDRC command channel is considered idle when there are no HIF commands outstanding. The hardware idle function is disabled when hw_lp_idle_x32=0. Unit: Multiples of 32 DFI clocks. FOR PERFORMANCE ONLY.
15-2 —	Reserved
1 hw_lp_exit_idle_en	When this bit is programmed to 1 the cactive_in_ddrc pin of the DDRC can be used to exit from the automatic clock stop, automatic power down or automatic self-refresh modes. Note, it will not cause exit of Self-Refresh that was caused by Hardware Low Power Interface and/or Software (PWRCTL.selfref_sw).
0 hw_lp_en	Enable for Hardware Low Power Interface.

9.3.3.1.15 Refresh Control Register 0 (RFSHCTL0)

9.3.3.1.15.1 Offset

Register	Offset
RFSHCTL0	50h

9.3.3.1.15.2 Diagram



9.3.3.1.15.3 Fields

Field	Function
31-24 —	Reserved
23-20 refresh_margin	Threshold value in number of DFI clock cycles before the critical refresh or page timer expires. A critical refresh is to be issued before this threshold is reached. It is recommended that this not be changed from the default value, currently shown as 0x2. It must always be less than internally used t_rfc_nom_x32. Note that, in LPDDR2/LPDDR3/LPDDR4, internally used t_rfc_nom_x32 may be equal to RFSHTMG.t_rfc_nom_x32>>2 if derating is enabled (DERATEEN.derate_enable=1). Otherwise, internally used t_rfc_nom_x32 will be equal to RFSHTMG.t_rfc_nom_x32. Unit: Multiples of 32 DFI clocks.
19-17 —	Reserved
16-12 refresh_to_x32	If the refresh timer (tRFCnom, also known as tREFI) has expired at least once, but it has not expired (RFSHCTL0.refresh_burst+1) times yet, then a speculative refresh may be performed. A speculative refresh is a refresh performed at a time when refresh would be useful, but before it is absolutely required. When the SDRAM bus is idle for a period of time determined by this RFSHCTL0.refresh_to_x32 and the refresh timer has expired at least once since the last refresh, then a speculative refresh is performed. Speculative refreshes continues successively until there are no refreshes pending or until new reads or writes are issued to the DDRC. FOR PERFORMANCE ONLY. Unit: Multiples of 32 DFI clocks.
11-9 —	Reserved
8-4 refresh_burst	The programmed value + 1 is the number of refresh timeouts that is allowed to accumulate before traffic is blocked and the refreshes are forced to execute. Closing pages to perform a refresh is a one-time penalty that must be paid for each group of refreshes. Therefore, performing refreshes in a burst reduces

Table continues on the next page...

Field	Function
	the per-refresh penalty of these page closings. Higher numbers for RFSHCTL.refresh_burst slightly increases utilization; lower numbers decreases the worst-case latency associated with refreshes. - 0 - single refresh - 1 - burst-of-2 refresh - 7 - burst-of-8 refresh For information on burst refresh feature refer to section 3.9 of DDR2 JEDEC specification - JESD79-2F.pdf. For DDR2/3, the refresh is always per-rank and not per-bank. The rank refresh can be accumulated over 8*tREFI cycles using the burst refresh feature. In DDR4 mode, according to Fine Granularity feature, 8 refreshes can be postponed in 1X mode, 16 refreshes in 2X mode and 32 refreshes in 4X mode. If using PHY-initiated updates, care must be taken in the setting of RFSHCTL0.refresh_burst, to ensure that tRFCmax is not violated due to a PHY-initiated update occurring shortly before a refresh burst was due. In this situation, the refresh burst will be delayed until the PHY-initiated update is complete.
3 —	Reserved
2 per_bank_refresh	Per bank refresh allows traffic to flow to other banks. Per bank refresh is not supported by all LPDDR2 devices but should be supported by all LPDDR3/LPDDR4 devices. Present only in designs configured to support LPDDR2/LPDDR3/LPDDR4 0b - All bank refresh 1b - Per bank refresh
1-0 —	Reserved

9.3.3.1.16 Refresh Control Register 1 (RFSHCTL1)

9.3.3.1.16.1 Offset

Register	Offset
RFSHCTL1	54h

9.3.3.1.16.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved				refresh_timer0_start_value_x32											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

9.3.3.1.16.3 Fields

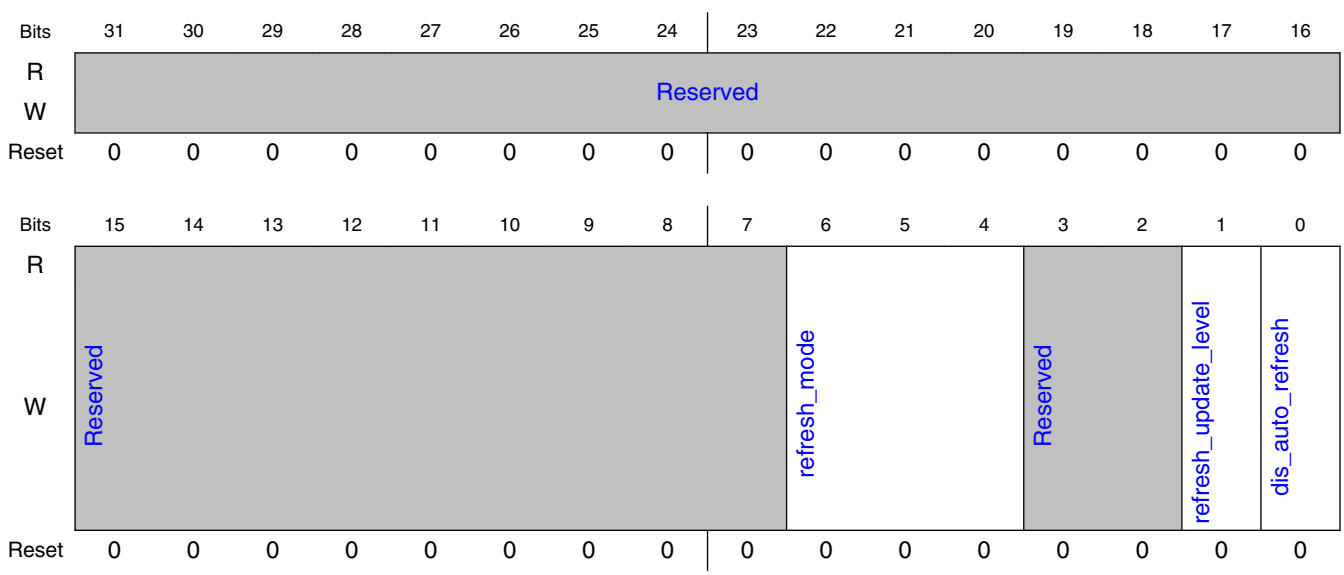
Field	Function
31-28 —	Reserved
27-16 refresh_timer1_start_value_x32	Refresh timer start for rank 1 (only present in multi-rank configurations). This is useful in staggering the refreshes to multiple ranks to help traffic to proceed. This is explained in Refresh Controls section of architecture chapter. Unit: Multiples of 32 DFI clock cycles. FOR PERFORMANCE ONLY.
15-12 —	Reserved
11-0 refresh_timer0_start_value_x32	Refresh timer start for rank 0 (only present in multi-rank configurations). This is useful in staggering the refreshes to multiple ranks to help traffic to proceed. This is explained in Refresh Controls section of architecture chapter. Unit: Multiples of 32 DFI clock cycles. FOR PERFORMANCE ONLY.

9.3.3.1.17 Refresh Control Register 3 (RFSHCTL3)

9.3.3.1.17.1 Offset

Register	Offset
RFSHCTL3	60h

9.3.3.1.17.2 Diagram



9.3.3.1.17.3 Fields

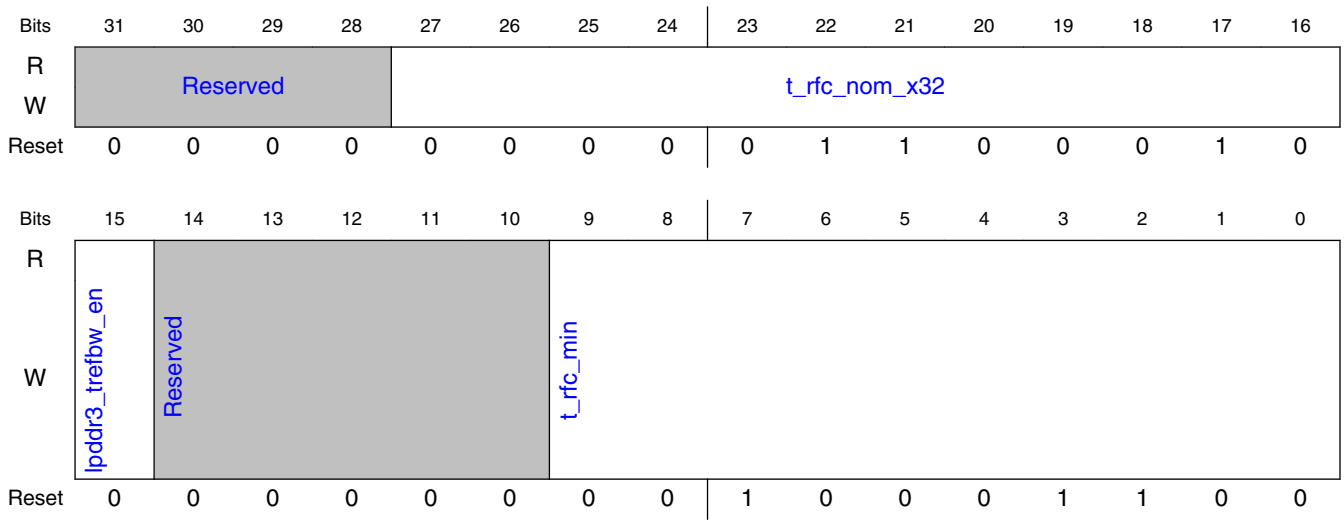
Field	Function
31-7 —	Reserved
6-4 refresh_mode	Fine Granularity Refresh Mode - 000 - Fixed 1x (Normal mode) - 001 - Fixed 2x - 010 - Fixed 4x - 101 - Enable on the fly 2x (not supported) - 110 - Enable on the fly 4x (not supported) - Everything else - reserved Note: Only Fixed 1x mode is supported if RFSHCTL3.dis_auto_refresh = 1. Note: The on-the-fly modes are not supported in this version of the DDRC. Note: This must be set up while the Controller is in reset or while the Controller is in self-refresh mode. Changing this during normal operation is not allowed. Making this a dynamic register will be supported in future version of the DDRC. Note: This register field has effect only if a DDR4 SDRAM device is in use (MSTR.ddr4 = 1).
3-2 —	Reserved
1 refresh_update_level	Toggle this signal (either from 0 to 1 or from 1 to 0) to indicate that the refresh register(s) have been updated. refresh_update_level must not be toggled when the DDRC is in reset (core_ddrc_rstn = 0). The refresh register(s) are automatically updated when exiting reset.
0 dis_auto_refresh	When '1', disable auto-refresh generated by the DDRC. When auto-refresh is disabled, the SoC core must generate refreshes using the registers reg_ddrc_rank0_refresh, reg_ddrc_rank1_refresh, reg_ddrc_rank2_refresh and reg_ddrc_rank3_refresh. When dis_auto_refresh transitions from 0 to 1, any pending refreshes are immediately scheduled by the DDRC. If DDR4 CRC/parity retry is enabled (CRCPARCTL1.crc_parity_retry_enable = 1), disable auto-refresh is not supported, and this bit must be set to '0'. (DDR4 only) If FGR mode is enabled (RFSHCTL3.refresh_mode > 0), disable auto-refresh is not supported, and this bit must be set to '0'. This register field is changeable on the fly.

9.3.3.1.18 Refresh Timing Register (RFSHTMG)

9.3.3.1.18.1 Offset

Register	Offset
RFSHTMG	64h

9.3.3.1.18.2 Diagram



9.3.3.1.18.3 Fields

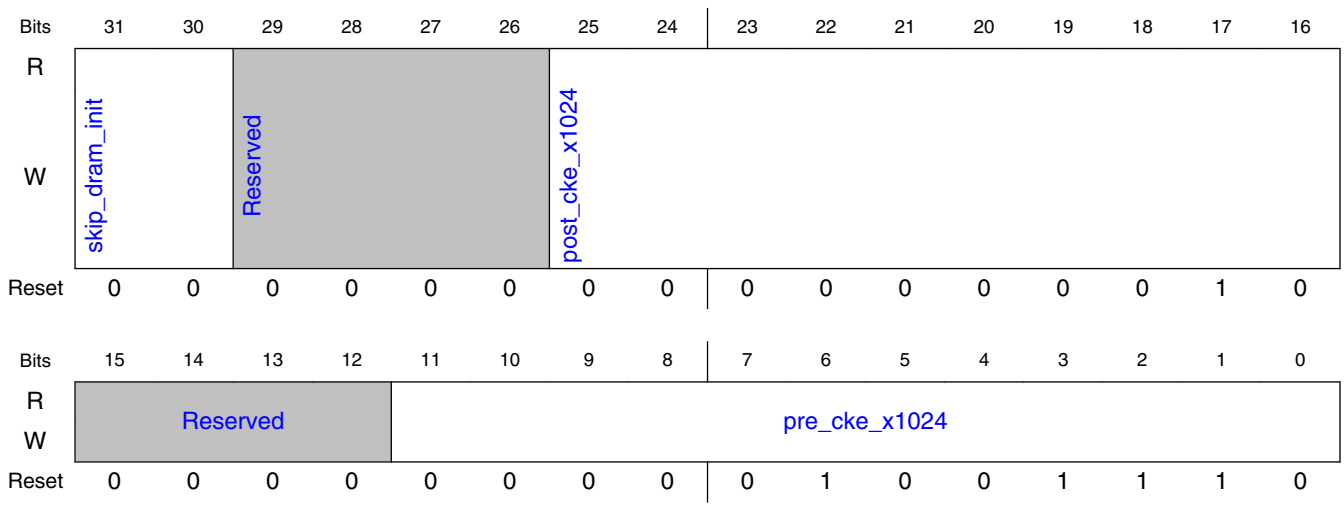
Field	Function
31-28 —	Reserved
27-16 t_rfc_nom_x32	tREFI: Average time interval between refreshes per rank (Specification: 7.8us for DDR2, DDR3 and DDR4. See JEDEC specification for mDDR, LPDDR2, LPDDR3 and LPDDR4). For LPDDR2/LPDDR3/LPDDR4: - if using all-bank refreshes (RFSHCTL0.per_bank_refresh = 0), this register should be set to tREFIab - if using per-bank refreshes (RFSHCTL0.per_bank_refresh = 1), this register should be set to tREFIpb When the controller is operating in 1:2 frequency ratio mode, program this to (tREFI/2), no rounding up. In DDR4 mode, tREFI value is different depending on the refresh mode. The user should program the appropriate value from the spec based on the value programmed in the refresh mode register. Note that RFSHTMG.t_rfc_nom_x32 * 32 must be greater than RFSHTMG.t_rfc_min, and RFSHTMG.t_rfc_nom_x32 must be greater than 0x1. - Non-DDR4 or DDR4 Fixed 1x mode: RFSHTMG.t_rfc_nom_x32 must be less than or equal to 0xFFE. - DDR4 Fixed 2x mode: RFSHTMG.t_rfc_nom_x32 must be less than or equal to 0x7FF. - DDR4 Fixed 4x mode: RFSHTMG.t_rfc_nom_x32 must be less than or equal to 0x3FF. Unit: Multiples of 32 clocks.
15 lpddr3_trefbw_en	Used only when LPDDR3 memory type is connected. Should only be changed when DDRC is in reset. Specifies whether to use the tREFBW parameter (required by some LPDDR3 devices which comply with earlier versions of the LPDDR3 JEDEC specification) or not: - 0 - tREFBW parameter not used - 1 - tREFBW parameter used
14-10 —	Reserved
9-0 t_rfc_min	tRFC (min): Minimum time from refresh to refresh or activate. When the controller is operating in 1:1 mode, t_rfc_min should be set to RoundUp(tRFCmin/tCK). When the controller is operating in 1:2 mode, t_rfc_min should be set to RoundUp(RoundUp(tRFCmin/tCK)/2). In LPDDR2/LPDDR3/LPDDR4 mode: - if using all-bank refreshes, the tRFCmin value in the above equations is equal to tRFCab - if using per-bank refreshes, the tRFCmin value in the above equations is equal to tRFCpb In DDR4 mode, the tRFCmin value in the above equations is different depending on the refresh mode (fixed 1X,2X,4X) and the device density. The user should program the appropriate value from the spec based on the 'refresh_mode' and the device density that is used. Unit: Clocks.

9.3.3.1.19 SDRAM Initialization Register 0 (INIT0)

9.3.3.1.19.1 Offset

Register	Offset
INIT0	D0h

9.3.3.1.19.2 Diagram



9.3.3.1.19.3 Fields

Field	Function
31-30 skip_dram_init	If lower bit is enabled the SDRAM initialization routine is skipped. The upper bit decides what state the controller starts up in when reset is removed - 00 - SDRAM Intialization routine is run after power-up - 01 - SDRAM Initialization routine is skipped after power-up. Controller starts up in Normal Mode - 11 - SDRAM Initialization routine is skipped after power-up. Controller starts up in Self-refresh Mode - 10 - SDRAM Initialization routine is run after power-up. 00b - SDRAM Initialization routine is run after power-up 01b - SDRAM Initialization routine is skipped after power-up 10b - SDRAM Initialization routine is run after power-up 11b - SDRAM Initialization routine is skipped after power-up
29-26 —	Reserved
25-16 post_cke_x1024	Cycles to wait after driving CKE high to start the SDRAM initialization sequence. Unit: 1024 DFI clock cycles. DDR2 typically requires a 400 ns delay, requiring this value to be programmed to 2 at all clock speeds. LPDDR2/LPDDR3 typically requires this to be programmed for a delay of 200 us. LPDDR4 typically requires this to be programmed for a delay of 2 us. When the controller is operating in 1:2 frequency ratio mode, program this to JEDEC spec value divided by 2, and round it up to the next integer value.

Table continues on the next page...

Field	Function
15-12 —	Reserved
11-0 pre_cke_x1024	Cycles to wait after reset before driving CKE high to start the SDRAM initialization sequence. Unit: 1024 DFI clock cycles. DDR2 specifications typically require this to be programmed for a delay of >= 200 us. LPDDR2/LPDDR3: tINIT1 of 100 ns (min) LPDDR4: tINIT3 of 2 ms (min) When the controller is operating in 1:2 frequency ratio mode, program this to JEDEC spec value divided by 2, and round it up to the next integer value. For DDR3/DDR4 RDIMMs, this should include the time needed to satisfy tSTAB

Field	Function
31-7	Reserved

Table continues on the next page...

Field	Function
—	
6 lrdimm_bcom_cmd_prot	Protects the timing restrictions (tBCW/tMRC) between consecutive BCOM commands defined in the Data Buffer specification. When using DDR4 LRDIMM, this bit must be set to 1. Otherwise, this bit must be set to 0.
5 dimm_dis_bg_mirroring	Disabling Address Mirroring for BG bits. When this is set to 1, BG0 and BG1 are NOT swapped even if Address Mirroring is enabled. This will be required for DDR4 DIMMs with x16 devices. 0b - BG0 and BG1 are swapped if address mirroring is enabled. 1b - BG0 and BG1 are NOT swapped.
4 mrs_bg1_en	Enable for BG1 bit of MRS command. BG1 bit of the mode register address is specified as RFU (Reserved for Future Use) and must be programmed to 0 during MRS. In case where DRAMs which do not have BG1 are attached and both the CA parity and the Output Inversion are enabled, this must be set to 0, so that the calculation of CA parity will not include BG1 bit. Note: This has no effect on the address of any other memory accesses, or of software-driven mode register accesses. If address mirroring is enabled, this is applied to BG1 of even ranks and BG0 of odd ranks. 0b - Disabled 1b - Enabled
3 mrs_a17_en	Enable for A17 bit of MRS command. A17 bit of the mode register address is specified as RFU (Reserved for Future Use) and must be programmed to 0 during MRS. In case where DRAMs which do not have A17 are attached and the Output Inversion are enabled, this must be set to 0, so that the calculation of CA parity will not include A17 bit. Note: This has no effect on the address of any other memory accesses, or of software-driven mode register accesses. 0b - Disabled 1b - Enabled
2 dimm_output_inv_en	Output Inversion Enable (for DDR4 RDIMM/LRDIMM implementations only). DDR4 RDIMM/LRDIMM implements the Output Inversion feature by default, which means that the following address, bank address and bank group bits of B-side DRAMs are inverted: A3-A9, A11, A13, A17, BA0-BA1, BG0-BG1. Setting this bit ensures that, for mode register accesses generated by the DDRC during the automatic initialization routine and enabling of a particular DDR4 feature, separate A-side and B-side mode register accesses are generated. For B-side mode register accesses, these bits are inverted within the DDRC to compensate for this RDIMM/LRDIMM inversion. It is recommended to set this bit always, if using DDR4 RDIMMs/LRDIMMs. Note: This has no effect on the address of any other memory accesses, or of software-driven mode register accesses. 0b - Do not implement output inversion for B-side DRAMs. 1b - Implement output inversion for B-side DRAMs.
1 dimm_addr_mirr_en	Address Mirroring Enable (for multi-rank UDIMM implementations and multi-rank DDR4 RDIMM/LRDIMM implementations). Some UDIMMs and DDR4 RDIMMs/LRDIMMs implement address mirroring for odd ranks, which means that the following address, bank address and bank group bits are swapped: (A3, A4), (A5, A6), (A7, A8), (BA0, BA1) and also (A11, A13), (BG0, BG1) for the DDR4. Setting this bit ensures that, for mode register accesses during the automatic initialization routine, these bits are swapped within the DDRC to compensate for this UDIMM/RDIMM/LRDIMM swapping. In addition to the automatic initialization routine, in case of DDR4 UDIMM/RDIMM/LRDIMM, they are swapped during the automatic MRS access to enable/disable of a particular DDR4 feature. Note: This has no effect on the address of any other memory accesses, or of software-driven mode register accesses. This is not supported for mDDR, LPDDR2, LPDDR3 or LPDDR4 SDRAMs. Note: In case of x16 DDR4 DIMMs, BG1 output of MRS for the odd ranks is same as BG0 because BG1 is invalid, hence dimm_dis_bg_mirroring register must be set to 1. 0b - Do not implement address mirroring 1b - For odd ranks, implement address mirroring for MRS commands to during initialization and for any automatic DDR4 MRS commands (to be used if UDIMM/RDIMM/LRDIMM implements address mirroring)
0 dimm_stagger_cs_en	Staggering enable for multi-rank accesses (for multi-rank UDIMM, RDIMM and LRDIMM implementations only). This is not supported for mDDR, LPDDR2, LPDDR3 or LPDDR4 SDRAMs. Even if this bit is set it does not take care of software driven MR commands (via MRCTRL0/MRCTRL1), where software is responsible to send them to separate ranks as appropriate.

Field	Function
	0b - Do not stagger accesses 1b - (non-DDR4) Send all commands to even and odd ranks separately

Field	Function
31-12 —	Reserved
11-8 diff_rank_wr_gap	Only present for multi-rank configurations. Indicates the number of clocks of gap in data responses when performing consecutive writes to different ranks. This is used to switch the delays in the PHY to match the rank requirements. This value should consider both PHY requirement and ODT requirement. - PHY requirement: tphy_wrcsgap + 1 (see PHY databook for value of tphy_wrcsgap) If CRC feature is enabled, should be increased by 1. If write preamble is set to 2tCK(DDR4/LPDDR4 only), should be increased by 1. If write postamble is set to 1.5tCK(LPDDR4 only), should be increased by 1. - ODT requirement: The value programmed in this register takes care of the ODT switch off timing requirement when switching ranks during writes. For LPDDR4, the requirement is ODTLoff - ODTLon - BL/2 + 1 When the controller is

Table continues on the next page...

Field	Function
	operating in 1:1 mode, program this to the larger of PHY requirement or ODT requirement. When the controller is operating in 1:2 mode, program this to the larger value divided by two and round it up to the next integer. Note that, if using DDR4-LRDIMM, refer to TWRWR timing requirements in JEDEC DDR4 Data Buffer (DDR4DB01) Specification.
7-4 diff_rank_rd_gap	Only present for multi-rank configurations. Indicates the number of clocks of gap in data responses when performing consecutive reads to different ranks. This is used to switch the delays in the PHY to match the rank requirements. This value should consider both PHY requirement and ODT requirement. - PHY requirement: tphy_rdcsgap + 1 (see PHY databook for value of tphy_rdcsgap) If read preamble is set to 2tCK(DDR4/LPDDR4 only), should be increased by 1. If read postamble is set to 1.5tCK(LPDDR4 only), should be increased by 1. - ODT requirement: The value programmed in this register takes care of the ODT switch off timing requirement when switching ranks during reads. When the controller is operating in 1:1 mode, program this to the larger of PHY requirement or ODT requirement. When the controller is operating in 1:2 mode, program this to the larger value divided by two and round it up to the next integer. Note that, if using DDR4-LRDIMM, refer to TRDRD timing requirements in JEDEC DDR4 Data Buffer (DDR4DB01) Specification.
3-0 max_rank_rd	Only present for multi-rank configurations. Background: Reads to the same rank can be performed back-to-back. Reads to different ranks require additional gap dictated by the register RANKCTL.diff_rank_rd_gap. This is to avoid possible data bus contention as well as to give PHY enough time to switch the delay when changing ranks. The DDRC arbitrates for bus access on a cycle-by-cycle basis; therefore after a read is scheduled, there are few clock cycles (determined by the value on RANKCTL.diff_rank_rd_gap register) in which only reads from the same rank are eligible to be scheduled. This prevents reads from other ranks from having fair access to the data bus. This parameter represents the maximum number of reads that can be scheduled consecutively to the same rank. After this number is reached, a delay equal to RANKCTL.diff_rank_rd_gap is inserted by the scheduler to allow all ranks a fair opportunity to be scheduled. Higher numbers increase bandwidth utilization, lower numbers increase fairness. This feature can be DISABLED by setting this register to 0. When set to 0, the Controller will stay on the same rank as long as commands are available for it. Minimum programmable value is 0 (feature disabled) and maximum programmable value is 0xF. FOR PERFORMANCE ONLY.

9.3.3.1.29 SDRAM Timing Register 0 (DRAMTMG0)

31 —	Reserved
30-24 wr2pre	Minimum time between write and precharge to same bank. Unit: Clocks Specifications: WL + BL/2 + tWR = approximately 8 cycles + 15 ns = 14 clocks @400MHz and less for lower frequencies where: - WL = write latency - BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM. BST (burst terminate) is not supported at present. - tWR = Write recovery time. This comes directly from the SDRAM specification. Add one extra cycle for LPDDR2/LPDDR3/LPDDR4 for this parameter. When the controller is operating in 1:2 frequency ratio mode, 1T mode, divide the above value by 2. No rounding up. When the controller is operating in 1:2 frequency ratio mode, 2T mode or LPDDR4 mode, divide the above value by 2 and round it up to the next integer value. Note that, depending on the PHY, if using LRDIMM, it may be necessary to adjust the value of this parameter to compensate for the extra cycle of latency through the LRDIMM.
23-22 —	Reserved
21-16 t_faw	tFAW Valid only when 8 or more banks(or banks x bank groups) are present. In 8-bank design, at most 4 banks must be activated in a rolling window of tFAW cycles. When the controller is operating in 1:2 frequency ratio mode, program this to (tFAW/2) and round up to next integer value. In a 4-bank design, set this register to 0x1 independent of the 1:1/1:2 frequency mode. Unit: Clocks
15 —	Reserved
14-8 t_ras_max	tRAS(max): Maximum time between activate and precharge to same bank. This is the maximum time that a page can be kept open Minimum value of this register is 1. Zero is invalid. When the controller is operating in 1:2 frequency ratio mode, program this to (tRAS(max)-1)/2. No rounding up. Unit: Multiples of 1024 clocks.
7-6 —	Reserved
5-0 t_ras_min	tRAS(min): Minimum time between activate and precharge to the same bank. When the controller is operating in 1:2 frequency mode, 1T mode, program this to tRAS(min)/2. No rounding up. When the

Field	Function
	controller is operating in 1:2 frequency ratio mode, 2T mode or LPDDR4 mode, program this to (tRAS(min)/2) and round it up to the next integer value. Unit: Clocks

Field	Function
29-24 write_latency	Set to WL Time from write command to write data on SDRAM interface. This must be set to WL. For mDDR, it should normally be set to 1. Note that, depending on the PHY, if using RDIMM/LRDIMM, it may be necessary to adjust the value of WL to compensate for the extra cycle of latency through the RDIMM/ LRDIMM. When the controller is operating in 1:2 frequency ratio mode, divide the value calculated using the above equation by 2, and round it up to next integer. This register field is not required for DDR2 and DDR3 (except if MEMC_TRAINING is set), as the DFI read and write latencies defined in DFITMG0 and DFITMG1 are sufficient for those protocols Unit: clocks
23-22 —	Reserved
21-16 read_latency	Set to RL Time from read command to read data on SDRAM interface. This must be set to RL. Note that, depending on the PHY, if using RDIMM/LRDIMM, it may be necessary to adjust the value of RL to compensate for the extra cycle of latency through the RDIMM/LRDIMM. When the controller is operating in 1:2 frequency ratio mode, divide the value calculated using the above equation by 2, and round it up to next integer. This register field is not required for DDR2 and DDR3 (except if MEMC_TRAINING is set), as the DFI read and write latencies defined in DFITMG0 and DFITMG1 are sufficient for those protocols Unit: clocks
15-14 —	Reserved
13-8 rd2wr	DDR2/3/mDDR: RL + BL/2 + 2 - WL DDR4: RL + BL/2 + 1 + WR_PREAMBLE - WL LPDDR2/LPDDR3: RL + BL/2 + RU(tDQSCKmax/tCK) + 1 - WL LPDDR4(DQ ODT is Disabled): RL + BL/2 + RU(tDQSCKmax/tCK) + WR_PREAMBLE + RD_POSTAMBLE - WL LPDDR4(DQ ODT is Enabled) : RL + BL/2 + RU(tDQSCKmax/tCK) + RD_POSTAMBLE - ODTLon - RU(tODTon(min)/tCK) Minimum time from read command to write command. Include time for bus turnaround and all per-bank, per-rank, and global constraints. Please see the relevant PHY databook for details of what should be included here. Unit: Clocks. Where: - WL = write latency - BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM - RL = read latency = CAS latency - WR_PREAMBLE = write preamble. This is unique to DDR4 and LPDDR4. - RD_POSTAMBLE = read postamble. This is unique to LPDDR4. For LPDDR2/LPDDR3/LPDDR4, if derating is enabled (DERATEEN.derate_enable=1), derated tDQSCKmax should be used. When the controller is operating in 1:2 frequency ratio mode, divide the value calculated using the above equation by 2, and round it up to next integer. Note that, depending on the PHY, if using LRDIMM, it may be necessary to adjust the value of this parameter to compensate for the extra cycle of latency through the LRDIMM.
7-6 —	Reserved
5-0 wr2rd	DDR4: CWL + PL + BL/2 + tWTR_L Others: CWL + BL/2 + tWTR In DDR4, minimum time from write command to read command for same bank group. In others, minimum time from write command to read command. Includes time for bus turnaround, recovery times, and all per-bank, per-rank, and global constraints. Unit: Clocks. Where: - CWL = CAS write latency - PL = Parity latency - BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM - tWTR_L = internal write to read command delay for same bank group. This comes directly from the SDRAM specification. - tWTR = internal write to read command delay. This comes directly from the SDRAM specification. Add one extra cycle for LPDDR2/LPDDR3/LPDDR4 operation. When the controller is operating in 1:2 mode, divide the value calculated using the above equation by 2, and round it up to next integer.

9.3.3.1.32 SDRAM Timing Register 3 (DRAMTMG3)

9.3.3.1.32.1 Offset

Field	Function
31-30 —	Reserved
29-20 t_mrw	Time to wait after a mode register write or read (MRW or MRR). Present only in designs configured to support LPDDR2, LPDDR3 or LPDDR4. LPDDR2 typically requires value of 5. LPDDR3 typically requires value of 10. LPDDR4: Set this to the larger of tMRW and tMRWCKEL. For LPDDR2, this register is used for the time from a MRW/MRR to all other commands. When the controller is operating in 1:2 frequency ratio mode, program this to the above values divided by 2 and round it up to the next integer value. For LDPDR3, this register is used for the time from a MRW/MRR to a MRW/MRR.
19-18 —	Reserved
17-12 t_mrd	tMRD: Cycles to wait after a mode register write or read. Depending on the connected SDRAM, tMRD represents: DDR2/mDDR: Time from MRS to any command DDR3/4: Time from MRS to MRS command LPDDR2: not used LPDDR3/4: Time from MRS to non-MRS command. When the controller is operating in 1:2 frequency ratio mode, program this to (tMRD/2) and round it up to the next integer value. If C/A parity for DDR4 is used, set to tMRD_PAR(tMOD+PL) instead.
11-10 —	Reserved
9-0 t_mod	tMOD: Parameter used only in DDR3 and DDR4. Cycles between load mode command and following non-load mode command. If C/A parity for DDR4 is used, set to tMOD_PAR(tMOD+PL) instead. Set to tMOD if controller is operating in 1:1 frequency ratio mode, or tMOD/2 (rounded up to next integer) if controller is operating in 1:2 frequency ratio mode. Note that if using RDIMM/LRDIMM, depending on the

Field	Function
	PHY, it may be necessary to adjust the value of this parameter to compensate for the extra cycle of latency applied to mode register writes by the RDIMM/LRDIMM chip. Also note that if using LRDIMM, the minimum value of this register is tMRD_L2 if controller is operating in 1:1 frequency ratio mode, or tMRD_L2/2 (rounded up to next integer) if controller is operating in 1:2 frequency ratio mode.

9.3.3.1.35.3 Fields

Field	Function
31-28 —	Reserved
27-24 t_ckdpde	This is the time after Deep Power Down Entry that CK is maintained as a valid clock. Specifies the clock disable delay after DPDE. Recommended settings: - mDDR: 0 - LPDDR2: 2 - LPDDR3: 2 When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer. This is only present for designs supporting mDDR or LPDDR2/LPDDR3 devices.
23-20 —	Reserved
19-16 t_ckdpdx	This is the time before Deep Power Down Exit that CK is maintained as a valid clock before issuing DPDX. Specifies the clock stable time before DPDX. Recommended settings: - mDDR: 1 - LPDDR2: 2 - LPDDR3: 2 When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer. This is only present for designs supporting mDDR or LPDDR2 devices.
15-4 —	Reserved
3-0 t_ckcsx	This is the time before Clock Stop Exit that CK is maintained as a valid clock before issuing Clock Stop Exit. Specifies the clock stable time before next command after Clock Stop Exit. Recommended settings: - mDDR: 1 - LPDDR2: tXP + 2 - LPDDR3: tXP + 2 - LPDDR4: tXP + 2 When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer. This is only present for designs supporting mDDR or LPDDR2/LPDDR3/LPDDR4 devices.

9.3.3.1.36 SDRAM Timing Register 7 (DRAMTMG7)

9.3.3.1.36.1 Offset

Register	Offset
DRAMTMG7	11Ch

9.3.3.1.37.3 Fields

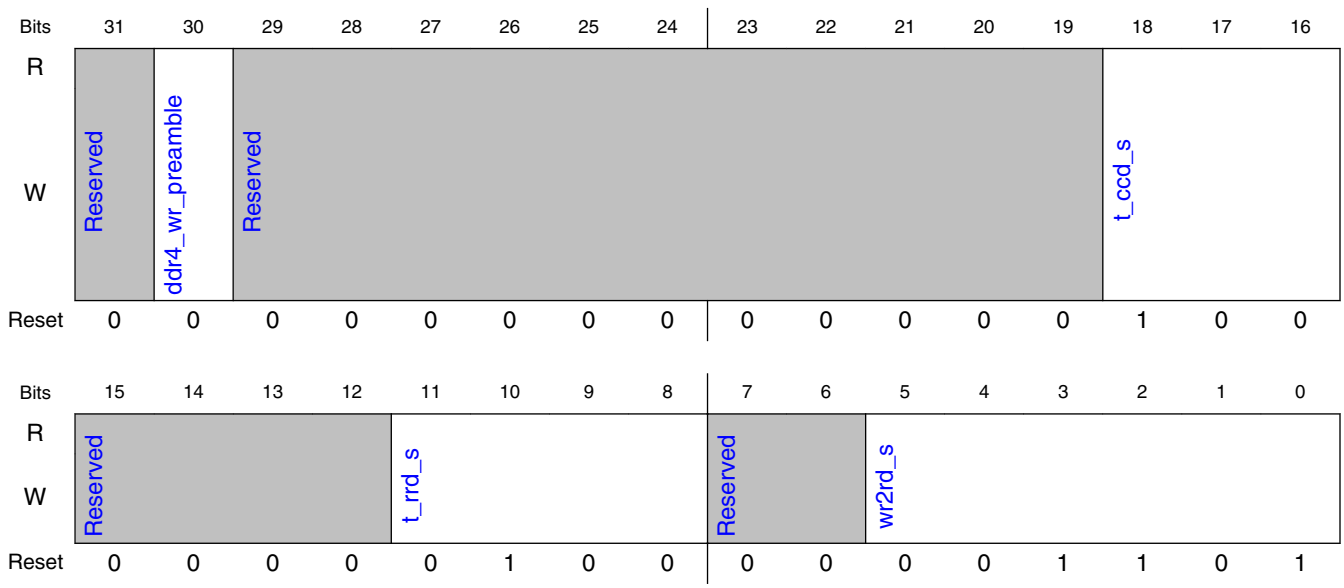
Field	Function
31 —	Reserved
30-24 t_xs_fast_x32	tXS_FAST: Exit Self Refresh to ZQCL, ZQCS and MRS (only CL, WR, RTP and Geardown mode). When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided by 2 and round up to next integer value. Unit: Multiples of 32 clocks. Note: This is applicable to only ZQCL/ZQCS commands. Note: Ensure this is less than or equal to t_xs_x32.
23 —	Reserved
22-16 t_xs_abort_x32	tXS_ABORT: Exit Self Refresh to commands not requiring a locked DLL in Self Refresh Abort. When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided by 2 and round up to next integer value. Unit: Multiples of 32 clocks. Note: Ensure this is less than or equal to t_xs_x32.
15 —	Reserved
14-8 t_xs_dll_x32	tXSDLL: Exit Self Refresh to commands requiring a locked DLL. When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided by 2 and round up to next integer value. Unit: Multiples of 32 clocks. Note: Used only for DDR2, DDR3 and DDR4 SDRAMs.
7 —	Reserved
6-0 t_xs_x32	tXS: Exit Self Refresh to commands not requiring a locked DLL. When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided by 2 and round up to next integer value. Unit: Multiples of 32 clocks. Note: Used only for DDR2, DDR3 and DDR4 SDRAMs.

9.3.3.1.38 SDRAM Timing Register 9 (DRAMTMG9)

9.3.3.1.38.1 Offset

Register	Offset
DRAMTMG9	124h

9.3.3.1.38.2 Diagram



9.3.3.1.38.3 Fields

Field	Function
31 —	Reserved
30 ddr4_wr_preamble	DDR4 Write preamble mode - 0: 1tCK preamble - 1: 2tCK preamble Present only with MEMC_FREQ_RATIO=2
29-19 —	Reserved
18-16 t_ccd_s	tCCD_S: This is the minimum time between two reads or two writes for different bank group. For bank switching (from bank "a" to bank "b"), the minimum time is this value + 1. When the controller is operating in 1:2 frequency ratio mode, program this to (tCCD_S/2) and round it up to the next integer value. Present only in designs configured to support DDR4. Unit: clocks.
15-12 —	Reserved

Table continues on the next page...

Field	Function
11-8 t_rrd_s	tRRD_S: Minimum time between activates from bank "a" to bank "b" for different bank group. When the controller is operating in 1:2 frequency ratio mode, program this to (tRRD_S/2) and round it up to the next integer value. Present only in designs configured to support DDR4. Unit: Clocks.
7-6 —	Reserved
5-0 wr2rd_s	CWL + PL + BL/2 + tWTR_S Minimum time from write command to read command for different bank group. Includes time for bus turnaround, recovery times, and all per-bank, per-rank, and global constraints. Present only in designs configured to support DDR4. Unit: Clocks. Where: - CWL = CAS write latency - PL = Parity latency - BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM - tWTR_S = internal write to read command delay for different bank group. This comes directly from the SDRAM specification. When the controller is operating in 1:2 mode, divide the value calculated using the above equation by 2, and round it up to next integer.

9.3.3.1.39 SDRAM Timing Register 10 (DRAMTMG10)

Field	Function
—	
20-16 t_sync_gear	Indicates the time between MRS command and the sync pulse time. This must be even number of clocks. For DDR4-2666 and DDR4-3200, this parameter is defined as tMOD(min)+4nCK tMOD(min) is greater of 24nCK or 15ns 15ns / .625ns = 24 Max value for this register is 24+4 = 28 When the controller is operating in 1:2 mode, program this to (tSYNC_GEAR/2) and round it up to the next integer value. Unit: Clocks
15-13 —	Reserved
12-8 t_cmd_gear	Sync pulse to first valid command. For DDR4-2666 and DDR4-3200, this parameter is defined as tMOD(min) tMOD(min) is greater of 24nCK or 15ns 15ns / .625ns = 24 Max value for this register is 24 When the controller is operating in 1:2 mode, program this to (tCMD_GEAR/2) and round it up to the next integer value. Unit: Clocks
7-4 —	Reserved
3-2 t_gear_setup	Geardown setup time. Minimum value of this register is 1. Zero is invalid. For DDR4-2666 and DDR4-3200, this parameter is defined as 2 clks When the controller is operating in 1:2 frequency ratio mode, program this to (tGEAR_setup/2) and round it up to the next integer value. Unit: Clocks
1-0 t_gear_hold	Geardown hold time. Minimum value of this register is 1. Zero is invalid. For DDR4-2666 and DDR4-3200, this parameter is defined as 2 clks When the controller is operating in 1:2 frequency ratio mode, program this to (tGEAR_hold/2) and round it up to the next integer value. Unit: Clocks

9.3.3.1.40 SDRAM Timing Register 11 (DRAMTMG11)

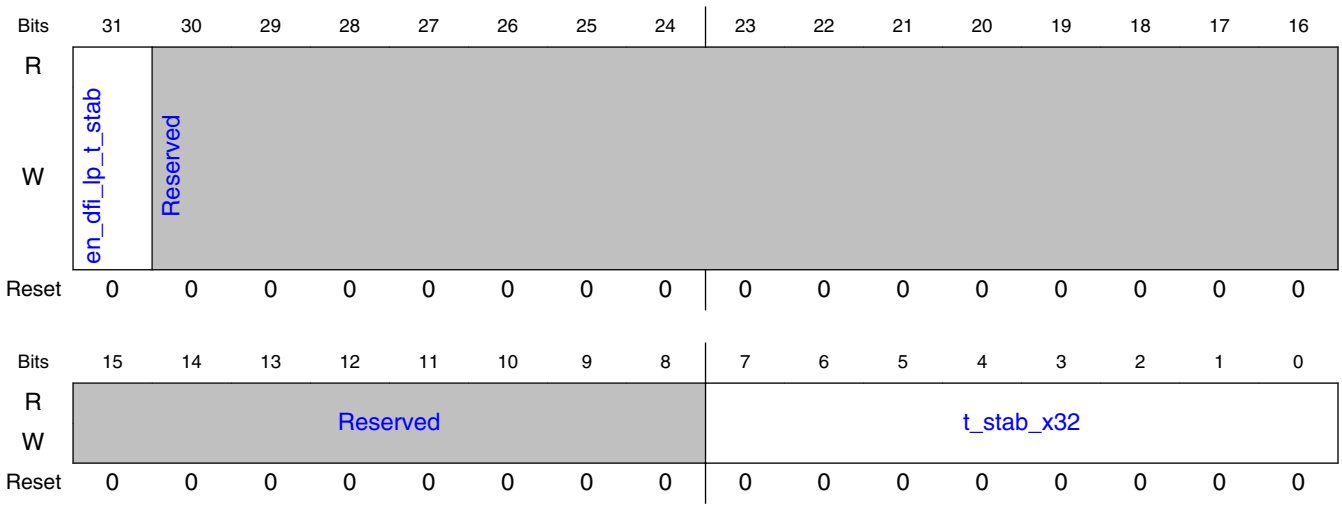
11-0 t_xsr	tXSR: Exit Self Refresh to any command. When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided by 2 and round up to next integer value. Note: Used only for mDDR/LPDDR2/LPDDR3/LPDDR4 mode.

9.3.3.1.44 SDRAM Timing Register 15 (DRAMTMG15)

9.3.3.1.44.1 Offset

Register	Offset
DRAMTMG15	13Ch

9.3.3.1.44.2 Diagram



9.3.3.1.44.3 Fields

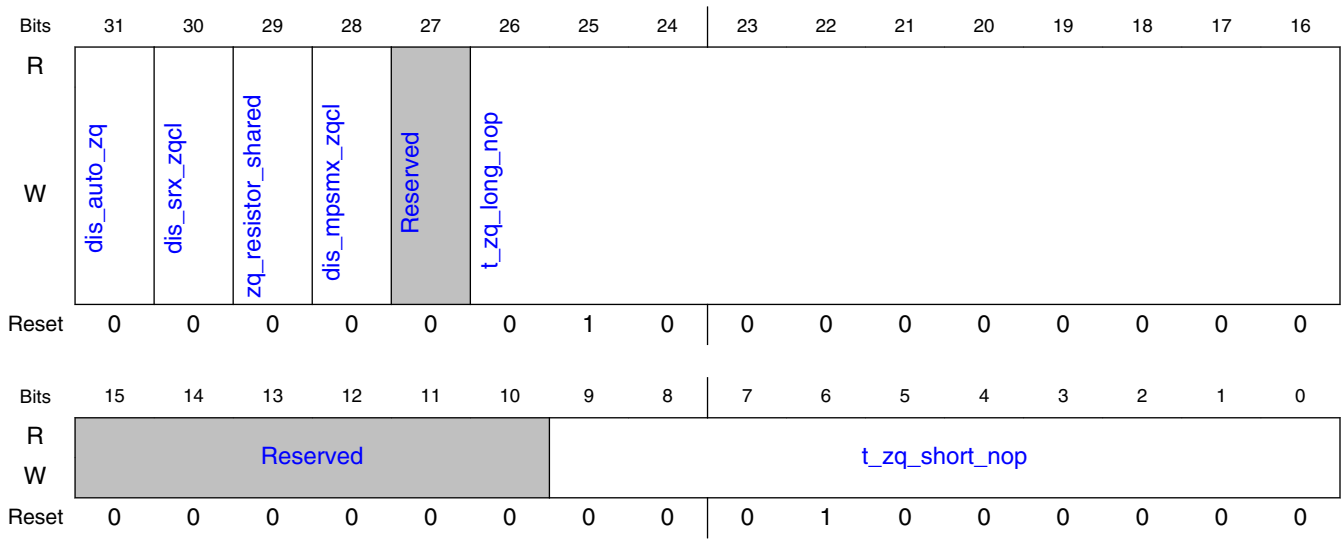
Field	Function
31 en_dfi_lp_t_stab	Enable DFI tSTAB 0b - Disable using tSTAB when exiting DFI LP 1b - Enable using tSTAB when exiting DFI LP. Needs to be set when the PHY is stopping the clock during DFI LP to save maximum power.
30-8 —	Reserved
7-0 t_stab_x32	tSTAB: Stabilization time. It is required in the following two cases for DDR3/DDR4 RDIMM : - when exiting power saving mode, if the clock was stopped, after re-enabling it the clock must be stable for a time specified by tSTAB - in the case of input clock frequency change (DDR4) - after issuing control words that refers to clock timing (Specification: 6us for DDR3, 5us for DDR4) When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer. Unit: Multiples of 32 clock cycles.

9.3.3.1.45 ZQ Control Register 0 (ZQCTL0)

9.3.3.1.45.1 Offset

Register	Offset
ZQCTL0	180h

9.3.3.1.45.2 Diagram



9.3.3.1.45.3 Fields

Field	Function
31 dis_auto_zq	Disable Auto ZQCS/MPC 0b - Internally generate ZQCS/MPC(ZQ calibration) commands based on ZQCTL1.t_zq_short_interval_x1024. 1b - Disable DDRC generation of ZQCS/MPC(ZQ calibration) command. Register DBGCMD.zq_calib_short can be used instead to issue ZQ calibration request from APB module.
30 dis_srx_zqcl	Disable ZQCL/MPC 0b - Enable issuing of ZQCL/MPC(ZQ calibration) command at Self-Refresh/SR-Powerdown exit. Only applicable when run in DDR3 or DDR4 or LPDDR2 or LPDDR3 or LPDDR4 mode. This is only present for designs supporting DDR3/DDR4 or LPDDR2/LPDDR3/LPDDR4 devices. 1b - Disable issuing of ZQCL/MPC(ZQ calibration) command at Self-Refresh/SR-Powerdown exit. Only applicable when run in DDR3 or DDR4 or LPDDR2 or LPDDR3 or LPDDR4 mode.
29 zq_resistor_shared	ZQ resistor sharing 0b - ZQ resistor is not shared. This is only present for designs supporting DDR3/DDR4 or LPDDR2/LPDDR3/LPDDR4 devices. 1b - Denotes that ZQ resistor is shared between ranks. Means ZQinit/ZQCL/ZQCS/MPC(ZQ calibration) commands are sent to one rank at a time with tZQinit/tZQCL/tZQCS/tZQCAL/tZQLAT timing met between commands so that commands to different ranks do not overlap.
28 dis_mpsmx_zqcl	Do not issue ZQCL command at Maximum Power Save Mode exit if the DDRC_SHARED_AC configuration parameter is set. Program it to 1'b1. The software can send ZQCS after exiting MPSM mode. 0b - Enable issuing of ZQCL command at Maximum Power Saving Mode exit. Only applicable when run in DDR4 mode. This is only present for designs supporting DDR4 devices. 1b - Disable issuing of ZQCL command at Maximum Power Saving Mode exit. Only applicable when run in DDR4 mode.
27 —	Reserved
26-16 t_zq_long_nop	tZQoper for DDR3/DDR4, tZQCL for LPDDR2/LPDDR3, tZQCAL for LPDDR4: Number of DFI clock cycles of NOP required after a ZQCL (ZQ calibration long)/MPC(ZQ Start) command is issued to

Table continues on the next page...

Field	Function
	SDRAM. When the controller is operating in 1:2 frequency ratio mode: DDR3/DDR4: program this to tZQoper/2 and round it up to the next integer value. LPDDR2/LPDDR3: program this to tZQCL/2 and round it up to the next integer value. LPDDR4: program this to tZQCAL/2 and round it up to the next integer value. This is only present for designs supporting DDR3/DDR4 or LPDDR2/LPDDR3/LPDDR4 devices.
15-10 —	Reserved
9-0 t_zq_short_nop	tZQCS for DDR3/DD4/LPDDR2/LPDDR3, tZQLAT for LPDDR4: Number of DFI clock cycles of NOP required after a ZQCS (ZQ calibration short)/MPC(ZQ Latch) command is issued to SDRAM. When the controller is operating in 1:2 frequency ratio mode, program this to tZQCS/2 and round it up to the next integer value. This is only present for designs supporting DDR3/DDR4 or LPDDR2/LPDDR3/LPDDR4 devices.

9.3.3.1.46 ZQ Control Register 1 (ZQCTL1)

Field	Function
31-1 —	Reserved
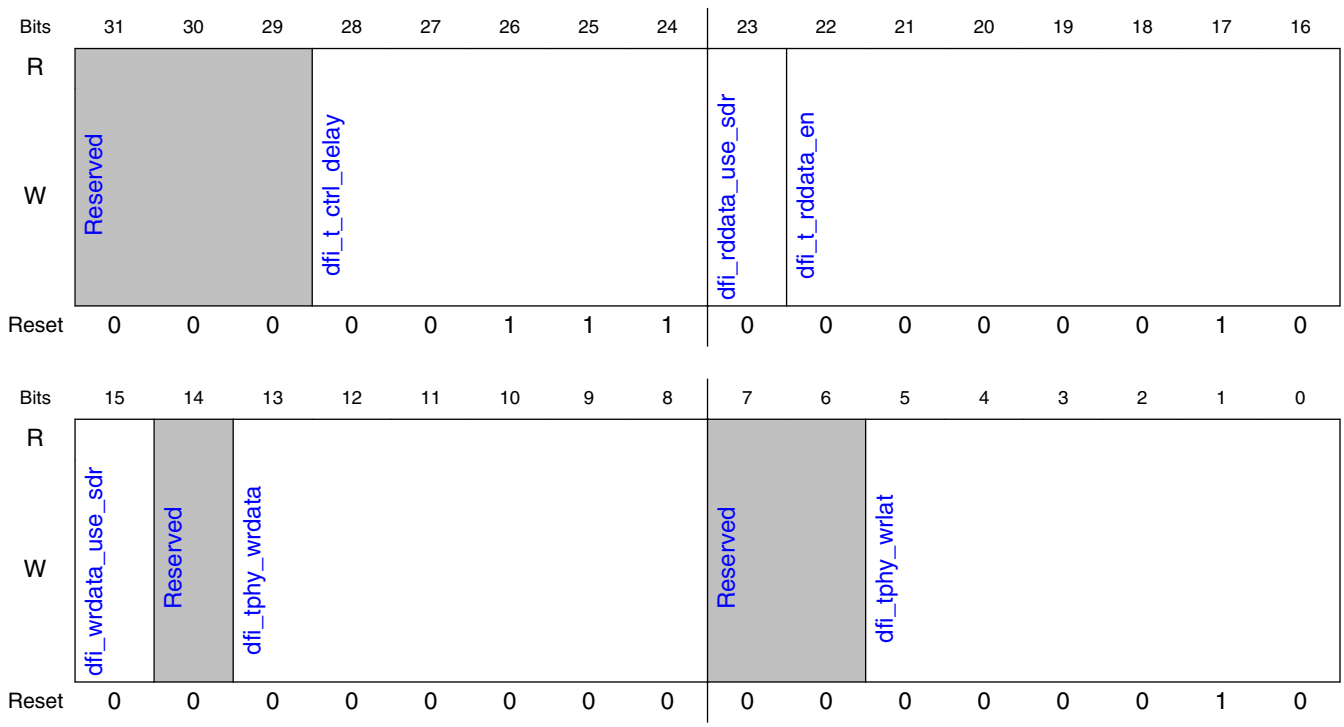
0 zq_reset_busy	SoC core may initiate a ZQ Reset operation only if this signal is low. This signal goes high in the clock after the DDRC accepts the ZQ Reset request. It goes low when the ZQ Reset command is issued to the SDRAM and the associated NOP period is over. It is recommended not to perform ZQ Reset commands when this signal is high. 0b - Indicates that the SoC core can initiate a ZQ Reset operation 1b - Indicates that ZQ Reset operation is in progress

9.3.3.1.49 DFI Timing Register 0 (DFITMG0)

9.3.3.1.49.1 Offset

Register	Offset
DFITMG0	190h

9.3.3.1.49.2 Diagram



9.3.3.1.49.3 Fields

Field	Function
31-29 —	Reserved
28-24 dfi_t_ctrl_delay	Specifies the number of DFI clock cycles after an assertion or de-assertion of the DFI control signals that the control signals at the PHY-DRAM interface reflect the assertion or de-assertion. If the DFI clock and the memory clock are not phase-aligned, this timing parameter should be rounded up to the next integer value. Note that if using RDIMM/LRDIMM, it is necessary to increment this parameter by RDIMM's/ LRDIMM's extra cycle of latency in terms of DFI clock.
23	Defines whether dfi_rddata_en/dfi_rddata/dfi_rddata_valid is generated using HDR (DFI clock) or SDR (DFI PHY clock) values. Selects whether value in DFITMG0.dfi_t_rddata_en is in terms of HDR (DFI

Table continues on the next page...

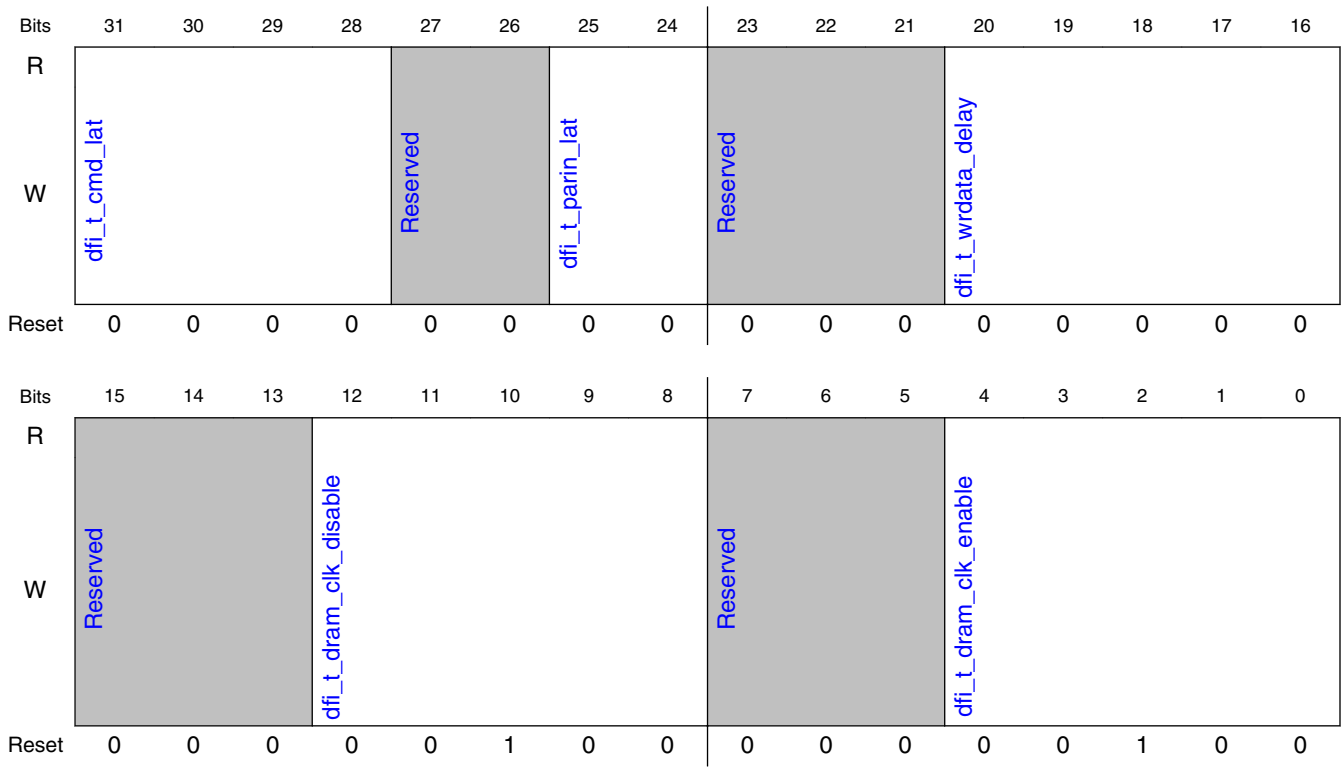
Field	Function
dfi_rddata_use_sdr	clock) or SDR (DFI PHY clock) cycles: - 0 in terms of HDR (DFI clock) cycles - 1 in terms of SDR (DFI PHY clock) cycles Refer to PHY specification for correct value.
22-16 dfi_t_rddata_en	Time from the assertion of a read command on the DFI interface to the assertion of the dfi_rddata_en signal. Refer to PHY specification for correct value. This corresponds to the DFI parameter trddata_en. Note that, depending on the PHY, if using RDIMM/LRDIMM, it may be necessary to use the adjusted value of CL in the calculation of trddata_en. This is to compensate for the extra cycle(s) of latency through the RDIMM/LRDIMM. Unit: DFI clock cycles or DFI PHY clock cycles, depending on DFITMG0.dfi_rddata_use_sdr.
15 dfi_wrdata_use_sdr	Defines whether dfi_wrdata_en/dfi_wrdata/dfi_wrdata_mask is generated using HDR (DFI clock) or SDR (DFI PHY clock) values Selects whether value in DFITMG0.dfi_tphy_wrlat is in terms of HDR (DFI clock) or SDR (DFI PHY clock) cycles Selects whether value in DFITMG0.dfi_tphy_wrdata is in terms of HDR (DFI clock) or SDR (DFI PHY clock) cycles - 0 in terms of HDR (DFI clock) cycles - 1 in terms of SDR (DFI PHY clock) cycles Refer to PHY specification for correct value.
14 —	Reserved
13-8 dfi_tphy_wrdata	Specifies the number of clock cycles between when dfi_wrdata_en is asserted to when the associated write data is driven on the dfi_wrdata signal. This corresponds to the DFI timing parameter tphy_wrdata. Refer to PHY specification for correct value. Note, max supported value is 8. Unit: DFI clock cycles or DFI PHY clock cycles, depending on DFITMG0.dfi_wrdata_use_sdr.
7-6 —	Reserved
5-0 dfi_tphy_wrlat	Write latency Number of clocks from the write command to write data enable (dfi_wrdata_en). This corresponds to the DFI timing parameter tphy_wrlat. Refer to PHY specification for correct value.Note that, depending on the PHY, if using RDIMM/LRDIMM, it may be necessary to use the adjusted value of CL in the calculation of tphy_wrlat. This is to compensate for the extra cycle(s) of latency through the RDIMM/LRDIMM. Unit: DFI clock cycles or DFI PHY clock cycles, depending on DFITMG0.dfi_wrdata_use_sdr.

9.3.3.1.50 DFI Timing Register 1 (DFITMG1)

9.3.3.1.50.1 Offset

Register	Offset
DFITMG1	194h

9.3.3.1.50.2 Diagram



9.3.3.1.50.3 Fields

Field	Function
31-28 dfi_t_cmd_lat	Specifies the number of DFI PHY clock cycles between when the dfi_cs signal is asserted and when the associated command is driven. This field is used for CAL mode, should be set to '0' or the value which matches the CAL mode register setting in the DRAM. If the PHY can add the latency for CAL mode, this should be set to '0'. Valid Range: 0, 3, 4, 5, 6, and 8
27-26 —	Reserved
25-24 dfi_t_parin_lat	Specifies the number of DFI PHY clock cycles between when the dfi_cs signal is asserted and when the associated dfi_parity_in signal is driven.
23-21 —	Reserved
20-16 dfi_t_wrdata_delay	Specifies the number of DFI clock cycles between when the dfi_wrdata_en signal is asserted and when the corresponding write data transfer is completed on the DRAM bus. This corresponds to the DFI timing parameter twrdata_delay. Refer to PHY specification for correct value. For DFI 3.0 PHY, set to twrdata_delay, a new timing parameter introduced in DFI 3.0. For DFI 2.1 PHY, set to tphy_wrdata + (delay of DFI write data to the DRAM). Value to be programmed is in terms of DFI clocks, not PHY clocks. In FREQ_RATIO=2, divide PHY's value by 2 and round up to next integer. If using DFITMG0.dfi_wrdata_use_sdr=1, add 1 to the value. Unit: Clocks
15-13 —	Reserved

Table continues on the next page...

Field	Function
12-8 dfi_t_dram_clk_disable	Specifies the number of DFI clock cycles from the assertion of the dfi_dram_clk_disable signal on the DFI until the clock to the DRAM memory devices, at the PHY-DRAM boundary, maintains a low value. If the DFI clock and the memory clock are not phase aligned, this timing parameter should be rounded up to the next integer value.
7-5 —	Reserved
4-0 dfi_t_dram_clk_enable	Specifies the number of DFI clock cycles from the de-assertion of the dfi_dram_clk_disable signal on the DFI until the first valid rising edge of the clock to the DRAM memory devices, at the PHY-DRAM boundary. If the DFI clock and the memory clock are not phase aligned, this timing parameter should be rounded up to the next integer value.

Field	Function
31-29 —	Reserved
28-24 dfi_tlp_resp	Setting in DFI clock cycles for DFI's tlp_resp time. Same value is used for both Power Down, Self Refresh, Deep Power Down and Maximum Power Saving modes. DFI 2.1 specification onwards, recommends using a fixed value of 7 always.
23-20 dfi_lp_wakeup_dpd	Value in DFI clock cycles to drive on dfi_lp_wakeup signal when Deep Power Down mode is entered. Determines the DFI's tlp_wakeup time: This is only present for designs supporting mDDR or LPDDR2/ LPDDR3 devices. 0000b - 16 cycles 0001b - 32 cycles 0010b - 64 cycles 0011b - 128 cycles 0100b - 256 cycles 0101b - 512 cycles 0110b - 1024 cycles 0111b - 2048 cycles 1000b - 4096 cycles 1001b - 8192 cycles 1010b - 16384 cycles 1011b - 32768 cycles 1100b - 65536 cycles 1101b - 131072 cycles 1110b - 262144 cycles 1111b - Unlimited cycles
19-17 —	Reserved
16 dfi_lp_en_dpd	Enables DFI Low Power interface handshaking during Deep Power Down Entry/Exit. - 0 - Disabled - 1 - Enabled This is only present for designs supporting mDDR or LPDDR2/LPDDR3 devices.
15-12 dfi_lp_wakeup_sr	Value in DFI clpck cycles to drive on dfi_lp_wakeup signal when Self Refresh mode is entered. Determines the DFI's tlp_wakeup time: 0000b - 16 cycles 0001b - 32 cycles 0010b - 64 cycles 0011b - 128 cycles 0100b - 256 cycles 0101b - 512 cycles 0110b - 1024 cycles 0111b - 2048 cycles 1000b - 4096 cycles 1001b - 8192 cycles 1010b - 16384 cycles 1011b - 32768 cycles 1100b - 65536 cycles 1101b - 131072 cycles 1110b - 262144 cycles 1111b - Unlimited cycles
11-9 —	Reserved
8	Enables DFI Low Power interface handshaking during Self Refresh Entry/Exit. - 0 - Disabled - 1 - Enabled 0b - Disabled

Table continues on the next page...

Field	Function
dfi_lp_en_sr	1b - Enabled
7-4 dfi_lp_wakeup_pd	Value in DFI clock cycles to drive on dfi_lp_wakeup signal when Power Down mode is entered. Determines the DFI's tlp_wakeup time: 0000b - 16 cycles 0001b - 32 cycles 0010b - 64 cycles 0011b - 128 cycles 0100b - 256 cycles 0101b - 512 cycles 0110b - 1024 cycles 0111b - 2048 cycles 1000b - 4096 cycles 1001b - 8192 cycles 1010b - 16384 cycles 1011b - 32768 cycles 1100b - 65536 cycles 1101b - 131072 cycles 1110b - 262144 cycles 1111b - Unlimited cycles
3-1 —	Reserved
0 dfi_lp_en_pd	Enables DFI Low Power interface handshaking during Power Down Entry/Exit. - 0 - Disabled - 1 - Enabled

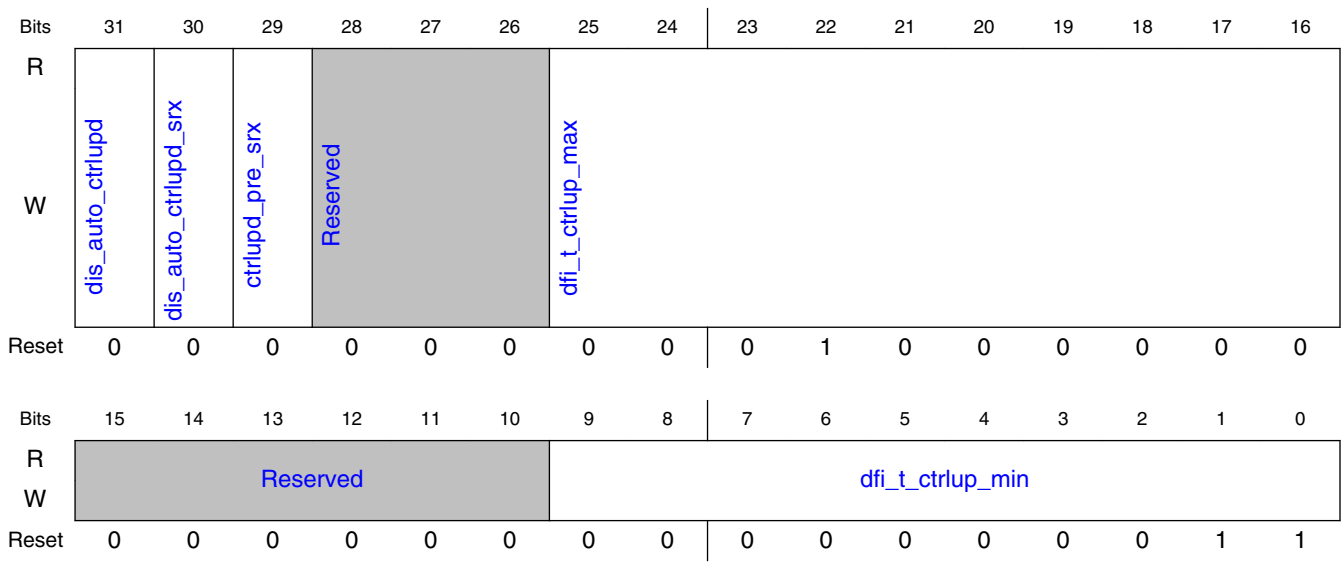
31-8 —	Reserved
7-4 dfi_lp_wakeup_mpsm	Value in DFI clock cycles to drive on dfi_lp_wakeup signal when Maximum Power Saving Mode is entered. Determines the DFI's tlp_wakeup time: 0000b - 16 cycles 0001b - 32 cycles 0010b - 64 cycles 0011b - 128 cycles 0100b - 256 cycles 0101b - 512 cycles 0110b - 1024 cycles 0111b - 2048 cycles 1000b - 4096 cycles 1001b - 8192 cycles 1010b - 16384 cycles 1011b - 32768 cycles 1100b - 65536 cycles 1101b - 131072 cycles 1110b - 262144 cycles 1111b - Unlimited cycles
3-1 —	Reserved
0 dfi_lp_en_mpsm	Enables DFI Low Power interface handshaking during Maximum Power Saving Mode Entry/Exit. - 0 - Disabled - 1 - Enabled This is only present for designs supporting DDR4 devices.

9.3.3.1.53 DFI Update Register 0 (DFIUPD0)

9.3.3.1.53.1 Offset

Register	Offset
DFIUPD0	1A0h

9.3.3.1.53.2 Diagram



9.3.3.1.53.3 Fields

Field	Function
31 dis_auto_ctrlupd	automatic dfi_ctrlupd_req generation by the DDRC 0b - DDRC issues dfi_ctrlupd_req periodically. 1b - disable the automatic dfi_ctrlupd_req generation by the DDRC. The core must issue the dfi_ctrlupd_req signal using register reg_ddrc_ctrlupd.
30 dis_auto_ctrlupd_srx	Auto ctrlupd request generation 0b - DDRC issues a dfi_ctrlupd_req before or after exiting self-refresh, depending on DFIUPD0.ctrlupd_pre_srx. 1b - disable the automatic dfi_ctrlupd_req generation by the DDRC at self-refresh exit.
29 ctrlupd_pre_srx	Selects dfi_ctrlupd_req requirements at SRX: - 0 : send ctrlupd after SRX - 1 : send ctrlupd before SRX If DFIUPD0.dis_auto_ctrlupd_srx=1, this register has no impact, because no dfi_ctrlupd_req will be issued when SRX. 0b - send ctrlupd after SRX 1b - send ctrlupd before SRX
28-26 —	Reserved

Table continues on the next page...

Field	Function
25-16 dfi_t_ctrlup_max	Specifies the maximum number of DFI clock cycles that the dfi_ctrlupd_req signal can assert. Lowest value to assign to this variable is 0x40.
15-10 —	Reserved
9-0 dfi_t_ctrlup_min	Specifies the minimum number of DFI clock cycles that the dfi_ctrlupd_req signal must be asserted. The DDRC expects the PHY to respond within this time. If the PHY does not respond, the DDRC will de-assert dfi_ctrlupd_req after dfi_t_ctrlup_min + 2 cycles. Lowest value to assign to this variable is 0x3.

9.3.3.1.54 DFI Update Register 1 (DFIUPD1)

9.3.3.1.54.1 Offset

Register	Offset
DFIUPD1	1A4h

9.3.3.1.54.3 Fields

Field	Function
31-24 —	Reserved
23-16 dfi_t_ctrlupd_interval_min_x1024	This is the minimum amount of time between DDRC initiated DFI update requests (which is executed whenever the DDRC is idle). Set this number higher to reduce the frequency of update requests, which can have a small impact on the latency of the first read request when the DDRC is idle. Minimum allowed value for this field is 1. Unit: 1024 DFI clock cycles
15-8 —	Reserved

Table continues on the next page...

Field	Function
7-0 dfi_t_ctrlupd_interval_max_x1024	This is the maximum amount of time between DDRC initiated DFI update requests. This timer resets with each update request; when the timer expires dfi_ctrlupd_req is sent and traffic is blocked until the dfi_ctrlupd_ackx is received. PHY can use this idle time to recalibrate the delay lines to the DLLs. The DFI controller update is also used to reset PHY FIFO pointers in case of data capture errors. Updates are required to maintain calibration over PVT, but frequent updates may impact performance. Minimum allowed value for this field is 1. Note: Value programmed for DFIUPD1.dfi_t_ctrlupd_interval_max_x1024 must be greater than DFIUPD1.dfi_t_ctrlupd_interval_min_x1024. Unit: 1024 DFI clock cycles

9.3.3.1.55 DFI Update Register 2 (DFIUPD2)

31-14 —	Reserved
13-12 rank1_rd_odt	Indicates which remote ODTs must be turned on during a read from rank 1. Each rank has a remote ODT (in the SDRAM) which can be turned on by setting the appropriate bit here. Rank 0 is controlled by the LSB; rank 1 is controlled by bit next to the LSB, etc. For each rank, set its bit to 1 to enable its ODT. Present only in configurations that have 2 or more ranks
11-10 —	Reserved

Table continues on the next page...

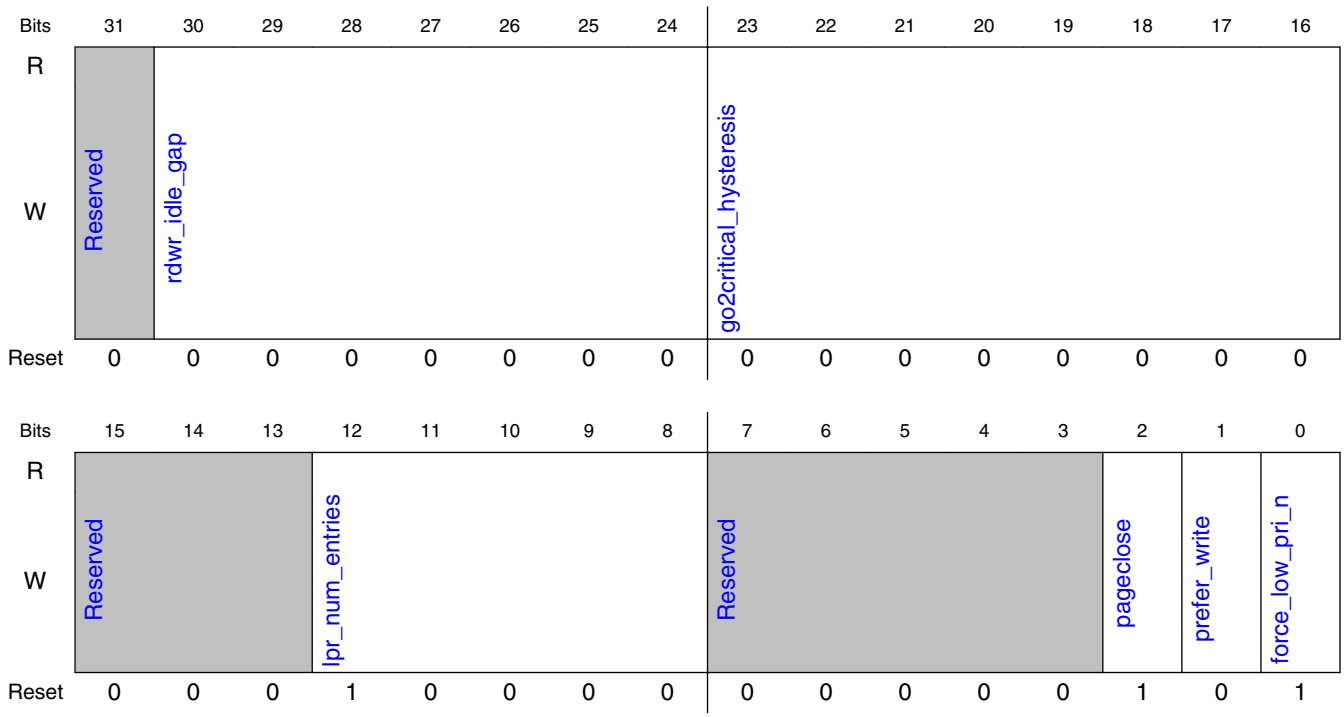
Field	Function
9-8 rank1_wr_odt	Indicates which remote ODTs must be turned on during a write to rank 1. Each rank has a remote ODT (in the SDRAM) which can be turned on by setting the appropriate bit here. Rank 0 is controlled by the LSB; rank 1 is controlled by bit next to the LSB, etc. For each rank, set its bit to 1 to enable its ODT. Present only in configurations that have 2 or more ranks
7-6 —	Reserved
5-4 rank0_rd_odt	Indicates which remote ODTs must be turned on during a read from rank 0. Each rank has a remote ODT (in the SDRAM) which can be turned on by setting the appropriate bit here. Rank 0 is controlled by the LSB; rank 1 is controlled by bit next to the LSB, etc. For each rank, set its bit to 1 to enable its ODT.
3-2 —	Reserved
1-0 rank0_wr_odt	Indicates which remote ODTs must be turned on during a write to rank 0. Each rank has a remote ODT (in the SDRAM) which can be turned on by setting the appropriate bit here. Rank 0 is controlled by the LSB; rank 1 is controlled by bit next to the LSB, etc. For each rank, set its bit to 1 to enable its ODT.

9.3.3.1.75 Scheduler Control Register (SCHED)

9.3.3.1.75.1 Offset

Register	Offset
SCHED	250h

9.3.3.1.75.2 Diagram



9.3.3.1.75.3 Fields

Field	Function
31 —	Reserved
30-24 rdwr_idle_gap	When the preferred transaction store is empty for these many clock cycles, switch to the alternate transaction store if it is non-empty. The read transaction store (both high and low priority) is the default preferred transaction store and the write transaction store is the alternative store. When prefer write over read is set this is reversed. 0x0 is a legal value for this register. When set to 0x0, the transaction store switching will happen immediately when the switching conditions become true. FOR PERFORMANCE ONLY
23-16 go2critical_hysteresis	UNUSED
15-13 —	Reserved
12-8 lpr_num_entries	Number of entries in the low priority transaction store is this value + 1. (MEMC_NO_OF_ENTRY - (SCHED.lpr_num_entries + 1)) is the number of entries available for the high priority transaction store. Setting this to maximum value allocates all entries to low priority transaction store. Setting this to 0 allocates 1 entry to low priority transaction store and the rest to high priority transaction store. Note: In ECC configurations, the numbers of write and low priority read credits issued is one less than in the non-ECC case. One entry each is reserved in the write and low-priority read CAMs for storing the RMW requests arising out of single bit error correction RMW operation.
7-3	Reserved

Table continues on the next page...

Field	Function
—	
2 pageclose	If true, bank is kept open only while there are page hit transactions available in the CAM to that bank. The last read or write command in the CAM with a bank and page hit will be executed with auto-precharge if SCHED1.pageclose_timer=0. Even if this register set to 1 and SCHED1.pageclose_timer is set to 0, explicit precharge (and not auto-precharge) may be issued in some cases where there is a mode switch between Write and Read or between LPR and HPR. The Read and Write commands that are executed as part of the ECC scrub requests are also executed without auto-precharge. If false, the bank remains open until there is a need to close it (to open a different page, or for page timeout or refresh timeout) - also known as open page policy. The open page policy can be overridden by setting the per-command-autopre bit on the HIF interface (hif_cmd_autopre). The pageclose feature provids a midway between Open and Close page policies. FOR PERFORMANCE ONLY.
1 prefer_write	If set then the bank selector prefers writes over reads. FOR DEBUG ONLY.
0 force_low_pri_n	Active low signal. When asserted ('0'), all incoming transactions are forced to low priority. This implies that all High Priority Read (HPR) and Variable Priority Read commands (VPR) will be treated as Low Priority Read (LPR) commands. On the write side, all Variable Priority Write (VPW) commands will be treated as Normal Priority Write (NPW) commands. Forcing the incoming transactions to low priority implicitly turns off Bypass path for read commands. FOR PERFORMANCE ONLY.

9.3.3.1.76 Scheduler Control Register 1 (SCHED1)

9.3.3.1.76.1 Offset

Register	Offset
SCHED1	254h

9.3.3.1.76.2 Diagram

R W	Reserved								pageclose_timer							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

9.3.3.1.76.3 Fields

Field	Function
31-8 —	Reserved
7-0 pageclose_timer	This field works in conjunction with SCHED.pageclose. It only has meaning if SCHED.pageclose==1. If SCHED.pageclose==1 and pageclose_timer==0, then an auto-precharge may be scheduled for last read or write command in the CAM with a bank and page hit. Note, sometimes an explicit precharge is scheduled instead of the auto-precharge. See SCHED.pageclose for details of when this may happen. If SCHED.pageclose==1 and pageclose_timer>0, then an auto-precharge is not scheduled for last read or write command in the CAM with a bank and page hit. Instead, a timer is started, with pageclose_timer as the initial value. There is a timer on a per bank basis. The timer decrements unless the next read or write in the CAM to a bank is a page hit. It gets reset to pageclose_timer value if the next read or write in the CAM to a bank is a page hit. Once the timer has reached zero, an explcit precharge will be attempted to be scheduled.

1 dis_hif	When 1, DDRC asserts the HIF command signal hif_cmd_stall. DDRC will ignore the hif_cmd_valid and all other associated request signals. This bit is intended to be switched on-the-fly.
0 dis_dq	When 1, DDRC will not de-queue any transactions from the CAM. Bypass is also disabled. All transactions are queued in the CAM. No reads or writes are issued to SDRAM as long as this is asserted. This bit may be used to prevent reads or writes being issued by the DDRC, which makes it safe to modify certain register fields associated with reads and writes (see User Guide for details). After setting this bit, it is strongly recommended to poll DBGCAM.wr_data_pipeline_empty and DBGCAM.rd_data_pipeline_empty, before making changes to any registers which affect reads and writes. This will ensure that the relevant logic in the DDRC is idle. This bit is intended to be switched on-the-fly.

Field	Function
31-6 —	Reserved
5 ctrlupd	Setting this register bit to 1 indicates to the DDRC to issue a dfi_ctrlupd_req to the PHY. When this request is stored in the DDRC, the bit is automatically cleared. This operation must only be performed when DFIUPD0.dis_auto_ctrlupd=1.
4 zq_calib_short	Setting this register bit to 1 indicates to the DDRC to issue a ZQCS (ZQ calibration short)/MPC(ZQ calibration) command to the SDRAM. When this request is stored in the DDRC, the bit is automatically cleared. This operation can be performed only when ZQCTL0.dis_auto_zq=1. It is recommended NOT to set this register bit if in Init operating mode. This register bit is ignored when in Self-Refresh(except LPDDR4) and SR-Powerdown(LPDDR4) and Deep power-down operating modes and Maximum Power Saving Mode.
3-2 —	Reserved
1 rank1_refresh	Setting this register bit to 1 indicates to the DDRC to issue a refresh to rank 1. Writing to this bit causes DBGSTAT.rank1_refresh_busy to be set. When DBGSTAT.rank1_refresh_busy is cleared, the command has been stored in DDRC. For 3DS configuration, refresh is sent to rank index 1. This operation can be performed only when RFSHCTL3.dis_auto_refresh=1. It is recommended NOT to set this register bit if in Init or Deep power-down operating modes or Maximum Power Saving Mode.
0 rank0_refresh	Setting this register bit to 1 indicates to the DDRC to issue a refresh to rank 0. Writing to this bit causes DBGSTAT.rank0_refresh_busy to be set. When DBGSTAT.rank0_refresh_busy is cleared, the command has been stored in DDRC. For 3DS configuration, refresh is sent to rank index 0. This operation can be performed only when RFSHCTL3.dis_auto_refresh=1. It is recommended NOT to set this register bit if in Init or Deep power-down operating modes or Maximum Power Saving Mode.

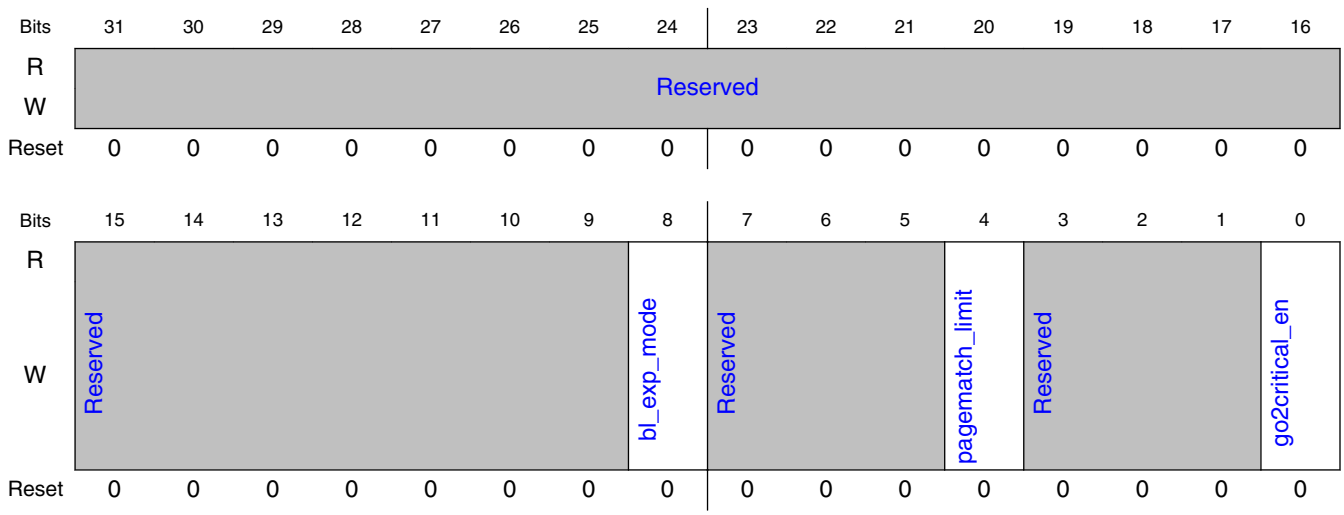
9.3.3.1.90.1 Offset

Register	Offset
PCCFG	400h

9.3.3.1.90.2 Diagram



9.3.3.1.90.3 Fields

Field	Function
31-9 —	Reserved
8 bl_exp_mode	Burst length expansion mode. By default (i.e. bl_exp_mode==0) XPI expands every AXI burst into multiple HIF commands, using the memory burst length as a unit. If set to 1, then XPI will use half of the memory burst length as a unit. This applies to both reads and writes. When MSTR.data_bus_width==00, setting bl_exp_mode to 1 has no effect. This can be used in cases where Partial Writes is enabled (DDRC_PARTIAL_WR=1), in order to avoid or minimize t_ccd_l penalty in DDR4 and t_ccd_mw penalty in LPDDR4. Hence, bl_exp_mode=1 is only recommended if DDR4 or LPDDR4. Note that if DBICTL.reg_ddrc_dm_en=0, functionality is not supported in the following cases: - DDRC_PARTIAL_WR=0 - DDRC_PARTIAL_WR=1, MSTR.data_bus_width=01, MEMC_BURST_LENGTH=8 and MSTR.burst_rdwr=1000 (LPDDR4 only) - DDRC_PARTIAL_WR=1, MSTR.data_bus_width=01, MEMC_BURST_LENGTH=4 and MSTR.burst_rdwr=0100 (DDR4 only), with either MSTR.reg_ddrc_burstchop=0 or CRCPARCTL1.reg_ddrc_crc_enable=1 Functionality is also not supported if Data Channel Interleave is enabled
7-5 —	Reserved

Table continues on the next page...

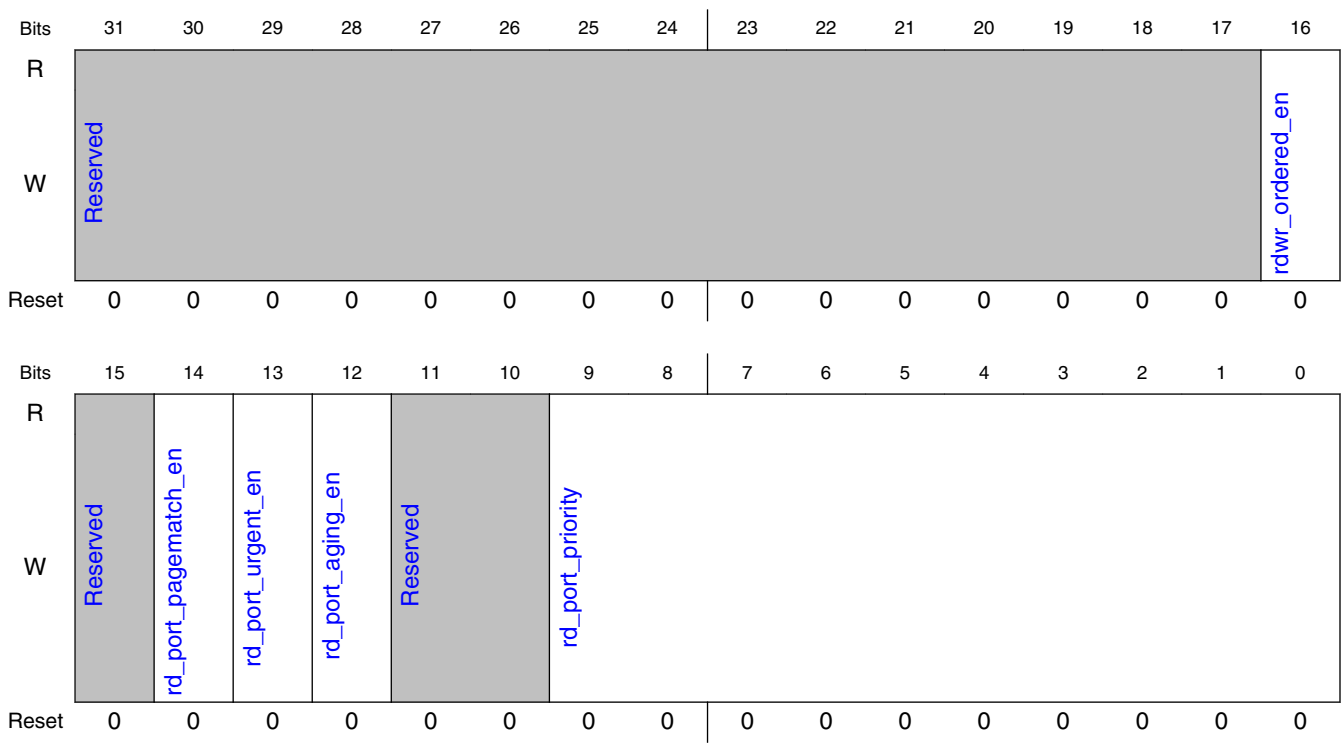
Field	Function
4 pagematch_limit	Page match four limit. If set to 1, limits the number of consecutive same page DDRC transactions that can be granted by the Port Arbiter to four when Page Match feature is enabled. If set to 0, there is no limit imposed on number of consecutive same page DDRC transactions.
3-1 —	Reserved
0 go2critical_en	If set to 1 (enabled), sets co_gs_go2critical_wr and co_gs_go2critical_lpr/co_gs_go2critical_hpr signals going to DDRC based on urgent input (awurgent, arurgent) coming from AXI master. If set to 0 (disabled), co_gs_go2critical_wr and co_gs_go2critical_lpr/co_gs_go2critical_hpr signals at DDRC are driven to 1b'0.

9.3.3.1.91 Port n Configuration Read Register (PCFGR_0)

9.3.3.1.91.1 Offset

Register	Offset
PCFGR_0	404h

9.3.3.1.91.2 Diagram



9.3.3.1.91.3 Fields

Field	Function
31-17 —	Reserved
16 rdwr_ordered_en	Enable ordered read/writes. If set to 1, preserves the ordering between read transaction and write transaction issued to the same address, on a given port. In other words, the controller ensures that all same address read and write commands from the application port interface are transported to the DFI interface in the order of acceptance. This feature is useful in cases where software coherency is desired for masters issuing back-to-back read/write transactions without waiting for write/read responses. Note that this register has an effect only if necessary logic is instantiated via the DDRC_RDWR_ORDERED_n parameter.
15 —	Reserved
14 rd_port_pagematch_en	If set to 1, enables the Page Match feature. If enabled, once a requesting port is granted, the port is continued to be granted if the following immediate commands are to the same memory page (same bank and same row). See also related PCCFG.pagematch_limit register.
13 rd_port_urgent_en	If set to 1, enables the AXI urgent sideband signal (arurgent). When enabled and arurgent is asserted by the master, that port becomes the highest priority and co_gs_go2critical_lpr/co_gs_go2critical_hpr signal to DDRC is asserted if enabled in PCCFG.go2critical_en register. Note that arurgent signal can be asserted anytime and as long as required which is independent of address handshaking (it is not associated with any particular command).
12 rd_port_aging_en	If set to 1, enables aging function for the read channel of the port.
11-10 —	Reserved
9-0 rd_port_priority	Determines the initial load value of read aging counters. These counters will be parallel loaded after reset, or after each grant to the corresponding port. The aging counters down-count every clock cycle where the port is requesting but not granted. The higher significant 5-bits of the read aging counter sets the priority of the read channel of a given port. Port's priority will increase as the higher significant 5-bits of the counter starts to decrease. When the aging counter becomes 0, the corresponding port channel will have the highest priority level (timeout condition - Priority0). For multi-port configurations, the aging counters cannot be used to set port priorities when external dynamic priority inputs (arqos) are enabled (timeout is still applicable). For single port configurations, the aging counters are only used when they timeout (become 0) to force read-write direction switching. In this case, external dynamic priority input, arqos (for reads only) can still be used to set the DDRC read priority (2 priority levels: low priority read - LPR, high priority read - HPR) on a command by command basis. Note: The two LSBs of this register field are tied internally to 2'b00.

14 wr_port_pagematch_en	If set to 1, enables the Page Match feature. If enabled, once a requesting port is granted, the port is continued to be granted if the following immediate commands are to the same memory page (same bank and same row). See also related PCCFG.pagematch_limit register.
13 wr_port_urgent_en	If set to 1, enables the AXI urgent sideband signal (awurgent). When enabled and awurgent is asserted by the master, that port becomes the highest priority and co_gs_go2critical_wr signal to DDRC is asserted if enabled in PCCFG.go2critical_en register. Note that awurgent signal can be asserted anytime and as long as required which is independent of address handshaking (it is not associated with any particular command).
12 wr_port_aging_en	If set to 1, enables aging function for the write channel of the port.
11-10 —	Reserved
9-0 wr_port_priority	Determines the initial load value of write aging counters. These counters will be parallel loaded after reset, or after each grant to the corresponding port. The aging counters down-count every clock cycle where the port is requesting but not granted. The higher significant 5-bits of the write aging counter sets the initial priority of the write channel of a given port. Port's priority will increase as the higher significant 5-bits of the counter starts to decrease. When the aging counter becomes 0, the corresponding port channel will have the highest priority level. For multi-port configurations, the aging counters cannot be used to set port priorities when external dynamic priority inputs (awqos) are enabled (timeout is still applicable). For single port configurations, the aging counters are only used when they timeout (become

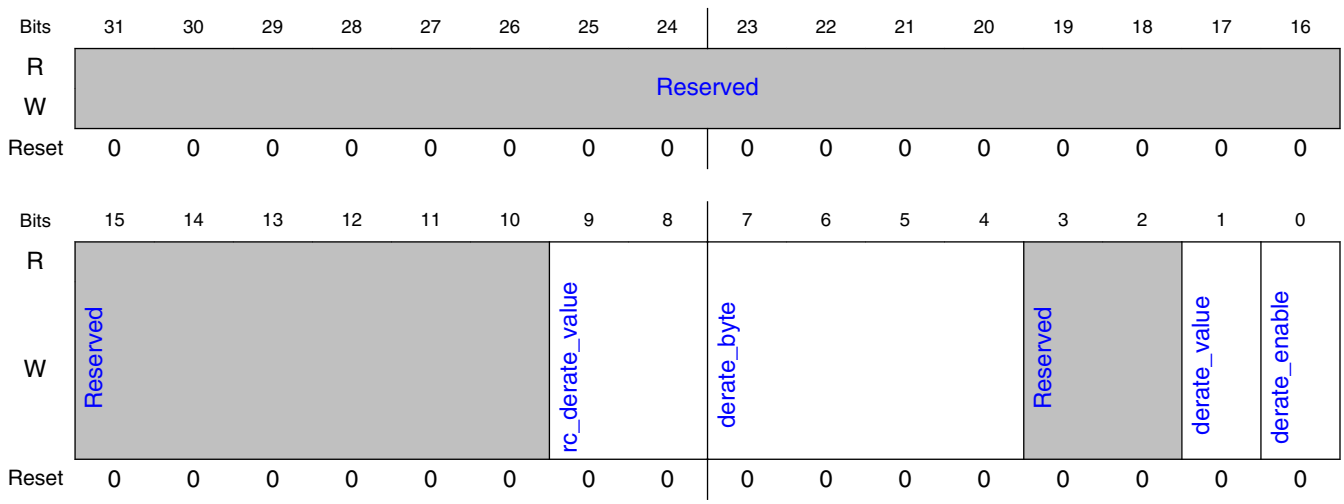
9.3.3.1.98 [SHADOW] Temperature Derate Enable Register (DERATEEN_SHADOW)

9.3.3.1.98.1 Offset

Register	Offset
DERATEEN_SHADOW	2020h

9.3.3.1.98.2 Diagram



9.3.3.1.98.3 Fields

Field	Function
31-10 —	Reserved
9-8 rc_derate_value	Derate value of tRC for LPDDR4 - 0 - Derating uses +1. - 1 - Derating uses +2. - 2 - Derating uses +3. - 3 - Derating uses +4. Present only in designs configured to support LPDDR4. The required number of cycles for derating can be determined by dividing 3.75ns by the core_ddrc_core_clk period, and rounding up the next integer.
7-4 derate_byte	Derate byte Present only in designs configured to support LPDDR2/LPDDR3/LPDDR4 Indicates which byte of the MRR data is used for derating. The maximum valid value depends on MEMC_DRAM_TOTAL_DATA_WIDTH.
3-2 —	Reserved
1 derate_value	Derate value - 0 - Derating uses +1. - 1 - Derating uses +2. Present only in designs configured to support LPDDR2/LPDDR3/LPDDR4 Set to 0 for all LPDDR2 speed grades as derating value of +1.875 ns is less than a core_ddrc_core_clk period. For LPDDR3/4, if the period of core_ddrc_core_clk is less than 1.875ns, this register field should be set to 1; otherwise it should be set to 0.

Table continues on the next page...

Field	Function
0 derate_enable	Enables derating - 0 - Timing parameter derating is disabled - 1 - Timing parameter derating is enabled using MR4 read value. Present only in designs configured to support LPDDR2/LPDDR3/LPDDR4 This field must be set to '0' for non-LPDDR2/LPDDR3/LPDDR4 mode.

R W	mr4_read_interval															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

9.3.3.1.99.3 Fields

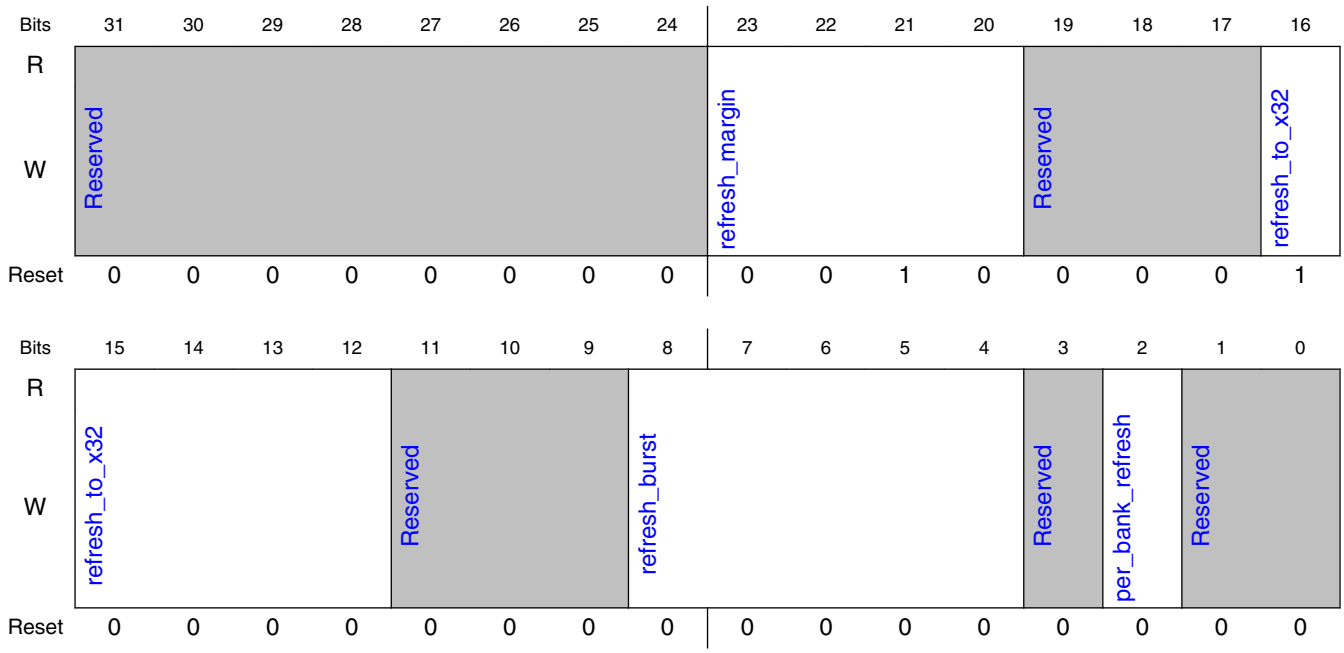
Field	Function
31-0 mr4_read_interval	Interval between two MR4 reads, used to derate the timing parameters. Present only in designs configured to support LPDDR2/LPDDR3/LPDDR4. This register must not be set to zero. Unit: DFI clock cycle.

9.3.3.1.100 [SHADOW] Refresh Control Register 0 (RFSHCTL0_SHADOW)

9.3.3.1.100.1 Offset

Register	Offset
RFSHCTL0_SHADOW	2050h

9.3.3.1.100.2 Diagram



9.3.3.1.100.3 Fields

Field	Function
31-24 —	Reserved
23-20 refresh_margin	Threshold value in number of DFI clock cycles before the critical refresh or page timer expires. A critical refresh is to be issued before this threshold is reached. It is recommended that this not be changed from the default value, currently shown as 0x2. It must always be less than internally used t_rfc_nom_x32. Note that, in LPDDR2/LPDDR3/LPDDR4, internally used t_rfc_nom_x32 may be equal to RFSHTMG.t_rfc_nom_x32>>2 if derating is enabled (DERATEEN.derate_enable=1). Otherwise, internally used t_rfc_nom_x32 will be equal to RFSHTMG.t_rfc_nom_x32. Unit: Multiples of 32 DFI clocks.
19-17 —	Reserved
16-12 refresh_to_x32	If the refresh timer (tRFCnom, also known as tREFI) has expired at least once, but it has not expired (RFSHCTL0.refresh_burst+1) times yet, then a speculative refresh may be performed. A speculative refresh is a refresh performed at a time when refresh would be useful, but before it is absolutely required. When the SDRAM bus is idle for a period of time determined by this RFSHCTL0.refresh_to_x32 and the refresh timer has expired at least once since the last refresh, then a speculative refresh is performed.

Table continues on the next page...

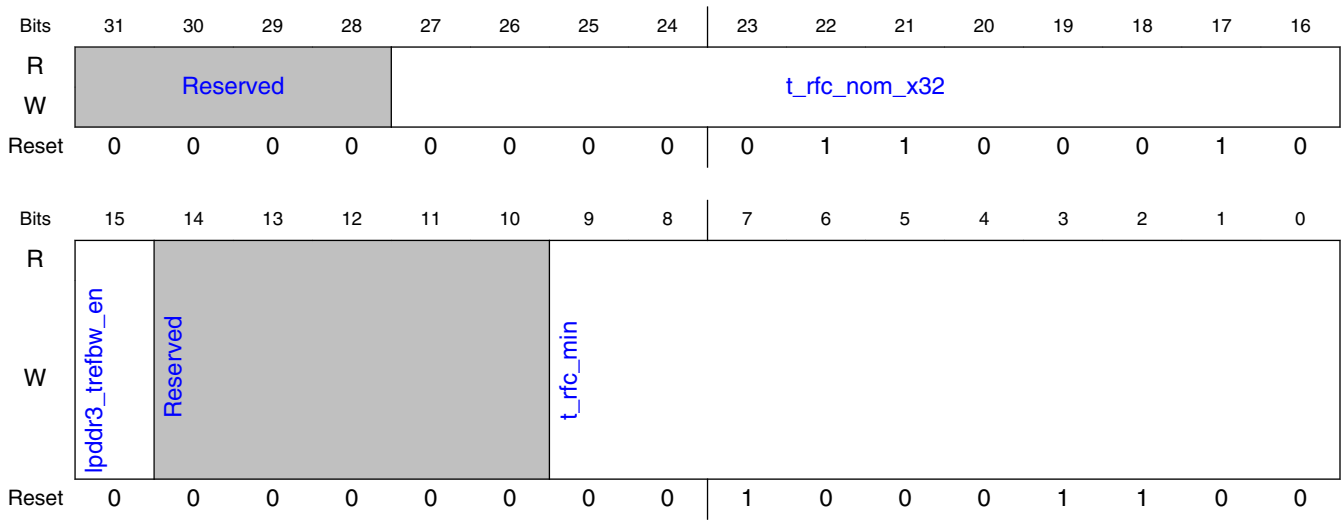
Field	Function
	Speculative refreshes continues successively until there are no refreshes pending or until new reads or writes are issued to the DDRC. FOR PERFORMANCE ONLY. Unit: Multiples of 32 DFI clocks.
11-9 —	Reserved
8-4 refresh_burst	The programmed value + 1 is the number of refresh timeouts that is allowed to accumulate before traffic is blocked and the refreshes are forced to execute. Closing pages to perform a refresh is a one-time penalty that must be paid for each group of refreshes. Therefore, performing refreshes in a burst reduces the per-refresh penalty of these page closings. Higher numbers for RFSHCTL.refresh_burst slightly increases utilization; lower numbers decreases the worst-case latency associated with refreshes. - 0 - single refresh - 1 - burst-of-2 refresh - 7 - burst-of-8 refresh For information on burst refresh feature refer to section 3.9 of DDR2 JEDEC specification - JESD79-2F.pdf. For DDR2/3, the refresh is always per-rank and not per-bank. The rank refresh can be accumulated over 8*tREFI cycles using the burst refresh feature. In DDR4 mode, according to Fine Granularity feature, 8 refreshes can be postponed in 1X mode, 16 refreshes in 2X mode and 32 refreshes in 4X mode. If using PHY-initiated updates, care must be taken in the setting of RFSHCTL0.refresh_burst, to ensure that tRFCmax is not violated due to a PHY-initiated update occurring shortly before a refresh burst was due. In this situation, the refresh burst will be delayed until the PHY-initiated update is complete.
3 —	Reserved
2 per_bank_refresh	- 1 - Per bank refresh; - 0 - All bank refresh. Per bank refresh allows traffic to flow to other banks. Per bank refresh is not supported by all LPDDR2 devices but should be supported by all LPDDR3/LPDDR4 devices. Present only in designs configured to support LPDDR2/LPDDR3/LPDDR4
1-0 —	Reserved

9.3.3.1.101 [SHADOW] Refresh Timing Register (RFSHTMG_SHADOW)

9.3.3.1.101.1 Offset

Register	Offset
RFSHTMG_SHADOW	2064h

9.3.3.1.101.2 Diagram



9.3.3.1.101.3 Fields

Field	Function
31-28 —	Reserved
27-16 t_rfc_nom_x32	tREFI: Average time interval between refreshes per rank (Specification: 7.8us for DDR2, DDR3 and DDR4. See JEDEC specification for mDDR, LPDDR2, LPDDR3 and LPDDR4). For LPDDR2/LPDDR3/LPDDR4: - if using all-bank refreshes (RFSHCTL0.per_bank_refresh = 0), this register should be set to tREFIab - if using per-bank refreshes (RFSHCTL0.per_bank_refresh = 1), this register should be set to tREFIpb When the controller is operating in 1:2 frequency ratio mode, program this to (tREFI/2), no rounding up. In DDR4 mode, tREFI value is different depending on the refresh mode. The user should program the appropriate value from the spec based on the value programmed in the refresh mode register. Note that RFSHTMG.t_rfc_nom_x32 * 32 must be greater than RFSHTMG.t_rfc_min, and RFSHTMG.t_rfc_nom_x32 must be greater than 0x1. - Non-DDR4 or DDR4 Fixed 1x mode: RFSHTMG.t_rfc_nom_x32 must be less than or equal to 0xFFE. - DDR4 Fixed 2x mode: RFSHTMG.t_rfc_nom_x32 must be less than or equal to 0x7FF. - DDR4 Fixed 4x mode: RFSHTMG.t_rfc_nom_x32 must be less than or equal to 0x3FF. Unit: Multiples of 32 clocks.
15 lpddr3_trefbw_en	Used only when LPDDR3 memory type is connected. Should only be changed when DDRC is in reset. Specifies whether to use the tREFBW parameter (required by some LPDDR3 devices which comply with earlier versions of the LPDDR3 JEDEC specification) or not: - 0 - tREFBW parameter not used - 1 - tREFBW parameter used
14-10 —	Reserved
9-0 t_rfc_min	tRFC (min): Minimum time from refresh to refresh or activate. When the controller is operating in 1:1 mode, t_rfc_min should be set to RoundUp(tRFCmin/tCK). When the controller is operating in 1:2 mode, t_rfc_min should be set to RoundUp(RoundUp(tRFCmin/tCK)/2). In LPDDR2/LPDDR3/LPDDR4 mode: - if using all-bank refreshes, the tRFCmin value in the above equations is equal to tRFCab - if using per-bank refreshes, the tRFCmin value in the above equations is equal to tRFCpb In DDR4 mode, the tRFCmin value in the above equations is different depending on the refresh mode (fixed 1X,2X,4X) and the device density. The user should program the appropriate value from the spec based on the 'refresh_mode' and the device density that is used. Unit: Clocks.

9.3.3.1.106.3 Fields

Field	Function
31 —	Reserved
30-24 wr2pre	Minimum time between write and precharge to same bank. Unit: Clocks Specifications: WL + BL/2 + tWR = approximately 8 cycles + 15 ns = 14 clocks @400MHz and less for lower frequencies where: - WL = write latency - BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM. BST (burst terminate) is not supported at present. - tWR = Write recovery time. This comes directly from the SDRAM specification. Add one extra cycle for LPDDR2/LPDDR3/LPDDR4 for this parameter. When the controller is operating in 1:2 frequency ratio mode, 1T mode, divide the above value by 2. No rounding up. When the controller is operating in 1:2 frequency ratio mode, 2T mode or LPDDR4 mode, divide the above value by 2 and round it up to the next integer value. Note that, depending on the PHY, if using LRDIMM, it may be necessary to adjust the value of this parameter to compensate for the extra cycle of latency through the LRDIMM.
23-22 —	Reserved
21-16 t_faw	tFAW Valid only when 8 or more banks(or banks x bank groups) are present. In 8-bank design, at most 4 banks must be activated in a rolling window of tFAW cycles. When the controller is operating in 1:2 frequency ratio mode, program this to (tFAW/2) and round up to next integer value. In a 4-bank design, set this register to 0x1 independent of the 1:1/1:2 frequency mode. Unit: Clocks

Table continues on the next page...

Field	Function
15 —	Reserved
14-8 t_ras_max	tRAS(max): Maximum time between activate and precharge to same bank. This is the maximum time that a page can be kept open Minimum value of this register is 1. Zero is invalid. When the controller is operating in 1:2 frequency ratio mode, program this to (tRAS(max)-1)/2. No rounding up. Unit: Multiples of 1024 clocks.
7-6 —	Reserved
5-0 t_ras_min	tRAS(min): Minimum time between activate and precharge to the same bank. When the controller is operating in 1:2 frequency mode, 1T mode, program this to tRAS(min)/2. No rounding up. When the controller is operating in 1:2 frequency ratio mode, 2T mode or LPDDR4 mode, program this to (tRAS(min)/2) and round it up to the next integer value. Unit: Clocks

Field	Function
31-30 —	Reserved
29-24 write_latency	Set to WL Time from write command to write data on SDRAM interface. This must be set to WL. For mDDR, it should normally be set to 1. Note that, depending on the PHY, if using RDIMM/LRDIMM, it may be necessary to adjust the value of WL to compensate for the extra cycle of latency through the RDIMM/LRDIMM. When the controller is operating in 1:2 frequency ratio mode, divide the value calculated using the above equation by 2, and round it up to next integer. This register field is not required for DDR2 and DDR3 (except if MEMC_TRAINING is set), as the DFI read and write latencies defined in DFITMG0 and DFITMG1 are sufficient for those protocols Unit: clocks
23-22 —	Reserved
21-16 read_latency	Set to RL Time from read command to read data on SDRAM interface. This must be set to RL. Note that, depending on the PHY, if using RDIMM/LRDIMM, it may be necessary to adjust the value of RL to compensate for the extra cycle of latency through the RDIMM/LRDIMM. When the controller is operating in 1:2 frequency ratio mode, divide the value calculated using the above equation by 2, and round it up to next integer. This register field is not required for DDR2 and DDR3 (except if MEMC_TRAINING is set), as the DFI read and write latencies defined in DFITMG0 and DFITMG1 are sufficient for those protocols Unit: clocks
15-14 —	Reserved
13-8 rd2wr	DDR2/3/mDDR: RL + BL/2 + 2 - WL DDR4: RL + BL/2 + 1 + WR_PREAMBLE - WL LPDDR2/LPDDR3: RL + BL/2 + RU(tDQSCKmax/tCK) + 1 - WL LPDDR4(DQ ODT is Disabled): RL + BL/2 + RU(tDQSCKmax/tCK) + WR_PREAMBLE + RD_POSTAMBLE - WL LPDDR4(DQ ODT is Enabled) : RL + BL/2 + RU(tDQSCKmax/tCK) + RD_POSTAMBLE - ODTLon - RU(tODTon(min)/tCK) Minimum time from read command to write command. Include time for bus turnaround and all per-bank, per-rank, and global constraints. Please see the relevant PHY databook for details of what should be included here. Unit: Clocks. Where: - WL = write latency - BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM - RL = read latency = CAS latency - WR_PREAMBLE = write preamble. This is unique to DDR4 and LPDDR4. - RD_POSTAMBLE = read postamble. This is unique to LPDDR4. For LPDDR2/LPDDR3/LPDDR4, if derating is enabled (DERATEEN.derate_enable=1), derated tDQSCKmax should be used. When the controller is operating in 1:2 frequency ratio mode, divide the value calculated using the above equation by 2, and round it up to next integer. Note that, depending on the PHY, if using LRDIMM, it may be necessary to adjust the value of this parameter to compensate for the extra cycle of latency through the LRDIMM.
7-6 —	Reserved
5-0 wr2rd	DDR4: CWL + PL + BL/2 + tWTR_L Others: CWL + BL/2 + tWTR In DDR4, minimum time from write command to read command for same bank group. In others, minimum time from write command to read command. Includes time for bus turnaround, recovery times, and all per-bank, per-rank, and global constraints. Unit: Clocks. Where: - CWL = CAS write latency - PL = Parity latency - BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM - tWTR_L = internal write to read command delay for same bank group. This comes directly from the SDRAM specification. - tWTR = internal write to read command delay. This comes directly from the SDRAM specification. Add one extra cycle for LPDDR2/LPDDR3/LPDDR4 operation. When the controller is operating in 1:2 mode, divide the value calculated using the above equation by 2, and round it up to next integer.

9.3.3.1.109 [SHADOW] SDRAM Timing Register 3 (DRAMTMG3_SHADOW)

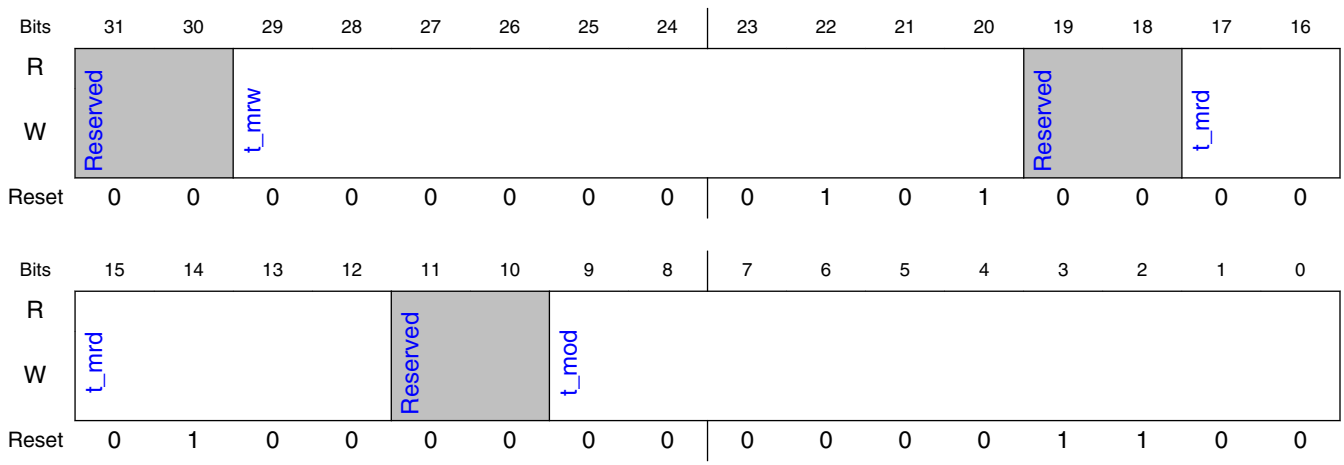
Register	Offset
DRAMTMG3_SHADOW	210Ch

9.3.3.1.109.2 Diagram



9.3.3.1.109.3 Fields

Field	Function
31-30 —	Reserved
29-20 t_mrw	Time to wait after a mode register write or read (MRW or MRR). Present only in designs configured to support LPDDR2, LPDDR3 or LPDDR4. LPDDR2 typically requires value of 5. LPDDR3 typically requires value of 10. LPDDR4: Set this to the larger of tMRW and tMRWCKEL. For LPDDR2, this register is used for the time from a MRW/MRR to all other commands. When the controller is operating in 1:2 frequency ratio mode, program this to the above values divided by 2 and round it up to the next integer value. For LDPDR3, this register is used for the time from a MRW/MRR to a MRW/MRR.
19-18 —	Reserved
17-12 t_mrd	tMRD: Cycles to wait after a mode register write or read. Depending on the connected SDRAM, tMRD represents: DDR2/mDDR: Time from MRS to any command DDR3/4: Time from MRS to MRS command LPDDR2: not used LPDDR3/4: Time from MRS to non-MRS command. When the controller is operating in 1:2 frequency ratio mode, program this to (tMRD/2) and round it up to the next integer value. If C/A parity for DDR4 is used, set to tMRD_PAR(tMOD+PL) instead.
11-10 —	Reserved

Table continues on the next page...

Field	Function
9-0 t_mod	tMOD: Parameter used only in DDR3 and DDR4. Cycles between load mode command and following non-load mode command. If C/A parity for DDR4 is used, set to tMOD_PAR(tMOD+PL) instead. Set to tMOD if controller is operating in 1:1 frequency ratio mode, or tMOD/2 (rounded up to next integer) if controller is operating in 1:2 frequency ratio mode. Note that if using RDIMM/LRDIMM, depending on the PHY, it may be necessary to adjust the value of this parameter to compensate for the extra cycle of latency applied to mode register writes by the RDIMM/LRDIMM chip. Also note that if using LRDIMM, the minimum value of this register is tMRD_L2 if controller is operating in 1:1 frequency ratio mode, or tMRD_L2/2 (rounded up to next integer) if controller is operating in 1:2 frequency ratio mode.

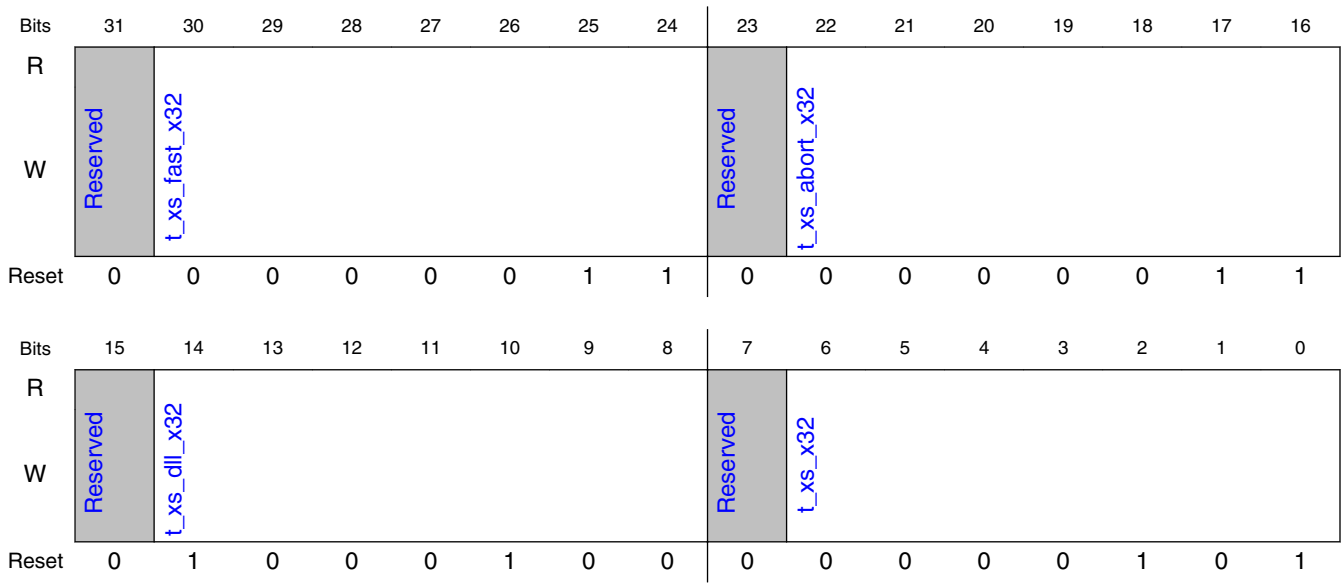
11-8 t_ckpde	This is the time after Power Down Entry that CK is maintained as a valid clock. Specifies the clock disable delay after PDE. Recommended settings: - mDDR: 0 - LPDDR2: 2 - LPDDR3: 2 - LPDDR4: tCKCKEL When using DDR2/3/4 SDRAM, this register should be set to the same value as DRAMTMG5.t_cksre. When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer. This is only present for designs supporting mDDR or LPDDR2/ LPDDR3/LPDDR4 devices.
7-4 —	Reserved
3-0 t_ckpdx	This is the time before Power Down Exit that CK is maintained as a valid clock before issuing PDX. Specifies the clock stable time before PDX. Recommended settings: - mDDR: 0 - LPDDR2: 2 - LPDDR3: 2 - LPDDR4: 2 When using DDR2/3/4 SDRAM, this register should be set to the same value as DRAMTMG5.t_cksrx. When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer. This is only present for designs supporting mDDR or LPDDR2/LPDDR3/LPDDR4 devices.

9.3.3.1.114 [SHADOW] SDRAM Timing Register 8 (DRAMTMG8_SHADOW)

9.3.3.1.114.1 Offset

Register	Offset
DRAMTMG8_SHADOW	2120h

9.3.3.1.114.2 Diagram



9.3.3.1.114.3 Fields

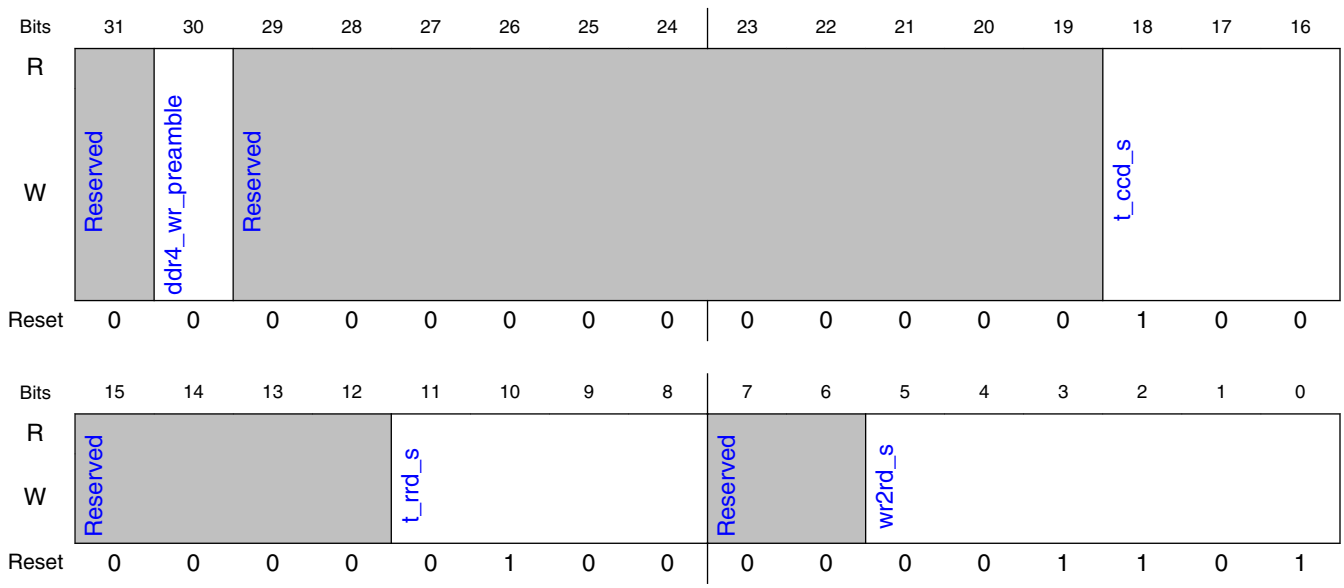
Field	Function
31 —	Reserved
30-24 t_xs_fast_x32	tXS_FAST: Exit Self Refresh to ZQCL, ZQCS and MRS (only CL, WR, RTP and Geardown mode). When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided by 2 and round up to next integer value. Unit: Multiples of 32 clocks. Note: This is applicable to only ZQCL/ZQCS commands. Note: Ensure this is less than or equal to t_xs_x32.
23 —	Reserved
22-16 t_xs_abort_x32	tXS_ABORT: Exit Self Refresh to commands not requiring a locked DLL in Self Refresh Abort. When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided by 2 and round up to next integer value. Unit: Multiples of 32 clocks. Note: Ensure this is less than or equal to t_xs_x32.
15 —	Reserved
14-8 t_xs_dll_x32	tXSDLL: Exit Self Refresh to commands requiring a locked DLL. When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided by 2 and round up to next integer value. Unit: Multiples of 32 clocks. Note: Used only for DDR2, DDR3 and DDR4 SDRAMs.
7 —	Reserved
6-0 t_xs_x32	tXS: Exit Self Refresh to commands not requiring a locked DLL. When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided by 2 and round up to next integer value. Unit: Multiples of 32 clocks. Note: Used only for DDR2, DDR3 and DDR4 SDRAMs.

9.3.3.1.115 [SHADOW] SDRAM Timing Register 9 (DRAMTMG9_SHADOW)

9.3.3.1.115.1 Offset

Register	Offset
DRAMTMG9_SHADOW	2124h

9.3.3.1.115.2 Diagram



9.3.3.1.115.3 Fields

Field	Function
31 —	Reserved
30 ddr4_wr_preamble	DDR4 Write preamble mode - 0: 1tCK preamble - 1: 2tCK preamble Present only with MEMC_FREQ_RATIO=2
29-19 —	Reserved
18-16 t_ccd_s	tCCD_S: This is the minimum time between two reads or two writes for different bank group. For bank switching (from bank "a" to bank "b"), the minimum time is this value + 1. When the controller is operating in 1:2 frequency ratio mode, program this to (tCCD_S/2) and round it up to the next integer value. Present only in designs configured to support DDR4. Unit: clocks.
15-12 —	Reserved

Table continues on the next page...

Field	Function
11-8 t_rrd_s	tRRD_S: Minimum time between activates from bank "a" to bank "b" for different bank group. When the controller is operating in 1:2 frequency ratio mode, program this to (tRRD_S/2) and round it up to the next integer value. Present only in designs configured to support DDR4. Unit: Clocks.
7-6 —	Reserved
5-0 wr2rd_s	CWL + PL + BL/2 + tWTR_S Minimum time from write command to read command for different bank group. Includes time for bus turnaround, recovery times, and all per-bank, per-rank, and global constraints. Present only in designs configured to support DDR4. Unit: Clocks. Where: - CWL = CAS write latency - PL = Parity latency - BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM - tWTR_S = internal write to read command delay for different bank group. This comes directly from the SDRAM specification. When the controller is operating in 1:2 mode, divide the value calculated using the above equation by 2, and round it up to next integer.

20-16 t_sync_gear	Indicates the time between MRS command and the sync pulse time. This must be even number of clocks. For DDR4-2666 and DDR4-3200, this parameter is defined as tMOD(min)+4nCK tMOD(min) is greater of 24nCK or 15ns 15ns / .625ns = 24 Max value for this register is 24+4 = 28 When the controller is operating in 1:2 mode, program this to (tSYNC_GEAR/2) and round it up to the next integer value. Unit: Clocks
15-13 —	Reserved
12-8 t_cmd_gear	Sync pulse to first valid command. For DDR4-2666 and DDR4-3200, this parameter is defined as tMOD(min) tMOD(min) is greater of 24nCK or 15ns 15ns / .625ns = 24 Max value for this register is 24 When the controller is operating in 1:2 mode, program this to (tCMD_GEAR/2) and round it up to the next integer value. Unit: Clocks
7-4 —	Reserved
3-2 t_gear_setup	Geardown setup time. Minimum value of this register is 1. Zero is invalid. For DDR4-2666 and DDR4-3200, this parameter is defined as 2 clks When the controller is operating in 1:2 frequency ratio mode, program this to (tGEAR_setup/2) and round it up to the next integer value. Unit: Clocks
1-0 t_gear_hold	Geardown hold time. Minimum value of this register is 1. Zero is invalid. For DDR4-2666 and DDR4-3200, this parameter is defined as 2 clks When the controller is operating in 1:2 frequency ratio mode, program this to (tGEAR_hold/2) and round it up to the next integer value. Unit: Clocks

9.3.3.1.121.3 Fields

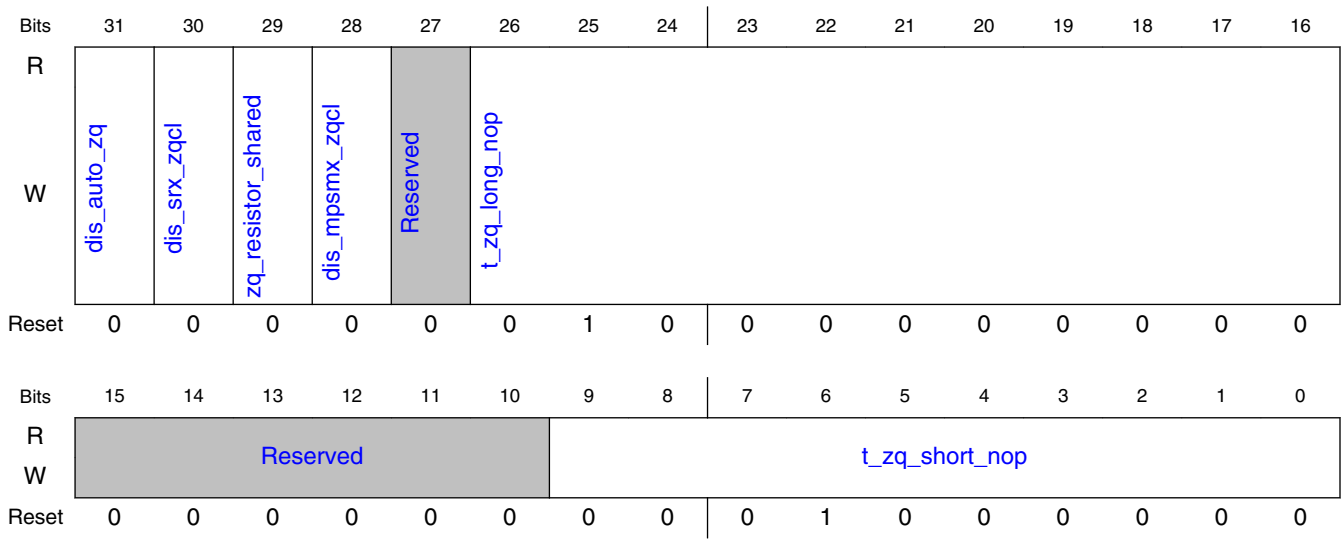
Field	Function
31 en_dfi_lp_t_stab	- 1 - Enable using tSTAB when exiting DFI LP. Needs to be set when the PHY is stopping the clock during DFI LP to save maximum power. - 0 - Disable using tSTAB when exiting DFI LP
30-8 —	Reserved
7-0 t_stab_x32	tSTAB: Stabilization time. It is required in the following two cases for DDR3/DDR4 RDIMM : - when exiting power saving mode, if the clock was stopped, after re-enabling it the clock must be stable for a time specified by tSTAB - in the case of input clock frequency change (DDR4) - after issuing control words that refers to clock timing (Specification: 6us for DDR3, 5us for DDR4) When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer. Unit: Multiples of 32 clock cycles.

9.3.3.1.122 [SHADOW] ZQ Control Register 0 (ZQCTL0_SHADOW)

9.3.3.1.122.1 Offset

Register	Offset
ZQCTL0_SHADOW	2180h

9.3.3.1.122.2 Diagram



9.3.3.1.122.3 Fields

Field	Function
31 dis_auto_zq	- 1 - Disable DDRC generation of ZQCS/MPC(ZQ calibration) command. Register DBGCMD.zq_calib_short can be used instead to issue ZQ calibration request from APB module. - 0 - Internally generate ZQCS/MPC(ZQ calibration) commands based on ZQCTL1.t_zq_short_interval_x1024. This is only present for designs supporting DDR3/DDR4 or LPDDR2/LPDDR3/LPDDR4 devices.
30 dis_srx_zqcl	- 1 - Disable issuing of ZQCL/MPC(ZQ calibration) command at Self-Refresh/SR-Powerdown exit. Only applicable when run in DDR3 or DDR4 or LPDDR2 or LPDDR3 or LPDDR4 mode. - 0 - Enable issuing of ZQCL/MPC(ZQ calibration) command at Self-Refresh/SR-Powerdown exit. Only applicable when run in DDR3 or DDR4 or LPDDR2 or LPDDR3 or LPDDR4 mode. This is only present for designs supporting DDR3/DDR4 or LPDDR2/LPDDR3/LPDDR4 devices.
29 zq_resistor_shared	- 1 - Denotes that ZQ resistor is shared between ranks. Means ZQinit/ZQCL/ZQCS/MPC(ZQ calibration) commands are sent to one rank at a time with tZQinit/tZQCL/tZQCS/tZQCAL/tZQLAT timing met between commands so that commands to different ranks do not overlap. - 0 - ZQ resistor is not shared. This is only present for designs supporting DDR3/DDR4 or LPDDR2/LPDDR3/LPDDR4 devices.
28 dis_mpsmx_zqcl	- 1 - Disable issuing of ZQCL command at Maximum Power Saving Mode exit. Only applicable when run in DDR4 mode. - 0 - Enable issuing of ZQCL command at Maximum Power Saving Mode exit. Only applicable when run in DDR4 mode. This is only present for designs supporting DDR4 devices. Note: Do not issue ZQCL command at Maximum Power Save Mode exit if the DDRC_SHARED_AC configuration parameter is set. Program it to 1'b1. The software can send ZQCS after exiting MPSM mode.
27 —	Reserved
26-16 t_zq_long_nop	tZQoper for DDR3/DDR4, tZQCL for LPDDR2/LPDDR3, tZQCAL for LPDDR4: Number of DFI clock cycles of NOP required after a ZQCL (ZQ calibration long)/MPC(ZQ Start) command is issued to SDRAM. When the controller is operating in 1:2 frequency ratio mode: DDR3/DDR4: program this to tZQoper/2 and round it up to the next integer value. LPDDR2/LPDDR3: program this to tZQCL/2 and round it up to the next integer value. LPDDR4: program this to tZQCAL/2 and round it up to the next integer value. This is only present for designs supporting DDR3/DDR4 or LPDDR2/LPDDR3/LPDDR4 devices.
15-10	Reserved

Table continues on the next page...

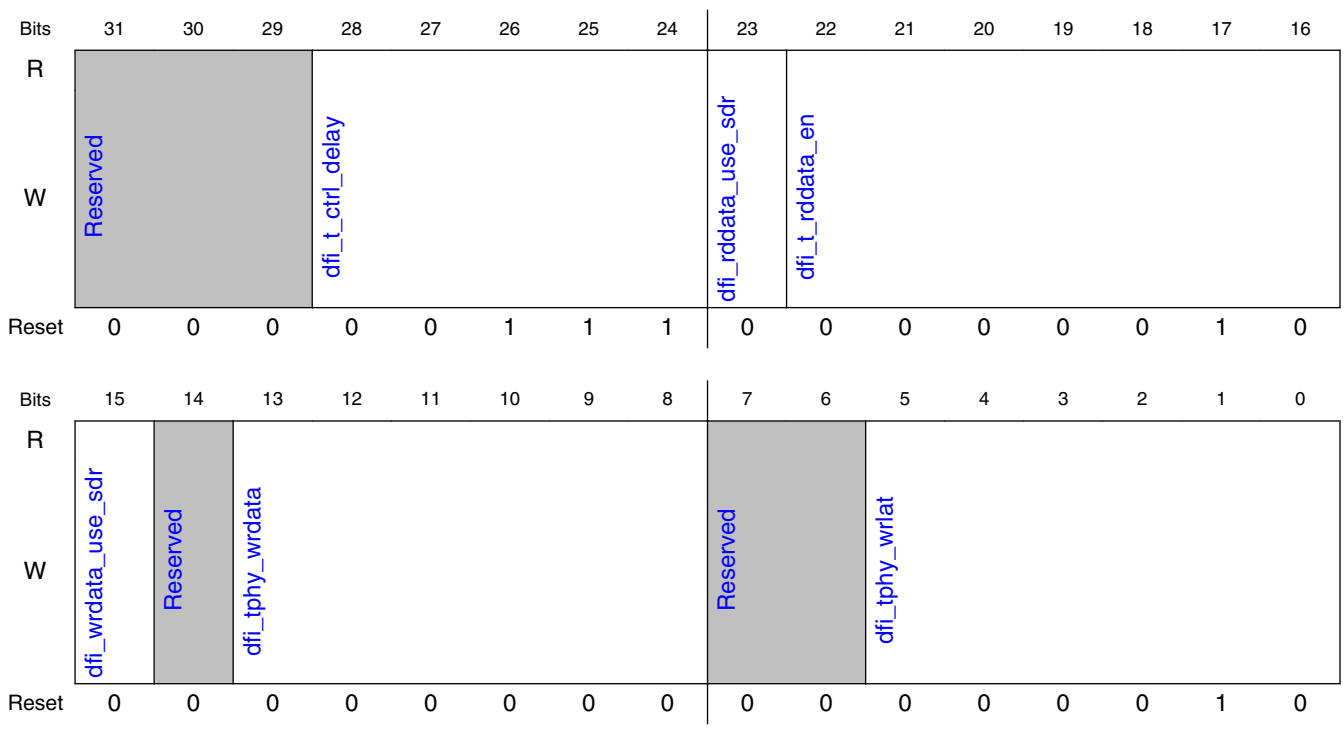
Field	Function
—	
9-0 t_zq_short_nop	tZQCS for DDR3/DD4/LPDDR2/LPDDR3, tZQLAT for LPDDR4: Number of DFI clock cycles of NOP required after a ZQCS (ZQ calibration short)/MPC(ZQ Latch) command is issued to SDRAM. When the controller is operating in 1:2 frequency ratio mode, program this to tZQCS/2 and round it up to the next integer value. This is only present for designs supporting DDR3/DDR4 or LPDDR2/LPDDR3/LPDDR4 devices.

9.3.3.1.123 [SHADOW] DFI Timing Register 0 (DFITMG0_SHADOW)

9.3.3.1.123.1 Offset

Register	Offset
DFITMG0_SHADOW	2190h

9.3.3.1.123.2 Diagram



9.3.3.1.123.3 Fields

Field	Function
31-29	Reserved

Table continues on the next page...

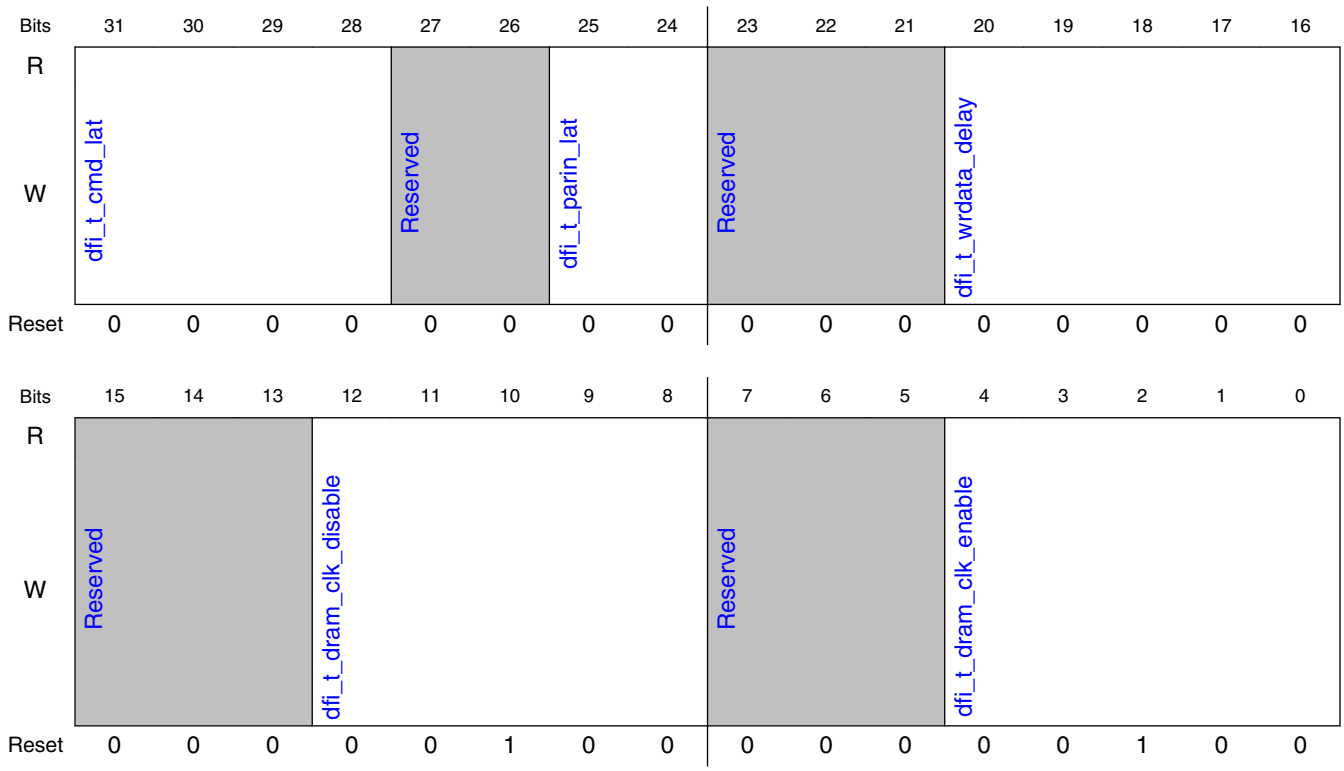
Field	Function
—	
28-24 dfi_t_ctrl_delay	Specifies the number of DFI clock cycles after an assertion or de-assertion of the DFI control signals that the control signals at the PHY-DRAM interface reflect the assertion or de-assertion. If the DFI clock and the memory clock are not phase-aligned, this timing parameter should be rounded up to the next integer value. Note that if using RDIMM/LRDIMM, it is necessary to increment this parameter by RDIMM's/ LRDIMM's extra cycle of latency in terms of DFI clock.
23 dfi_rddata_use_sdr	Defines whether dfi_rddata_en/dfi_rddata/dfi_rddata_valid is generated using HDR (DFI clock) or SDR (DFI PHY clock) values. Selects whether value in DFITMG0.dfi_t_rddata_en is in terms of HDR (DFI clock) or SDR (DFI PHY clock) cycles: - 0 in terms of HDR (DFI clock) cycles - 1 in terms of SDR (DFI PHY clock) cycles Refer to PHY specification for correct value.
22-16 dfi_t_rddata_en	Time from the assertion of a read command on the DFI interface to the assertion of the dfi_rddata_en signal. Refer to PHY specification for correct value. This corresponds to the DFI parameter trddata_en. Note that, depending on the PHY, if using RDIMM/LRDIMM, it may be necessary to use the adjusted value of CL in the calculation of trddata_en. This is to compensate for the extra cycle(s) of latency through the RDIMM/LRDIMM. Unit: DFI clock cycles or DFI PHY clock cycles, depending on DFITMG0.dfi_rddata_use_sdr.
15 dfi_wrdata_use_sdr	Defines whether dfi_wrdata_en/dfi_wrdata/dfi_wrdata_mask is generated using HDR (DFI clock) or SDR (DFI PHY clock) values Selects whether value in DFITMG0.dfi_tphy_wrlat is in terms of HDR (DFI clock) or SDR (DFI PHY clock) cycles Selects whether value in DFITMG0.dfi_tphy_wrdata is in terms of HDR (DFI clock) or SDR (DFI PHY clock) cycles - 0 in terms of HDR (DFI clock) cycles - 1 in terms of SDR (DFI PHY clock) cycles Refer to PHY specification for correct value.
14 —	Reserved
13-8 dfi_tphy_wrdata	Specifies the number of clock cycles between when dfi_wrdata_en is asserted to when the associated write data is driven on the dfi_wrdata signal. This corresponds to the DFI timing parameter tphy_wrdata. Refer to PHY specification for correct value. Note, max supported value is 8. Unit: DFI clock cycles or DFI PHY clock cycles, depending on DFITMG0.dfi_wrdata_use_sdr.
7-6 —	Reserved
5-0 dfi_tphy_wrlat	Write latency Number of clocks from the write command to write data enable (dfi_wrdata_en). This corresponds to the DFI timing parameter tphy_wrlat. Refer to PHY specification for correct value.Note that, depending on the PHY, if using RDIMM/LRDIMM, it may be necessary to use the adjusted value of CL in the calculation of tphy_wrlat. This is to compensate for the extra cycle(s) of latency through the RDIMM/LRDIMM. Unit: DFI clock cycles or DFI PHY clock cycles, depending on DFITMG0.dfi_wrdata_use_sdr.

9.3.3.1.124 [SHADOW] DFI Timing Register 1 (DFITMG1_SHADOW)

9.3.3.1.124.1 Offset

Register	Offset
DFITMG1_SHADOW	2194h

9.3.3.1.124.2 Diagram



9.3.3.1.124.3 Fields

Field	Function
31-28 dfi_t_cmd_lat	Specifies the number of DFI PHY clock cycles between when the dfi_cs signal is asserted and when the associated command is driven. This field is used for CAL mode, should be set to '0' or the value which matches the CAL mode register setting in the DRAM. If the PHY can add the latency for CAL mode, this should be set to '0'. Valid Range: 0, 3, 4, 5, 6, and 8
27-26 —	Reserved
25-24 dfi_t_parin_lat	Specifies the number of DFI PHY clock cycles between when the dfi_cs signal is asserted and when the associated dfi_parity_in signal is driven.
23-21 —	Reserved
20-16 dfi_t_wrdata_delay	Specifies the number of DFI clock cycles between when the dfi_wrdata_en signal is asserted and when the corresponding write data transfer is completed on the DRAM bus. This corresponds to the DFI timing parameter twrdata_delay. Refer to PHY specification for correct value. For DFI 3.0 PHY, set to twrdata_delay, a new timing parameter introduced in DFI 3.0. For DFI 2.1 PHY, set to tphy_wrdata + (delay of DFI write data to the DRAM). Value to be programmed is in terms of DFI clocks, not PHY clocks. In FREQ_RATIO=2, divide PHY's value by 2 and round up to next integer. If using DFITMG0.dfi_wrdata_use_sdr=1, add 1 to the value. Unit: Clocks
15-13 —	Reserved

Table continues on the next page...

Field	Function
12-8 dfi_t_dram_clk_disable	Specifies the number of DFI clock cycles from the assertion of the dfi_dram_clk_disable signal on the DFI until the clock to the DRAM memory devices, at the PHY-DRAM boundary, maintains a low value. If the DFI clock and the memory clock are not phase aligned, this timing parameter should be rounded up to the next integer value.
7-5 —	Reserved
4-0 dfi_t_dram_clk_enable	Specifies the number of DFI clock cycles from the de-assertion of the dfi_dram_clk_disable signal on the DFI until the first valid rising edge of the clock to the DRAM memory devices, at the PHY-DRAM boundary. If the DFI clock and the memory clock are not phase aligned, this timing parameter should be rounded up to the next integer value.

15-12 —	Reserved
11-8 rd_odt_hold	DFI PHY clock cycles to hold ODT for a read command. The minimum supported value is 2. Recommended values: DDR2: - BL8: 0x6 (not DDR2-1066), 0x7 (DDR2-1066) - BL4: 0x4 (not DDR2-1066), 0x5 (DDR2-1066) DDR3: - BL8 - 0x6 DDR4: - BL8: 5 + RD_PREAMBLE RD_PREAMBLE = 1 (1tCK write preamble), 2 (2tCK write preamble) LPDDR3: - BL8: 5 + RU(tDQSCK(max)/tCK) - RD(tDQSCK(min)/tCK) + RU(tODTon(max)/tCK)
7 —	Reserved
6-2 rd_odt_delay	The delay, in DFI PHY clock cycles, from issuing a read command to setting ODT values associated with that command. ODT setting must remain constant for the entire time that DQS is driven by the DDRC. Recommended values: DDR2: - CL + AL - 4 (not DDR2-1066), CL + AL - 5 (DDR2-1066) If (CL + AL - 4 < 0), DDRC does not support ODT for read operation. DDR3: - CL - CWL DDR4: - CL - CWL - RD_PREAMBLE + WR_PREAMBLE + DFITMG1.dfi_t_cmd_lat (to adjust for CAL mode) WR_PREAMBLE = 1 (1tCK write preamble), 2 (2tCK write preamble) RD_PREAMBLE = 1 (1tCK write preamble), 2 (2tCK write preamble) If (CL - CWL - RD_PREAMBLE + WR_PREAMBLE) < 0, DDRC does not support ODT for read operation. LPDDR3: - RL + RD(tDQSCK(min)/tCK) - 1 - RU(tODTon(max)/tCK)
1-0 —	Reserved

9.4 DDR PHY (DDR_PHY)

9.4.1 Overview

The Double Data Rate Physical Layer (DDR PHY), provides an interface between universal controllers and external DDR3/DDR3L/DDR4/LPDDR3/LPDDR4 SDRAM devices.

NOTE

The information within this block guide is Synopsys Proprietary. Used with permission.

The block digram of the DDR PHY is shown below.

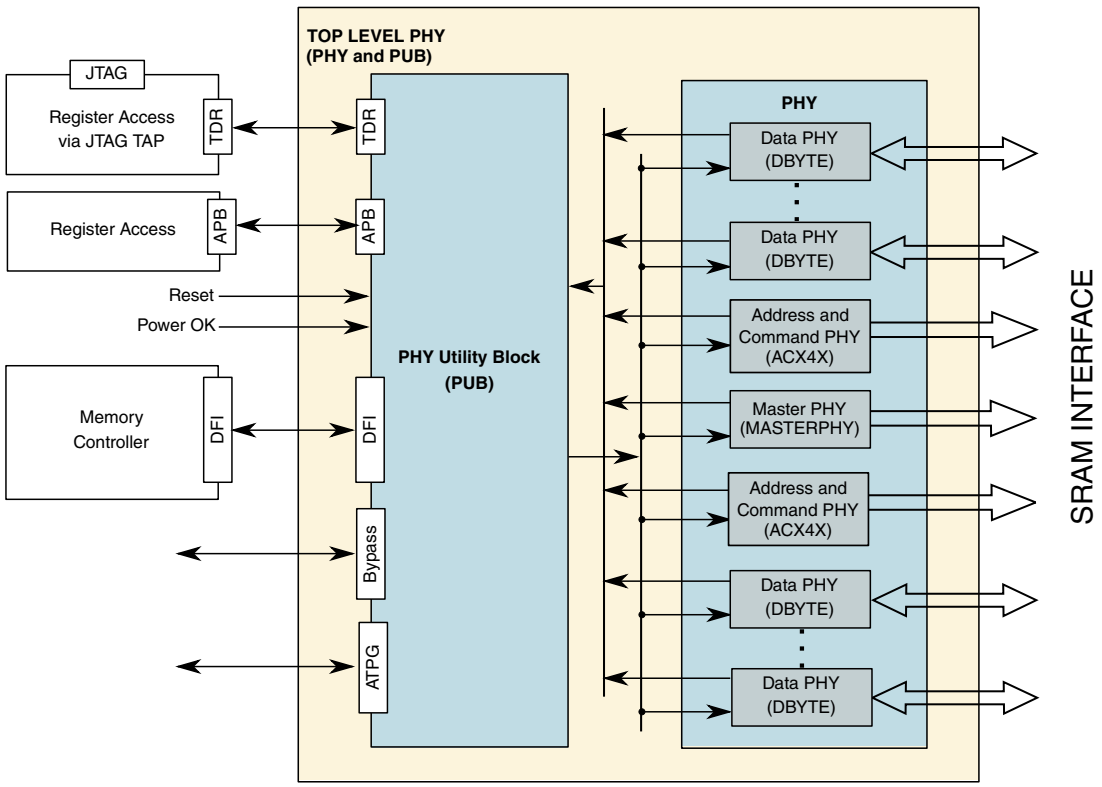

Figure 9-6. Block Diagram

9.4.1.1 Features

The following features are supported in the DDR PHY:

- LPDDR4, LPDDR3, DDR4, DDR3, and DDR3L operation
- Multiple memory rank support:
  - Four ranks supported for DDR4, DDR3, and DDR3L
  - Two ranks supported for LPDDR4 and LPDDR3
- DFI interface (DFI v4.0 Addendum 2, March 2015)
- At-speed loopback testing on both the address and data channels
- Mux-scan ATPG
- High-speed PLL used to generate the high speed clock for data transmit and high speed digital pipelines
- PHY Utility Block (PUB), which provides configuration and control
- Power on reset (POR) circuit, DRAM reset, DRAM alert and PHY debug
- A global voltage reference generation and observation circuit
- Impedance calibration circuits

9.4.2 Functional Description

The DDR PHY is composed of the following:

- DBYTE - The eight-lane data IO unit
- ACX4 - The four-lane address/command hard IP unit
- MASTERPHY - Contains the PLL, the voltage reference, thermal calibration, and reset
- PUB - PHY Utility Block

9.4.2.1 DDR Address/Command PHY (ACX4)

Info to be included at a future date.

The DDR SDRAM address/command PHY (DDRPHYACX4) provides an address and command interface to the external SDRAM memories. A memory interface typically contains a single address/command PHY and one or more data PHYs (one for each byte lane). Figure 2-1 shows the organization of the AC component.

The AC consists of multiple design slices. The address/command (AC) slice is used for all address and command and clk/cs/odt signals. Each slice contains all logic required for both the output (address/command) and input (loopback) paths of the respective signals.

All clocking inside the AC is derived from an input clock, which is generated by the PLL in the MASTERPHY. The PLL generates the higher frequency clocks that are is used inside the macro and minimizes input clock jitter.

9.4.2.1.1 ACX4 Transmit Lanes

The ACX4 component contains 4 transmit only lanes which are grouped as follows:

- Clock group: {CK_t, CK_c}
- CA group: {ras_n, cas_n, we_n, addr…}
- CKE,CS,ODT group{CKE, CS_n, ODT…}

In DDR4 systems, 12 ACs are required to control one 72b/64b channel with four independent ranks.

In LPDDR3 and LPDDR4 systems, the 12 ACs are broken up into two independently controllable groups, enabling up to two independent 32b channels (each with a maximum of two ranks.

9.4.2.1.2 ACX4 Command Path

Each SDRAM address and command signal is driven from the memory controller to the SDRAM through an address/command slice. Controlled address/command pipeline logic inside the AC slice converts the DFI-rate signals from the controller to single data rate (SDR) Address/Command signals going to the SDRAM. The last launching register inside the address/command slice is clocked by a delay-shifted DDR clock. For SDR operation, as required by DDR3 DRAMs, all outputs remain constants for two cycles at a time.

The path for the SDRAM clock (CK) is through a standard AC slice which is configured to act as a dedicated clock (CK) slice. This shifted address/command output makes the CK centered into the data eye of the address/command signals.

All AC outputs going to the SDRAM have a LCDL, which can be used to align or shift the outputs of the data PHY. This delay element can also be used to provide delay adjustment during functional or loopback modes.

9.4.2.1.3 ACX4 Loopback/DFT Paths

For every lane there will be a loopback-only receive path. The loopback path is stimulated and checked by utilizing a FirmWare image.

9.4.2.2 DDR Data PHY (DBYTE)

The DDR SDRAM Data PHY (DBYTE) provides data interface to external SDRAM memory. Features of the DBYTE include:

- High speed digital logic pipeline for transmit datapaths to the SDRAM
- High speed digital logic pipeline for receive datapaths from the SDRAM
- Drivers and receivers for the DQ and DQS signals as well as all the necessary high voltage analog macros to interface off chip
- I/O component that includes PVT-compensated on-die termination (ODT) and output impedance
- Loop-back test mode and PRBS checkers to help verify the integrity of the internal datapath of all DBYTE I/O lanes

9.4.2.2.1 DBYTE Write Path

Each SDRAM data is driven from the PUB to the SDRAM through a data (DQ) slice. Controlled data pipeline logic inside the DBYTE slice converts the DFI-rate signals from the PUB to double-data rate (DDR) signals going to the SDRAM. The last launching register inside the data slice is clocked by the DDR clock.

The path for the SDRAM write strobe is through a dedicated data strobe (DQS) slice. The output register of the DQS slice is clocked by a delayed version of PclkIn. PclkIn drives the output register in the DQ slice is shifted using the DLL in training mode. This centers the write data strobe signal in the write data eye.

All DBYTE outputs going to the SDRAM, including write data, write data strobe read DQS gate, driver power down, receiver power down, on-die termination enable, and output enable have a DLL that is used to deskew the outputs in order to maximize the write data eye.

Apart from the DQS pipeline, the DQS slice also contains a similar pipeline for output enables, on-die termination enable, driver power down, and receiver power down. This matches the I/O control signals to the corresponding data and data strobe.

9.4.2.2.2 DBYTE Read and Loopback Path

Read data from the SDRAM is written into a four-deep asynchronous FIFO that is implemented inside the DQ slice.

NOTE

The FIFO is 16 deep in terms of the DRAM DQS writing into the FIFO; it is 8 deep on the core side when a half-speed DFICLK is employed and it is 8 deep on the core side when a full speed DFICLK is employed.

The FIFO is written using the DQS clock and read using the Controller clock. A per-bit delay line at the input of the DQ slice is used to optionally de-skew read data with respect to the read strobe in order to maximize the read data eye.

The read data strobe path and a read DQS gate path is implemented inside the DQS slice. A delay line at the input of the slice shifts the read DQS by nominal 90 degrees (with the actual value arrived at through training) so that the strobe is centered into the read data eye before clocking the data into the FIFO. A Bit- Wise Delay Line (BDL) in the read DQS path is used to match a corresponding bit de-skew BDL in the DQ slice.

The DQS slice also generates the write pointers for the data FIFO. These pointers, together with the strobe, are then distributed to all DQ slices. The PUB generates a trained read-valid signal to read the data from the PHY.

The DBI uses DQS Slice 1, configured to behave as a DQ slice in x8 mode only.

9.4.2.2.2.1 DBYTE Loopback/DFT Paths

High speed loopback is implemented on all DBYTE I/Os. The DBYTE read path also doubles as the loopback path. During loopback, the PUB enables the gating of the DQS signal in the same way as it would normally gate the DQS during reads. This allows the looped back data to be clocked into the read data FIFO using the looped back DQS signal.

9.4.2.2.2.2 Memory Controller based DBYTE Loopback

This high speed PHY loopback mode uses all the DBYTE control and data paths in mission mode like operation modes. In this mode, the memory controller issues simultaneous Read/Write commands to the PHY, resulting in transmitting and receiving the same data on each DQ pad.

9.4.2.3 Master PHY (MASTERPHY)

The Master block contains the PLL, the Primary Voltage Reference, thermal calibration, reset, and I/O cells for test and control.

9.4.2.3.1 PLL

The PLL in the MASTER is a simplified PLL that has DFICLK as an input and creates an internal clock by quadrupling the DFICLK frequency. The PLL in the MASTER can only multiply the input clock frequency to produce an output clock that is four times the frequency of the input clock. The internal clock is the output of the MASTER to the ACX4 and DBYTE.

9.4.2.3.1.1 Optimal PLL Settings for Mission Mode Frequency Bins

Table 9-4. Optimal PLL Settings for Mission Mode Frequency Bins (PLL Max Bandwidth = 2 MHz)

9.4.2.3.2 Voltage Reference

This primary voltage reference generates the VREF global out used by the receivers in the ACX4 and DBYTE.

9.4.2.3.3 Calibration

The MASTER contains the analog blocks to perform output drive and input termination impedance calibration. Through the use of a digital control state machine, located in the PUB, the full mixed-signal calibration loop matches the impedance of the driver and termination with that of an external precision resistor. The resulting digital calibration code is fed to the address/command, DQ, and DQS blocks to control their impedance.

9.4.2.3.4 Reset

Reset takes the asynchronous reset bump, the PwrOk bump, and dfi_reset_n signal and combines them and synchronizes to the DFI clock. This is used by the ACX4 and DBYTE.

9.4.2.4 PHY Utility Block (PUB)

The following is an overview of the different functionality of the PHY Utility Block (PUB):

- Registers required to configure, control, train and self-test the PHY. Also contains registers required to initialize the DRAM.
- Initialization - this includes locking of the PLL, delay line calibration and calibration of I/O impedances.
- Data Training- train the PHY for optimum timing margins. This includes finding the best positioning of the DQS gating window during reads, write leveling, data bit deskew, and optimizing the read and write data eye.
- Implements a DFI-compliant interface between the external controller and the PHY.

9.4.2.4.1 DDR PHY Control and Configuration

The DDR PHY's PUB registers provide the required configuration, control, training and self-testing of the PHY. Also contains registers required to initialize the DRAM.

Refer to the DDR PHY register descriptions for more information.

9.4.2.4.2 Initialization and Training Sequence

The following outlines the general initialization and training sequence. Unless otherwise stated, these functions occur within the DDR PHY.

1. Bring up VDD, VDDQ, and VAA. This occurs outside of the DDR PHY.
2. Start the clocks and reset the PHY. This also occurs outside of the PHY.
3. Initialize PHY configuration.
4. Load the PHY training firmware into instruction memory SRAM.
5. Set the PHY input clocks to the desired frequency. This occurs outside of the PHY.

6. Write the Message Block parameters for the training firmware.There are several locations in the data memory that must be written for the training firmware to have these parameters.
7. Execute the training firmware.
8. Once the training firmware completes, the results are returned to the data memory in the message block structure. This message block can be read. The result may be that another frequency needs to be trained (return to step 5).
9. Load the PHY Initialization Engine registers with the provided initialization sequence.
10. Initialize the PHY to mission mode by performing a DFI initialization sequence per the DFI specification.
11. The PHY is now in mission mode.

9.4.2.4.3 DFI Interface

The DDR PHY and the DDR Controller both require a standard interface to transfer address, data, and control between these two blocks. These interfaces are DFI compliant. The PUB contains the DFI interface for the PHY.

For more information regarding the DFI specification, refer to the following:

- DDR PHY Interface (DFI) Specification, Revision 3.1 (Preliminary), 21, March 2014
- DDR PHY Interface (DFI) Specification Preliminary DFI 4.0 Specification - Addendum to DFI 3.1, 2 April 2014

The DFI interface is sub-divided into the following interface groups:

- Control Interface
- Write Data Interface
- Read Data Interface
- Update Interface
- Status Interface
- Training Interface (PHY-independent mode supported by the DDRC)
- Low Power Control Interface

9.4.3 Memory Map and Register Definition

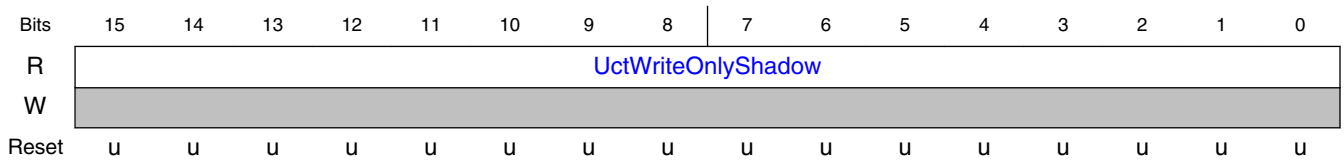
0 DctWriteProt	By setting this register to 0, the user acknowledges the receipt of the message.

9.4.3.2.6 Read-only view of the csr UctDatWriteOnly (UctWriteOnlyShadow)

9.4.3.2.6.1 Offset

Register	Offset
UctWriteOnlyShadow	64h

9.4.3.2.6.2 Diagram



9.4.3.2.6.3 Fields

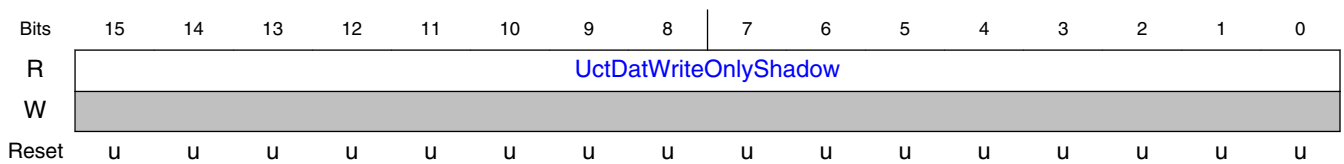
Field	Function
15-0 UctWriteOnlyShadow	Used to pass the message ID for major messages. Used to pass the message ID for major messages. Also used to pass the lower 16 bits for streaming messages.

9.4.3.2.7 Read-only view of the csr UctDatWriteOnly (UctDatWriteOnlyShadow)

9.4.3.2.7.1 Offset

Register	Offset
UctDatWriteOnlyShadow	68h

9.4.3.2.7.2 Diagram



9.4.3.2.7.3 Fields

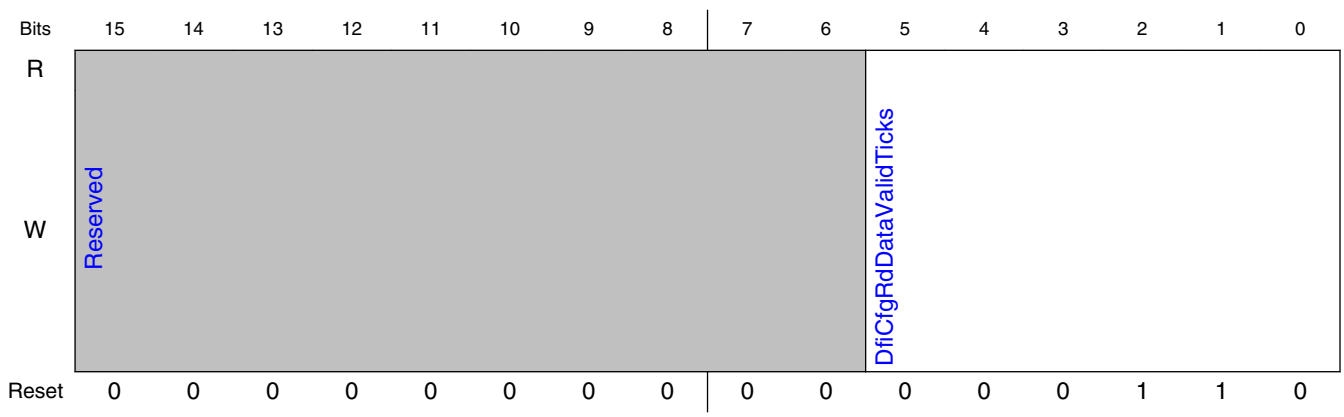
Field	Function
15-0 UctDatWriteOnlyShadow	Used to pass the upper 16 bits for streaming messages. Used to pass the upper 16 bits for streaming messages. Not used in passing major messages.

9.4.3.2.8 Number of DfiClk ticks required for valid csr Rd Data. (DfiCfgRdDataValidTicks)

9.4.3.2.8.1 Offset

Register	Offset
DfiCfgRdDataValidTicks	6Eh

9.4.3.2.8.2 Diagram



9.4.3.2.8.3 Fields

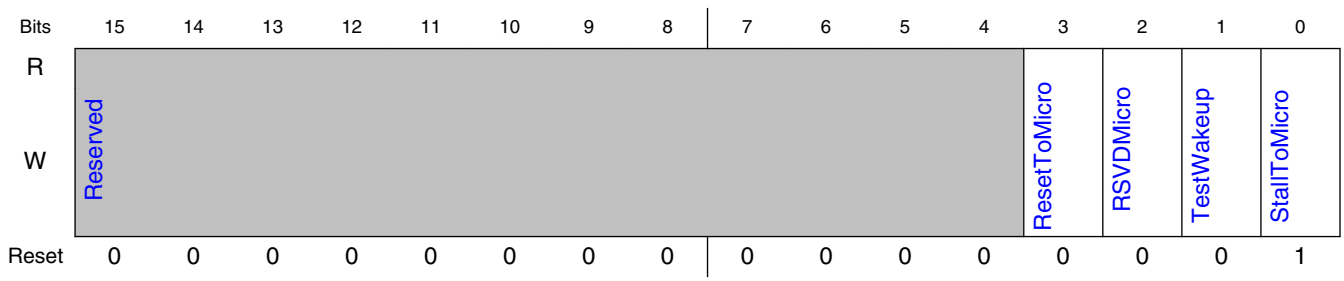
Field	Function
15-6 —	Reserved
5-0 DfiCfgRdDataValidTicks	Roundtrip delay of a register read access. Roundtrip delay of a register read access. This value must not be changed from its reset value.

9.4.3.2.9 Controls reset and clock shutdown on the local microcontroller (MicroReset)

9.4.3.2.9.1 Offset

Register	Offset
MicroReset	132h

9.4.3.2.9.2 Diagram



9.4.3.2.9.3 Fields

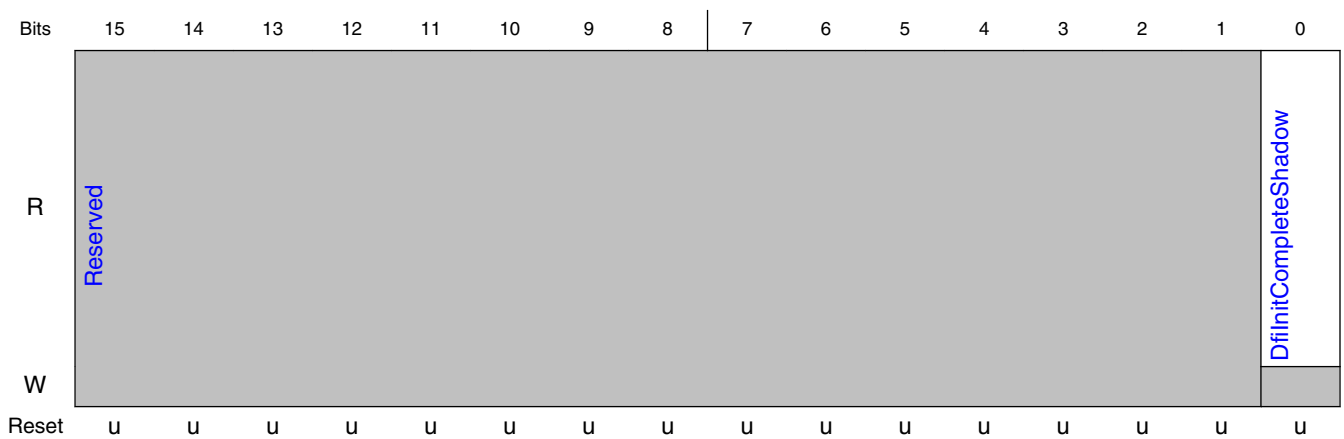
Field	Function
15-4 —	Reserved
3 ResetToMicro	Set this bit to apply synchronous reset to the microcontroller. Set this bit to apply synchronous reset to the microcontroller. Clear this bit to release reset to the microcontroller. This reset initializes the program counter to begin execution from the boot vector. This reset also clears the interrupt sticky bits.
2 RSVDMicro	RSVD
1 TestWakeup	Reserved Reserved. Must always be set to 0.
0 StallToMicro	Set this bit to stall the microcontroller by hardware. Set this bit to stall the microcontroller by hardware. Clear this bit to allow the microcontroller to continue executing from its current program counter location. Typically, this bit is used at power up to hold the program counter at the boot vector while BIOS loads the microcontroller program code. While stalled, the microcontroller clocks are gated off for power reduction.

9.4.3.2.10 dfi_init_complete - Controller Read-only Shadow (DfiInitCompleteShadow)

9.4.3.2.10.1 Offset

Register	Offset
DfiInitCompleteShadow	1F4h

9.4.3.2.10.2 Diagram



9.4.3.2.10.3 Fields

Field	Function
15-1 —	Reserved
0 DfiInitCompleteShadow	This csr presents a read-only view (a shadow) of the Register DfiInitComplete which is used by the sequencer to control the state of dfi_init_complete. This csr presents a read-only view (a shadow) of the Register DfiInitComplete which is used by the sequencer to control the state of dfi_init_complete. The value in this Register is not affected by the BlockSeq0BAck field of the SequencerOverride register. While the Register MicroContMuxSel is set, access to this Shadow register will not steal config bus bandwidth from the micro controller. That is polling won't have a performance penalty.

9.4.3.3 DWC_DDRPHYA_DBYTE register descriptions

9.4.3.3.1 DWC_DDRPHYA_DBYTE Memory map

DDR4/3 PHY address block

DWC_DDRPHYA_DBYTE0 base address: 1_0000h

DWC_DDRPHYA_DBYTE1 base address: 1_1000h

DWC_DDRPHYA_DBYTE2 base address: 1_2000h

DWC_DDRPHYA_DBYTE3 base address: 1_3000h

Offset	Register	Width (In bits)	Access	Reset value
0h	DBYTE Module Disable (DbyteMiscMode)	16	RW	Table 9-4
34h	Digital Observation Pin control (MtestMuxSel)	16	RW	0000h
40h	DFI MaxReadLatency (DFIMRL_p0)	16	RW	0006h
60h - 1060h	VrefDAC1 control for DQ Receiver (used only when DFE is enabled in DDR4) (VrefDAC1_r0 - VrefDAC1_r8)	16	RW	0000h

9.4.3.3.43.3 Fields

Field	Function
15-10 —	Reserved
9-0 TxDqsDlyTg3_un_px	Write DQS Delay (Timing Group DEST=3). Write DQS Delay (Timing Group DEST=3). Trained to set the delay from the memory-write command to the signal driving the write DQS Tx DQS Delay (10 bits, includes coarse and fine delays); (For Timing Group 3) TxDqsDlyTg3[9:6] is the coarse delay, ie one unit of delay is 1 UI. TxDqsDlyTg3[4:0] is the fine delay, ie one unit of delay is one-thirtysecond of a UI = UI/32. TxDqsDlyTg3[5] is reserved. Register is per nibble, per timing-group, per pstate. Register Block Offset Address 0x0D3 controls the lower DQ nibble write DQS timing. (For Timing Group 3) Register Block Offset Address 0x1D3 controls the upper DQ nibble write DQS timing. (For Timing Group 3) . Note: Timing Group 3 = RANK3 for all systems except 3DS/LRDIMM.

9.4.3.3.44 Debug status of the DBYTE LCDL (DxLcdlStatus)

9.4.3.6.4.3 Fields

Field	Function
15-1 —	Reserved
0 ForceInternalUpdate	This Register is used by Training Firmware to force an internal PHY Update Event. This Register is used by Training Firmware to force an internal PHY Update Event. Optionally can be used by System Software to issue a PHY update Event. The register may be written to 1'b1 only when all of the following are true: [+] The DFI interface is offline. [+] The Training Hardware is sending only DES and all transactions have retired. Additionally, this Register must stay asserted for at least 32 DFICLKs before clearing. Prematurely clearing this register may result in an incomplete update.

Field	Function
15-1 —	Reserved
0 DoFrequentRxFifoChecks	When 0, read data FIFO pointer consistency checks are performed only during sideband transactions (i. When 0, read data FIFO pointer consistency checks are performed only during sideband transactions (i.e., phyupd, ctrlupd, lp_data, phymstr) or when dfi_init_start is asserted. This option relies upon intentional quiescing of the DFI interface in order for the check to be performed. When 1, read data FIFO consistency checks are performed as when this bit is 0, and also at the beginning of each break in read data traffic from the DRAM. This options provides the lowest latency in reporting of a discrepancy in the read data FIFO pointer values.

9.4.3.6.114 Maps PHY CAA lane 0 from dfi0_address of the index of the register contents (MapCAA0toDfi)

4-0 HwtSwizzleHwtAddress0	This set of registers is used in DDR3/DDR4 mode where a user has re-mapped the DFI inputs to the PHY. This set of registers is used in DDR3/DDR4 mode where a user has re-mapped the DFI inputs to the PHY. This register does not affect the mapping of those signals, or remap the tristate properties of the bumps. However, when the user remaps the DFI signals, the HWT inputs must be mapped in a similar fashion using this register. Each remappable hwt bit has a register associated with it. When the register value is zero, the bit is not re-mapped. When the register value is non-zero, the signal associated with the number in the table below is mapped to the signal associated with the register. So, for example, if you set the value for the register associated with hwt_act_n (HwtSwizzleHwtActN) to 27, then hwt_parity_in will be mapped to hwt_act_n. These registers should always be 0 for LPDDR3 and LPDDR4. Some registers are used only for DDR3 or DDR4. These are noted in the descriptions. Note: If the system uses DDR3-RDIMM or

Field	Function
	DDR4-RDIMM/LRDIMM, it is strongly recommended NOT to swizzle the PAR pin (parity). If the PAR pin is swizzled, the Dynamic Address Tristate feature must be disabled. (see the DisDynAdrTri field of the TristateMode CA Register). ----- Index: Signal 0: No-remapping 1: hwt_address[0] 2: hwt_address[1] 3: hwt_address[2] 4: hwt_address[3] 5: hwt_address[4] 6: hwt_address[5] 7: hwt_address[6] 8: hwt_address[7] 9: hwt_address[8] 10: hwt_address[9] 11: hwt_address[10] 12: hwt_address[11] 13: hwt_address[12] 14: hwt_address[13] 15: hwt_address[14] (DDR3 Only) 16: hwt_address[15] (DDR3 Only) 17: hwt_address[17] (DDR4 Only) 18: hwt_act_n (DDR4 Only) 19: hwt_bank[0] 20: hwt_bank[1] 21: hwt_bank[2] (DDR3 Only) 22: hwt_bg[0] (DDR4 Only) 23: hwt_bg[1] (DDR4 Only) 24: hwt_cas_n 25: hwt_ras_n 26: hwt_we_n 27: hwt_parity_in

9.5 AHB-to-APBH Bridge with DMA (APBH-Bridge-DMA)

9.5.1 Overview

The AHB-to-APBH bridge provides the chip with an inexpensive peripheral attachment bus running on the AHB's HCLK. (The H in APBH denotes that the APB*H* is synchronous to HCLK.)

As shown in the figure below, the AHB-to-APBH bridge includes the AHB-to-APB PIO bridge for a memory-mapped I/O to the APB devices, as well as a central DMA facility for devices on this bus and a vectored interrupt controller for the Arm core. Each one of the APB peripherals, including the vectored interrupt controller, is documented in their respective chapters.

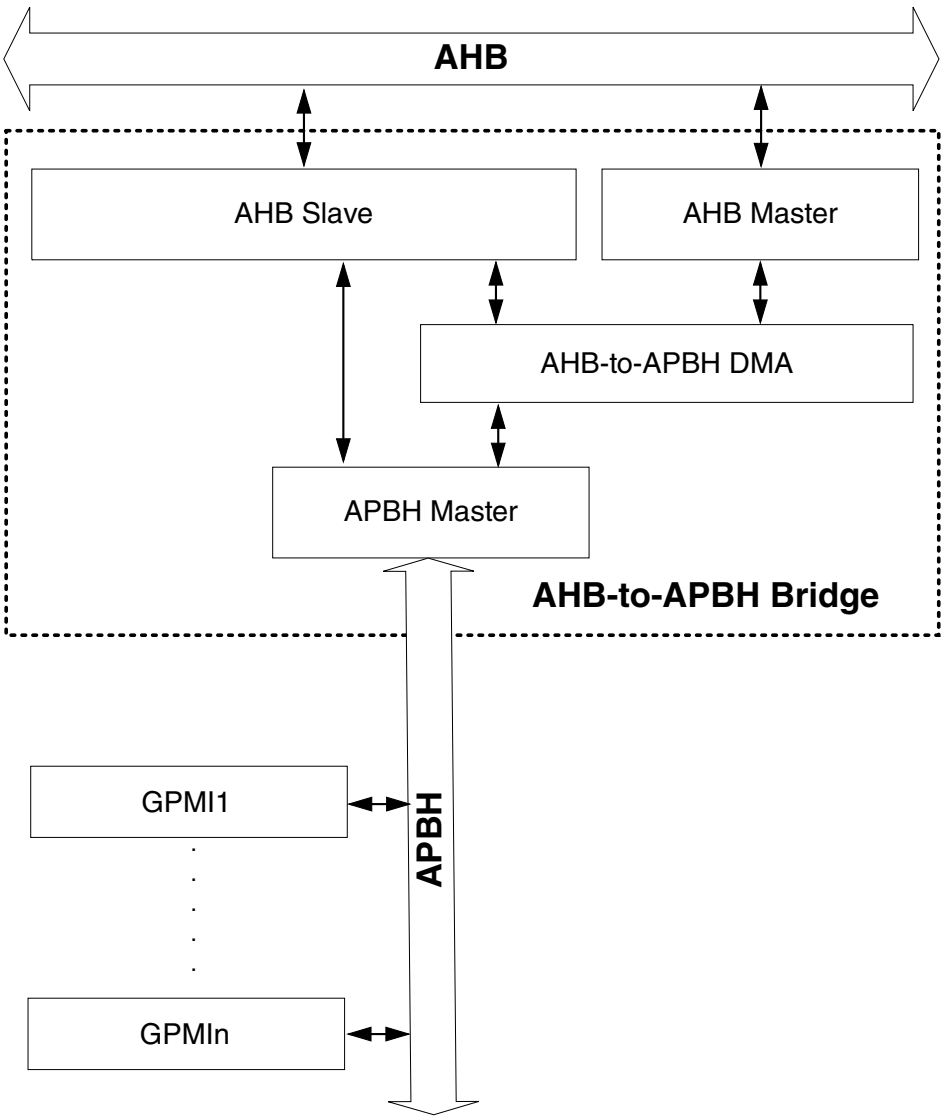

Figure 9-7. AHB-to-APBH Bridge DMA Block Diagram

The DMA controller uses the APBH bus to transfer read and write data to and from each peripheral. There is no separate DMA bus for these devices. Contention between the DMA's use of the APBH bus and the AHB-to-APB bridge functions' use of the APBH is mediated by an internal arbitration logic. For contention between these two units, the DMA is favored and the AHB slave will report "not ready" through its HREADY output until the bridge transfer can complete. The arbiter tracks repeated lockouts and inverts the priority, guaranteeing the Arm platform every fourth transfer on the APB.

9.5.2 Clocks

The table found here describes the clock sources for APBH. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 9-5. APBH Clocks

Clock name	Clock Root	Description
hclk		Module clock

9.5.3 APBH DMA

The DMA supports four channels of DMA services, as shown in the following table. The shared DMA resource allows each independent channel to follow a simple chained command list. Command chains are built up using the general structure, as shown in Figure 9-8.

Table 9-6. APBH DMA channel assignments

APBH DMA Channel #	Usage
0	GPMI0
1	GPMI1
2	GPMI2
3	GPMI3

A single command structure or channel command word specifies a number of operations to be performed by the DMA in support of a given device. Thus, the Arm platform can set up large units of work, chaining together many DMA channel command words, pass them off to the DMA, and have no further concern for the device until the DMA completion interrupt occurs. The goal is to have enough intelligence in the DMA and the devices to keep the interrupt frequency from any device below 1 KHz (arrival intervals longer than 1 ms).

A single command structure can issue 32-bit PIO write operations to key registers in the associated device using the same APB bus and controls that it uses to write DMA data bytes to the device. For example, this allows a chain of operations to be issued to the GPMI controller to send NAND command bytes, address bytes, and data transfers where the command and the address structure is completely under software control, but the administration of that transfer is handled autonomously by the DMA. Each DMA

structure can have 0–15 PIO words appended to it. The CMDPIOWORDS field, if non-zero, instructs the DMA engine to copy these words to the APB, beginning at the first register address offset for the peripheral and incrementing the register offset each cycle.

The DMA master generates only normal read/write transfers to the APBH. It does *not* generate set, clear, or toggle (SCT) transfers.

After any requested PIO words have been transferred to the peripheral, the DMA examines the two-bit command field in the channel command structure. Table 9-7 shows the four commands implemented by the DMA.

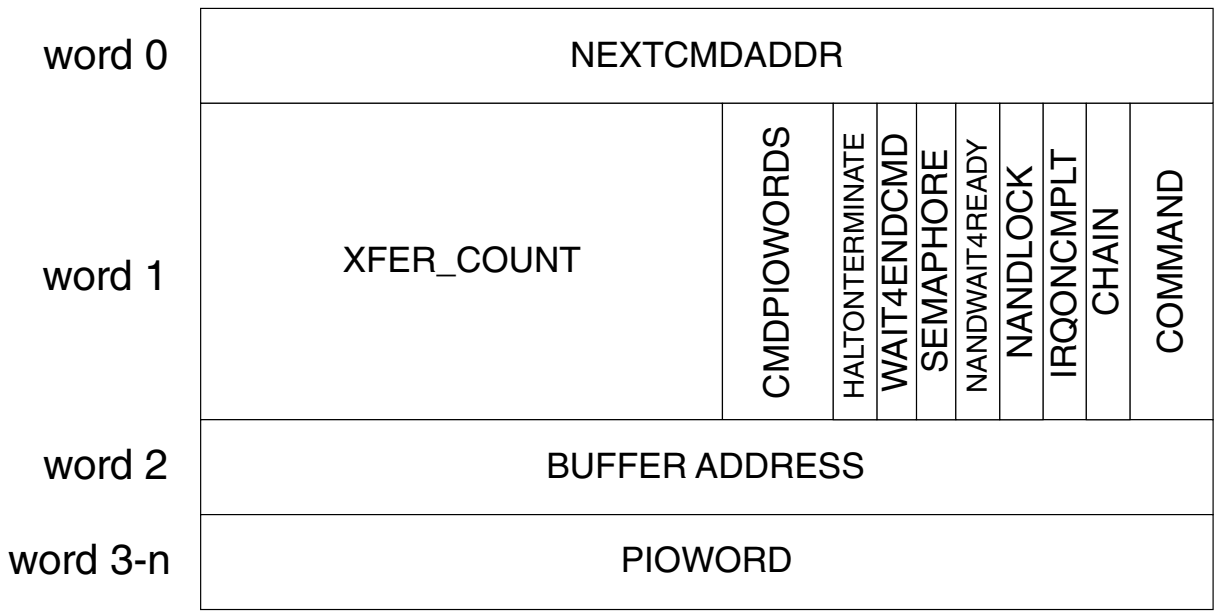

Figure 9-8. AHB-to-APBH Bridge DMA channel command structure

Table 9-7. APBH DMA commands

DMA Command	Usage
00	NO_DMA_XFER. Perform any requested PIO word transfers, but terminate the command before any DMA transfer.
01	DMA_WRITE. Perform any requested PIO word transfers, then perform a DMA transfer from the peripheral for the specified number of bytes.
10	DMA_READ. Perform any requested PIO word transfers and then perform a DMA transfer to the peripheral for the specified number of bytes.
11	DMA_SENSE. Perform any requested PIO word transfers, then perform a conditional branch to the next chained device. Follow the NEXTCMD_ADDR pointer if the peripheral sense is false. Follow the BUFFER_ADDRESS as a chain pointer if the peripheral sense line is true. This command becomes a no-operation for any channel other than a GPMI channel.

DMA_WRITE operations copy data bytes to the system memory (on-chip RAM or SDRAM) from the associated peripheral.

DMA_READ operations copy data bytes to the APB peripheral from the system memory. The DMA engine contains a shared byte aligner that aligns bytes from system memory to or from the peripherals. Peripherals always assume little-endian-aligned data arrives or departs on their 32-bit APB. The DMA_READ transfer uses the BUFFER_ADDRESS word in the command structure to point to the DMA data buffer to be read by the DMA_READ command.

The NO_DMA_XFER command is used to write PIO words to a device without performing any DMA data byte transfers. This command is useful in such applications as activating the NAND devices CHECKSTATUS operation. The check status command reads a status byte from the NAND device, performs an XOR and MASK against an expected value supplied as part of the PIO transfer. Once the read check completes (see NAND Read Status Polling Example), the NO_DMA_XFER command completes. The result in the peripheral is that its sense line is driven by the results of the comparison. The sense flip-flop is only updated by CHECKSTATUS for the device that is executed. At some future point, the chain contains a DMA command structure with the fourth and final command value, that is, the DMA_SENSE command.

As each DMA command completes, it triggers the DMA to load the next DMA command structure in the chain. The normal flow list of DMA commands is found by following the NEXTCMD_ADDR pointer in the DMA command structure. The DMA_SENSE command uses the DMA buffer pointer word of the command structure to point to an alternate DMA command structure chain or list. The DMA_SENSE command examines the sense line of the associated peripheral. If the sense line is false, then the DMA follows the standard list found whose next command is found from the pointer in the NEXTCMD_ADDR word of the command structure. If the sense line is true, then the DMA follows the alternate list whose next command is found from the pointer in the DMA Buffer Pointer word of the DMA_SENSE command structure (see Figure 9-8). The sense command ignores the CHAIN bit, so that both pointers must be valid when the DMA comes to a sense command.

If the wait-for-end-command bit (WAIT4ENDCMD) is set in a command structure, the DMA channel waits for the device to signal completion of a command by toggling the endcmd signal before proceeding to load and execute the next command structure. Then, if DECREMENT_SEMAPHORE is set, the semaphore is decremented after the end command is seen.

A detailed bit-field view of the DMA command structure is shown in the following table, which shows a field that specifies the number of bytes to be transferred by this DMA command. The transfer-count mechanism is duplicated in the associated peripheral, either as an implied or as a specified count in the peripheral.

Table 9-8. DMA channel command word in system memory

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	09	08	07	06	05	04	03	02	01	00
NEXT_COMMAND_ADDRESS																															
Number DMA Bytes to Transfer																Number PIO Words to Write							HALTONTERMINATE	WAIT4ENDCMD	DECREMENT SEMAPHORE	NANDwAIT4READY	NANDLOCK	IRQ_COMPLETE	CHAIN	COMMAND	
DMA Buffer or Alternate CCW																															
Zero or More PIO Words to Write to the Associated Peripheral Starting at its Base Address on the APBH Bus																															

Figure 9-8 also shows the CHAIN bit in bit 2 of the second word of the command structure. This bit is set to 1, if the NEXT_COMMAND_ADDRESS contains a pointer to another DMA command structure. If a null pointer (0) is loaded into the NEXT_COMMAND_ADDRESS, it is not detected by the DMA hardware. Only the CHAIN bit indicates whether a valid list exists beyond the current structure.

If the IRQ_COMPLETE bit is set in the command structure, then the last act of the DMA before loading the next command is to set the interrupt-status bit corresponding to the current channel. The sticky interrupt request bit in the DMA CSR remains set until cleared by the software. It can be used to interrupt the Arm platform.

The NAND_LOCK bit is monitored by the DMA channel arbiter. Once a NAND channel (from channel 0 to channel 3) succeeds in the arbiter with its NAND_LOCK bit set, then the arbiter ignores the other NAND channels until a command is completed in which the NAND_LOCK is not set. Notice that the semantic here is that the NAND_LOCK state is to limit scheduling of a non-locked DMA. A DMA channel can go from unlocked to locked in the arbiter at the beginning of a command when the NAND_LOCK bit is set. When the last DMA command of an atomic sequence is completed, the lock should be removed. To accomplish this, the last command does not have the NAND_LOCK bit. It is still locked in the atomic state within the arbiter when the command starts, so that it is the only NAND command that can be executed. At the end, it drops from the atomic state within the arbiter.

The NAND_WAIT4READY bit also has a special use for GPMI channels (from channel 0 to channel 3), i.e., the NAND device channels. The GPMI peripheral supplies a sample of the ready line from the NAND device. This ready value is used to hold off of a command with this bit set until the ready line is asserted to 1. Once the arbiter sees a command with a wait-for-ready set, it holds off that channel until ready is asserted.

Receiving an IRQ for HALTONTERMINATE (HOT) is a feature in the APBH DMA descriptor that allows GPMI to signal to the DMA engine that an error has occurred. If a command is stalled due to an error, a HOT signal is sent from the peripheral to the DMA engine and causes an IRQ after terminating the DMA descriptor being executed.

Therefore, it is recommended that software use this signal as follows:

- Always set HALTONTERMINATE to 1 in a DMA descriptor. That way, if a peripheral signals HOT, the transfer will end, leaving the peripheral block and the DMA engine synchronized (but at the end of a command).
- When an IRQ from an APBH channel is received, and the IRQ is determined to be due to an error (as opposed to an IRQONCOMPLETE interrupt) the software should:
  - Reset the channel.
  - Determine the error from error reporting in the peripheral block, then manage the error in the peripheral that is attached to that channel in whatever appropriate way exists for that device (software recovery, device reset, block reset, etc).

Each channel has an eight-bit counting semaphore that controls whether it is in the idle state. When the semaphore is non-zero, the channel is ready to run, process commands and perform DMA transfers. Whenever a command finishes its DMA transfer, it checks the DECREMENT_SEMAPHORE bit. If set, it decrements the counting semaphore. If the semaphore goes to 0 as a result, then the channel enters the idle state and remains there until the semaphore is incremented by the software. When the semaphore goes to non-zero and the channel is in its idle state, then it uses the value in the APBH_CHn_NXTCMDAR register (next command address register) to fetch a pointer to the next command to process.

NOTE

This is a double indirect case. This method allows the software to append to a running command list under the protection of the counting semaphore.

To start processing the first time, software creates the command list to be processed. It writes the address of the first command into the APBH_CHn_NXTCMDAR register, and then writes 1 to the counting semaphore in APBH_CHn_SEMA. The DMA channel loads APBH_CHn_CURCMDAR register and then enters the normal state machine processing for the next command. When the software writes a value to the counting semaphore, it is added to the semaphore count by hardware, protecting the case where both hardware and software are trying to change the semaphore on the same clock edge.

Software can examine the value of APBH_CHn_CURCMDAR at any time to determine the location of the command structure currently being processed.

9.5.4 NAND Read Status Polling Example

The following figure shows a more complicated scenario.

This subset of a NAND device workload shows that the first two command structures are used during the data-write phase of an NAND device write operation (CLE and ALE transfers omitted for clarity).

- After writing the data, one must wait until the NAND device status register indicates that the write charge has been transferred. This is built into the workload using a check status command in the NAND in a loop created from the next two DMA command structures.
- The NO_DMA_TRANSFER command is shown here performing the read check, followed by a DMA_SENSE command to branch the DMA command structure list, based on the status of a bit in the external NAND device.

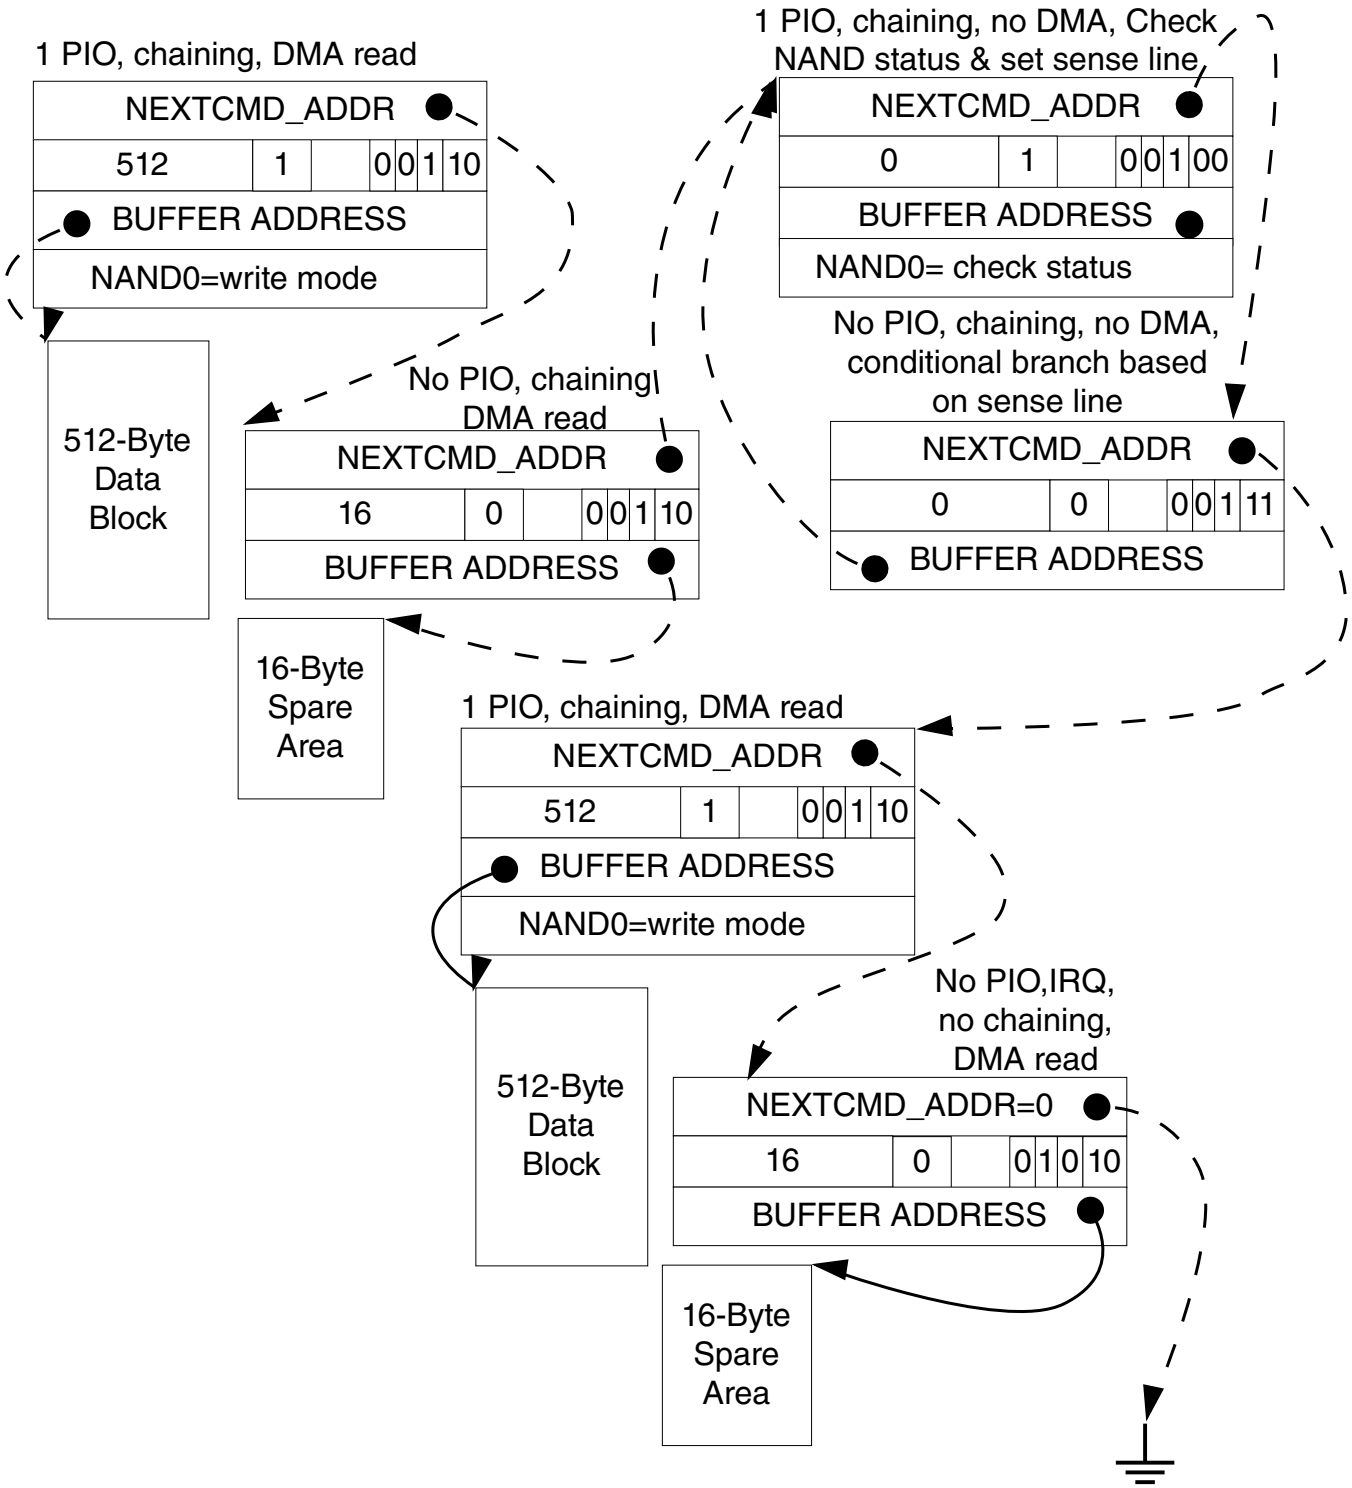

Figure 9-9. AHB-to-APBH Bridge DMA NAND Read Status Polling with DMA Sense Command

The example in the above figure shows the workload continuing immediately to the next NAND page transfer. However, one could perform a second sense operation to see if an error has occurred after the write. One could then point the sense command alternate branch at a NO_DMA_XFER command with the interrupt bit set. If the CHAIN bit is not

set on this failure branch, then the Arm platform is interrupted immediately, and the channel process is also immediately terminated in the presence of a workload-detected NAND error bit.

Note that each word of the three-word DMA command structure corresponds to a PIO register of the DMA that is accessible on the APBH bus. Normally, the DMA copies the next command structure onto these registers for processing at the start of each command by following the value of the pointer previously loaded into the NEXTCMD_ADDR register.

To start DMA processing for the first command, initialize the PIO registers of the desired channel, as follows:

- First, load the next command address register with a pointer to the first command to be loaded.
- Then, write 1 to the counting semaphore register. This causes the DMA to schedule the targeted channel for the DMA command structure load, just as if it had finished its previous command.

9.5.5 APBH Memory Map/Register Definition

APBH Hardware Register Format Summary

9.5.5.1 AHB to APBH Bridge Control and Status Register 0 (APBH_CTRL0*n*)

The APBH CTRL 0 provides overall control of the AHB to APBH bridge and DMA.

This register contains module softreset, clock gating, channel clock gating/freeze bits.

Address: 3300_0000h base + 0h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

APBH_CTRL0*n* field descriptions

Field	Description
31 SFTRST	Set this bit to zero to enable normal APBH DMA operation. Set this bit to one (default) to disable clocking with the APBH DMA and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the APBH DMA block to its default state.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.
29 AHB_BURST8_EN	Set this bit to one (default) to enable AHB 8-beat burst. Set to zero to disable 8-beat burst on AHB interface.
28 APB_BURST_EN	Set this bit to one to enable apb master do a continous transfers when a device request a burst dma. Set to zero will treat a burst dma request as 4/8 individual requests.
27–16 RSVD0	This field is reserved. Reserved, always set to zero.
CLKGATE_CHANNEL	These bits must be set to zero for normal operation of each channel. When set to one they gate off the individual clocks to the channels. 0x0001 **NAND0** — 0x0002 **NAND1** — 0x0004 **NAND2** — 0x0008 **NAND3** — 0x0010 **NAND4** — 0x0020 **NAND5** — 0x0040 **NAND6** — 0x0080 **NAND7** — 0x0100 **SSP** —

9.5.5.2 AHB to APBH Bridge Control and Status Register 1 (APBH_CTRL1*n*)

The APBH CTRL one provides overall control of the interrupts generated by the AHB to APBH DMA. This register contains the per channel interrupt status bits and the per channel interrupt enable bits. Each channel has a dedicated interrupt vector in the vectored interrupt controller.

EXAMPLE

```
                    BF_WR(APBH_CTRL1, CH5_CMDCMPLT_IRQ, 0);  // use bitfield write macro
                    BF_APBH_CTRL1.CH5_CMDCMPLT_IRQ = 0;      // or, assign to register
struct's bitfield
```

Address: 3300_0000h base + 10h offset + (4d × i), where i=0d to 3d

Field	Description
29 CH13_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 13.
28 CH12_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 12.
27 CH11_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 11.
26 CH10_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 10.
25 CH9_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 9.
24 CH8_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 8.
23 CH7_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 7.
22 CH6_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 6.
21 CH5_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 5.
20 CH4_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 4.
19 CH3_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 3.
18 CH2_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 2.

Table continues on the next page...

APBH_CTRL1*n* field descriptions (continued)

Field	Description
17 CH1_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 1.
16 CH0_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 0.
15 CH15_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 15. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
14 CH14_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 14. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
13 CH13_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 13. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
12 CH12_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 12. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
11 CH11_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 11. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
10 CH10_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 10. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
9 CH9_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 9. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
8 CH8_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 8. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
7 CH7_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 7. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
6 CH6_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 6. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.

Table continues on the next page...

APBH_CTRL1*n* field descriptions (continued)

Field	Description
5 CH5_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 5. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
4 CH4_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 4. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
3 CH3_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 3. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
2 CH2_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 2. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
1 CH1_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 1. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
0 CH0_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 0. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.

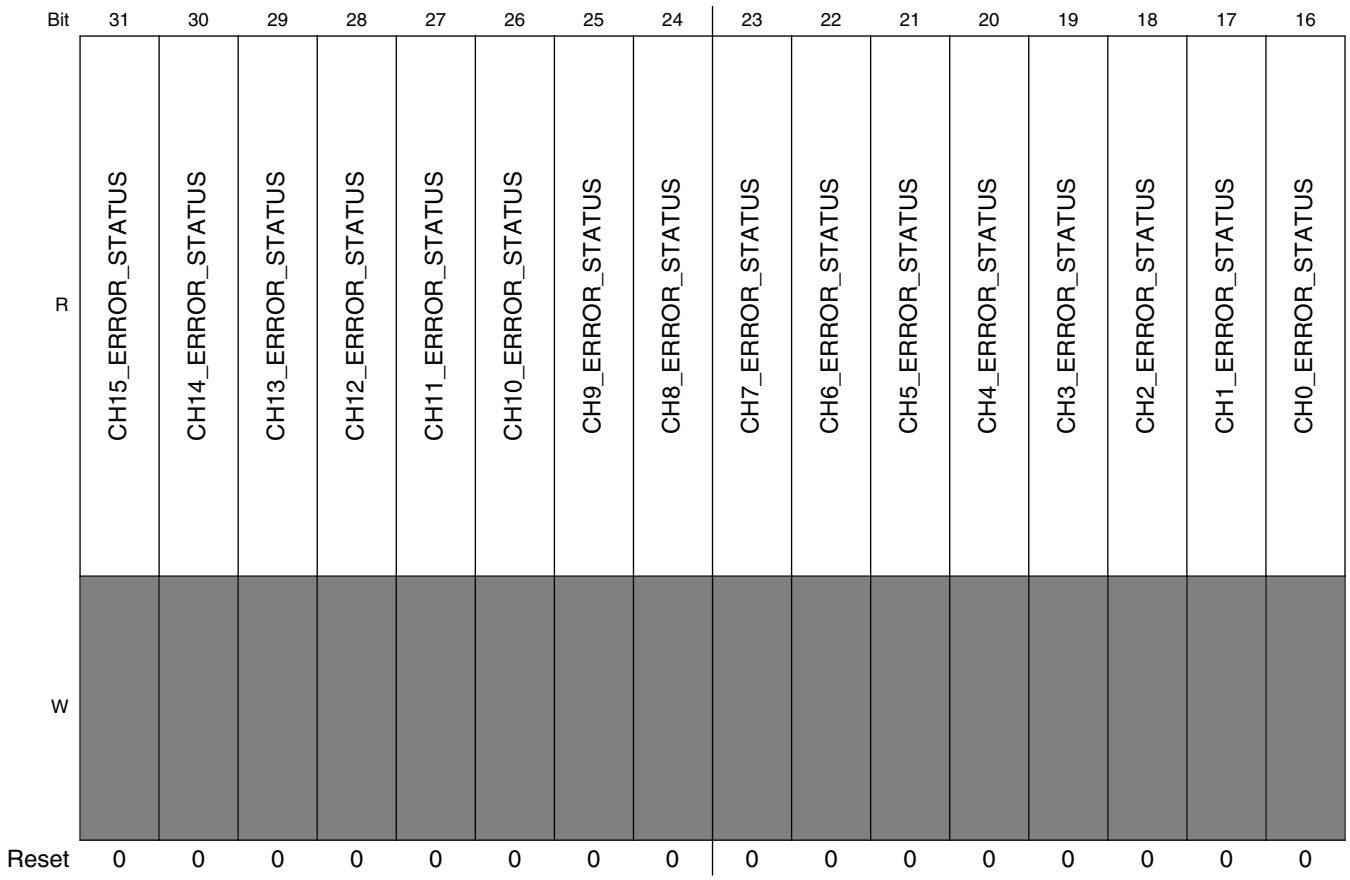
9.5.5.3 AHB to APBH Bridge Control and Status Register 2 (APBH_CTRL2*n*)

The APBH CTRL 2 provides channel error interrupts generated by the AHB to APBH DMA. This register contains the per channel interrupt status bits and the per channel interrupt enable bits. Each channel has a dedicated interrupt vector in the vectored interrupt controller.

EXAMPLE

```
                    BF_WR(APBH_CTRL1, CH5_CMDCMPLT_IRQ, 0);  // use bitfield write macro
                    BF_APBH_CTRL1.CH5_CMDCMPLT_IRQ = 0;      // or, assign to register
struct's bitfield
```

Address: 3300_0000h base + 20h offset + (4d × i), where i=0d to 3d



APBH_CTRL2*n* field descriptions

Field	Description
31 CH15_ERROR_STATUS	Error status bit for APBH DMA Channel 15. Valid when corresponding Error IRQ is set. 1 - AHB bus error

Table continues on the next page...

APBH_CTRL2*n* field descriptions (continued)

Field	Description
	0 - channel early termination. 0x0 **TERMINATION** — An early termination from the device causes error IRQ. 0x1 **BUS_ERROR** — An AHB bus error causes error IRQ.
30 CH14_ERROR_ STATUS	Error status bit for APBH DMA Channel 14. Valid when corresponding Error IRQ is set. 1 - AHB bus error 0 - channel early termination. 0x0 **TERMINATION** — An early termination from the device causes error IRQ. 0x1 **BUS_ERROR** — An AHB bus error causes error IRQ.
29 CH13_ERROR_ STATUS	Error status bit for APBH DMA Channel 13. Valid when corresponding Error IRQ is set. 1 - AHB bus error 0 - channel early termination. 0x0 **TERMINATION** — An early termination from the device causes error IRQ. 0x1 **BUS_ERROR** — An AHB bus error causes error IRQ.
28 CH12_ERROR_ STATUS	Error status bit for APBH DMA Channel 12. Valid when corresponding Error IRQ is set. 1 - AHB bus error 0 - channel early termination. 0x0 **TERMINATION** — An early termination from the device causes error IRQ. 0x1 **BUS_ERROR** — An AHB bus error causes error IRQ.
27 CH11_ERROR_ STATUS	Error status bit for APBH DMA Channel 11. Valid when corresponding Error IRQ is set. 1 - AHB bus error 0 - channel early termination. 0x0 **TERMINATION** — An early termination from the device causes error IRQ. 0x1 **BUS_ERROR** — An AHB bus error causes error IRQ.
26 CH10_ERROR_ STATUS	Error status bit for APBH DMA Channel 10. Valid when corresponding Error IRQ is set. 1 - AHB bus error 0 - channel early termination. 0x0 **TERMINATION** — An early termination from the device causes error IRQ. 0x1 **BUS_ERROR** — An AHB bus error causes error IRQ.
25 CH9_ERROR_ STATUS	Error status bit for APBH DMA Channel 9. Valid when corresponding Error IRQ is set. 1 - AHB bus error 0 - channel early termination. 0x0 **TERMINATION** — An early termination from the device causes error IRQ. 0x1 **BUS_ERROR** — An AHB bus error causes error IRQ.
24 CH8_ERROR_ STATUS	Error status bit for APBH DMA Channel 8. Valid when corresponding Error IRQ is set. 1 - AHB bus error 0 - channel early termination.

Table continues on the next page...

APBH_CTRL2*n* field descriptions (continued)

Field	Description
	0x0 **TERMINATION** — An early termination from the device causes error IRQ. 0x1 **BUS_ERROR** — An AHB bus error causes error IRQ.

9.5.5.4 AHB to APBH Bridge Channel Register (APBH_CHANNEL_CTRL*n*)

The APBH CHANNEL CTRL provides reset/freeze control of each DMA channel. This register contains individual channel reset/freeze bits.

Address: 3300_0000h base + 30h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

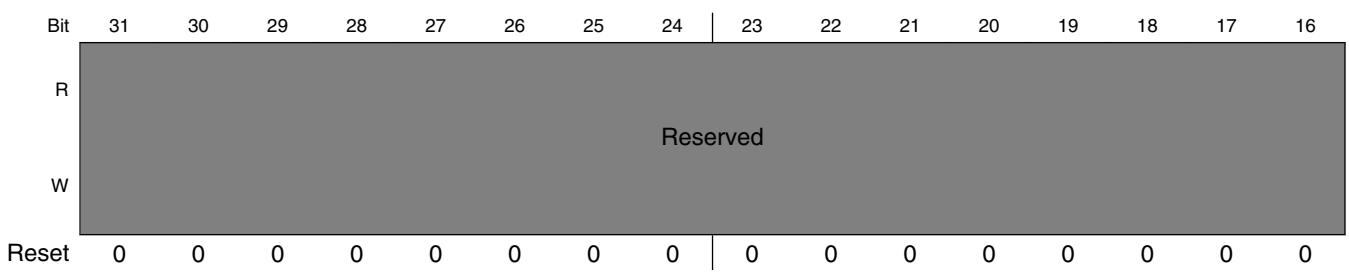
9–8 CH4	DMA burst size for GPMI channel 4. Do not change. GPMI only support burst size 4.
7–6 CH3	DMA burst size for GPMI channel 3. Do not change. GPMI only support burst size 4.
5–4 CH2	DMA burst size for GPMI channel 2. Do not change. GPMI only support burst size 4.
3–2 CH1	DMA burst size for GPMI channel 1. Do not change. GPMI only support burst size 4.
CH0	DMA burst size for GPMI channel 0. Do not change. GPMI only support burst size 4.

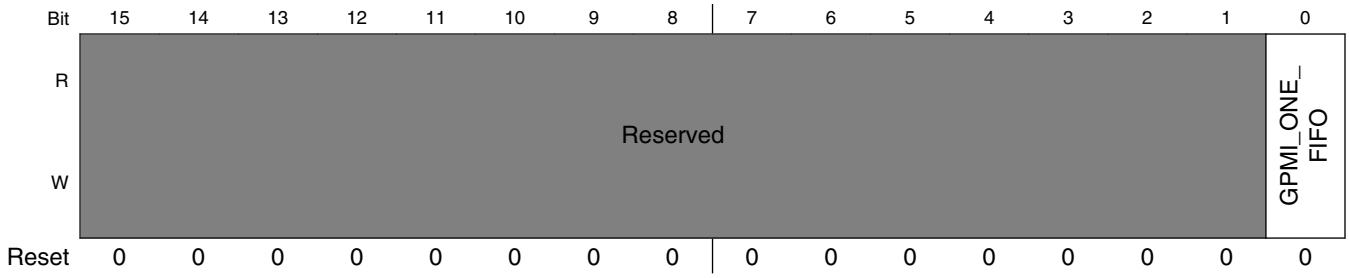
9.5.5.7 AHB to APBH DMA Debug Register (APBH_DEBUG)

This register is for debug purpose.

The debug register is for internal use only. Not recommend for customer useage.

Address: 3300_0000h base + 60h offset = 3300_0060h





APBH_DEBUG field descriptions

Field	Description
31–1 -	This field is reserved. Reserved, always set to zero.
0 GPMI_ONE_FIFO	Set to 0ne and the 8 GPMI channels will share the DMA FIFO, and when set to zero, the 8 GPMI channels will use its own DMA FIFO.

9.5.5.8 APBH DMA Channel n Current Command Address Register (APBH_CH*n*_CURCMDAR)

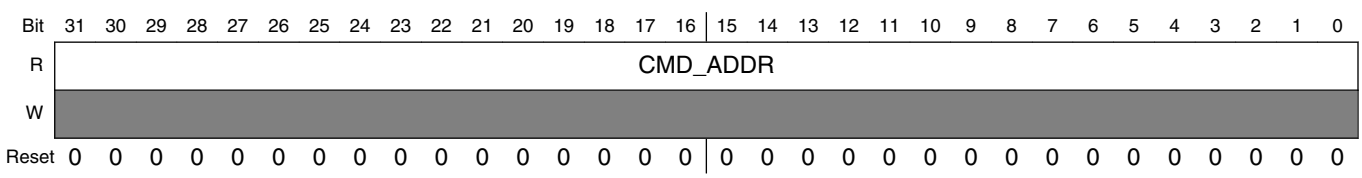
The APBH DMA channel n current command address register points to the multiword command that is currently being executed. Commands are threaded on the command address.

APBH DMA Channel n is controlled by a variable sized command structure. This register points to the command structure currently being executed.

EXAMPLE

```
pCurCmd = (apbh_chn_cmd_t *) APBH_CHn_CURCMDAR_RD(0);              // read the whole
register, since there is only one field
pCurCmd = (apbh_chn_cmd_t *) BF_RDn(APBH_CHn_CURCMDAR, 0, CMD_ADDR);  // or, use multi-
register bitfield read macro
pCurCmd = (apbh_chn_cmd_t *) APBH_CHn_CURCMDAR(0).CMD_ADDR;        // or, assign from
bitfield of indexed register's struct
```

Address: 3300_0000h base + 100h offset + (112d × i), where i=0d to 15d



APBH_CH*n*_CURCMDAR field descriptions

Field	Description
CMD_ADDR	Pointer to command structure currently being processed for channel n.

9.5.5.9 APBH DMA Channel n Next Command Address Register (APBH_CH*n*_NXTCMDAR)

The APBH DMA Channel n Next Command Address register contains the address of the next multiword command to be executed. Commands are threaded on the command address. Set CHAIN to 1 in the DMA command word to process command lists.

APBH DMA Channel n is controlled by a variable sized command structure. Software loads this register with the address of the first command structure to process and increments the Channel n semaphore to start processing. This register points to the next command structure to be executed when the current command is completed.

EXAMPLE

```
APBH_CHn_NXTCMDAR_WR(0, (reg32_t) pCommandTwoStructure);         // write the entire
register, since there is only one field
BF_WRn(APBH_CHn_NXTCMDAR, 0, (reg32_t) pCommandTwoStructure);       // or, use multi-
register bitfield write macro
APBH_CHn_NXTCMDAR(0).CMD_ADDR = (reg32_t) pCommandTwoStructure;  // or, assign to bitfield
of indexed register's struct
```

Address: 3300_0000h base + 110h offset + (112d × i), where i=0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

APBH_CH*n*_NXTCMDAR field descriptions

Field	Description
CMD_ADDR	Pointer to next command structure for channel n.

9.5.5.10 APBH DMA Channel n Command Register (APBH_CH*n*_CMD)

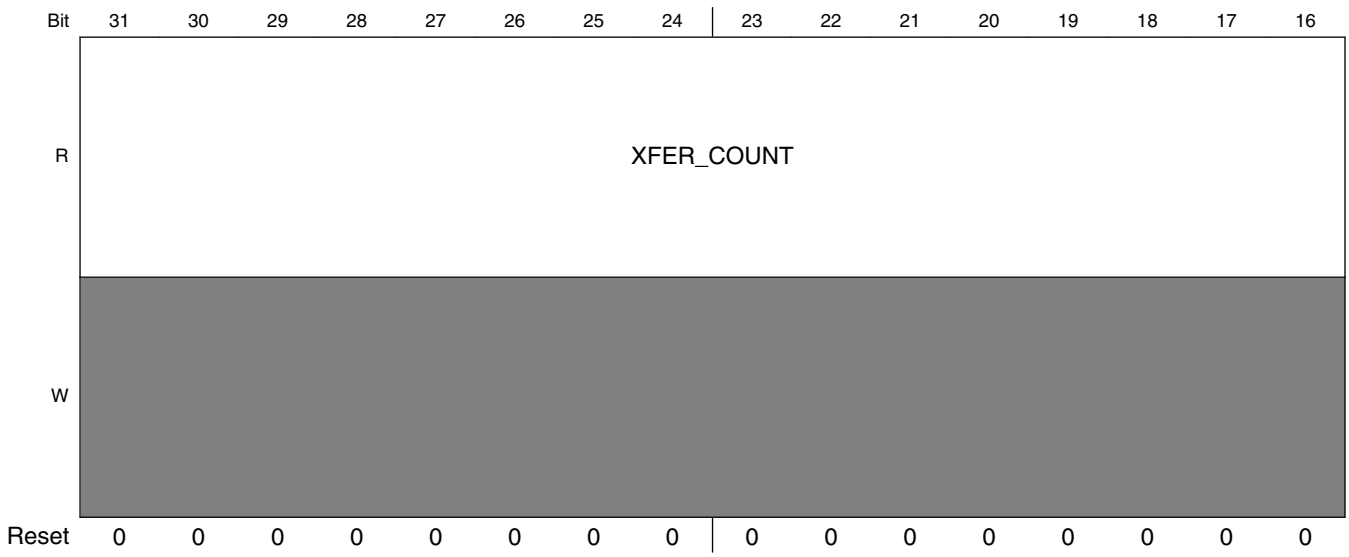
The APBH DMA Channel n command register specifies the DMA transaction to perform for the current command chain item.

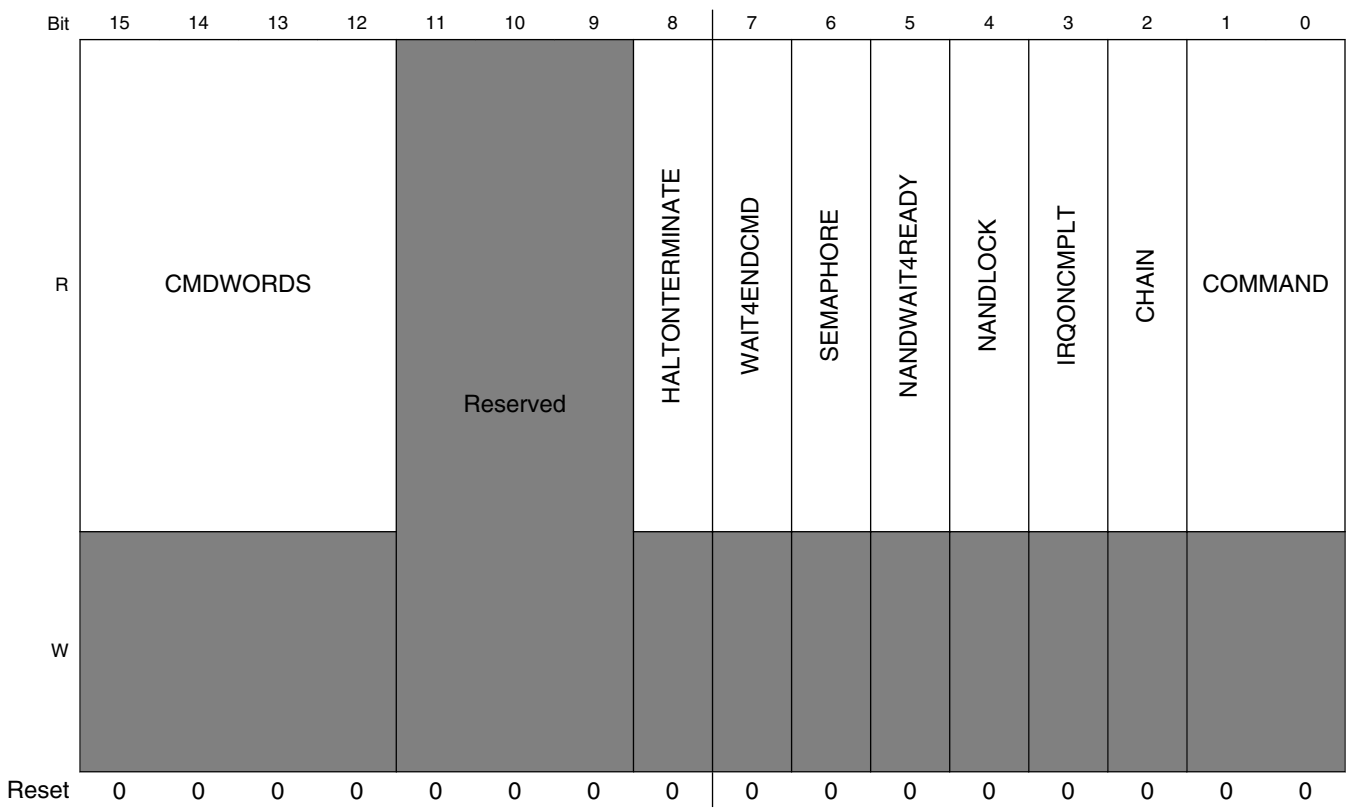
The command register controls the overall operation of each DMA command for this channel. It includes the number of bytes to transfer to or from the device, the number of APB PIO command words included with this command structure, whether to interrupt at command completion, whether to chain an additional command to the end of this one and whether this transfer is a read or write DMA transfer.

EXAMPLE

```
apbh_chn_cmd_t  dma_cmd;
dma_cmd.XFER_COUNT = 512;                                    // transfer 512 bytes
dma_cmd.COMMAND = BV_APBH_CHn_CMD_COMMAND__DMA_WRITE;  // transfer to system memory from
peripheral device
dma_cmd.CHAIN = 1;                                           // chain an additional command
structure on to the list
dma_cmd.IRQONCMPLT = 1;                                      // generate an interrupt on
completion of this command structure
```

Address: 3300_0000h base + 120h offset + (112d × i), where i=0d to 15d





APBH_CH*n*_CMD field descriptions

Field	Description
31–16 XFER_COUNT	This field indicates the number of bytes to transfer to or from the appropriate PIO register in the GPMI0 device. A value of 0 indicates a 64 KBytes transfer.
15–12 CMDWORDS	This field indicates the number of command words to send to the GPMI0, starting with the base PIO address of the GPMI0 control register and incrementing from there. Zero means transfer NO command words
11–9 -	This field is reserved. Reserved, always set to zero.
8 HALTONTERMINATE	A value of one indicates that the channel will immeditately terminate the current descriptor and halt the DMA channel if a terminate signal is set. A value of 0 will still cause an immediate terminate of the channel if the terminate signal is set, but the channel will continue as if the count had been exhausted, meaning it will honor IRQONCMPLT, CHAIN, SEMAPHORE, and WAIT4ENDCMD.
7 WAIT4ENDCMD	A value of one indicates that the channel will wait for the end of command signal to be sent from the APBH device to the DMA before starting the next DMA command.
6 SEMAPHORE	A value of one indicates that the channel will decrement its semaphore at the completion of the current command structure. If the semaphore decrements to zero, then this channel stalls until software increments it again.
5 NANDWAIT4READY	A value of one indicates that the NAND DMA channel will will wait until the NAND device reports "ready" before executing the command. It is ignored for non-NAND DMA channels.
4 NANDLOCK	A value of one indicates that the NAND DMA channel will remain "locked" in the arbiter at the expense of other NAND DMA channels. It is ignored for non-NAND DMA channels.
3 IRQONCMPLT	A value of one indicates that the channel will cause the interrupt status bit to be set upon completion of the current command, i.e. after the DMA transfer is complete.
2 CHAIN	A value of one indicates that another command is chained onto the end of the current command structure. At the completion of the current command, this channel will follow the pointer in APBH_CHn_CMDAR to find the next command.
COMMAND	This bitfield indicates the type of current command: 0x0 **NO_DMA_XFER** — Perform any requested PIO word transfers but terminate command before any DMA transfer. 0x1 **DMA_WRITE** — Perform any requested PIO word transfers and then perform a DMA transfer from the peripheral for the specified number of bytes. 0x2 **DMA_READ** — Perform any requested PIO word transfers and then perform a DMA transfer to the peripheral for the specified number of bytes. 0x3 **DMA_SENSE** — Perform any requested PIO word transfers and then perform a conditional branch to the next chained device. Follow the NEXCMD_ADDR pointer if the perpheral sense is true. Follow the BUFFER_ADDRESS as a chain pointer if the peripheral sense line is false.

9.5.5.11 APBH DMA Channel n Buffer Address Register (APBH_CH*n*_BAR)

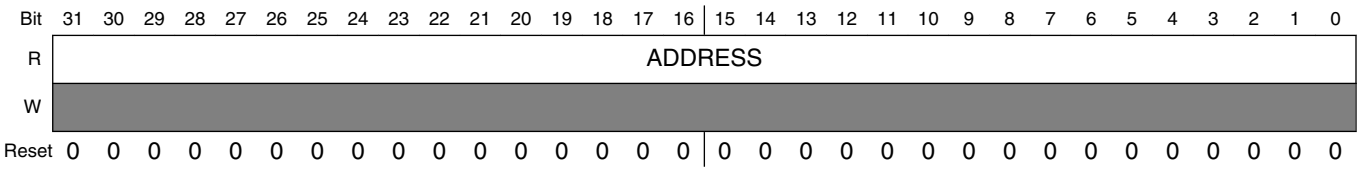
The APBH DMA Channel n buffer address register contains a pointer to the data buffer for the transfer. For immediate forms, the data is taken from this register. This is a byte address which means transfers can start on any byte boundary.

This register holds a pointer to the data buffer in system memory. After the command values have been read into the DMA controller and the device controlled by this channel, then the DMA transfer will begin, to or from the buffer pointed to by this register.

EXAMPLE

```
apbh_chn_bar_t  dma_data;
dma_data.ADDRESS = (reg32_t) pDataBuffer;
```

Address: 3300_0000h base + 130h offset + (112d × i), where i=0d to 15d



APBH_CH*n*_BAR field descriptions

Field	Description
ADDRESS	Address of system memory buffer to be read or written over the AHB bus.

9.5.5.12 APBH DMA Channel n Semaphore Register (APBH_CH*n*_SEMA)

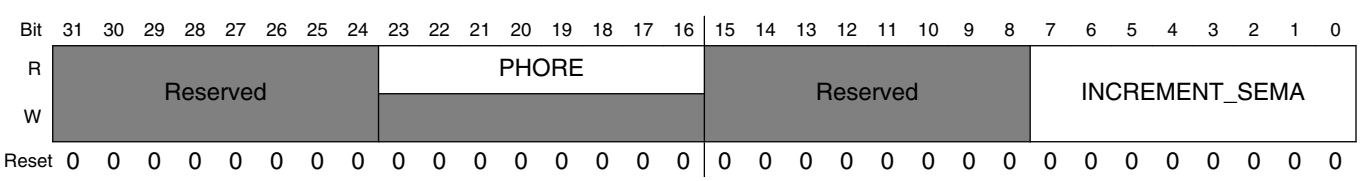
The APBH DMA Channel n semaphore register is used to synchronize the Arm platform instruction stream and the DMA chain processing state.

Each DMA channel has an 8 bit counting semaphore that is used to synchronize between the program stream and and the DMA chain processing. DMA processing continues until the DMA attempts to decrement a semaphore that has already reached a value of zero. When the attempt is made, the DMA channel is stalled until software increments the semaphore count.

EXAMPLE

```
BF_WR(APBH_CHn_SEMA, 0, INCREMENT_SEMA, 2);     // increment semaphore by two
current_sema = BF_RD(APBH_CHn_SEMA, 0, PHORE);  // get instantaneous value
```

Address: 3300_0000h base + 140h offset + (112d × i), where i=0d to 15d



APBH_CH*n*_SEMA field descriptions

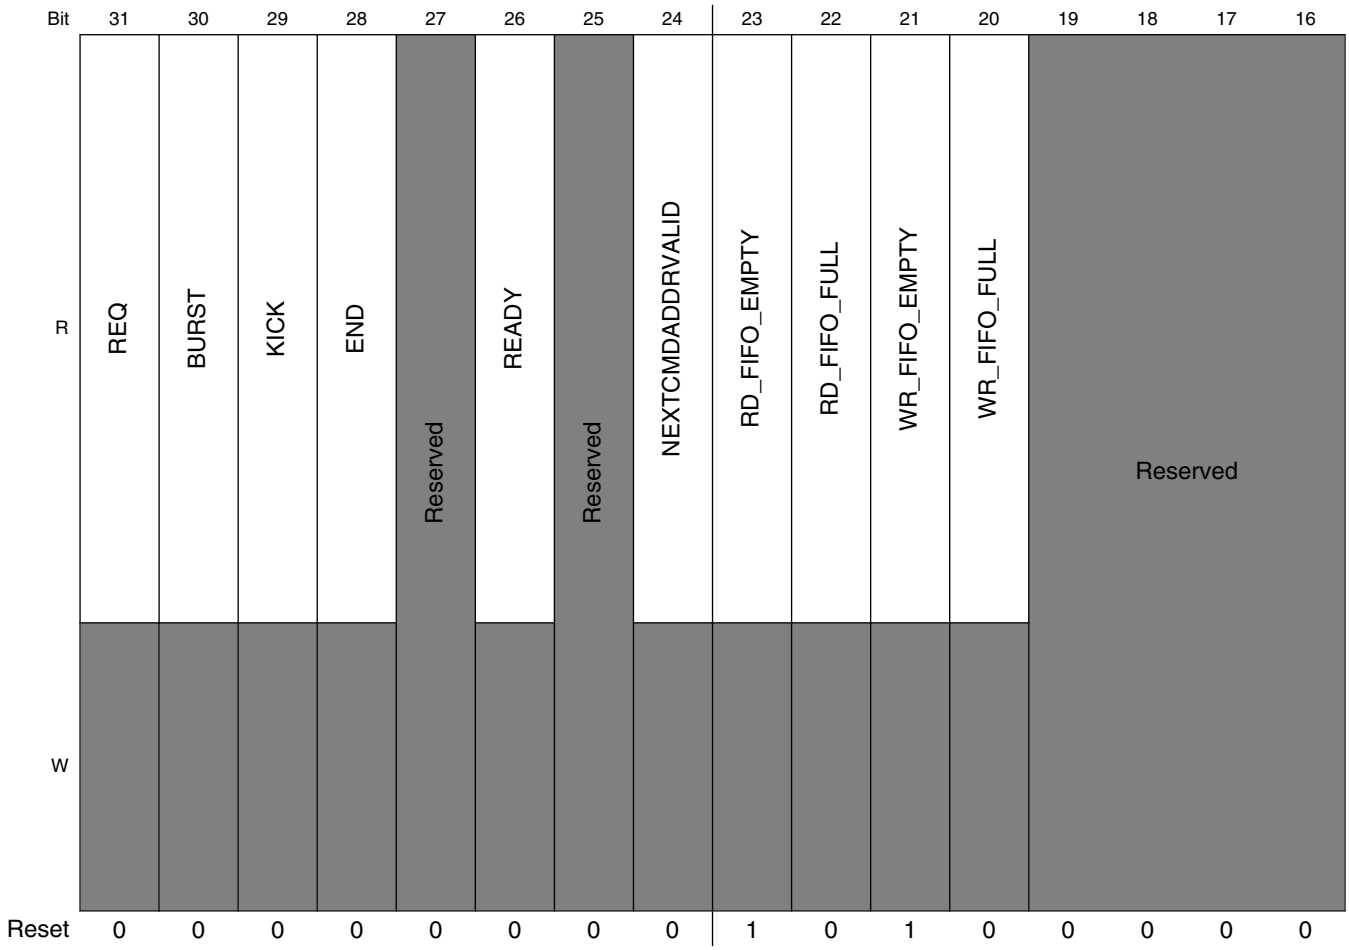
Field	Description
31–24 -	This field is reserved. Reserved, always set to zero.
23–16 PHORE	This read-only field shows the current (instantaneous) value of the semaphore counter.
15–8 -	This field is reserved. Reserved, always set to zero.
INCREMENT_ SEMA	The value written to this field is added to the semaphore count in an atomic way such that simultaneous software adds and DMA hardware substracts happening on the same clock are protected. This bit field reads back a value of 0x00. Writing a value of 0x02 increments the semaphore count by two, unless the DMA channel decrements the count on the same clock, then the count is incremented by a net one.

9.5.5.13 AHB to APBH DMA Channel n Debug Information (APBH_CH*n*_DEBUG1)

This register gives debug visibility into the APBH DMA Channel n state machine and controls.

This register allows debug visibility of the APBH DMA Channel n.

Address: 3300_0000h base + 150h offset + (112d × i), where i=0d to 15d



APBH_CH*n*_DEBUG1 field descriptions

Field	Description
31 REQ	This bit reflects the current state of the DMA Request Signal from the APB device
30 BURST	This bit reflects the current state of the DMA Burst Signal from the APB device
29 KICK	This bit reflects the current state of the DMA Kick Signal sent to the APB Device
28 END	This bit reflects the current state of the DMA End Command Signal sent from the APB Device
27 SENSE	This field is reserved. This bit is reserved for this DMA Channel and always reads 0.
26 READY	This bit is reserved for this DMA Channel and always reads 0.
25 LOCK	This field is reserved. This bit is reserved for this Channel and always reads 0.
24 NEXTCMDADDRVALID	This bit reflects the internal bit which indicates whether the channel's next command address is valid.
23 RD_FIFO_EMPTY	This bit reflects the current state of the DMA Channel's Read FIFO Empty signal.
22 RD_FIFO_FULL	This bit reflects the current state of the DMA Channel's Read FIFO Full signal.
21 WR_FIFO_EMPTY	This bit reflects the current state of the DMA Channel's Write FIFO Empty signal.
20 WR_FIFO_FULL	This bit reflects the current state of the DMA Channel's Write FIFO Full signal.
19–5 RSVD1	This field is reserved. Reserved
STATEMACHINE	PIO Display of the DMA Channel n state machine state. 0x00 **IDLE** — This is the idle state of the DMA state machine. 0x01 **REQ_CMD1** — State in which the DMA is waiting to receive the first word of a command. 0x02 **REQ_CMD3** — State in which the DMA is waiting to receive the third word of a command. 0x03 **REQ_CMD2** — State in which the DMA is waiting to receive the second word of a command. 0x04 **XFER_DECODE** — The state machine processes the descriptor command field in this state and branches accordingly. 0x05 **REQ_WAIT** — The state machine waits in this state for the PIO APB cycles to complete. 0x06 **REQ_CMD4** — State in which the DMA is waiting to receive the fourth word of a command, or waiting to receive the PIO words when PIO count is greater than 1. 0x07 **PIO_REQ** — This state determines whether another PIO cycle needs to occur before starting DMA transfers. 0x08 **READ_FLUSH** — During a read transfers, the state machine enters this state waiting for the last bytes to be pushed out on the APB. 0x09 **READ_WAIT** — When an AHB read request occurs, the state machine waits in this state for the AHB transfer to complete. 0x0C **WRITE** — During DMA Write transfers, the state machine waits in this state until the AHB master arbiter accepts the request from this channel. 0x0D **READ_REQ** — During DMA Read transfers, the state machine waits in this state until the AHB master arbiter accepts the request from this channel.

Table continues on the next page...

APBH_CH*n*_DEBUG1 field descriptions (continued)

Field	Description
	0x0E **CHECK_CHAIN** — Upon completion of the DMA transfers, this state checks the value of the Chain bit and branches accordingly. 0x0F **XFER_COMPLETE** — The state machine goes to this state after the DMA transfers are complete, and determines what step to take next. 0x14 **TERMINATE** — When a terminate signal is set, the state machine enters this state until the current AHB transfer is completed. 0x15 **WAIT_END** — When the Wait for Command End bit is set, the state machine enters this state until the DMA device indicates that the command is complete. 0x1C **WRITE_WAIT** — During DMA Write transfers, the state machine waits in this state until the AHB master completes the write to the AHB memory space. 0x1D **HALT_AFTER_TERM** — If HALTONTERMINATE is set and a terminate signal is set, the state machine enters this state and effectively halts. A channel reset is required to exit this state 0x1E **CHECK_WAIT** — If the Chain bit is a 0, the state machine enters this state and effectively halts. 0x1F **WAIT_READY** — When the NAND Wait for Ready bit is set, the state machine enters this state until the GPMI device indicates that the external device is ready.

9.5.5.14 AHB to APBH DMA Channel n Debug Information (APBH_CH*n*_DEBUG2)

This register gives debug visibility for the APB and AHB byte counts for DMA Channel n.

This register allows debug visibility of the APBH DMA Channel n.

Address: 3300_0000h base + 160h offset + (112d × i), where i=0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

APBH_CH*n*_DEBUG2 field descriptions

Field	Description
31–16 APB_BYTES	This value reflects the current number of APB bytes remaining to be transfered in the current transfer.
AHB_BYTES	This value reflects the current number of AHB bytes remaining to be transfered in the current transfer.

9.5.5.15 APBH Bridge Version Register (APBH_VERSION)

This register always returns a known read value for debug purposes it indicates the version of the block.

This register indicates the RTL version in use.

EXAMPLE

```
if (APBH_VERSION.B.MAJOR != 3)
   Error();
```

Address: 3300_0000h base + 800h offset = 3300_0800h

APBH_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
STEP	Fixed read-only value reflecting the stepping of the RTL version.

9.6 62BIT Correcting ECC Accelerator (BCH)

9.6.1 Overview

The hardware ECC accelerator provides a forward error-correction function for improving the reliability of various storage media that may be attached to the device.

For example, NAND flash devices use a spare area to store ecc codes to correct some hard bit errors in data stored within the device, allowing higher device yields and, therefore, lower NAND device costs.

The Bose, Ray-Chaudhuri, Hocquenghem (BCH) Encoder and Decoder module is capable of correcting from 2 to 62 single bit errors within a block of data no larger than about 1900 bytes (512 bytes or 1024 bytes are typical) in applications such as protecting data and resources stored on modern NAND flash devices. The correction level in the BCH block is programmable to provide flexibility for varying applications and configurations of flash page size. The design can be programmed to encode protection of 2 to 62 bit errors when writing flash and to correct the corresponding number of errors on decode. The correction level when decoding MUST be programmed to the same correction level as was used during the encode phase.

BCH-codes are a type of block-code, which implies that all error-correction is performed over a block of N-symbols. The BCH operation will be performed over GF(2^{13} = 8192) or GF(2^{14} = 16384), which is the Galois Field consisting of 8191 or 16383 one-bit symbols. BCH-encoding (or encode for any block-code) can be performed by two algorithms: systematic encoding or multiplicative encoding. Systematic encoding is the process of reading all the symbols which constitute a block, dividing continuously these symbols by the generator polynomial for the GF(8192) or GF(16384) and appending the resulting ***t*** parity symbols to the block to create a BCH codeword (where ***t*** is the number of correctable bits).

The BCH encode process creates *t**13 (or *t**14)-bit parity symbols for each data block when the data is written to the flash device. The parity symbols are written to the flash device after the corresponding data block, and together these are collectively called the codeword. The codeword can be used during the decode process to correct errors that occur in either the data or parity blocks.

The BCH decoder processes code words in a 4-step fashion:

1. Syndrome Calculation (SC): This is the process of reading in all of the symbols of the codeword and continuously dividing by the generator polynomial for the field. 2**t* syndromes must be calculated for each codeword and inspection of the syndromes determines if there are errors: a non-zero set of syndromes indicates one or more errors. This process is implemented parallel hardware to minimize processing time since it must be done every time the decode is performed.
2. Key Equation Solver (KES): The syndromes represent 2t-linear equations with 2t-unknown variables. The process of solving these equations and selecting from the numerous solutions constitutes the KES module. When the KES block completes its operations, it generates an error locator polynomial (sigma) that is used in the proceeding block to determine the locations and values of the errors.
3. Chien Search (CS): This block takes input from the KES block and uses the Chien Algorithm for finding the locations of the errors based on the error locator polynomial. The method basically involves substituting all 8191 symbols from the GF(8192) or 16383 symbols from the GF(16383) into the locator polynomial. All evaluations that produce a zero solution indicate locations of the various errors. Since each located error corresponds to a single bit, the bit in the original data may be corrected by simply flipping the polarity of the incorrect location.
4. Correction: this block has to convert the symbol index and mask information to memory byte indexes and masks.

The BCH block, shown in the figure, was designed to operate in a pipelined fashion to maximize throughput. Aside from the initial latency to fill the pipeline stages, the BCH throughput is about 7/4 cycles/byte. Thus, the bottleneck in performing NAND reads and error corrections is the BCH rate. Current GPMI read rates are approximately 1/2 cycles/byte maximally for the current generation of NAND flash. Fortunately, BCH has a different master clock from GPMI, this gives some flexibility to match the throughput rate. The CPU is not directly involved in generating parity symbols, checking for errors, or correcting them.

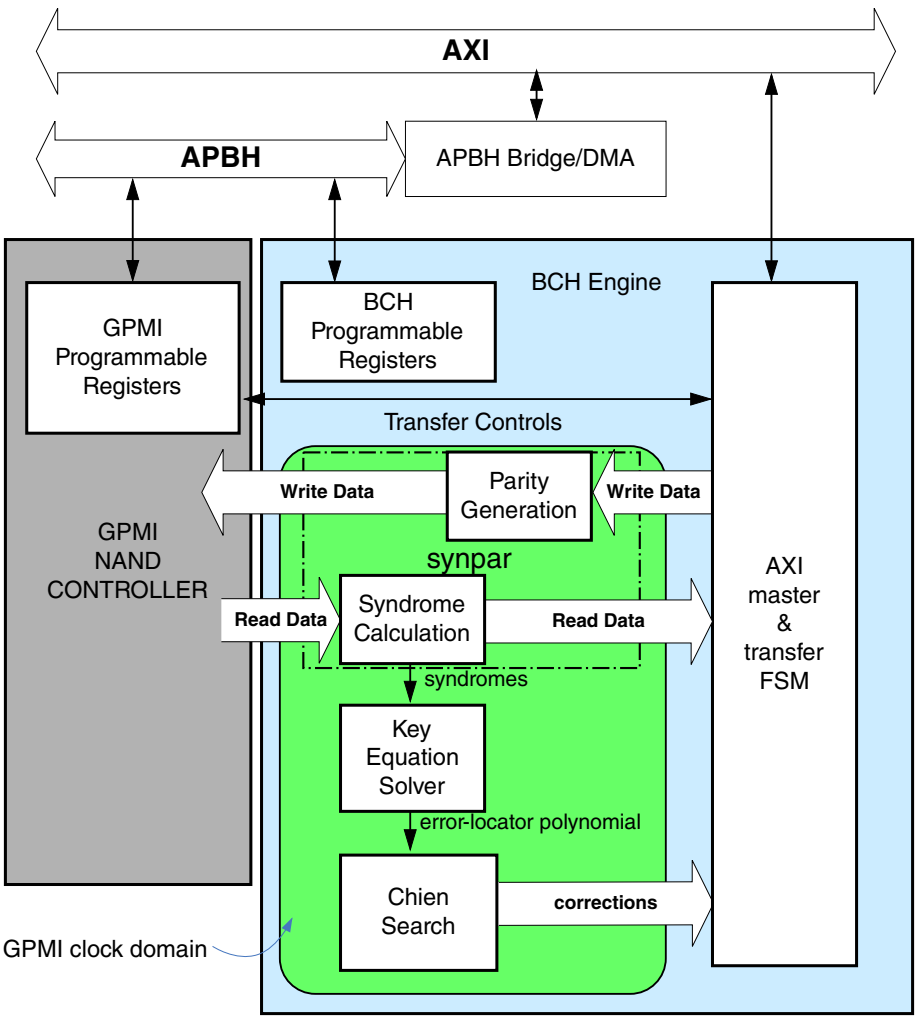

Figure 9-10. Hardware BCH Accelerator

9.6.2 Operation

Before performing any NAND flash read or write operations, software should first program the BCH's flash layout registers (see Flash Page Layout) to specify how data is to be formatted on the flash device. The BCH hardware allows full programmability over the flash page layout to enable users flexibility in balancing ECC correction levels and ever-changing flash page sizes.

To initiate a NAND Flash write, software will program a GPMI DMA operation. The DMA need only program the GPMI control registers (and handle the requisite flash addressing handshakes) since the BCH will handle all data operations using its AXI bus interface. The BCH will then send the data to the GPMI controller to be written to flash as it computes the parity symbols. At the end of each data block the BCH will insert the parity symbols into the data stream so that the GPMI sees only a continuous stream of data to be written.

NAND Flash read operations operate in a similar manner. As the GPMI controller reads the device, all data is sent to the BCH hardware for error detection/correction. The BCH controller writes all incoming read data to system memory and in parallel computes the syndromes used to detect bit errors. If errors are detected within a block, the BCH hardware activates the error correction logic to determine where bit errors have occurred and ultimately correct them in the data buffer in system memory. After an entire flash page has been read and corrected, the BCH will signal an interrupt to the CPU.

The figure below indicates how data read from the GPMI is operated on within the BCH hardware. As the BCH receives data from the GPMI (top row), it is written to memory by the BCH's Bus Interface Unit (BIU) (second row). For blocks requiring correction, the KES logic will be activated after the entire block has been received. Once the error locator polynomial has been computed, the corrections are determined by the Chien Search and fed back to the BIU, which performs a read, modify, write operation on the buffer in memory to correct the data.

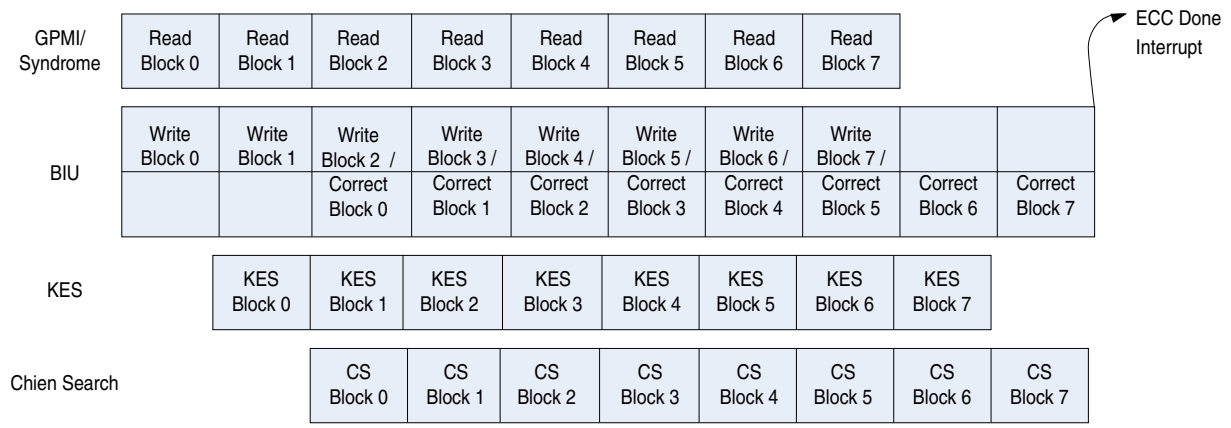

Figure 9-11. Block Pipeline while Reading Flash

9.6.2.1 BCH Limitations and Assumptions

- The BCH is programmable to support 2 to 62 bit error correction. ECC0 is supported as a pass-through, non-correcting mode.
- Data block sizes must be a multiple of 4 bytes and be aligned in system memory.
- The BCH supports a programmable number of metadata/auxiliary data bytes, from 0 to 255.
- Metadata will be written at the beginning of the flash page to facilitate fast access for filesystem operations.
- Metadata may be treated as an independent block for ECC purposes or combined with the first data block to conserve bits in the flash.
- The BCH does not support a partial page write (this can be accomplished by programming the BCH layout registers such that the BCH only sees a portion of the page).
- Flash read operations can read the entire page or the first block on the page.
- The BCH also supports a memory-to-memory mode of operation that does not require the use of DMA or the GPMI.

9.6.2.2 Flash Page Layout

The BCH supports a fully programmable flash page layout. The BCH maintains four independent layout registers that can describe four completely different NAND devices or layouts.

When the BCH initiates an operation, it selects one of the layouts by using the chip select as an index into the BCH_LAYOUTSELECT register that determines which layout should be used for the operation.

Three possible (generic) flash layout schemes are supported, as indicated in the figure below. (In each case, the metadata size may also be programmed to 0 bytes). Metadata may either be combined with the first block of data or the size of the first data block can be programmed to 0 to allow the metadata to be protected by its own ECC parity bits.

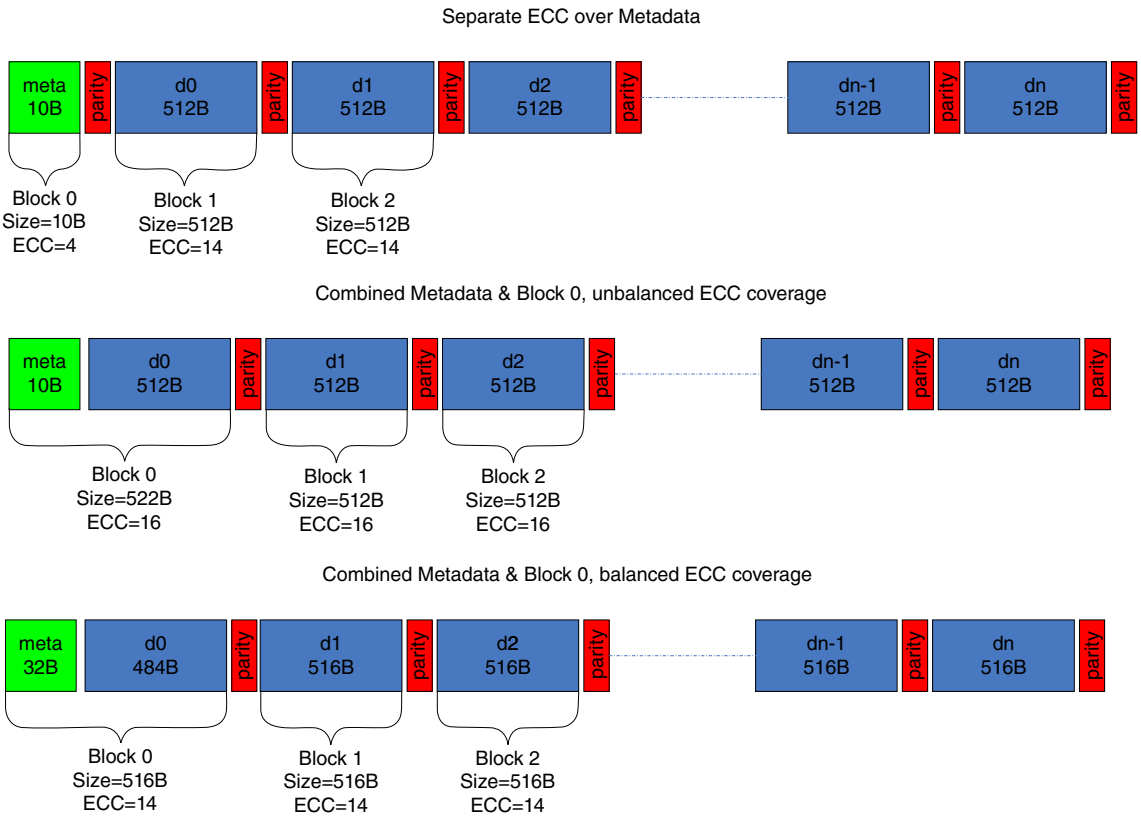

Figure 9-12. FLASH Page Layout Options

Each layout is determined by a pair of registers that define the following parameters:

- DATA0_SIZE: Indicates the number of data bytes in the first block on the page (this should not include parity or metadata bytes). This should be set to 0 when the metadata is to be covered separately with its own ECC. This must be a multiple of 4 bytes.
- ECC0: Indicates the ECC level to be used for the first block on the flash (data0+metadata).
- META_SIZE: Indicates the number of bytes (from 0-255) that are stored as metadata.

- NBLOCKS: Indicates the number of subsequent DATAN blocks on the flash, or the number of blocks following the DATA0 block.
- DATAN_SIZE: Indicates the number of data bytes in all subsequent data blocks. This MUST be a multiple of 4 bytes.
- ECCN: Indicates the ECC level to be used for the subsequent data blocks.
- GF0 or GFN: Indicates the Galois field the meta / data blocks are using
- PAGE_SIZE: Indicates the total number of bytes available per page on the physical flash device. This includes the spare area and is typically 4096+128, 4096+218, or 2048+64 bytes.

9.6.2.3 Determining the ECC layout for a device

Since the BCH is programmable, a system can trade off ECC levels for flash size and layout configurations.

The following examples indicate how to determine a valid layout based on the required storage space and flash size. For all cases, the size of the parity will be 13 (or 14 for GF(2^{14}))*ECC level ***bits***-- so for ECC8, 13 (or 14) bytes are required (per block).

9.6.2.3.1 4K+218 flash, 10 bytes metadata, 512 byte data blocks, separate metadata, Assuming GF(2^{13})

In this case, we have 8 data blocks each consisting of 512 bytes. Since the flash has 218 spare bytes (1744 bits), first estimate an ECC level for the data blocks by first subtracting the number of metadata bytes from the spare bytes (218 – 10 = 208 bytes = 1664 bits) then dividing the number of bits by 8 (number of blocks) and then by 13 (bits per ECC level).

(218 - 10) x 8 = 1664/13(8) = 16

Therefore all the data blocks could be covered by ECC16 if the metadata had no parity. This isn't acceptable, so assume ECC14 for all the data blocks. Now calculate the number of free bits for the metadata parity as

1664 - (14) x 13 x 8 = 208

Therefore, 208 bits remain for metadata parity. Dividing by 13 (bits/ECC) gives 16, so the metadata can be covered with ECC16. The settings for this device would then be

Table 9-9. Settings for 4K+218 FLASH

Setting	Value
PAGE_SIZE	4096+218=4314=0x10DA
META_SIZE	10=0x0A
DATA0_SIZE	0
ECC0	16=0x10
GF0	GF(2^{13})
DATAN_SIZE	512=0x200 (in register interface, assigned as 0x80)
ECCN	14=0x0E
GFN	GF(2^{13})
NBLOCKS	8

9.6.2.3.2 4K+128 flash, 10 bytes metadata, 1024 byte data blocks, separate metadata, assuming GF(2^{13}) for data and GF(2^{14}) for metadata

This flash will have 118 bytes available for ECC (after subtracting the metadata size), therefore, 994 bits.

Dividing by 4*14 (number of blocks * ECC level) we get 17.75, therefore we can support ECC16 on the data blocks. The number of free spare bits becomes 944 - 16 * 4 * 14 = 944 - 896 = 48, divided by 13 = 3.69, therefore the metadata can be also covered by ECC2.

Table 9-10. Settings for 4K+128 FLASH

Setting	Value
PAGE_SIZE	4096+128=4224=0x1080
META_SIZE	10=0x0A
DATA0_SIZE	0
ECC0	2
GF0	GF(2^{13})
DATAN_SIZE	1024=0x400 (in register interface, assigned as 0x100)
ECCN	16
GFN	GF(2^{14})
NBLOCKS	4

In this case, there will be additional unused spare bits, with the BCH will pad out with zeros.

9.6.2.4 Data Buffers in System Memory

While the data on the flash is interleaved with parity symbols, the BCH assumes that the data buffers in memory are contiguous.

Metadata read from the flash will be stored to the location pointed to by the GPMI_AUXILIARY register and data will be written to the address specified in the GPMI_PAYLOAD register as is shown in the following figure where the block length is 512 bytes for example. Since the number of blocks on a flash page is programmable, the BCH also writes individual block correction status to the auxiliary pointer at the word-aligned address following the end of the metadata. Optionally, the computed syndromes may also be written to the auxiliary area if the DEBUGSYNDROME bit is set in the control register.

As blocks complete processing, the bus master will accumulate the status for each block and write it to the auxiliary data buffer following the metadata. The metadata area will be padded with 0's until the next word boundary and the status for blocks 0-3 will be written to the next word. The status for subsequent blocks will then be written to the buffer. The status for the first block (metadata block) is also stored in the STATUS_BLK0 register in the BCH_STATUS register. The completion codes for the blocks are indicated in the Table 9-11. Note that the definition of the bytes and their ordering in the auxiliary and payload storage areas are user defined. When this data is read back from the flash and put into memory, it will resemble the original buffer that was written out to the flash.

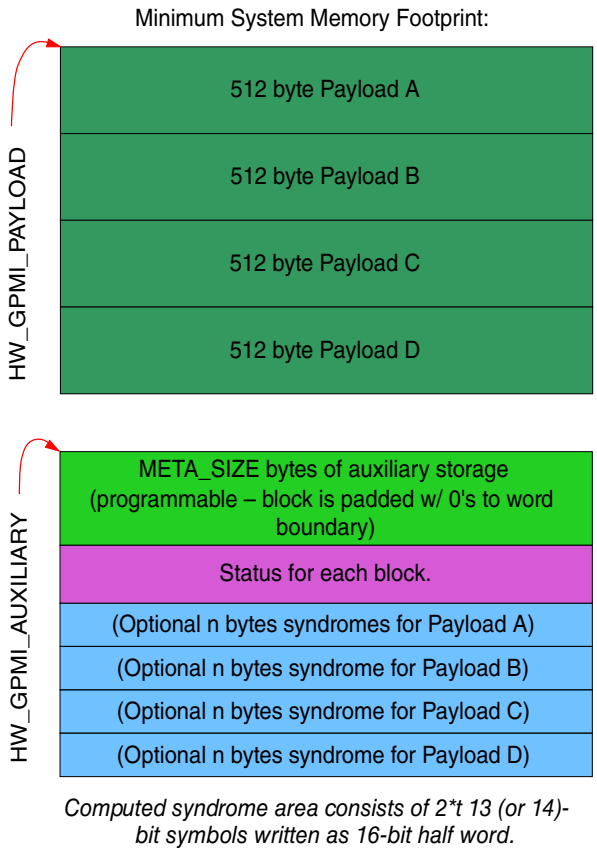

Figure 9-13. BCH Data Buffers in Memory

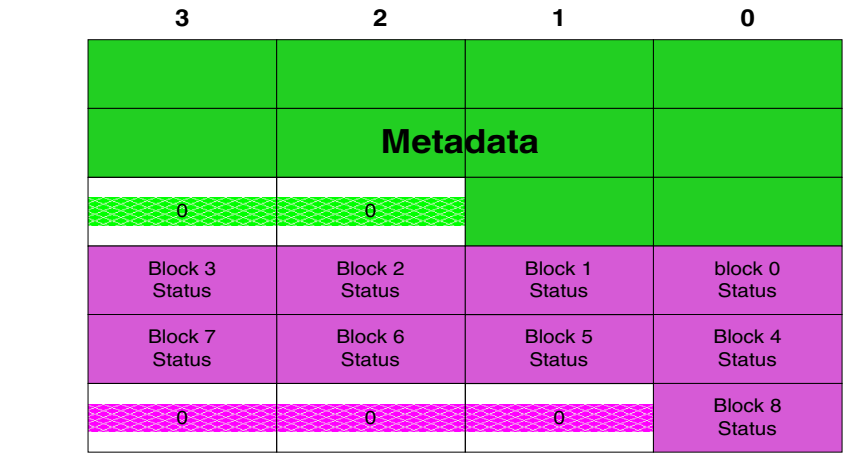
Table 9-11. Status Block Completion Codes

Code	Description
0xFF	Block is erased
0xFE	Block is uncorrectable
0x00	No errors found
0x01-0x3E	Number of errors corrected

The following figure shows the layout of the bytes within the status field.



Status bytes are allocated based on the NBLOCKS programmed into the flash format register. The number of status bytes are computed by NBLOCK+1. The status area will be padded with zeros to the next word boundary.

Syndrome data written for debug purposes follows the end of the status block.

Figure 9-14. Memory-to-Memory Operations

9.6.3 Memory to Memory (Loopback) Operation

The BCH supports a memory-to-memory mode of operation where both the encoded and decoded buffers reside in system memory.

This can be useful for applications where data must be protected by ECC, but the storage device does not reside on the GPMI bus.

The BCH operation in memory to memory mode is much simpler than in GPMI mode since DMAs are not required to manage the operation. Instead, software simply writes the BCH_DATAPTR and BCH_METAPTR with the addresses of the data and metadata (auxiliary) buffers and the BCH_ENCODEPTR with the address of the buffer for encoded data. To initiate the operation, software simply sets the M2M_ENCODE and M2M_ENABLE bits in the control register. The BCH can be programmed to either issue an interrupt at the end of the operation or software may poll the status bits for completion.

Memory to memory decode operations work in a similar manner. The encoded data address is written to the BCH_ENCODEPTR and the data and meta pointers are written to buffers that correspond to the desired decoded data addresses. To initiate a decode, software must set the M2M_ENCODE bit to 0 while writing the M2M_ENABLE bit. Note that the addresses written to the BCH_DATAPTR, BCH_METAPTR and BCH_ENCODEPTR registers should always be aligned on a 4 byte boundary. In other words, the 2 lower bits of the address should always be written with zeros.

9.6.4 Programming the BCH/GPMI Interfaces

Programming the BCH for NAND operations consists largely of disabling the soft reset and clock bits (SFTRST and CLKGATE) from the BCH_CTRL register and then programming the flash layout registers to correspond to the format of the attached NAND device(s).

The BCH_LAYOUTSELECT register should also be programmed to map the chip select of each attached device into one of the four layout registers.

The bulk of the programming is actually applied to the GPMI through PIO operations embedded in DMA command structures. The DMA will perform all the requisite handshaking with the GPMI interface to negotiate the address portion of the transfer, then the BCH will handle all the movement of data from memory to the GPMI (writes) or the GPMI to memory (reads). The BCH will direct all data blocks to the buffer pointed to by the PAYLOAD_BUFFER and the metadata will be written to the AUXILIARY_BUFFER. Both of these registers are located in the GPMI PIO data space and are communicated to the BCH hardware at the beginning of the transfer. Thus, the normal multi-NAND DMA based device interleaving is preserved, that is, four NANDs on four separate chip selects can be scheduled for read or write operations using the BCH. Whichever channel finishes its ready wait first and enters the DMA arbiter with its lock bit set owns the GPMI command interface and through it owns the BCH resources for the duration of its processing.

9.6.4.1 BCH Encoding for NAND Writes

The BCH encoder flowchart in Figure 9-15 shows the detailed steps involved in programming and using the BCH encoder. This flowchart shows how to use the BCH block with the GPMI.

To use the BCH encoder with the GPMI's DMA, create a DMA command chain containing ten descriptor structures, as shown in Figure 9-17 and detailed in the DMA structure code example that follows it in DMA Structure Code Example. The ten descriptors perform the following tasks:

1. Disable the BCH block (in case it was enabled) and issue NAND write setup command byte (under CLE) and address bytes (under ALE).
2. Configure and enable the BCH and GPMI blocks to perform the NAND write.
3. Disable the BCH block and issue NAND write execute command byte (under CLE).

4. Wait for the NAND device to finish writing the data by watching the ready signal.
5. Check for NAND timeout through PSENSE.
6. Issue NAND status command byte (under CLE).
7. Read the status and compare against expected.
8. If status is incorrect or incomplete, branch to error handling descriptor chain.
9. Otherwise, write is complete and emit GPMI interrupt.

```

9.6.4.1.2 Using the BCH Encoder

To use the BCH encoder, first turn off the module-wide soft reset bit in both the GPMI and BCH blocks before starting any DMA activity.

Turning off the soft reset must take place by itself, prior to programming the rest of the control registers. Turn off the BCH bus master soft reset bit. Turn off the clock gate bits.

Program the remainder of the GPMI, BCH and APBH DMA as follows:

```
// bring APBH out of reset
APBH_CTRL0_CLR(BM_APBH_CTRL0_SFRST);
APBH_CTRL0_CLR(BM_APBH_CTRL0_CLKGATE);

// bring BCH out of reset
BCH_CTRL_CLR(BM_BCH_CTRL_SFTRST);
BCH_CTRL_CLR(BM_BCH_CTRL_CLKGATE);

// bring gpmi out of reset
GPMI_CTRL0_CLR(BM_GPMI_CTRL0_SFTRST);
GPMI_CTRL0_CLR(BM_GPMI_CTRL0_CLKGATE);
GPMI_CTRL1_SET(BM_GPMI_CTRL1_DEV_RESET | // deassert reset
                   BM_GPMI_CTRL1_BCH_MODE  );    // enable BCH mode

// enable pinctrl
PINCTRL_CTRL_WR(0x00000000);

// enable gpmi pins
PINCTRL_MUXSEL0_CLR(0x0000ffff);    // data bits
PINCTRL_MUXSEL1_CLR(0x03ffffff);    // control bits
PINCTRL_MUXSEL8_CLR(0x0003f3ff);    // control bits
PINCTRL_MUXSEL8_SET(0x00015155);    // control bits
```

Note that for writing NANDs (ECC encoding), only GPMI DMA command complete interrupts are used. The BCH engine is used for writing to the NAND but may optionally produces an interrupt. From the sample code in DMA Structure Code Example :

- DMA descriptor 1 prepares the NAND for data write by using the GPMI to issue a write setup command byte under CLE, then sends a 5-byte address under ALE. The BCH engine is disabled and not used for these commands.
- DMA descriptor 2 enables the BCH engine for encoding to begin the initial writing of the NAND data by specifying where the data and auxiliary payload are coming from in system memory.

- DMA descriptor 3 issues the write commit command byte under CLE to the NAND.
- DMA descriptor 4 waits for the NAND to complete the write commit/transfer by watching the NAND's ready line status. This descriptor relinquishes the NANDLOCK on the GPMI to enable the other DMA channels to initiate NAND transactions on different NAND CS lines.
- DMA descriptor 6 issues a NAND status command byte under "CLE" to check the status of the NAND device following the page write.
- DMA descriptor 7 reads back the NAND status and compares the status with an expected value. If there are differences, then the DMA processing engine follows an error-handling DMA descriptor path.
- DMA descriptor 8 disables the BCH engine and emits a GPMI interrupt to indicate that the NAND write has been completed.

9.6.4.2 BCH Decoding for NAND Reads

When a page is read from NAND flash, BCH syndromes will be computed and, if correctable errors are found, they will be corrected on a per block basis within the NAND page. This decoding process is fully overlapped with other NAND data reads and with CPU execution. The BCH decoder flowchart in the figure below shows the steps involved in programming the decoder. The hardware flow of reading and decoding a 4096-byte page is shown in Figure 9-19.

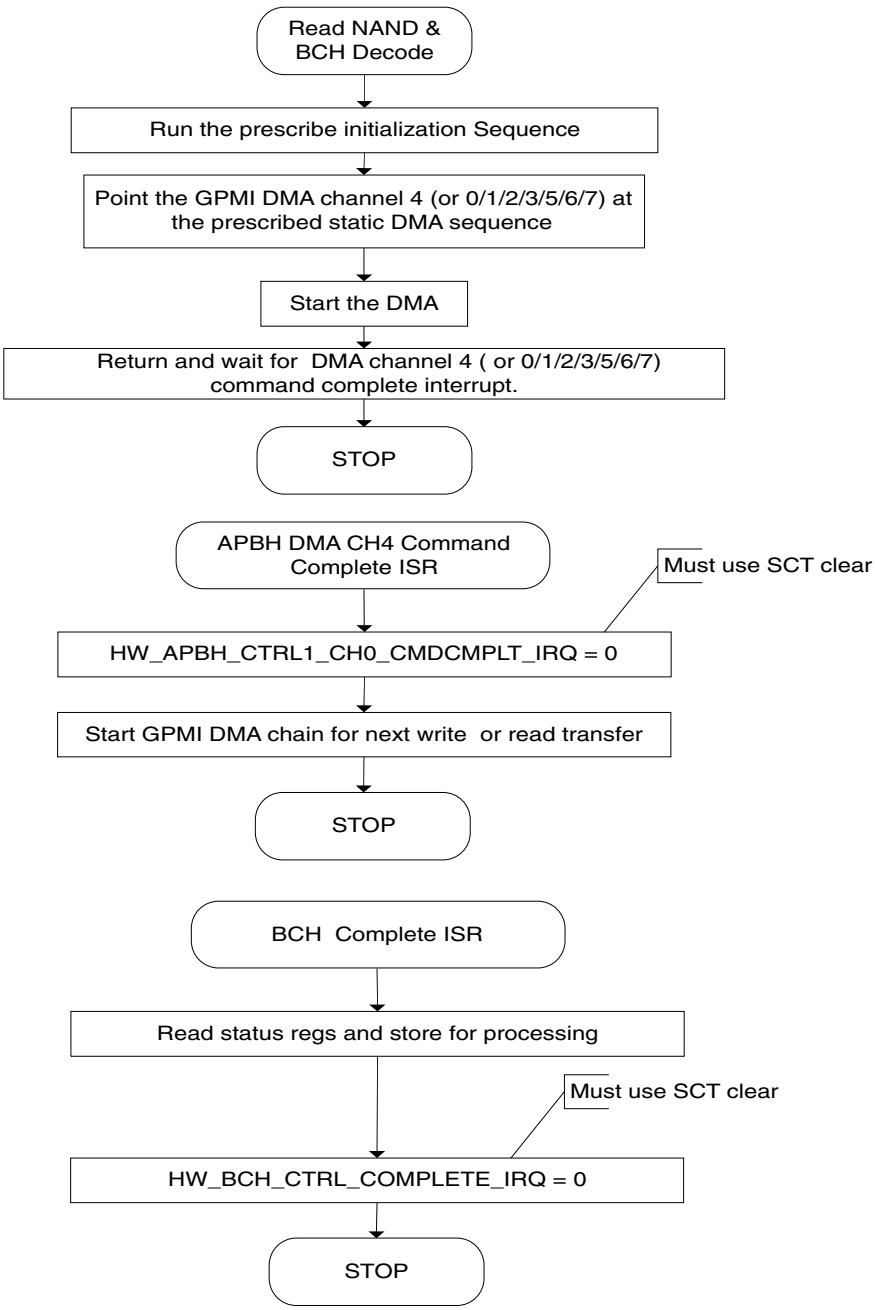

Figure 9-18. BCH Decode Flowchart

Conceptually, an APHB DMA Channel (0,1,2 or 3) command chain with seven command structures linked together is used to perform the BCH decode operation (as shown in Figure 9-19).

Note

The GPMI's DMA command structures controls the BCH decode operation.

To use the BCH decoder with the GPMI's DMA, create a DMA command chain containing seven descriptor structures, as shown in the figure below and detailed in the DMA structure code example that follows it in DMA Structure Code Example. The seven DMA descriptors perform the following tasks:

1. Issue NAND read setup command byte (under "CLE") and address bytes (under "ALE").
2. Issue NAND read execute command byte (under "CLE").
3. Wait for the NAND device to complete accessing the block data by watching the ready signal.
4. Check for NAND timeout through "PSENSE".
5. Configure and enable the BCH block and read the NAND block data.
6. Disable the BCH block.
7. Descriptor NOP to allow NANDLOCK in the previous descriptor to the thread-safe.

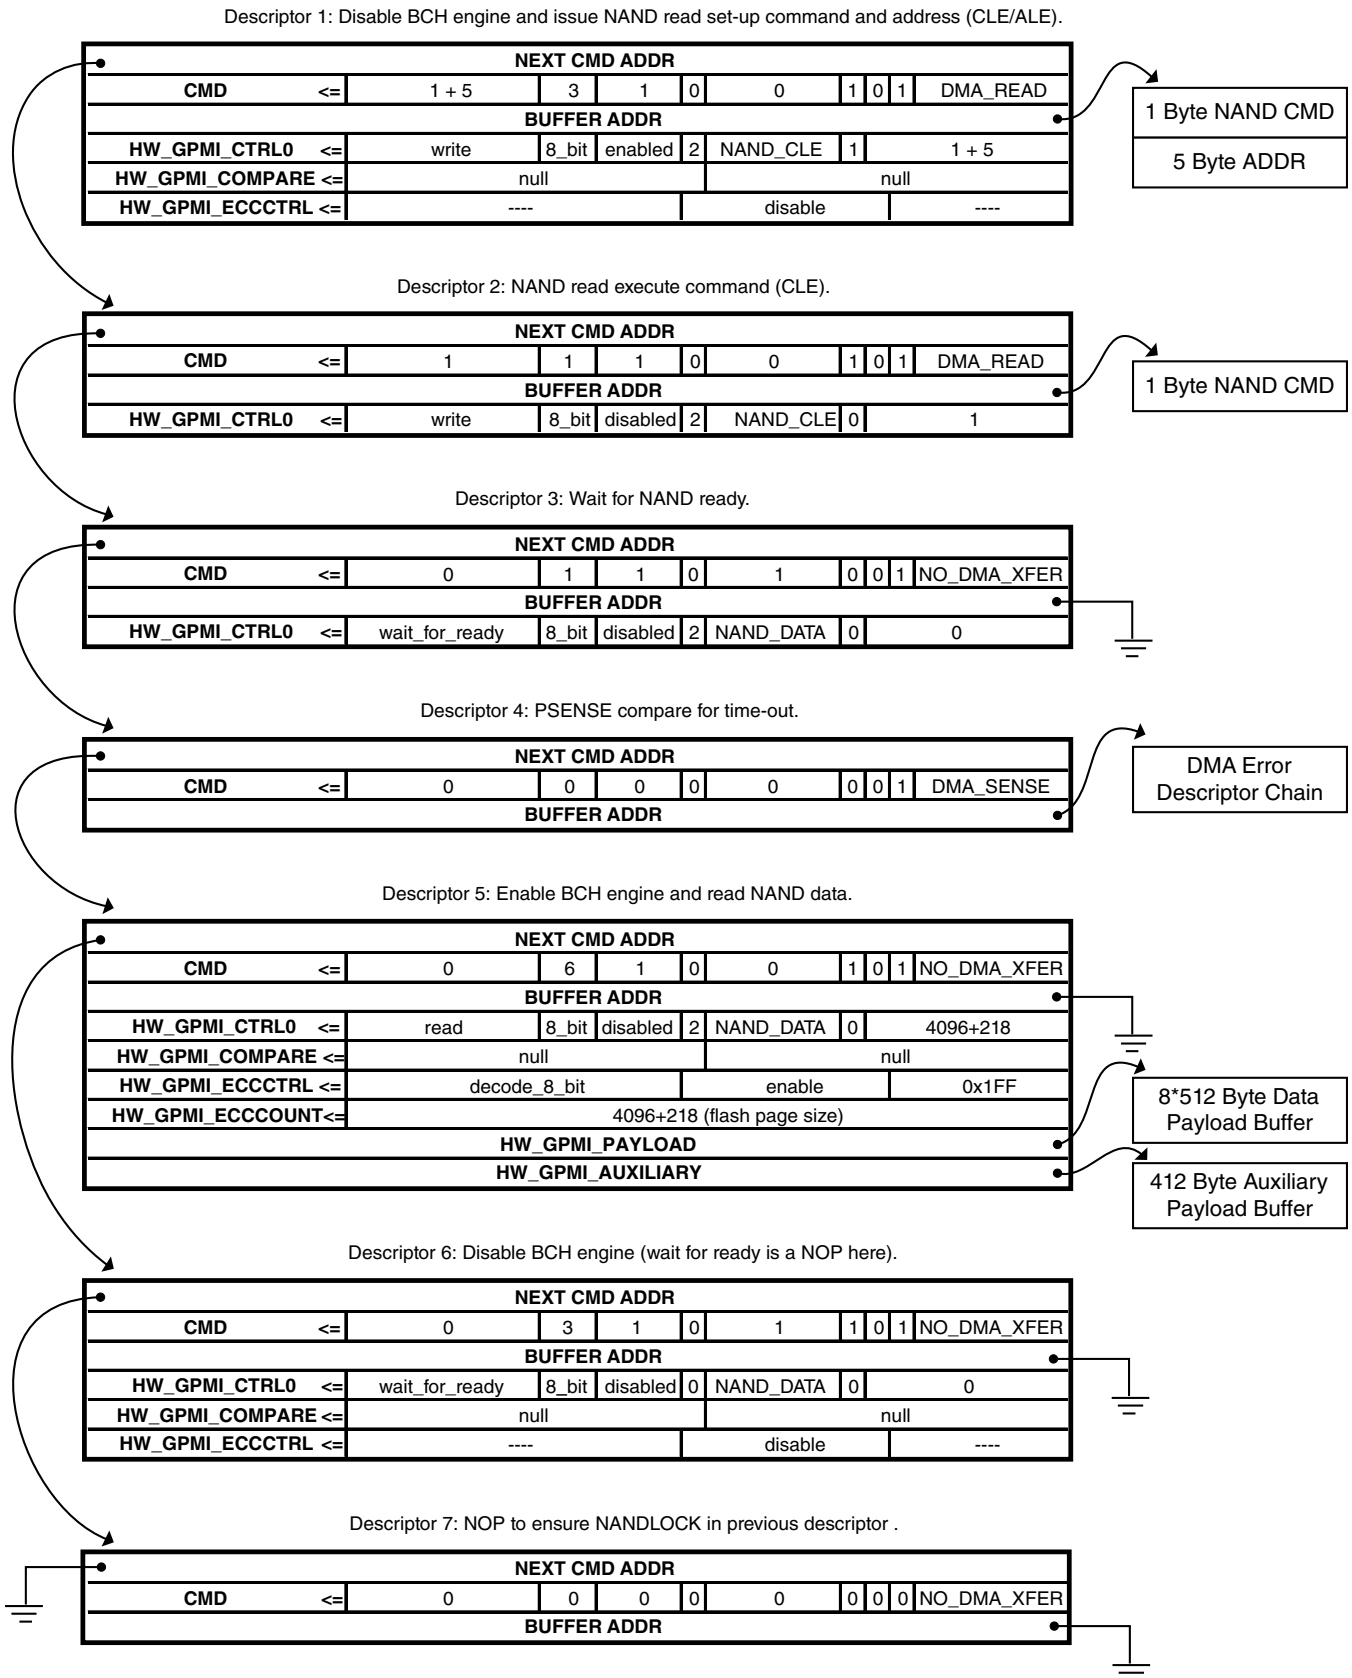

Figure 9-19. BCH Decode DMA Descriptor Chain

9.6.4.2.1 DMA Structure Code Example

The following sample code illustrates the coding for one read transaction, consisting of a seven DMA command structure chain for reading all 4096 bytes of payload data (eight 512-byte blocks) and 65 bytes of metadata with the associative parity bytes (8 * (18) + 9) from a 4K NAND page sitting on GPMI CS2.

9.6.4.2.2 Using the Decoder

As illustrated in Figure 9-19 and the sample code in DMA Structure Code Example :

- DMA descriptor 1 prepares the NAND for data read by using the GPMI to issue a NAND read setup command byte under CLE, then sends a 5-byte address under ALE. The BCH engine is not used for these commands.
- DMA descriptor 2 issues a one-byte read execute command to the NAND device that triggers its read access. The NAND then goes not ready.
- DMA descriptor 3 performs a wait for ready operation allowing the DMA chain to remain dormant until the NAND device completes its read access time.

- DMA descriptor 5 handles the reading and error correction of the NAND data. This command's PIOs activate the BCH engine to write the read NAND data to system memory and to process it for any errors that need to be corrected. This DMA descriptor contains two PIO values that are system memory addresses pointing to the PAYLOAD data area and to the AUXILIARY data area. These addresses are used by the BCH engine's AHB master to move data into system memory and to correct it. While this example is reading an entire 4K page—payload plus metadata—it is equally possible to read just one 512-byte payload block or just the uniquely protected metadata block in a single 7 DMA structure transfer.
- DMA descriptor 6 disables the BCH engine with the NANDLOCK asserted. This is necessary to ensure that the GPMI resource is not arbitrated to another DMA channel when multiple DMA channels are active concurrently.
- DMA descriptor 7 de-asserts the NANDLOCK to free up the GPMI resource to another channel.

As the BCH block receives data from the GPMI:

- The decoder transforms the read NAND data block into a BCH code word and computes the codeword syndrome.
- If no errors are present, then the BCH block can immediately report back to firmware. This report is passed as the BCH_CTRL_COMPLETE_IRQ interrupt status bit and the associated status registers in BCH_STATUS0/1 registers.
- If an error is present, then the BCH block corrects the necessary data block or parity block bytes, if possible (not all errors are correctable).

As the BCH decoder reads the data and parity blocks, it records a special condition, i.e., that all of the bits of a payload data block or metadata block are one, including any associated parity bytes. The all-ones case for both parity and data indicates an erased block in the NAND device.

The BCH_STATUS0 register contains a 4-bit field that indicates the final status of the auxiliary block. A value of 0x0 indicates no errors found for a block.

- A value of 1 to 20 inclusive indicates that many correctable errors were found and fixed.
- A value of 0xFE indicates uncorrectable errors detected on the block.

- A value of 0xFF indicates that the block was in the special ALL ONES state and is therefore considered to be an ERASED block.
- All other values are disallowed by the hardware design.

Recall that up to eight NAND devices can have DMA chains in-flight at once, i.e. they can all be contending for access to the GPMI data bus. It is impossible to predict which NAND device will enter the BCH engine with a transfer first, because each chain includes a wait4ready command structure. As a result, firmware should look at the BCH_STATUS0_COMPLETED_CE bit field to determine which block is being reported in the status register. There is also a 16-bit HANDLE field in the GPMI_ECCCTRL register that is passed down the pipeline with each transaction. This handle field can be used to speed firmware's detection of which transaction is being reported.

These examples of reading and writing have focused on full page transfers of 4K page NAND devices. Other device configurations can be specified by changing the ECCOUNT field in the GPMI registers and reprogramming the BCH's FLASHnLAYOUTm registers.

The BCH and GPMI blocks are designed to be very efficient at reading single 512 (or 1024)-byte pages in one transaction. With no errors, the transaction takes less than 20 HCLKs longer than the time to read the raw data from the NAND.

To summarize, the APBH DMA command chain for a BCH decode operation is shown in Figure 9-19. Seven DMA command structures must be present for each NAND read transaction decoded by the BCH. The seven DMA command structures for multiple NAND read transaction blocks can be chained together to make larger units of work for the BCH, and each will produce an appropriate error report in the BCH PIO space. Multiple NAND devices can have such multiple chains scheduled. The results can come back out of order with respect to the multiple chains.

9.6.4.3 Interrupts

There are two interrupt sources used in processing BCH protected NAND read and write transfers.

Since all BCH operations are initiated by GPMI DMA command structures, the DMA completion interrupt for the GPMI is an important ISR. Both of the flow charts of Figure 9-15 and Figure 9-18 show the GPMI DMA complete ISR skeleton. In both reads and writes, the GPMI DMA completion interrupt is used to schedule work ***INTO*** the error correction pipeline. As the front end processing completes, the DMA interrupt is

generated and additional work, such as DMA chains, are passed to the GPMI DMA to keep it *fed*. For write operations, this is the only interrupt that is generated for processing the NAND write transfer.

For reads, however, two interrupts are needed. Every read is started by a GPMI DMA command chain and the front end queue is fed as described above. The back end of the read pipeline is drained by monitoring the BCH completion interrupt found int HW_BCH_CTRL_COMPLETE_IRQ.

An BCH transaction consists of reading or writing all of the blocks requested in the HW_GPMI_ECCCTRL_BUFFER_MASK bit field. As every read transaction completes, it posts the status of all of the blocks to the HW_BCH_STATUS0 and HW_BCH_STATUS1 registers and sets the completion interrupt. The five stages of the BCH read pipeline completes, one in the GPMI and four in the BCH, are independently stalled as they complete and try to deliver to the next stage in the data flow. Several of these stages can be skipped if no-errors are found or once an uncorrectable error is found in a block.

In any case, the final stage will stall if the status register is busy waiting for the CPU to take status register results. The hardware monitors the state of the HW_BCH_CTRL_COMPLETE_IRQ bit. If it is still set when the last pipeline stage is ready to post data, then the stage will stall. It follows that the next previous stage will stall when it is ready to hand off work to the final stage, and so on up the pipeline.

CAUTION

It is important that firmware read the STATUS0/1 results and save them before clearing the interrupt request bit. Otherwise, a transaction and its results could be completely lost.

9.6.4.4 Randomizer

BCH ECC has a Randomizer module that is interfaced through the GPMI APBHDMA chain. The Randomizer can generate random data based on BCH ECC encoded/decoded data. It can be employed to reduce the disturbances caused by a neighboring cell in the NAND chip, thus reducing bit errors.

To enable the Randomizer module, set GPMI_ECCCTRL[RANDOMIZER_ENABLE] to 1, then set GPMI_ECCCOUNT[RANDOMIZER_PAGE] to select randomizer page number needed to be randomized. All these registers can be programmed by the DMA chain. The randomized data should start from the zero column address and be the size of the whole NAND page. If the randomizer function is enabled,

GPMI_ECCCTRL[ENABLE_ECC] should also be enabled. To bypass BCH error correction function, set BCH_FLASHxLAYOUT0[ECC0] and BCH_FLASHxLAYOUT1[ECCN] to 0.

9.6.5 Behavior During Reset

A soft reset (SFTRST) can take multiple clock periods to complete, so do NOT set CLKGATE when setting SFTRST.

The reset process gates the clocks automatically. The example code is shown below.

```
// A soft reset can take multiple clocks to complete, so do NOT gate the
// clock when setting soft reset. The reset process will gate the clock
// automatically. Poll until this has happened before subsequently
// preparing soft-reset and clock gate
  BCH_CTRL_CLR(BM_BCH_CTRL_SFTRST);
  BCH_CTRL_CLR(BM_BCH_CTRL_CLKGATE);
// asserting soft-reset
  BCH_CTRL_SET(BM_BCH_CTRL_SFTRST);
// waiting for confirmation of soft-reset
  while (!BCH_CTRL.B.CLKGATE)
  {
// busy wait
  }
// Done.
  BCH_CTRL_CLR(BM_BCH_CTRL_SFTRST);
  BCH_CTRL_CLR(BM_BCH_CTRL_CLKGATE);
```

9.6.6 BCH Memory Map/Register Definition

BCH Hardware Register Format Summary

BCH memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3300_4000	Hardware BCH ECC Accelerator Control Register (BCH_CTRL)	32	R/W	C000_0000h	9.6.6.1/ 2413
3300_4004	Hardware BCH ECC Accelerator Control Register (BCH_CTRL_SET)	32	R/W	C000_0000h	9.6.6.1/ 2413

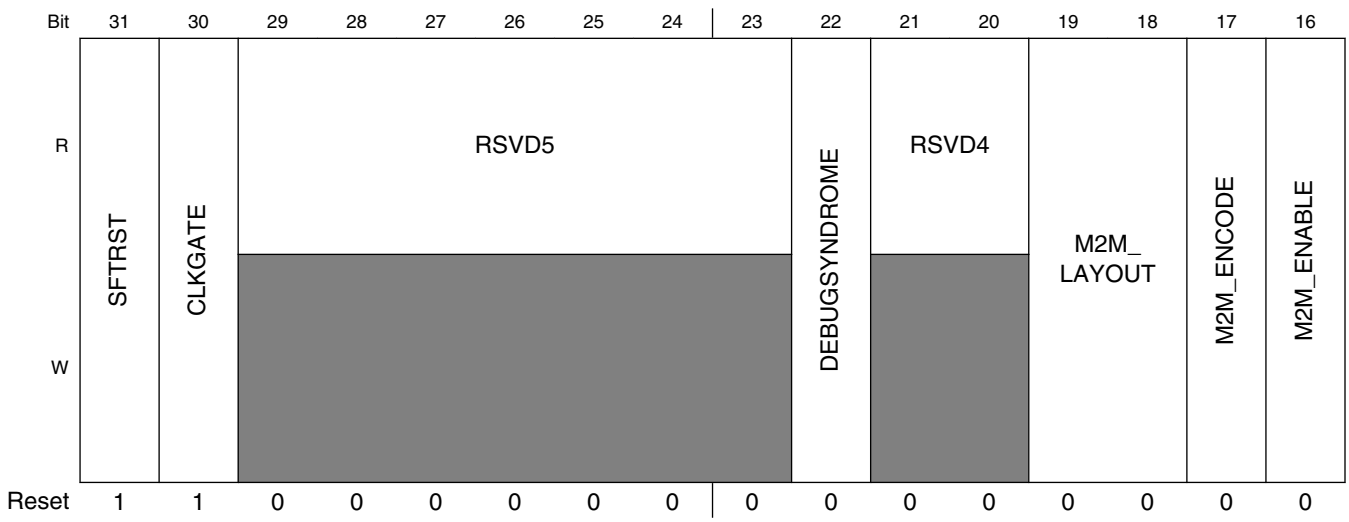
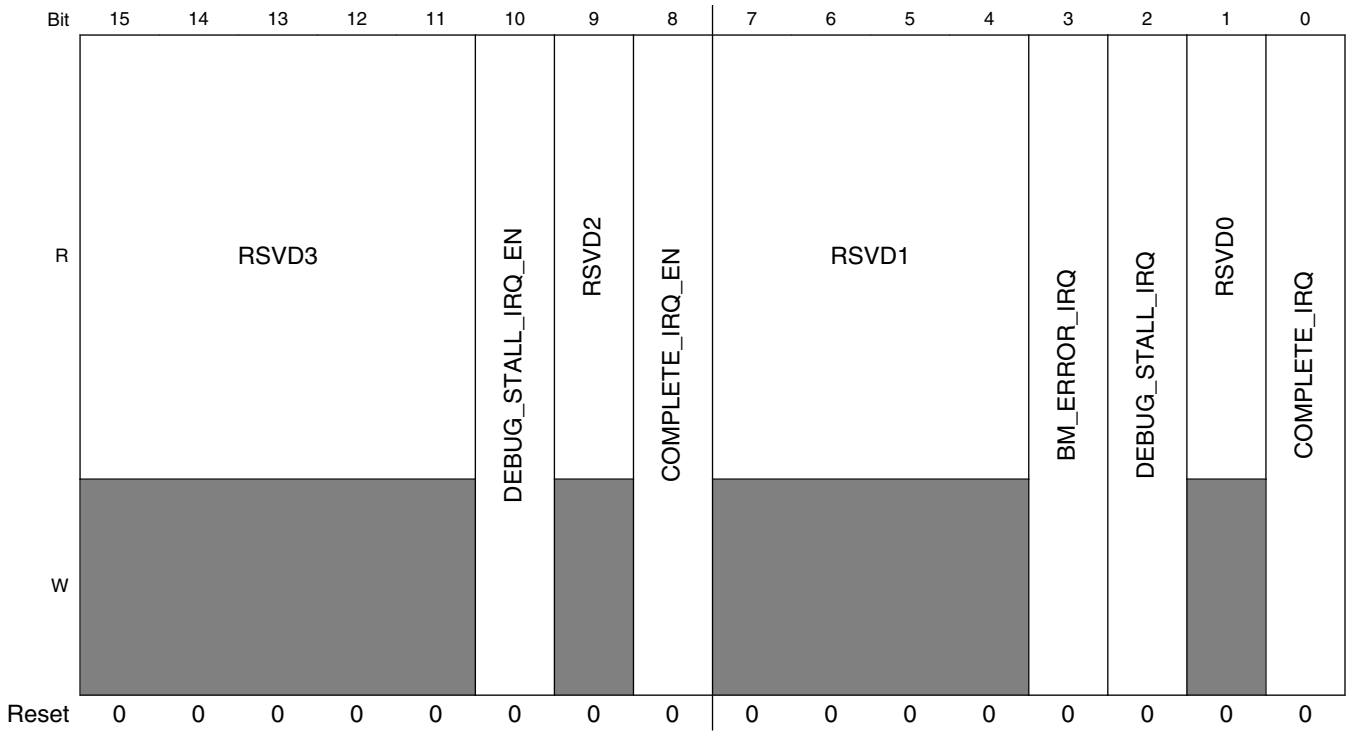
9.6.6.1 Hardware BCH ECC Accelerator Control Register (BCH_CTRL*n*)

The BCH CTRL provides overall control of the hardware ECC accelerator

Address: 3300_4000h base + 0h offset + (4d × i), where i=0d to 3d





BCH_CTRL*n* field descriptions

Field	Description
31 SFTRST	Set this bit to 0 to enable normal BCH operation. Set this bit to 1 (default) to disable clocking with the BCH and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the BCH block to its default state. This bit resets all state machines except for the AHB master state machine 0x0 **RUN** — Allow BCH to operate normally. 0x1 **RESET** — Hold BCH in reset.
30 CLKGATE	This bit must be set to 0 for normal operation. When set to 1 it gates off the clocks to the block. 0x0 **RUN** — Allow BCH to operate normally. 0x1 **NO_CLKS** — Do not clock BCH gates in order to minimize power consumption.
29–23 RSVD5	This field is reserved. This read-only field is reserved and always has the value 0.
22 DEBUGSYNDROME	(For debug purposes only). Enable write of computed syndromes to memory on BCH decode operations. Computed syndromes will be written to the auxiliary buffer after the status block. Syndromes will be written as padded 16-bit values.
21–20 RSVD4	This field is reserved. This read-only field is reserved and always has the value 0
19–18 M2M_LAYOUT	Selects the flash page format for memory-to-memory operations.
17 M2M_ENCODE	Selects encode (parity generation) or decode (correction) mode for memory-to-memory operations.
16 M2M_ENABLE	NOTE! WRITING THIS BIT INITIATES A MEMORY-TO-MEMORY OPERATION. The BCH module must be inactive (not processing data from the GPMI) when this bit is set. The M2M_ENCODE and

Table continues on the next page...

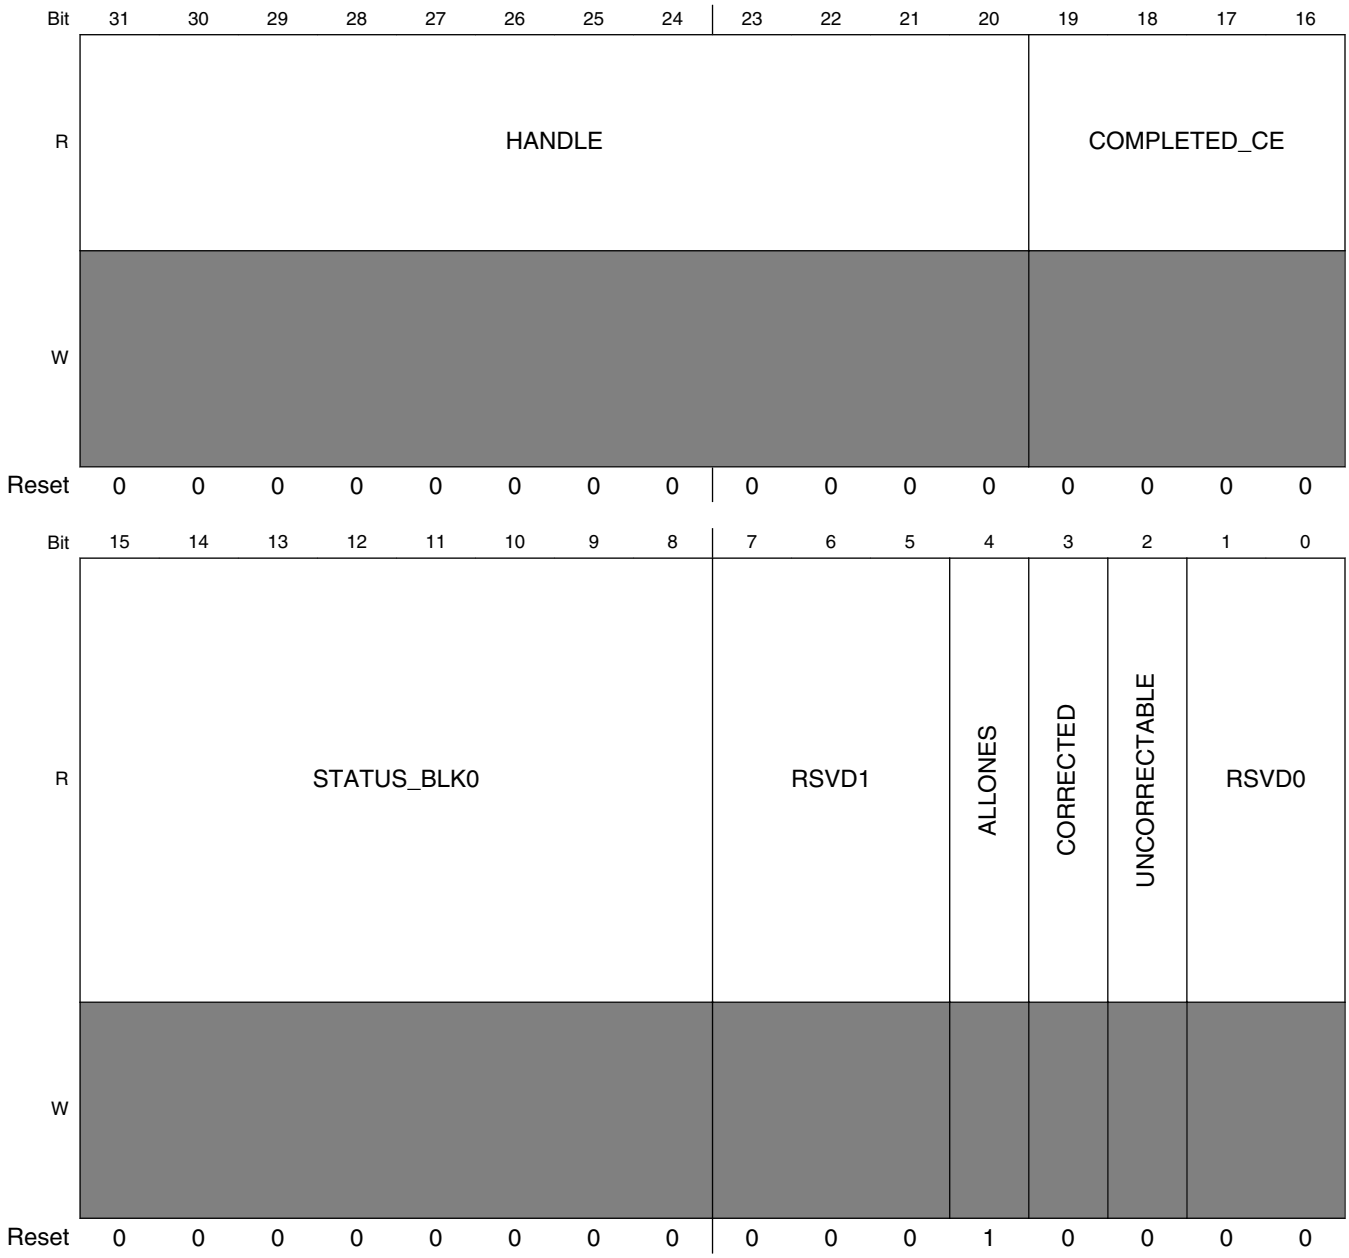
BCH_CTRL*n* field descriptions (continued)

Field	Description
	M2M_LAYOUT bits as well as the ENCODEPTR, DATAPTR, and METAPTR registers are used for memory-to-memory operations and must be correctly programmed before writing this bit.
15–11 RSVD3	This field is reserved. This read-only field is reserved and always has the value 0
10 DEBUG_STALL_ IRQ_EN	1 = interrupt on debug stall mode is enabled. The IRQ is raised on every block
9 RSVD2	This field is reserved. This read-only field is reserved and always has the value 0.
8 COMPLETE_IRQ_ EN	1 = interrupt on completion of correction is enabled.
7–4 RSVD1	This field is reserved. This read-only field is reserved and always has the value 0.
3 BM_ERROR_IRQ	AHB Bus interface Error Interrupt Status. Write a 1 to the SCT clear address to clear the interrupt status bit.
2 DEBUG_STALL_IRQ	DEBUG STALL Interrupt Status. Write a 1 to the SCT clear address to clear the interrupt status bit.
1 RSVD0	This field is reserved. This read-only field is reserved and always has the value 0.
0 COMPLETE_IRQ	This bit indicates the state of the external interrupt line. Write a 1 to the SCT clear address to clear the interrupt status bit. NOTE: subsequent ECC completions will be held off as long as this bit is set. Be sure to read the data from BCH_STATUS0, 1 before clearing this interrupt bit.

9.6.6.2 Hardware ECC Accelerator Status Register 0 (BCH_STATUS0)

The BCH STAT register provides visibility into the run-time status of the BCH and status information when processing is complete. It provides overall status of the hardware ECC accelerator.

Address: 3300_4000h base + 10h offset = 3300_4010h



BCH_STATUS0 field descriptions

Field	Description
31–20 HANDLE	Software supplies a 12 bit handle for this transfer as part of the GPMI DMA PIO operation that started the transaction. That handle passes down the pipeline and ends up here at the time the BCH interrupt is signaled.
19–16 COMPLETED_CE	This is the chip enable number corresponding to the NAND device from which this data came.
15–8 STATUS_BLK0	Count of symbols in error during processing of first block of flash (metadata block). The number of errors reported will be in the range of 0 to the ECC correction level for block 0. 0x00 **ZERO** — No errors found on block.

Table continues on the next page...

BCH_STATUS0 field descriptions (continued)

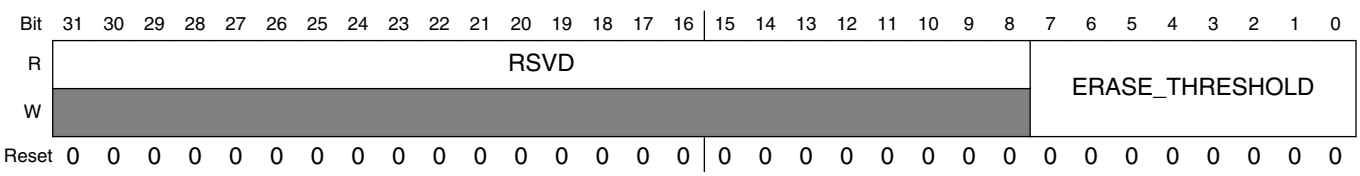
Field	Description
	0x01 **ERROR1** — One error found on block. 0x02 **ERROR2** — One errors found on block. 0x03 **ERROR3** — One errors found on block. 0x04 **ERROR4** — One errors found on block. 0xFE **UNCORRECTABLE** — Block exhibited uncorrectable errors. 0xFF **ERASED** — Page is erased.
7–5 RSVD1	This field is reserved. This read-only field is reserved and always has the value 0.
4 ALLONES	1 = All data bits of this transaction are ONE.
3 CORRECTED	1 = At least one correctable error encountered during last processing cycle.
2 UNCORRECTABLE	1 = Uncorrectable error encountered during last processing cycle.
RSVD0	This field is reserved. This read-only field is reserved and always has the value 0.

9.6.6.3 Hardware ECC Accelerator Mode Register (BCH_MODE)

The BCH MODE register provides additional mode controls.

Contains additional global mode controls for the BCH engine.

Address: 3300_4000h base + 20h offset = 3300_4020h



BCH_MODE field descriptions

Field	Description
31–8 RSVD	This field is reserved. This read-only field is reserved and always has the value 0.
ERASE_ THRESHOLD	This value indicates the maximum number of zero bits on a flash subpage for it to be considered erased. For SLC NAND devices, this value should be programmed to 0 (meaning that the entire page should consist of bytes of 0xFF. For MLC NAND devices, bit errors may occur on reads (even on blank pages), so this threshold can be used to tune the erased page checking algorithm.

9.6.6.4 Hardware BCH ECC Loopback Encode Buffer Register (BCH_ENCODEPTR)

When performing memory to memory operations, indicates the address of the encode buffer. This register should be programmed before writing a 1 to the M2M_ENABLE bit in the CTRL register.

For memory to memory operations, this register is used as the pointer to the encoded data, which is an output when encoding and an input while decoding.

Address: 3300_4000h base + 30h offset = 3300_4030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

BCH_ENCODEPTR field descriptions

Field	Description
ADDR	Address pointer to encode buffer. This is the source for decode operations and the destination for encode operations. This value must be aligned on a 4 bytes boundary.

9.6.6.5 Hardware BCH ECC Loopback Data Buffer Register (BCH_DATAPTR)

When performing memory to memory operations, indicates the address of the data buffer.

For memory to memory operations, this register is used as the pointer to the data to encode or the destination buffer for decode operations.

Address: 3300_4000h base + 40h offset = 3300_4040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

BCH_DATAPTR field descriptions

Field	Description
ADDR	Address pointer to data buffer. This is the source for encode operations and the destination for decode operations. This register should be programmed before writing a 1 to the M2M_ENABLE bit in the CTRL register. This value must be aligned on a 4 byte boundary.

9.6.6.6 Hardware BCH ECC Loopback Metadata Buffer Register (BCH_METAPTR)

When performing memory to memory operations, indicates the address of the metadata buffer.

For memory to memory operations, this register is used as the pointer to the metadata to encode or the extracted metadata for decode operations.

Address: 3300_4000h base + 50h offset = 3300_4050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

BCH_METAPTR field descriptions

Field	Description
ADDR	Address pointer to metadata buffer. This is the source for encode metadata read operations and the destination for metadata decode operations. This register should be programmed before writing a 1 to the M2M_ENABLE bit in the CTRL register. This value must be aligned on a 4 bytes boundary.

9.6.6.7 Hardware ECC Accelerator Layout Select Register (BCH_LAYOUTSELECT)

The BCH LAYOUTSELECT register provides a mapping of chip selects to layout registers.

When the BCH engine receives a request to process a data block from the GPMI interface, it will use this register to map the incoming chip select to one of the four possible flash layout registers

Address: 3300_4000h base + 70h offset = 3300_4070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	CS15_SELECT		CS14_SELECT		CS13_SELECT		CS12_SELECT		CS11_SELECT		CS10_SELECT		CS9_SELECT		CS8_SELECT	
Reset	1	1	1	0	0	1	0	0	1	1	1	0	0	1	0	0

BCH_LAYOUTSELECT field descriptions

Field	Description
31–30 CS15_SELECT	Selects which layout is used for chip select 15.
29–28 CS14_SELECT	Selects which layout is used for chip select 14.
27–26 CS13_SELECT	Selects which layout is used for chip select 13.
25–24 CS12_SELECT	Selects which layout is used for chip select 12.
23–22 CS11_SELECT	Selects which layout is used for chip select 11.
21–20 CS10_SELECT	Selects which layout is used for chip select 10.
19–18 CS9_SELECT	Selects which layout is used for chip select 9.
17–16 CS8_SELECT	Selects which layout is used for chip select 8.
15–14 CS7_SELECT	Selects which layout is used for chip select 7.
13–12 CS6_SELECT	Selects which layout is used for chip select 6.
11–10 CS5_SELECT	Selects which layout is used for chip select 5.
9–8 CS4_SELECT	Selects which layout is used for chip select 4.
7–6 CS3_SELECT	Selects which layout is used for chip select 3.
5–4 CS2_SELECT	Selects which layout is used for chip select 2.
3–2 CS1_SELECT	Selects which layout is used for chip select 1.
CS0_SELECT	Selects which layout is used for chip select 0.

9.6.6.8 Hardware BCH ECC Flash 0 Layout 0 Register (BCH_FLASH0LAYOUT0)

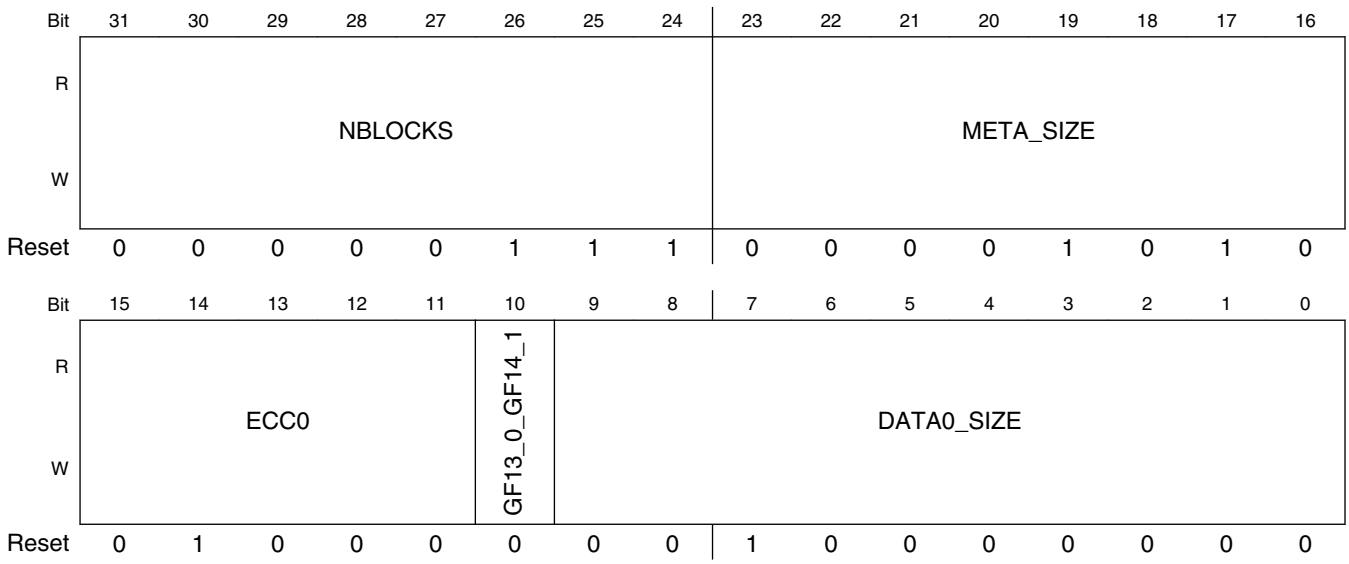
The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH0LAYOUT1 register to control the format for the devices selecting layout 0 in the LAYOUTSELECT register.

Each pair of layout registers describes one of four supported flash configurations. Software should program the LAYOUTSELECT register for each supported GPMI chip select to select from one of the four layout values. Each pair of registers contains settings that are used by the BCH block while reading / writing the flash page to control data,

metadata, and flash page sizes as well as the ECC correction level. The first block written to flash can be programmed to have different ECC, metadata, and data sizes from subsequent data blocks on the device. In addition, the number of blocks stored on a page of flash is not fixed, but instead is determined by the number of bytes consumed by the initial (block 0) and subsequent data blocks.

See sections Flash Page Layout and Determining the ECC layout for a device for more detail information on setting up the flash layout registers.

Address: 3300_4000h base + 80h offset = 3300_4080h



BCH_FLASH0LAYOUT0 field descriptions

Field	Description
31–24 NBLOCKS	Number of subsequent blocks on the flash page (excluding the data0 block). A value of 0 indicates that only the DATA0 block is present and a value of 8 indicates that 8 subsequent blocks are present for a total of 9 blocks on the flash (including the DATA0 block). Any values from 0 to 255 are supported by the hardware.
23–16 META_SIZE	Indicates the size of the metadata (in bytes) to be stored on a flash page. The BCH design support from 0 to 255 bytes for metadata—if set to 0, no metadata will be stored. Metadata is stored before the associated data in block 0. If the DATA0_SIZE field is programmed to a 0, then metadata effectively be stored with its own parity. When both the metadata and data0 fields are programmed with non-zero values, the first block will contain both portions of data and covered by a single parity block.
15–11 ECC0	Indicates the ECC level for the first block on the flash page. The first block covers metadata plus the associated data from the DATA0_SIZE field. 0x0 **NONE** — No ECC to be performed 0x1 **ECC2** — ECC 2 to be performed 0x2 **ECC4** — ECC 4 to be performed : — 0x1E **ECC60** — ECC 60 to be performed 0x1F **ECC62** — ECC 62 to be performed
10 GF13_0_GF14_1	Select GF13 or GF14: 0-GF13; 1-GF14

Table continues on the next page...

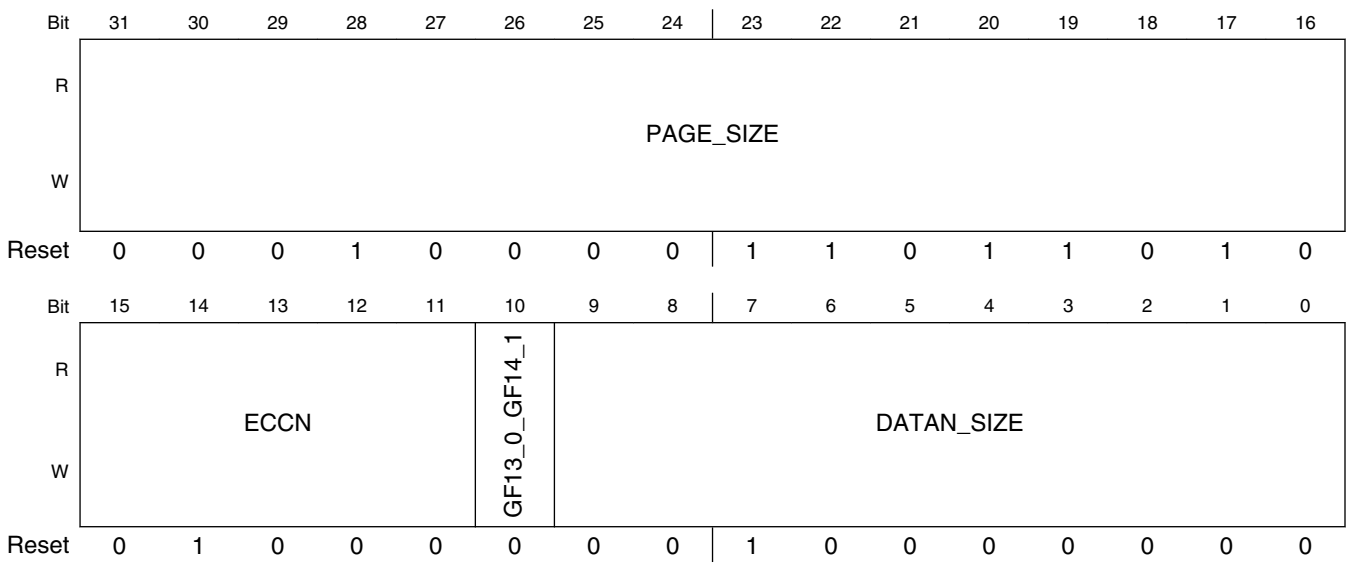
BCH_FLASH0LAYOUT0 field descriptions (continued)

Field	Description
DATA0_SIZE	Indicates the size of the data 0 block (in DWORDS / four bytes) to be stored on the flash page. If set to 0, the first block only contains metadata.

9.6.6.9 Hardware BCH ECC Flash 0 Layout 1 Register (BCH_FLASH0LAYOUT1)

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH0LAYOUT0 register to control the format for the device selecting layout 0 in the LAYOUTSELECT register.

Address: 3300_4000h base + 90h offset = 3300_4090h



BCH_FLASH0LAYOUT1 field descriptions

Field	Description
31–16 PAGE_SIZE	Indicates the total size of the flash page (in bytes). This should be set to the page size including spare area. The page size is programmable to accomodate different flash configurations that may be available in the future.
15–11 ECCN	Indicates the ECC level for the subsequent blocks on the flash page (blocks 1-n). Subsequent blocks only contain data (no metadata). 0x0 **NONE** — No ECC to be performed 0x1 **ECC2** — ECC 2 to be performed 0x2 **ECC4** — ECC 4 to be performed : —

Table continues on the next page...

BCH_FLASH0LAYOUT1 field descriptions (continued)

Field	Description
	0x1E **ECC60** — ECC 60 to be performed 0x1F **ECC62** — ECC 62 to be performed
10 GF13_0_GF14_1	Select GF13 or GF14: 0-GF13; 1-GF14
DATAN_SIZE	Indicates the size of the subsequent data blocks (in DWORDS / four bytes) to be stored on the flash page. The size of subsequent data blocks does not have to match the data size for block 0, which is important when metadata is stored separately or for balancing the amount of data stored in each block.

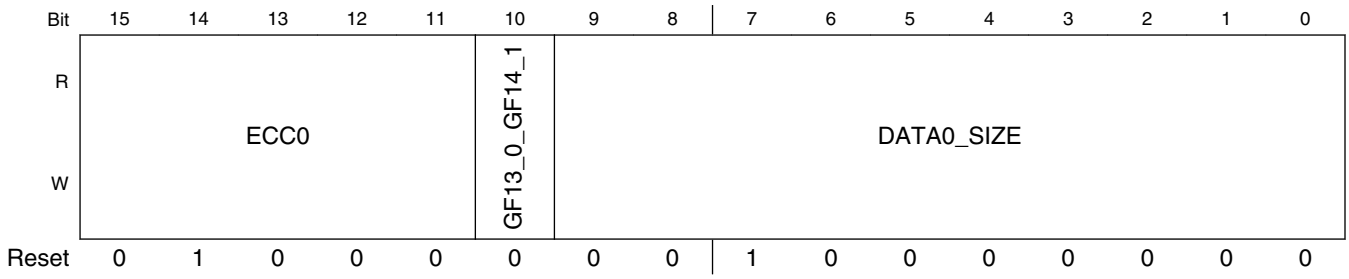
9.6.6.10 Hardware BCH ECC Flash 1 Layout 0 Register (BCH_FLASH1LAYOUT0)

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH1LAYOUT1 register to control the format for the devices selecting layout 1 in the LAYOUTSELECT register.

Each pair of layout registers describes one of four supported flash configurations. Software should program the LAYOUTSELECT register for each supported GPMI chip select to select from one of the four layout values. Each pair of registers contains settings that are used by the BCH block while reading / writing the flash page to control data, metadata, and flash page sizes as well as the ECC correction level. The first block written to flash can be programmed to have different ECC, metadata, and data sizes from subsequent data blocks on the device. In addition, the number of blocks stored on a page of flash is not fixed, but instead is determined by the number of bytes consumed by the initial (block 0) and subsequent data blocks.

See sections Flash Page Layout and Determining the ECC layout for a device for more detail information on setting up the flash layout registers.

Address: 3300_4000h base + A0h offset = 3300_40A0h



BCH_FLASH1LAYOUT0 field descriptions

Field	Description
31–24 NBLOCKS	Number of subsequent blocks on the flash page (excluding the data0 block). A value of 0 indicates that only the DATA0 block is present and a value of 8 indicates that 8 subsequent blocks are present for a total of 9 blocks on the flash (including the DATA0 block). Any values from 0 to 255 are supported by the hardware.
23–16 META_SIZE	Indicates the size of the metadata (in bytes) to be stored on a flash page. The BCH design supports from 0 to 255 bytes for metadata—if set to 0, no metadata will be stored. Metadata is stored before the associated data is in block 0. If the DATA0_SIZE field is programmed to a 0, then metadata effectively be stored with its own parity. When both the metadata and data0 fields are programmed with non-zero values, the first block will contain both portions of data and covered by a single parity block.
15–11 ECC0	Indicates the ECC level for the first block on the flash page. The first block covers metadata plus the associated data from the DATA0_SIZE field. 0x0 **NONE** — No ECC to be performed 0x1 **ECC2** — ECC 2 to be performed 0x2 **ECC4** — ECC 4 to be performed : — 0x1E **ECC60** — ECC 60 to be performed 0x1F **ECC62** — ECC 62 to be performed
10 GF13_0_GF14_1	Select GF13 or GF14: 0-GF13; 1-GF14
DATA0_SIZE	Indicates the size of the data 0 block (in DWORDS / four bytes) to be stored on the flash page. If set to 0, the first block will contains metadata.

9.6.6.11 Hardware BCH ECC Flash 1 Layout 1 Register (BCH_FLASH1LAYOUT1)

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH1LAYOUT0 register to control the format for the device selecting layout 1 in the LAYOUTSELECT register.

Address: 3300_4000h base + B0h offset = 3300_40B0h

BCH_FLASH1LAYOUT1 field descriptions

Field	Description
31–16 PAGE_SIZE	Indicates the total size of the flash page (in bytes). This should be set to the page size including spare area. The page size is programmable to accomodate different flash configurations that may be available in the future.
15–11 ECCN	Indicates the ECC level for the subsequent blocks on the flash page (blocks 1-n). Subsequent blocks only contain data (no metadata). 0x0 **NONE** — No ECC to be performed 0x1 **ECC2** — ECC 2 to be performed 0x2 **ECC4** — ECC 4 to be performed : — 0x1E **ECC60** — ECC 60 to be performed 0x1F **ECC62** — ECC 62 to be performed
10 GF13_0_GF14_1	Select GF13 or GF14: 0-GF13; 1-GF14
DATAN_SIZE	Indicates the size of the subsequent data blocks (in DWORDS / four bytes) to be stored on the flash page. The size of subsequent data blocks does not have to match the data size for block 0, which is important when metadata is stored separately or for balancing the amount of data stored in each block.

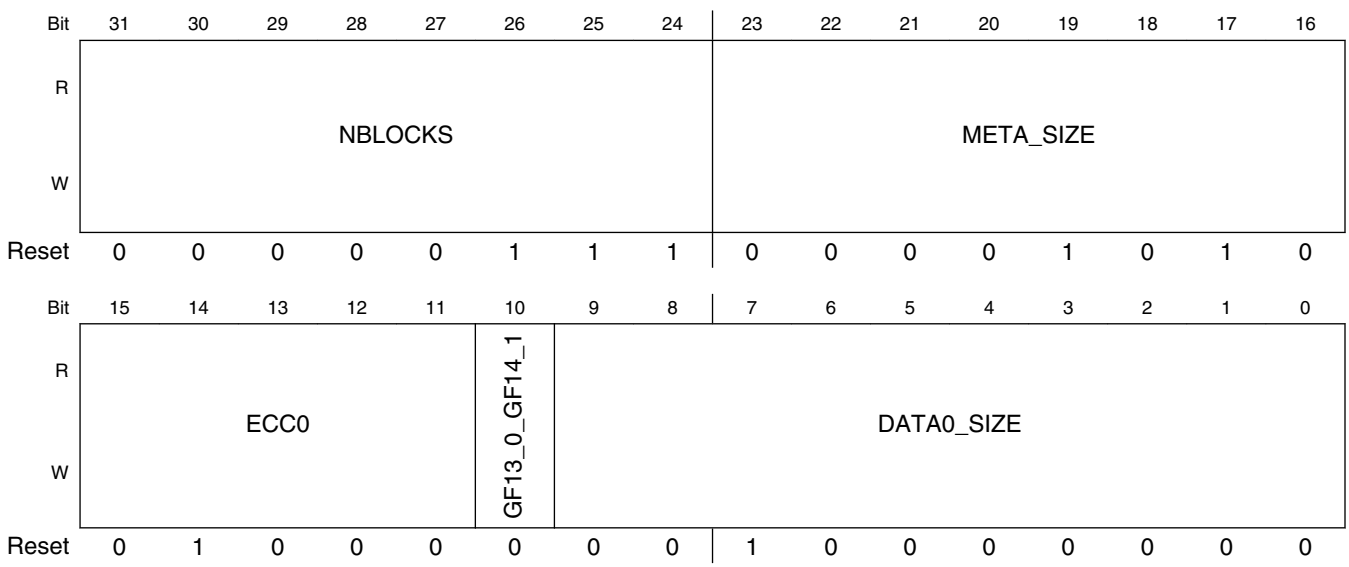
9.6.6.12 Hardware BCH ECC Flash 2 Layout 0 Register (BCH_FLASH2LAYOUT0)

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH2LAYOUT1 register to control the format for the devices selecting layout 2 in the LAYOUTSELECT register.

Each pair of layout registers describes one of four supported flash configurations. Software should program the LAYOUTSELECT register for each supported GPMI chip select to select from one of the four layout values. Each pair of registers contains settings that are used by the BCH block while reading / writing the flash page to control data, metadata, and flash page sizes as well as the ECC correction level. The first block written to flash can be programmed to have different ECC, metadata, and data sizes from subsequent data blocks on the device. In addition, the number of blocks stored on a page of flash is not fixed, but instead is determined by the number of bytes consumed by the initial (block 0) and subsequent data blocks.

See sections Flash Page Layout and Determining the ECC layout for a device for more detail information on setting up the flash layout registers.

Address: 3300_4000h base + C0h offset = 3300_40C0h



BCH_FLASH2LAYOUT0 field descriptions

Field	Description
31–24 NBLOCKS	Number of subsequent blocks on the flash page (excluding the data0 block). A value of 0 indicates that only the DATA0 block is present and a value of 8 indicates that eight subsequent blocks are present for a total of nine blocks on the flash (including the DATA0 block). Any values from 0 to 255 are supported by the hardware.

The size of subsequent data blocks does not have to match the data size for block 0, which is important when metadata is stored separately or for balancing the amount of data stored in each block.

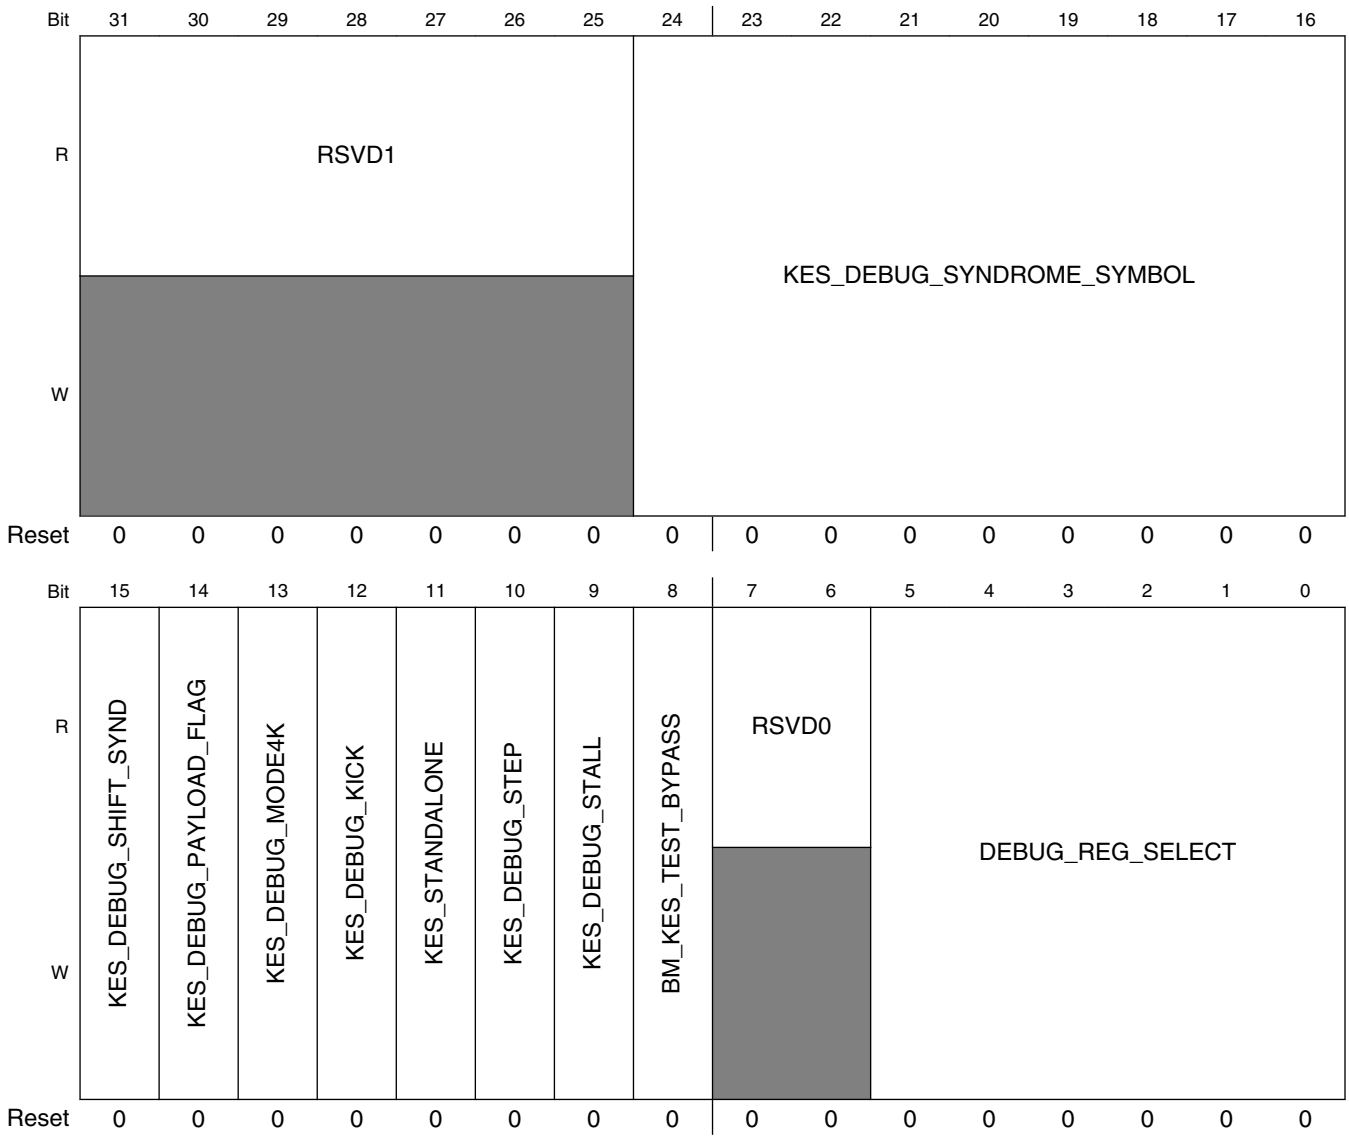
9.6.6.16 Hardware BCH ECC Debug Register0 (BCH_DEBUG0*n*)

The hardware BCH accelerator internal state machines and signals can be seen in the ECC debug register.

The BCH_DEBUG0 register provides access to various internal state information which might prove useful during hardware debug and validation.

Address: 3300_4000h base + 100h offset + (4d × i), where i=0d to 3d



BCH_DEBUG0*n* field descriptions

Field	Description
31–25 RSVD1	This field is reserved.

Table continues on the next page...

BCH_DEBUG0*n* field descriptions (continued)

Field	Description
	This read-only field is reserved and always has the value 0.
24–16 KES_DEBUG_ SYNDROME_ SYMBOL	The 9 bit value in this bit field shifts into the syndrome register array at the input of the KES engine whenever BCH_DEBUG0_KES_DEBUG_SHIFT_SYND is toggled. 0x0 **NORMAL** — Bus master address generator for SYND_GEN writes operates normally. 0x1 **TEST_MODE** — Bus master address generator always addresses last four bytes in Auxiliary block.
15 KES_DEBUG_ SHIFT_SYND	Toggling this bit causes the value in BCH_DEBUG0_KES_SYNDROME_SYMBOL to be shift into the syndrome register array at the input to the KES engine. After shifting in 16 symbols, one can kick off both KES and CF cycles by toggling BCH_DEBUG0_KES_DEBUG_KICK. Make sure that set KES_BCH_DEBUG0_KES_STANDALONE mode to 1 before kicking.
14 KES_DEBUG_ PAYLOAD_FLAG	When running the stand alone debug mode on the error calculator, the state of this bit is presented to the KES engine as the input payload flag. 0x1 **DATA** — Payload is set for 512 bytes data block. 0x1 **AUX** — Payload is set for 65 or 19 bytes auxiliary block.
13 KES_DEBUG_ MODE4K	When running the stand alone debug mode on the error calculator, the state of this bit is presented to the KES engine as the input mode (4K or 2K pages). 0x1 **4k** — Mode is set for 4K NAND pages. 0x1 **2k** — Mode is set for 2K NAND pages.
12 KES_DEBUG_ KICK	Toggling causes KES engine FSM to start as if kick by the Bus Master. This allows stand alone testing of the KES and Chien Search engines. Be sure to set KES_BCH_DEBUG0_KES_STANDALONE mode to 1 before kicking.
11 KES_ STANDALONE	Set to one, cause the KES engine to suppress toggling the KES_BM_DONE signal to the bus master and suppress toggling the CF_BM_DONE signal by the CF engine. 0x0 **NORMAL** — Bus master address generator for SYND_GEN writes operates normally. 0x1 **TEST_MODE** — Bus master address generator always addresses last four bytes in Auxiliary block.
10 KES_DEBUG_ STEP	Toggling this bit causes the KES FSM to skip passed the stall state if it is in DEBUG_STALL mode and completed processing a block.
9 KES_DEBUG_ STALL	Set to one to cause KES FSM to stall after notifying Chien search engine to start processing its block but before notifying the bus master that the KES computation is complete. This allows a diagnostic to stall the FSM after each blocks key equations are solved. This also has the effect of stalling the CSFE search engine so it's state can be examined after it finishes processing the KES stalled block. 0x0 **NORMAL** — KES FSM proceeds to next block supplied by bus master. 0x1 **WAIT** — KES FSM waits after current equations are solved and the search engine is started.
8 BM_KES_TEST_ BYPASS	1 = Point all SYND_GEN writes to dummy area at the end of the AUXILLIARY block so that diagnostics can preload all payload, parity bytes and computed syndrome bytes for test the KES engine. 0x0 **NORMAL** — Bus master address generator for SYND_GEN writes operates normally. 0x1 **TEST_MODE** — Bus master address generator always addresses last four bytes in Auxiliary block.
7–6 RSVD0	This field is reserved. This read-only field is reserved and always has the value 0.
DEBUG_REG_ SELECT	The value loaded in this bit field is used to select the internal register state view of KES engine or the Chien search engine.

9.6.6.17 KES Debug Read Register (BCH_DBGKESREAD)

The hardware BCH ECC accelerator key equation solver internal state machines and signals can be seen in the ECC debug registers.

Address: 3300_4000h base + 110h offset = 3300_4110h

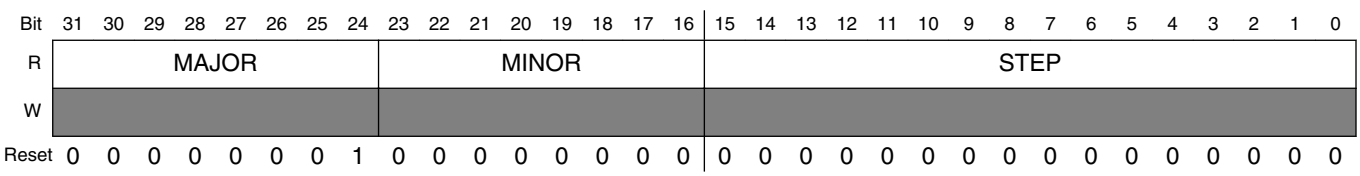
BCH_BLOCKNAME field descriptions

Field	Description
NAME	The name is in the ASCII characters BCH (0x20, H, C, B).

9.6.6.22 BCH Version Register (BCH_VERSION)

This register always returns a known read value for debug purposes and indicates the version of the block and RTL version in use.

Address: 3300_4000h base + 160h offset = 3300_4160h



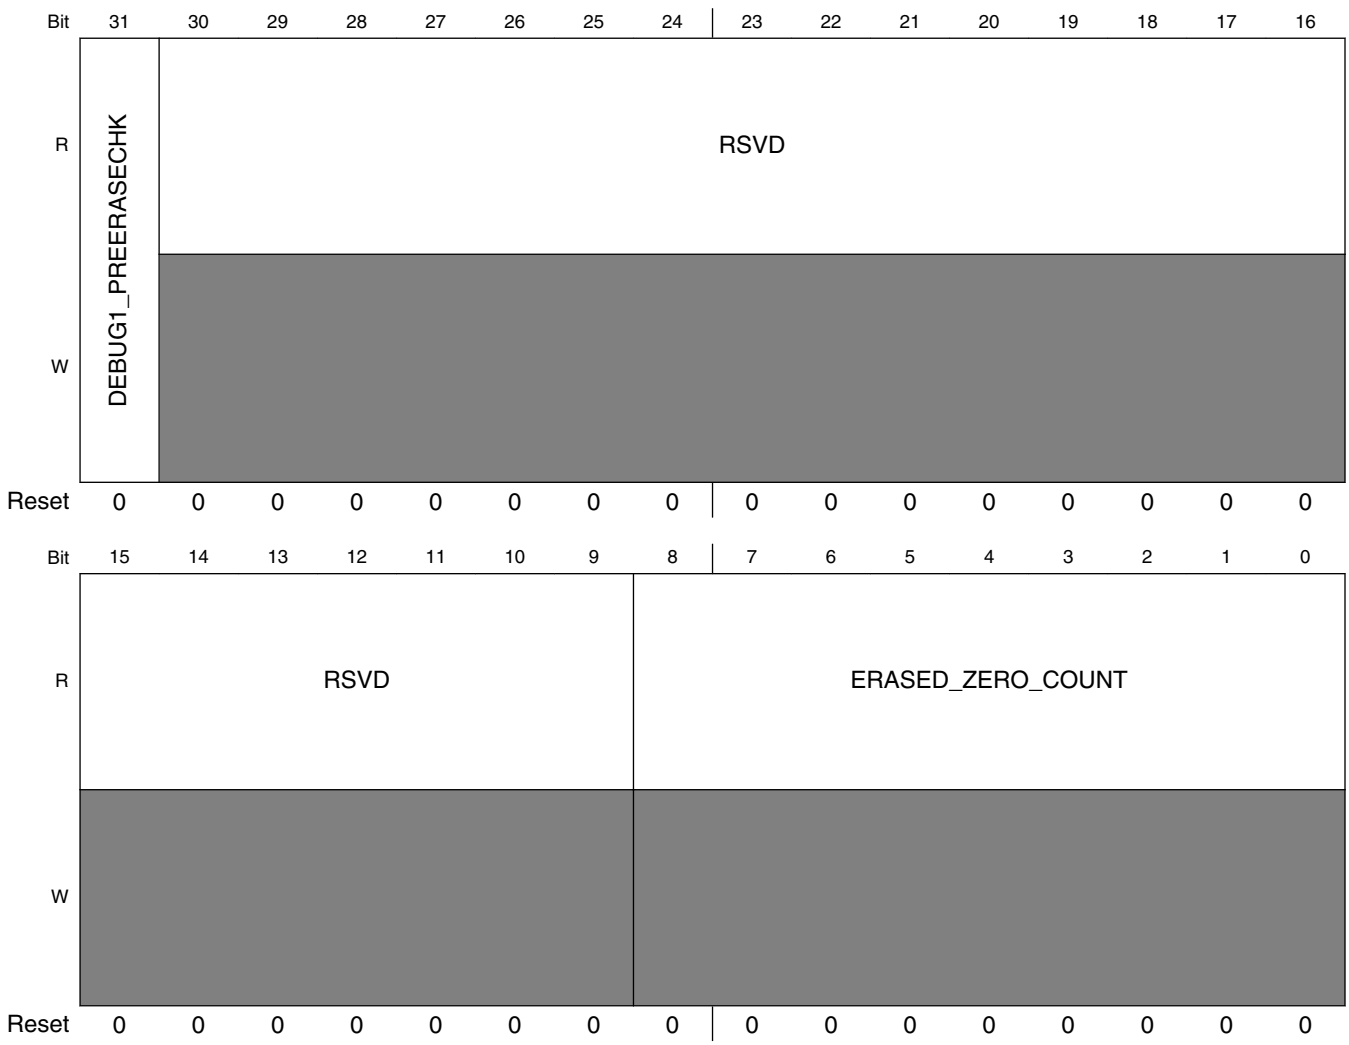
BCH_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value indicates the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value indicates the MINOR field of the RTL version.
STEP	Fixed read-only value reflecting the stepping of the RTL version.

9.6.6.23 Hardware BCH ECC Debug Register 1 (BCH_DEBUG1)

The BCH_DEBUG1 register provides erased zero count information and pre-erase check.

Address: 3300_4000h base + 170h offset = 3300_4170h



BCH_DEBUG1 field descriptions

Field	Description
31 DEBUG1_ PREERASECHK	Blank page enables pre-erase check. 0x0 Turn off pre-erase check 0x1 Turn on pre-erase check
30–9 RSVD	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

BCH_DEBUG1 field descriptions (continued)

Field	Description
ERASED_ ZERO_COUNT	The zero counts on one page.

9.7 General Purpose Media Interface (GPMI)

9.7.1 Overview

The GPMI controller is a flexible interface to supporting up to four NAND flash chip selects.

- ONFI3.2, DDR Mode, Samsung / Toshiba Toggle NAND protocol compatible.
- Fully configurable address and command behavior, providing support for future devices not yet specified.

The GPMI resides on the APBH. The GPMI also provides an interface to the BCH module to allow direct parity processing.

Registers are clocked on the HCLK domain. The I/O and pin timing are clocked on a dedicated GPMICLK domain. GPMICLK can be set to maximize I/O performance.

The following figure shows a block diagram of the GPMI controller.

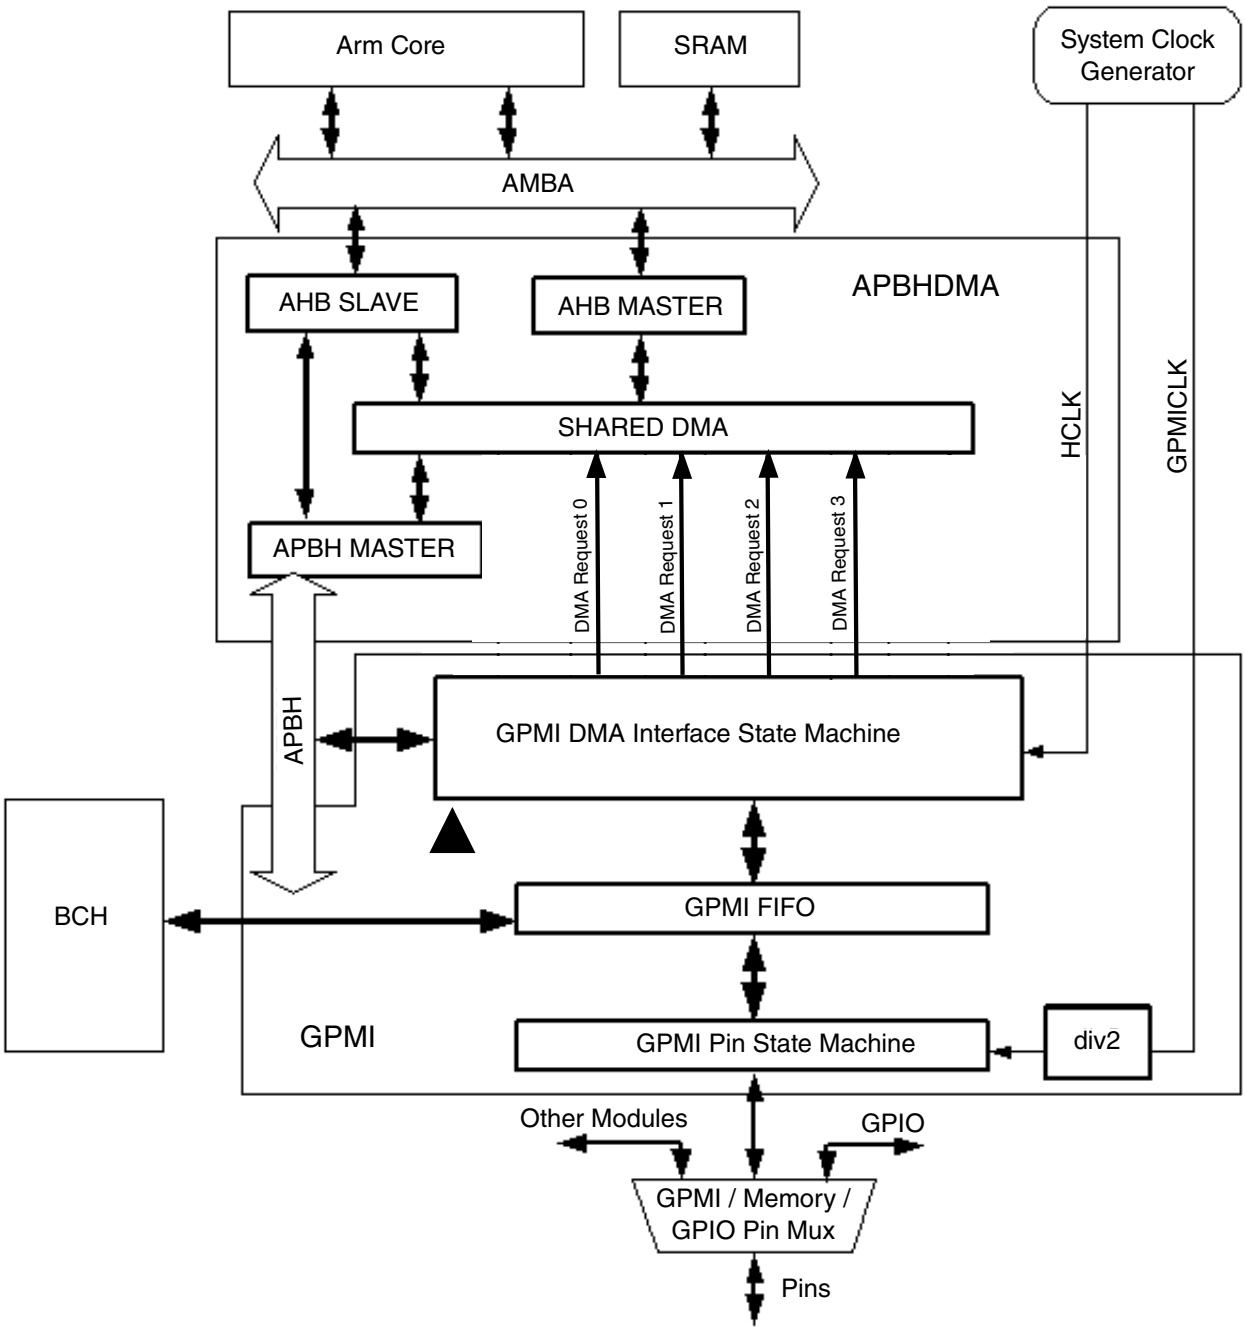


Figure 9-20. General-Purpose Media Interface Controller Block Diagram

9.7.2 Clocks

The table found here describes the clock sources for GPMI.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 9-12. GPMI Clocks

Clock name	Clock Root	Description
bch_input_apb_clk		BCH to APBH input clock
gpmi_bch_input_bch_clk		BCH input clock
gpmi_bch_input_gpmi_io_clk		GPMI IO input clock
gpmi_input_apb_clk		GPMI to APBH clock

9.7.3 GPMI NAND Mode

The general-purpose media interface has several features to efficiently support NAND:

- Individual chip select pins and ganged ready/busy pin for up to four NANDs.
- Individual state machine and DMA channel for each chip select.
- Special command modes work with DMA controller to perform all normal NAND functions without CPU intervention.
- Configurable timing based on a dedicated clock allows optimal balance of high NAND performance and low system power.

GPMI and DMA have been designed to handle complex multi-page operations without CPU intervention. The DMA uses a linked descriptor function with branching capability to automatically handle all of the operations needed to read/write multiple pages:

- **Data/Register Read/Write**-The GPMI can be programmed to read or write multiple cycles to the NAND address, command or data registers.
- **Wait for NAND Ready**-The GPMI's Wait-for-Ready mode can monitor the ready/busy signal of a single NAND flash and signal the DMA when the device has become ready. It also has a time-out counter and can indicate to the DMA that a time-out error has occurred. The DMAs can conditionally branch to a different descriptor in the case of an error.
- **Check Status**-The Read-and-Compare mode allows the GPMI to check NAND status against a reference. If an error is found, the GPMI can instruct the DMA to branch to an alternate descriptor, which attempts to fix the problem or asserts a CPU IRQ.

9.7.3.1 Multiple NAND Support

The GPMI supports up to four NAND chip selects, with ganged ready/busy pins. Since they share a data bus and control lines, the GPMI can only actively communicate with a single NAND at a time. However, all NANDs can concurrently perform internal read, write, or erase operations. With fast NAND flash and software support for concurrent NAND operations, this architecture allows the total throughput to approach the data bus speed, which can be as high as 50 MB/s (8-bit bus running at 50 MHz single clock edge) in asynchronous mode and 200MB/s (8-bit bus running at 100MHz both clock edges) in Source Synchronous mode.

There are two options for controlling the four NAND chip selects via the DMA interface. The first option is the one to one mapping, where the each DMA channel is tied to its own NAND chip select. For example DMA channel 'n' accesses only NAND attached to chip select 'n'. The second option is the decoupled mode where a DMA channel can access any or all NAND chip selects connected to the GPMI. A DMA channel will signify the NAND chip select it wants to access by writing its chip select value in the GPMI_CTRL0[CS] field and setting the GPMI_CTRL1[DECOUPLE_CS] to 1. This option is useful if software chooses to use only one DMA channel to access all the attached NAND devices.

9.7.3.2 GPMI NAND Timing and Clocking

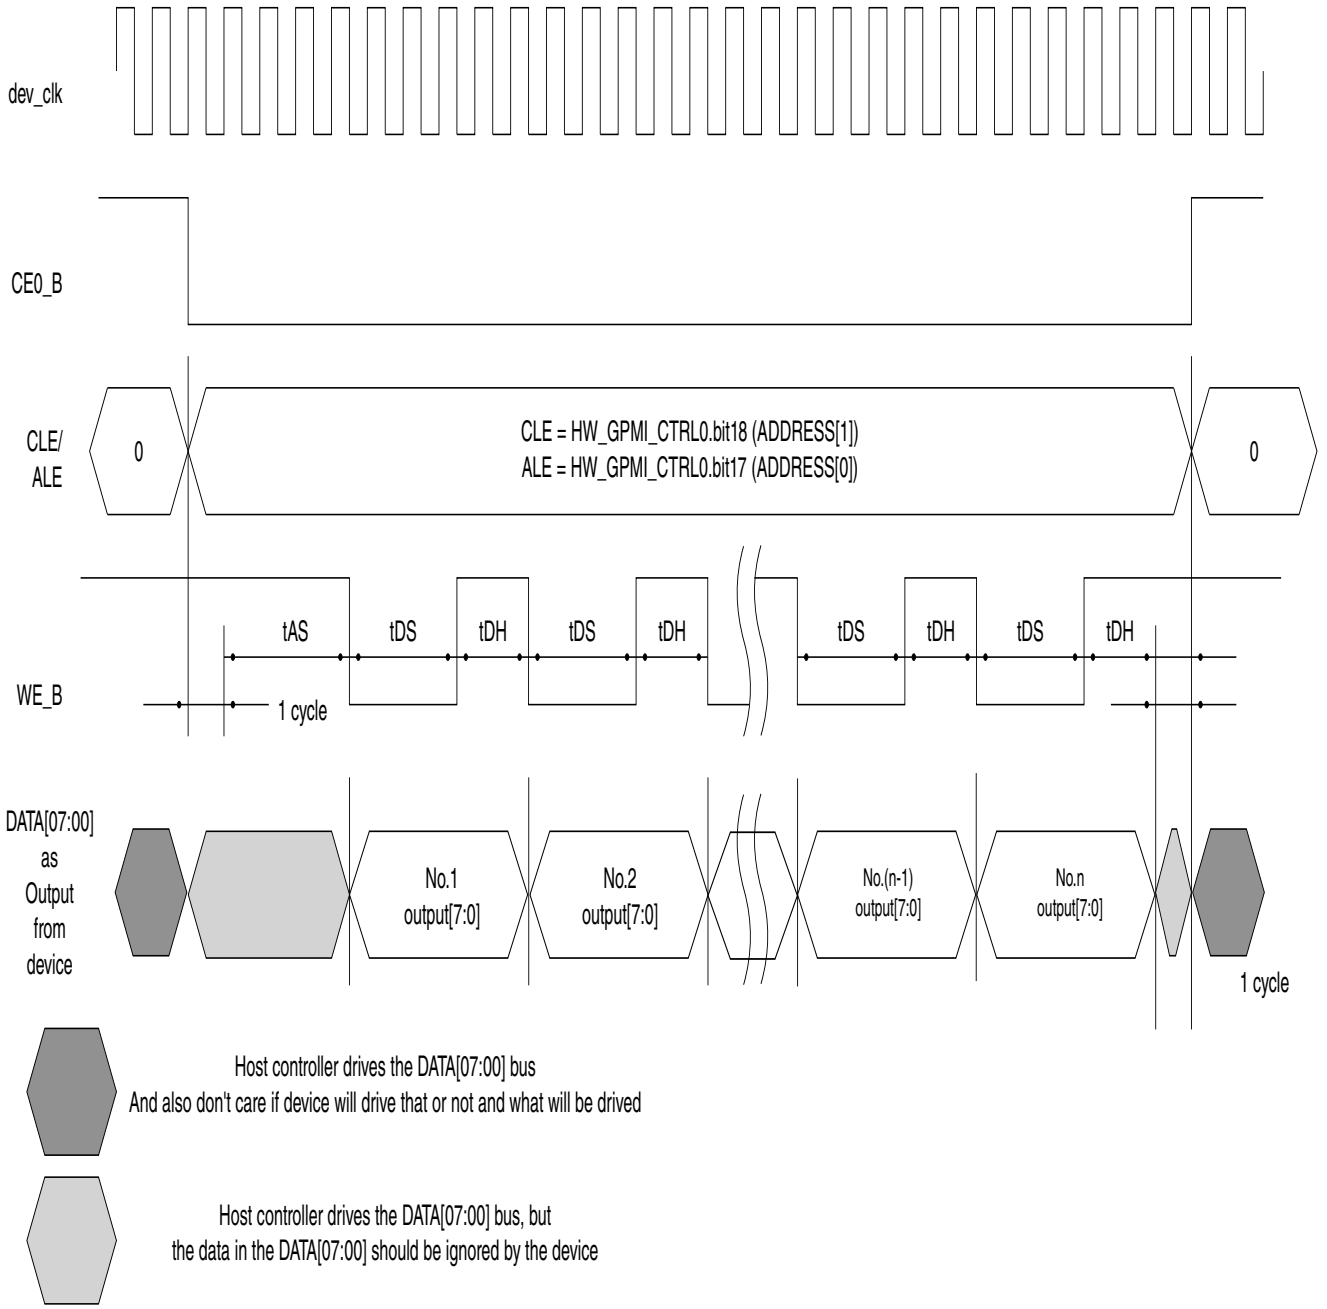
The dedicated clock, GPMICLK, is used as a timing reference for NAND flash I/O. Since various NANDs have different timing requirements, GPMICLK may need to be adjusted for each application.

While the actual pin timings are limited by the NAND chips used and the I/O pad configuration, the GPMI can support data bus speeds of up to 200 MHz x 8 bits. The actual read/write strobe timing parameters are adjusted as indicated in the register descriptions in Memory Map.

9.7.3.3 Basic NAND Timing

9.7.3.3.1 NAND Asynchronous Timing

Figure 9-22 and illustrates the operation of the output (from host to device) timing parameters in NAND ONFI asynchronous mode.



- tAS is configurable by programming HW_GPMI_TIMING0 Address_Setup: in this example, Address_Setup = 4, tAS is equal to 4 dev_clk cycles.
- tDS is configurable by programming HW_GPMI_TIMING0 Data_Setup; in this example, Data_Setup = 3, tDS is equal to 3 dev_clk cycles
- tDH is configuarble by programming HW_GPMI_TIMING0 Data_Hold: in this example, Data_Hold = 2, tDH is equal to 2 dev_clk cycles
- tAS/tDS/tDH will extend, if the output data is not ready in device fifo.

Figure 9-21. Asynchronous Mode Basic Write Timing Diagram (command write, address write, or data write

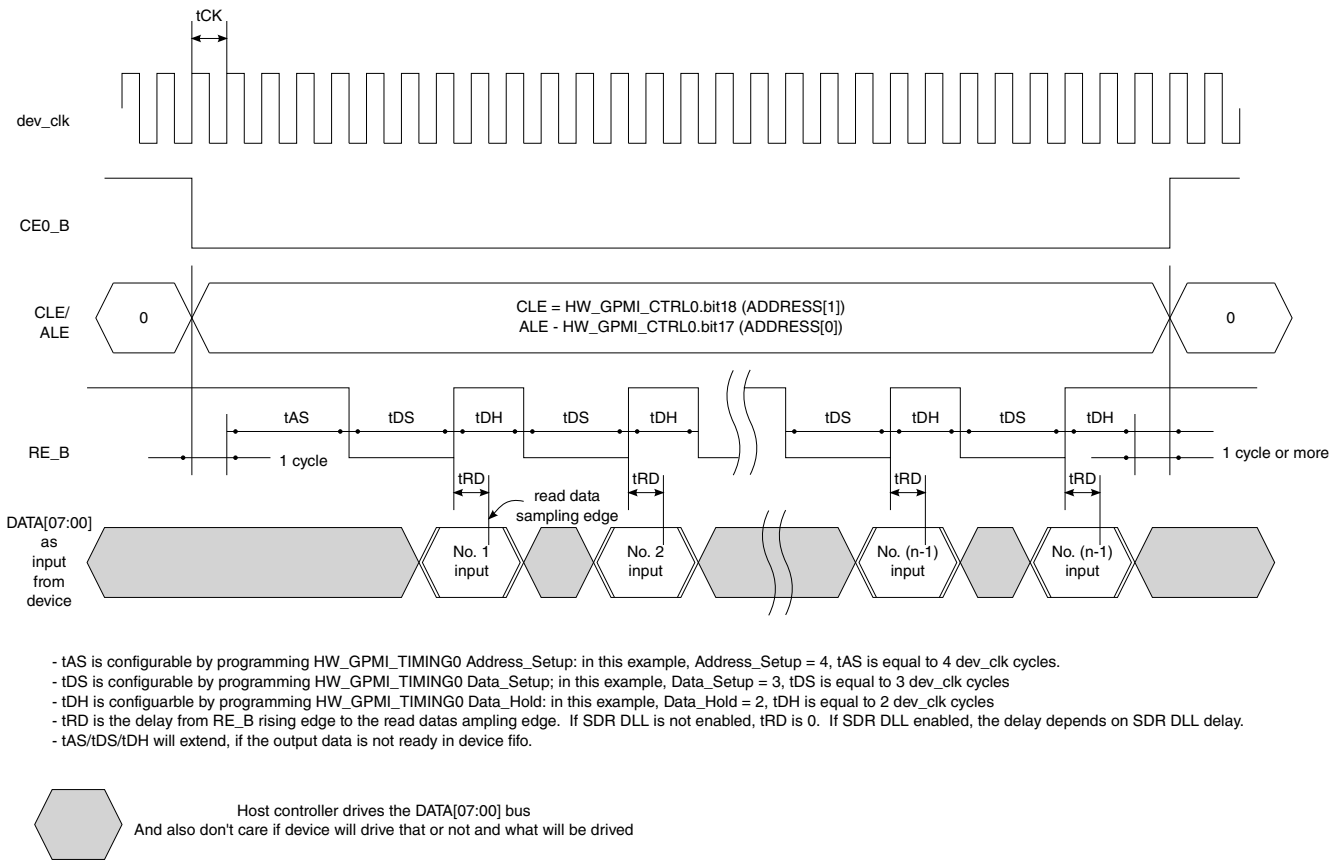


Figure 9-22. ONFI Asynchronous Mode Basic Read Timing Diagram (data read)

9.7.3.3.2 NAND Asynchronous EDO Mode Timing

In high-speed NANDS, the read data may not be valid until after the read strobe (NAND_RE_B) deasserts. This is the case when the minimum tDS is programmed to achieve higher bandwidth.

The GPMI implements a feedback read strobe to sample the read data. The feedback read strobe can be delayed to support fast nand EDO (Extended Data Out) timing where the read strobe may deassert before the read data is valid, and read data is valid for some time after read strobe. Nand EDO timings is applied typically for read cycle frequency above 33 MHz. See Figure 9-23.

The GPMI provides control over the amount of delay applied to the feedback read strobe. This delay depends on the maximum read access time (tREA) of the nand and the read pulse width (tRP) used to access the nand. tRP is specified by GPMI_TIMING0[DATA_SETUP] register. When (tREA + 4ns) is less than tRP, no

delay is required to sample to nand read data. (The 4ns provides adequate data setup time for the GPMI.) In this case set GPMI_CTRL1[HALF_PERIOD] = 0; GPMI_CTRL1[RDN_DELAY] = 0; GPMI_CTRL1[DLL_ENABLE] = 0.

When (tREA + 4ns) is greater than or equal to tRP, a delay of the feedback read strobe is required to sample to nand read data. This delay is equal to the difference between these two timings:

DELAY = tREA + 4ns - tRP.

Since the GPMI delay chain is limited to 6ns maximum, if DELAY > 6ns then increase tRP by increasing the value of GPMI_TIMING0[DATA_SETUP] until DELAY is less than or equal to 6ns.

The GPMI programming for this DELAY depends on the GPMICLK period. The GPMI DLL will not function properly if the GPMICLK period is greater than 12ns: disable the DLL if this is the case. If the GPMICLK period is greater than 6ns (and not greater than 12ns), set the GPMI_CTRL1[HALF_PERIOD]=1; This will cause the DLL reference period (RP) to be one-half of the GPMICLK period. If the GPMICLK period is 6ns or less then set the GPMI_CTRL1[HALF_PERIOD]=0; This will cause the DLL reference period (RP) to be equal to the GPMICLK period. DELAY is a multiple (0 to 1.875) of RP.

The GPMI_CTRL1[RDN_DELAY] is encoded as a 1-bit integer and 3-bit fraction delay factor. DELAY is a multiple of the delay factor and the reference period. See table below for details.

Table 9-13. RDN DELAY

HW_GPMI_CTRL1[RDN_DELAY]	Delay Factor
0	0.000
1	0.125
2	0.250
3	0.375
4	0.500
5	0.625
6	0.750
7	0.875
8	1.000
9	1.125
10	1.250
11	1.375
12	1.500
13	1.625

Table continues on the next page...

Table 9-13. RDN DELAY (continued)

HW_GPMI_CTRL1[RDN_DELAY]	Delay Factor
14	1.750
15	1.875

DELAY = DelayFactor x RP or DELAY = GPMI_CTRL1[RDN_DELAY] x 0.125 x RP.

Use this equation to calculate the value for GPMI_CTRL1[RDN_DELAY]. Then set GPMI_CTRL1[DLL_ENABLE]=1.

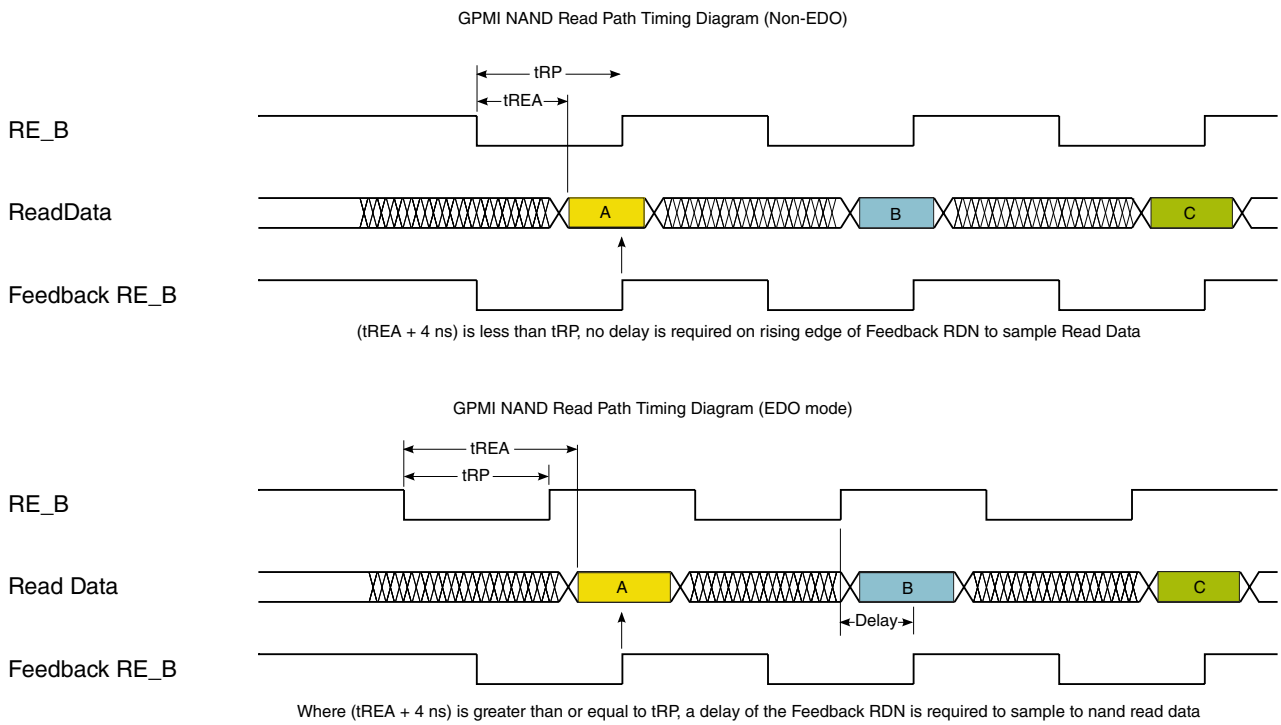

Figure 9-23. NAND Read Path Timing

For example, a NAND with tREAmax = 20 ns, tRPmin = 12 ns, and tRCmin = 25 ns (read cycle time) may be programmed as follows:

- GPMICLK clock frequency: Consider 480/6 = 80 MHz which is 12.5 ns clock period. This is too close to the minimum NAND spec if we program the data setup and hold to 1 GPMICLK cycle. Consider 480/7=68.57 MHz which is 14.58 ns clock period. With data setup and hold set to 1, we have a tRP of 14.58ns and a tRC of 29.16 ns (good margins).
- Since (tREA +4ns) is greater than tRP, required DELAY = tREA + 4ns - tRP = 20 + 4 - 14.58ns = 9.42 ns.

- GPMI_CTRL1[HALF_PERIOD] =, since GPMICLK period is ns. So RP=GPMICLK period = ns.
- DELAY = GPMI_CTRL1[RDN_DELAY] x 0.125 x RP. 9.42 ns = GPMI_CTRL1[RDN_DELAY] x 0.125 x ns. GPMI_CTRL1[RDN_DELAY] =

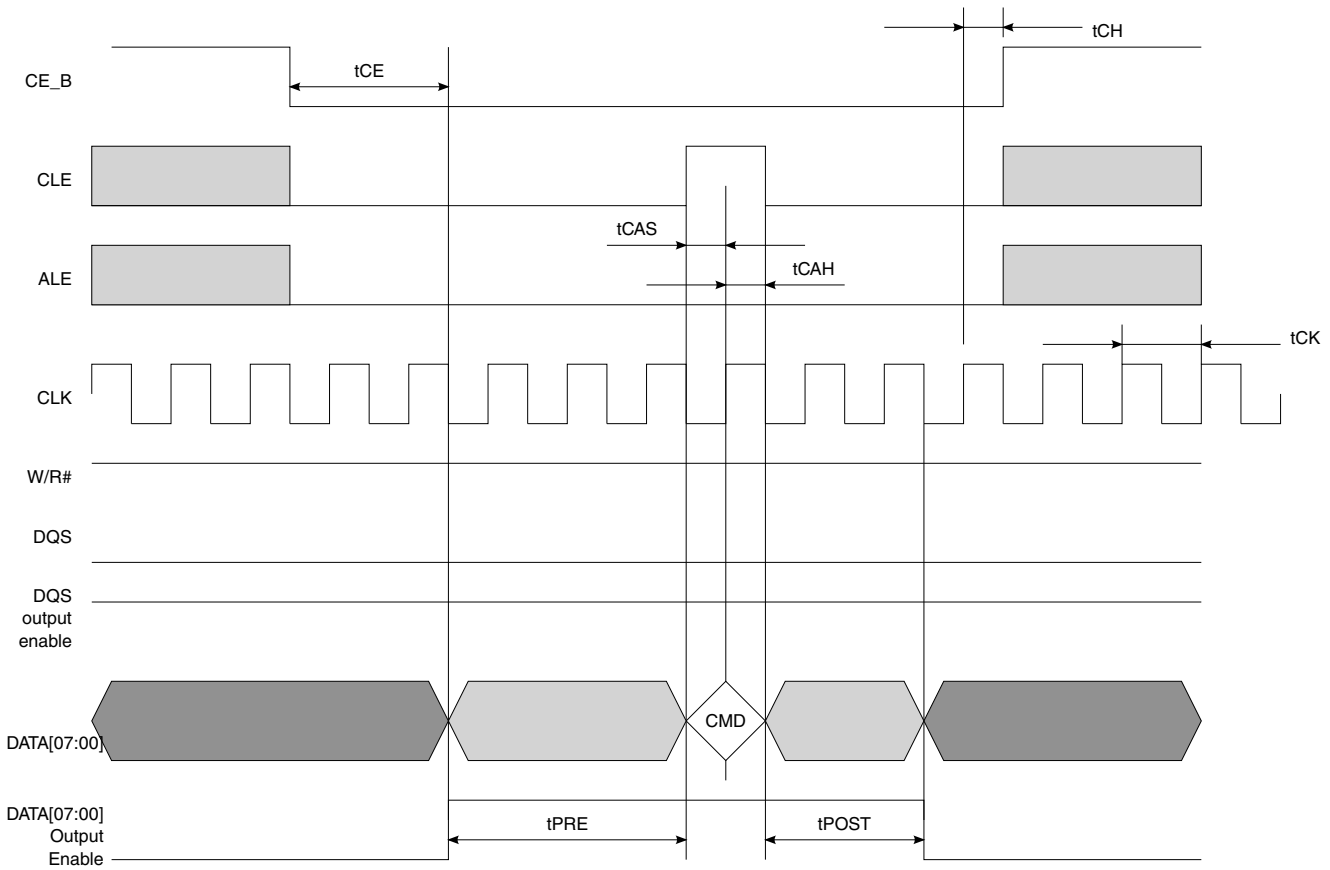
NOTE

It is recommended that the drive strength of NAND_RE_B and NAND_WE_B output pins be set to 8 mA. This will reduce the transition time under heavy loads. Low transition times will be important when NAND interface read and write cycle times are below 30 ns. The other GPMI pins may remain at 4 mA, since their frequency is only up to half that of NAND_RE_B and NAND_WE_B.

9.7.3.3.3 NAND ONFI Source Synchronous Mode Timing

NOTE

In the following figures, CLK shares the same pin as WE_B in Async Mode. And W/R# shares the same pin as RE_B in Async Mode.



tCK is equal to device clock period
tCAS = 0.5 * tCK
tCAH = 0.5 * tCK
tCE = HW_GPMI_TIMING2.CE_DELAY * tCK
tCH = 0.5 * tCK

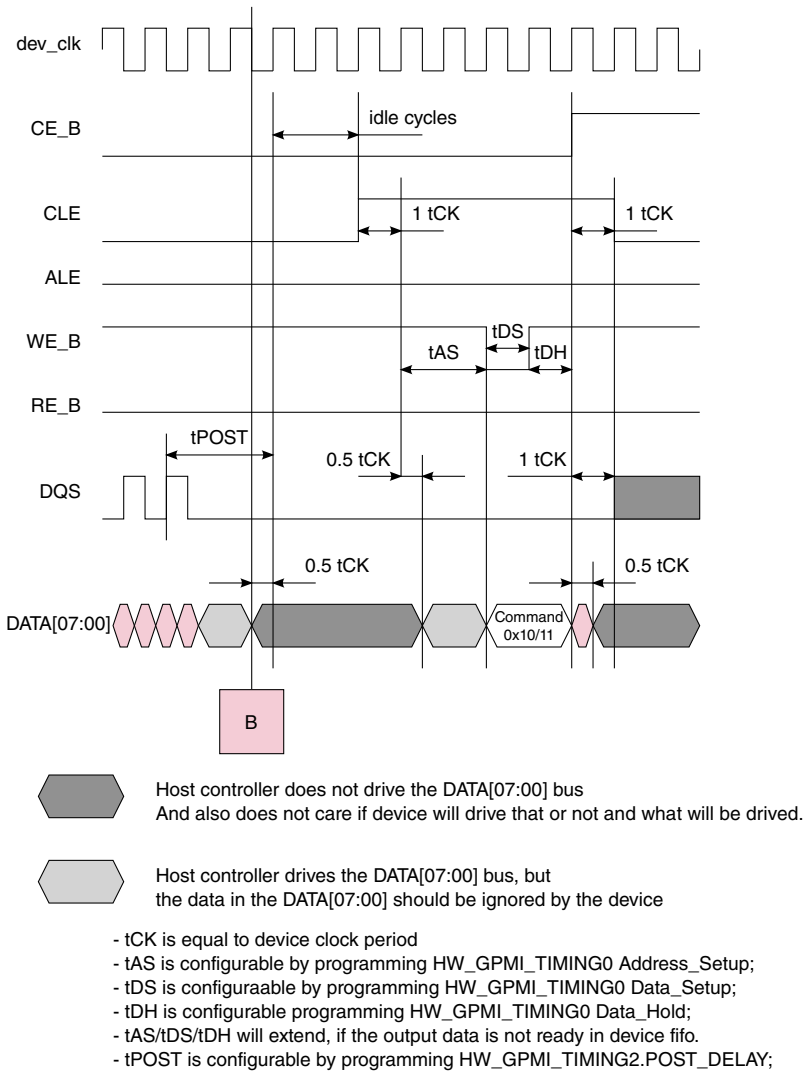

Figure 9-36. Toggle Mode Program Timing Diagram (C)

9.7.3.4 Hardware BCH Interface

The GPMI provides an interface to the BCH module. This reduces the SOC bus traffic and the software involvement.

The GPMI also provides an interface to the Randomizer module. The Randomizer can generate random data based on BCH ECC encoded / decoded data. It can be employed to reduce the disturbances caused by neighboring cells in the NAND chip, thus reducing bit errors. To enable the Randomizer module, set GPMI_ECCCTRL[RANDOMIZER_ENABLE] to 1, then set GPMI_ECCCOUNT[RANDOMIZER_PAGE] to select randomizer page number needed

to be randomized. All these registers can be programmed by the DMA chain. The randomized data should start from the zero column address and be the size of the whole NAND page. If the randomizer function is enabled, GPMI_ECCCTRL[ENABLE_ECC] should also be enabled. To bypass BCH error correction function, set BCH_FLASHxLAYOUT0[ECC0] and BCH_FLASHxLAYOUT1[ECCN] to 0.

When BCH ECC is enable, parity information is inserted on-the-fly during writes to 8-bit NAND devices. The BCH will supply payload and parity to the GPMI to write to the NAND. During NAND reads, parity is checked and ECC processing is performed after each read block. In this case the GPMI reads the NAND device and redirects the data and parity to the BCH module for ECC processing.

To program the BCH for NAND writes, remove the soft reset and clock gates from BCH_CTRL[SFTRST] and BCH_CTRL[CLKGATE]. The bulk of BCH programming is actually applied to the GPMI via PIO operations embedded in its DMA command structures. This has a subtle implication when writing to the GPMI ECC registers: access to the these registers must be written in progressive register order. Thus, to write to the GPMI_ECCCOUNT register, write first (in order) to registers GPMI_CTRL0, GPMI_COMPARE, and GPMI_ECCCTRL before writing to GPMI_ECCCOUNT. These additional register writes need to be accounted for in the CMDWORDS field of the respective DMA channel command register.

NOTE

Note that the GPMI_PAYLOAD and GPMI_AUXILIARY pointers need to be word-aligned for proper ECC operation. If those pointers are non-word-aligned, then the BCH engine will not operate properly and could possibly corrupt system memory in the adjoining memory regions.

9.7.4 Behavior During Reset

A soft reset (SFTRST) can take multiple clock periods to complete, so do NOT set CLKGATE when setting SFTRST. The reset process gates the clocks automatically.

9.7.5 GPMI Memory Map/Register Definition

The following registers provide control for programmable elements of the GPMI module.

NOTE

All ATA or UDMA features are not supported for the chip.

NOTE

GPMI does not support the Set feature command in Toggle mode. The NANDF_DQS output is only enabled in program operation for Toggle mode, but the Set feature command also needs to use the NANDF_DQS signal to write data to Toggle NAND flash. So the Set feature command in Toggle mode is not supported.

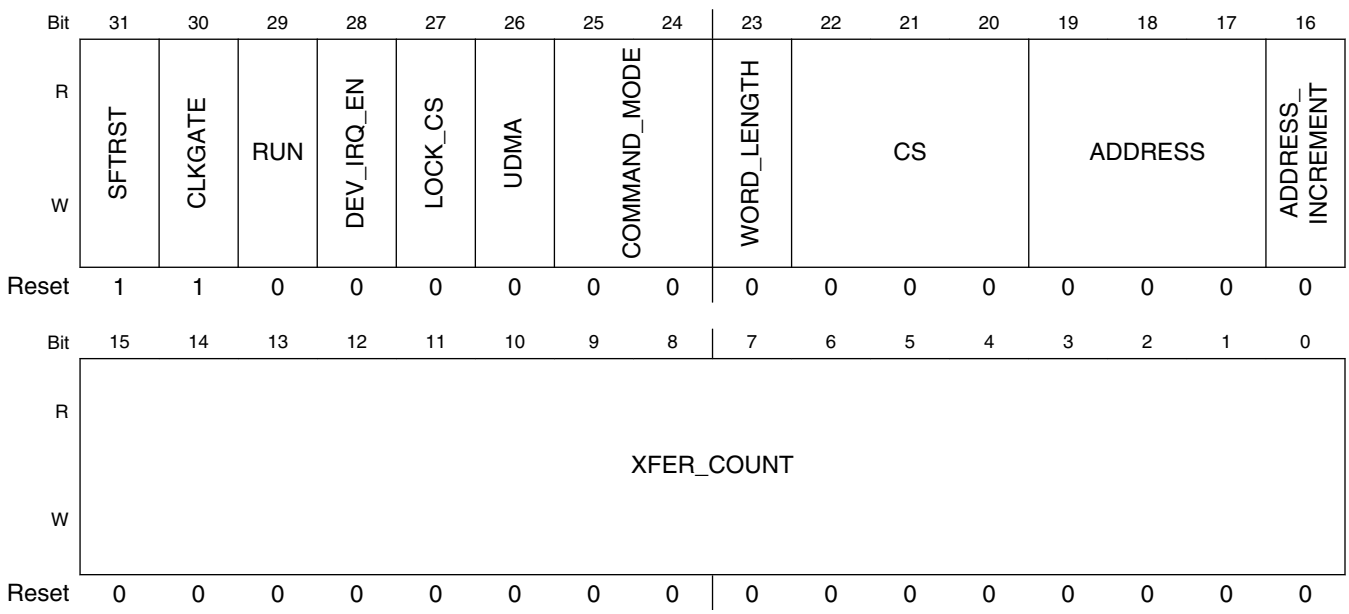
9.7.5.1 GPMI Control Register 0 Description (GPMI_CTRL0*n*)

The GPMI control register 0 specifies the GPMI transaction to perform for the current command chain item.

Address: 3300_2000h base + 0h offset + (4d × i), where i=0d to 3d



GPMI_CTRL0*n* field descriptions

Field	Description
31 SFTRST	Set to zero for normal operation. When this bit is set to one (default), then the entire block is held in its reset state. This will not work if the CLKGATE bit is already set to '1'. CLKGATE must be cleared to '0' before issuing a soft reset. Also the GPMICLK must be running for this to work properly. RUN = 0x0 Allow GPMI to operate normally. RESET = 0x1 Hold GPMI in reset.
30 CLKGATE	Set this bit zero for normal operation. Setting this bit to one (default), gates all of the block level clocks off for miniminizing AC energy consumption. RUN = 0x0 Allow GPMI to operate normally. NO_CLKS = 0x1 Do not clock GPMI gates in order to minimize power consumption.
29 RUN	The GPMI is busy running a command whenever this bit is set to '1'. The GPMI is idle whenever this bit set to zero. This can be set to one by a CPU write. In addition, the DMA sets this bit each time a DMA command has finished its PIO transfer phase. IDLE = 0x0 The GPMI is idle. BUSY = 0x1 The GPMI is busy running a command.

Table continues on the next page...

GPMI_CTRL0*n* field descriptions (continued)

Field	Description
28 DEV_IRQ_EN	When set to '1' and ATA_IRQ pin is asserted, the GPMI_IRQ output will assert.
27 LOCK_CS	For ATA/NAND mode: 0= Deassert chip select (CS) after RUN is complete. 1= Continue to assert chip select (CS) after RUN is complete. For Camera Mode: 0= Dont wait for VSYNC rising edge before capturing data. 1= Wait for VSYNC rising edge before capturing data (Camera mode only). DISABLED = 0x0 Deassert chip select (CS) after RUN is complete. ENABLED = 0x1 Continue to assert chip select (CS) after RUN is complete.
26 UDMA	DISABLED = 0x0 Use ATA-PIO mode on the external bus. ENABLED = 0x1 Use ATA-Ultra DMA mode on the external bus. 0 Use ATA-PIO mode on the external bus. 1 Use ATA-Ultra DMA mode on the external bus.
25–24 COMMAND_ MODE	WRITE = 0x0 Write mode. READ = 0x1 Read mode. READ_AND_COMPARE = 0x2 Read and Compare mode (setting sense flop). WAIT_FOR_READY = 0x3 Wait for Ready mode. For ATA WAIT_FOR_READY command set CS=01. 00 Write mode. 01 Read Mode. 10 Read and Compare Mode (setting sense flop). 11 Wait for Ready.
23 WORD_LENGTH	This bit should only be changed when RUN==0. Reserve = 0x0 Reserved. 8_BIT = 0x1 8-bit Data Bus mode. 0 Reserved. 1 8-bit Data Bus mode.
22–20 CS	Selects which chip select is active for this command. For ATA WAIT_FOR_READY command, this must be set to b01.
19–17 ADDRESS	Specifies the three address lines for ATA mode. In NAND mode, use A0 for CLE and A1 for ALE. NAND_DATA = 0x0 In NAND mode, this address is used to read and write data bytes. NAND_CLE = 0x1 In NAND mode, this address is used to write command bytes. NAND_ALE = 0x2 In NAND mode, this address is used to write address bytes.
16 ADDRESS_ INCREMENT	In ATA mode, the address will increment with each cycle. In NAND mode, the address will increment once, after the first cycle (going from CLE to ALE). DISABLED = 0x0 Address does not increment. ENABLED = 0x1 Increment address. 0 Address does not increment. 1 Increment address.
XFER_COUNT	Number of bytes to transfer for this command. A value of zero will transfer 64K bytes.

9.7.5.2 GPMI Compare Register Description (GPMI_COMPARE)

The GPMI compare register specifies the expect data and the xor mask for comparing to the status values read from the device. This register is used by the Read and Compare command.

GPMI_COMPARE 0x010

Address: 3300_2000h base + 10h offset = 3300_2010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	MASK																REFERENCE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

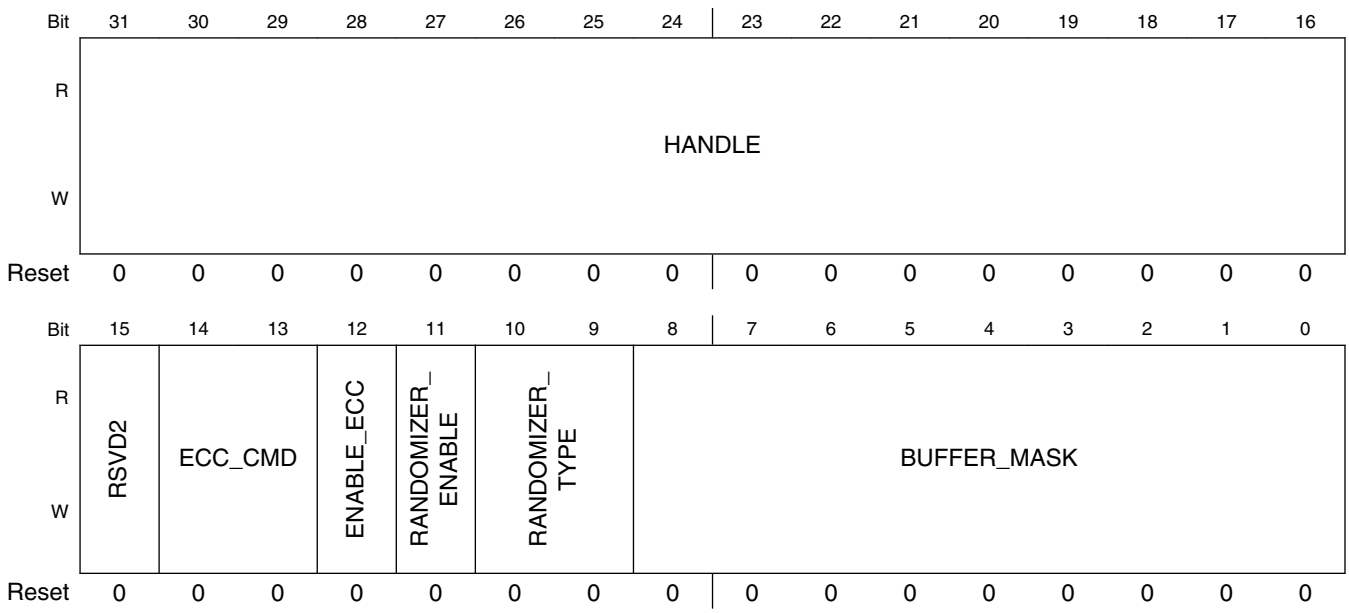
GPMI_COMPARE field descriptions

Field	Description
31–16 MASK	16-bit mask which is applied after the read data is XORed with the REFERENCE bit field.
REFERENCE	16-bit value which is XORed with data read from the NAND device.

9.7.5.3 GPMI Integrated ECC Control Register Description (GPMI_ECCCTRL*n*)

The GPMI ECC control register handles configuration of the integrated ECC / Randomizer accelerator.

Address: 3300_2000h base + 20h offset + (4d × i), where i=0d to 3d



GPMI_ECCCTRL*n* field descriptions

Field	Description
31–16 HANDLE	This is a register available to software to attach an identifier to a transaction in progress. This handle will be available from the ECC register space when the completion interrupt occurs.
15 RSVD2	Always write zeroes to this bit field.
14–13 ECC_CMD	ECC Command information. DECODE = 0x0 Decode. ENCODE = 0x1 Encode. RESERVE2 = 0x2 Reserved. RESERVE3 = 0x3 Reserved.
12 ENABLE_ECC	Enable ECC processing of GPMI transfers. ENABLE = 0x1 Use integrated ECC for read and write transfers. DISABLE = 0x0 Integrated ECC remains in idle.
11 RANDOMIZER_ ENABLE	Enable randomizer function. If this bit is set to enable, ENABLE_ECC should be also enable.

Table continues on the next page...

GPMI_ECCCTRL*n* field descriptions (continued)

Field	Description
	0x0 disable 0x1 enable
10–9 RANDOMIZER_TYPE	Set randomizer type 0x00 Type 0 0x01 Type 1 0x10 Type 2
BUFFER_MASK	ECC buffer information. The BCH error correction only allows two configurations of the buffer mask - software may either read just the first block on the flash page or the entire flash page. Write operations must be for the entire flash page. Invalid buffer mask values will cause the DMA descriptor command to be terminated. BCH_AUXONLY = 0x100 Set to request transfer from only the auxiliary buffer (block 0 on flash). BCH_PAGE = 0x1FF Set to request transfer to/from the entire page.

9.7.5.4 GPMI Integrated ECC Transfer Count Register Description (GPMI_ECCCOUNT)

The GPMI ECC Transfer Count Register contains the count of bytes that flow through the ECC / Randomizer subsystem.

GPMI_ECCCOUNT 0x030

Address: 3300_2000h base + 30h offset = 3300_2030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								RANDOMIZER_PAGE								COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_ECCCOUNT field descriptions

Field	Description
31–24 -	Always write zeroes to this bit field.
23–16 RANDOMIZER_PAGE	Set NAND page number needed to be randomized. The value is between 0-255
COUNT	Number of bytes to pass through ECC. This is the GPMI transfer count plus the syndrome count that will be inserted into the stream by the ECC. In DMA2ECC_MODE this count must match the GPMI_CTRL0_XFER_COUNT. A value of zero will transfer 64K words.

9.7.5.5 GPMI Payload Address Register Description (GPMI_PAYLOAD)

The GPMI payload address register specifies the location of the data buffers in system memory. This value must be word aligned.

GPMI_PAYLOAD 0x040

Address: 3300_2000h base + 40h offset = 3300_2040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDRESS														RSVD0	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_PAYLOAD field descriptions

Field	Description
31–2 ADDRESS	Pointer to an array of one or more 512 byte payload buffers.
RSVD0	Always write zeroes to this bit field.

9.7.5.6 GPMI Auxiliary Address Register Description (GPMI_AUXILIARY)

The GPMI auxiliary address register specifies the location of the auxiliary buffers in system memory. This value must be word aligned.

GPMI_AUXILIARY 0x050

Address: 3300_2000h base + 50h offset = 3300_2050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	ADDRESS														RSVD0	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_AUXILIARY field descriptions

Field	Description
31–2 ADDRESS	Pointer to ECC control structure and meta-data storage.
RSVD0	Always write zeroes to this bit field.

9.7.5.7 GPMI Control Register 1 Description (GPMI_CTRL1*n*)

The GPMI control register 1 specifies additional control fields that are not used on a per-transaction basis.

Address: 3300_2000h base + 60h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

GPMI_CTRL1*n* field descriptions

Field	Description
31 DEV_CLK_STOP	set this bit to 1 will stop gpmi io working clk.
30 SSYNC_CLK_STOP	set this bit to 1 will stop the source synchronous mode clk.

Table continues on the next page...

GPMI_CTRL1*n* field descriptions (continued)

Field	Description
29 WRITE_CLK_STOP	In onfi source synchronous mode, host may save power during the data write cycles by holding the CLK signal high (i.e. stopping the CLK). The host may only stop the CLK during data write, by setting this bit to 1, if the device supports this feature as indicated in the parameter page.
28 TOGGLE_MODE	enable samsung toggle mode.
27 GPMI_CLK_DIV2_EN	This bit should be reset to 0 in asynchronous mode. The frequence ratio of (device clock : ccm gpmi clock) will be (1 : 1). This bit should be set to 1, in source synchronous mode or toggle mode. The frequence raito of (device clock : ccm gpmi clock) will be (1 : 2). enable the gpmi clk divider. 0x0 internal factor-2 clock divider is disabled 0x1 internal factor-2 clock divider is enabled.
26 UPDATE_CS	force the CS value is be updated to external chip select pin, even GPMI is idle.
25 SSYNCMODE	source synchronouse mode 1 or asynchrous mode 0. ASYNC = 0x0 Asynchronous mode. SSYNC = 0x1 Source Synchronous mode.
24 DECOUPLE_CS	Decouple Chip Select from DMA Channel. Setting this bit to 1 will allow a DMA channel to specify any value in the CTRL0_CS register field. Software can use one DMA channel to access all 8 Nand devices.
23–22 WRN_DLY_SEL	Since the GPMI write strobe (WRN) is a fast clock pin, the delay on this signal can be programmed to match the load on this pin. 0 = ~2ns; 1 = ~4ns; 2 = ~6ns; 3 = no delay.
21 TEST_TRIGGER	Test Trigger Enable 0 Disable 1 Enable
20 TIMEOUT_IRQ_EN	Setting this bit to '1' will enable timeout IRQ for transfers in ATA mode only, and for WAIT_FOR_READY commands in both ATA and Nand mode. The Device_Busy_Timeout value is used for this timeout.
19 GANGED_RDYBUSY	Set this bit to 1 will force all Nand RDY_BUSY inputs to be sourced from (tied to) RDY_BUSY0. This will free up all, except one, RDY_BUSY input pins.
18 BCH_MODE	This bit selects which error correction unit will access GPMI. This bit must always be set to '1', since only the BCH unit is available in this design.
17 DLL_ENABLE	Set this bit to 1 to enable the GPMI DLL. This is required for fast NAND reads (above 30 MHz read strobe). After setting this bit, wait 64 GPMI clock cycles for the DLL to lock before performing a NAND read.
16 HALF_PERIOD	Set this bit to 1 if the GPMI clock period is greater than 16ns for proper DLL operation. DLL_ENABLE must be zero while changing this field.
15–12 RDN_DELAY	This variable is a factor in the calculated delay to apply to the internal read strobe for correct read data sampling. The applied delay (AD) is between 0 and 1.875 times the reference period (RP). RP is one half of the GPMI clock period if HALF_PERIOD=1 otherwise it is the full GPMI clock period. The equation is: AD = RDN_DELAY x 0.125 x RP. This value must not exceed 16ns.

Table continues on the next page...

GPMI_CTRL1*n* field descriptions (continued)

Field	Description
	This variable is used to achieve faster NAND access. For example if the Read Strobe is asserted from time 0 to 13ns but the read access time is 20ns, then choose AD=12ns will cause the data to be sampled at time 25ns (13+12) giving a 5ns data setup time. If RP=13ns then RDN_DELAY = 12/(0.125 x 13ns) = 7.38 (0111b). DLL_ENABLE must be zero while changing this field.
11 DMA2ECC_MODE	This is mainly for testing HWECC without involving the Nand device. Setting this bit will cause DMA write data to redirected to HWECC module (instead of Nand Device) for encoding or decoding.
10 DEV_IRQ	This bit is set when an Interrupt is received from the ATA device. Write 0 to clear.
9 TIMEOUT_IRQ	This bit is set when a timeout occurs using the Device_Busy_Timeout value. Write 0 to clear.
8 BURST_EN	When set to 1 each DMA request will generate a 4-transfer burst on the APB bus.
7 ABORT_WAIT_REQUEST	Request to abort "wait for ready" command on channel indicated by ABORT_WAIT_FOR_READY_CHANNEL. Hardware will clear this bit when abort is done.
6–4 ABORT_WAIT_FOR_READY_CHANNEL	Abort a wait for ready command on selected channel. Set the ABORT_WAIT_REQUEST to kick of operation.
3 DEV_RESET	ENABLED = 0x0 NANDF_WP_B(WPN) pin is held low (asserted). DISABLED = 0x1 NANDF_WP_B(WPN) pin is held high (de-asserted). 0 NANDF_WP_B pin is held low (asserted). 1 NANDF_WP_B pin is held high (de-asserted).
2 ATA_IRQRDY_POLARITY	For ATA MODE: Note NAND_RDY_BUSY[3:2] are not affected by this bit. ACTIVELOW = 0x0 ATA IORDY and IRQ are active low, or NAND_RDY_BUSY[1:0] are active low ready. ACTIVEHIGH = 0x1 ATA IORDY and IRQ are active high, or NAND_RDY_BUSY[1:0] are active high ready. 0 External ATA IORDY and IRQ are active low. 1 External ATA IORDY and IRQ are active high. For NAND MODE: 0 External RDY_BUSY[1] and RDY_BUSY[0] pins are ready when low and busy when high. 1 External RDY_BUSY[1] and RDY_BUSY[0] pins are ready when high and busy when low.
1 CAMERA_MODE	When set to 1 and ATA UDMA is enabled the UDMA interface becomes a camera interface.
0 GPMI_MODE	ATA mode is only supported on channel zero. If ATA mode is selected, then only channel three is available for NAND use. NAND = 0x0 NAND mode. ATA = 0x1 ATA mode.

Table continues on the next page...

GPMI_CTRL1*n* field descriptions (continued)

Field	Description
	0 NAND mode. 1 ATA mode.

9.7.5.8 GPMI Timing Register 0 Description (GPMI_TIMING0)

The GPMI timing register 0 specifies the timing parameters that are used by the cycle state machine to guarantee the various setup, hold and cycle times for the external media type.

GPMI_TIMING0 0x070

Address: 3300_2000h base + 70h offset = 3300_2070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

GPMI_TIMING0 field descriptions

Field	Description
31–24 RSVD1	Always write zeroes to this bit field.
23–16 ADDRESS_ SETUP	Number of GPMICLK cycles that the CE/ADDR signals are active before a strobe is asserted. A value of zero is interpreted as 0. For ATA PIO modes this is known in the ATA7 specification as "Address valid to DIOR-/DIOW- setup"
15–8 DATA_HOLD	Data bus hold time in GPMICLK cycles. Also the time that the data strobe is de-asserted in a cycle. A value of zero is interpreted as 256. For ATA PIO modes this is known in the ATA7 specification as "DIOR-/DIOW- recovery time"
DATA_SETUP	Data bus setup time in GPMICLK cycles. Also the time that the data strobe is asserted in a cycle. This value must be greater than 2 for ATA devices that use IORDY to extend transfer cycles. A value of zero is interpreted as 256. For ATA PIO modes this is known in the ATA7 specification as ""DIOR-/DIOW-"

9.7.5.9 GPMI Timing Register 1 Description (GPMI_TIMING1)

The GPMI timing register 1 specifies the timeouts used when monitoring the NAND READY pin or the ATA IRQ and IOWAIT signals.

GPMI_TIMING1 0x080

Address: 3300_2000h base + 80h offset = 3300_2080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

GPMI_TIMING1 field descriptions

Field	Description
31–16 DEVICE_BUSY_TIMEOUT	Timeout waiting for NAND Ready/Busy or ATA IRQ. Used in WAIT_FOR_READY mode. This value is the number of GPMI_CLK cycles multiplied by 4096.
RSVD1	Always write zeroes to this bit field.

9.7.5.10 GPMI Timing Register 2 Description (GPMI_TIMING2)

The GPMI timing register 2 specifies the double data rate timing parameters that are used by the cycle state machine to guarantee the various cs delay, pre-amble delay, post-amble delay, command/address delay, data delay, TCR, TRPSTH, and read latency cycle times for the external media type.

GPMI_TIMING2 0x090

Address: 3300_2000h base + 90h offset = 3300_2090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

GPMI_TIMING2 field descriptions

Field	Description
31–29 TRPSTH	Only for Toggle NAND timing control delay TRPSTH GPMICLK cycles for CEn_B high to RE_B high, A value of zero is interpreted as 8
28–27 TCR	Only for Toggle NAND timing control delay (TCR+1) GPMICLK cycles for CEn_B low to RE_B low, 0 is less than or equal to TCR, which is less than the PREAMBLE_DELAY
26–24 READ_LATENCY	This field is for double data rate read latency configuration. others READ LATENCY is 3 000 READ LATENCY is 0 001 READ LATENCY is 1 010 READ LATENCY is 2 011 READ LATENCY is 3 100 READ LATENCY is 4 101 READ LATENCY is 5

Table continues on the next page...

GPMI_TIMING2 field descriptions (continued)

Field	Description
23–21 RSVD0	Always write zeroes to this bit field.
20–16 CE_DELAY	GPMI dealy from CEn assert to W/Rn changing edge. value of zero is interpreted as 32.
15–12 PREAMBLE_ DELAY	GPMI pre-amble delay in GPMICLK cycles. A value of zero is interpreted as 16.
11–8 POSTAMBLE_ DELAY	GPMI post-amble delay in GPMICLK cycles. A value of zero is interpreted as 16.
7–4 CMDADD_ PAUSE	GPMI delay time from command or addres pause to command or address resume in GPMICLK cycles. A value of zero is interpreted as 16.
DATA_PAUSE	GPMI delay time from data pause to data resume in GPMICLK cycles. A value of zero is interpreted as 16.

9.7.5.11 GPMI DMA Data Transfer Register Description (GPMI_DATA)

The GPMI DMA data transfer register is used by the DMA to read or write data to or from the ATA/NAND control state machine.

GPMI_DATA 0x0A0

Address: 3300_2000h base + A0h offset = 3300_20A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R	DEV7_ERROR	DEV6_ERROR	DEV5_ERROR	DEV4_ERROR	DEV3_ERROR	DEV2_ERROR	DEV1_ERROR	DEV0_ERROR	RSVD1			ATA_IRQ	INVALID_BUFFER_MASK	FIFO_EMPTY	FIFO_FULL	PRESENT
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

GPMI_STAT field descriptions

Field	Description
31–24 READY_BUSY	Read-only view of NAND Ready_Busy Input pins.
23–16 RDY_TIMEOUT	State of the RDY/BUSY Timeout Flags. When any bit is set to '1' in this field, it indicates that a time out has occurred while waiting for the ready state of the requested NAND device. Multiple bits may be set simultaneously. When GPMI_CTRL1_DECOUPLE_CS = 0, RDY_TIMEOUT[n] is associated with the NAND device on chip_select[n]. When GPMI_CTRL1_DECOUPLE_CS = 1, these flags become associated to a DMA channel instead of a NAND device. For example if DMA channel 6 sends a WAIT_FOR_READY command for NAND Device 2, and a timeout occured on READY_BUSY2, then READY_TIMEOUT[6] will be set instead of READY_TIMEOUT[2].
15 DEV7_ERROR	DMA channel 7 (Timeout or compare failure, depending on COMMAND_MODE). 0 No error condition present on ATA/NAND Device accessed by DMA channel 7. 1 An Error has occurred on ATA/NAND Device accessed by
14 DEV6_ERROR	DMA channel 6 (Timeout or compare failure, depending on COMMAND_MODE). 0 No error condition present on ATA/NAND Device accessed by DMA channel 6. 1 An Error has occurred on ATA/NAND Device accessed by
13 DEV5_ERROR	DMA channel 5 (Timeout or compare failure, depending on COMMAND_MODE). 0 No error condition present on ATA/NAND Device accessed by DMA channel 5. 1 An Error has occurred on ATA/NAND Device accessed by
12 DEV4_ERROR	DMA channel 4 (Timeout or compare failure, depending on COMMAND_MODE). 0 No error condition present on ATA/NAND Device accessed by DMA channel 4. 1 An Error has occurred on ATA/NAND Device accessed by
11 DEV3_ERROR	DMA channel 3 (Timeout or compare failure, depending on COMMAND_MODE). 0 No error condition present on ATA/NAND Device accessed by DMA channel 3. 1 An Error has occurred on ATA/NAND Device accessed by
10 DEV2_ERROR	DMA channel 2 (Timeout or compare failure, depending on COMMAND_MODE). 0 No error condition present on ATA/NAND Device accessed by DMA channel 2. 1 An Error has occurred on ATA/NAND Device accessed by
9 DEV1_ERROR	DMA channel 1 (Timeout or compare failure, depending on COMMAND_MODE). 0 No error condition present on ATA/NAND Device accessed by DMA channel 1. 1 An Error has occurred on ATA/NAND Device accessed by
8 DEV0_ERROR	DMA channel 0 (Timeout or compare failure, depending on COMMAND_MODE). 0 No error condition present on ATA/NAND Device accessed by DMA channel 0. 1 An Error has occurred on ATA/NAND Device accessed by
7–5 RSVD1	Always write zeroes to this bit field.

Table continues on the next page...

GPMI_STAT field descriptions (continued)

Field	Description
4 ATA_IRQ	Status of the ATA_IRQ input pin.
3 INVALID_ BUFFER_MASK	Buffer Mask Validity bit. 0 ECC Buffer Mask is not invalid. 1 ECC Buffer Mask is invalid.
2 FIFO_EMPTY	NOT_EMPTY = 0x0 FIFO is not empty. EMPTY = 0x1 FIFO is empty. 0 FIFO is not empty. 1 FIFO is empty.
1 FIFO_FULL	NOT_FULL = 0x0 FIFO is not full. FULL = 0x1 FIFO is full. 0 FIFO is not full. 1 FIFO is full.
0 PRESENT	UNAVAILABLE = 0x0 GPMI is not present in this product. AVAILABLE = 0x1 GPMI is present in this product. 0 GPMI is not present in this product. 1 GPMI is present is in this product.

9.7.5.13 GPMI Debug Information Register Description (GPMI_DEBUG)

The GPMI debug information register provides a read back path for diagnostics to determine the current operating state of the GPMI controller.

GPMI_DEBUG 0x0C0

Address: 3300_2000h base + C0h offset = 3300_20C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

GPMI_DEBUG3 field descriptions

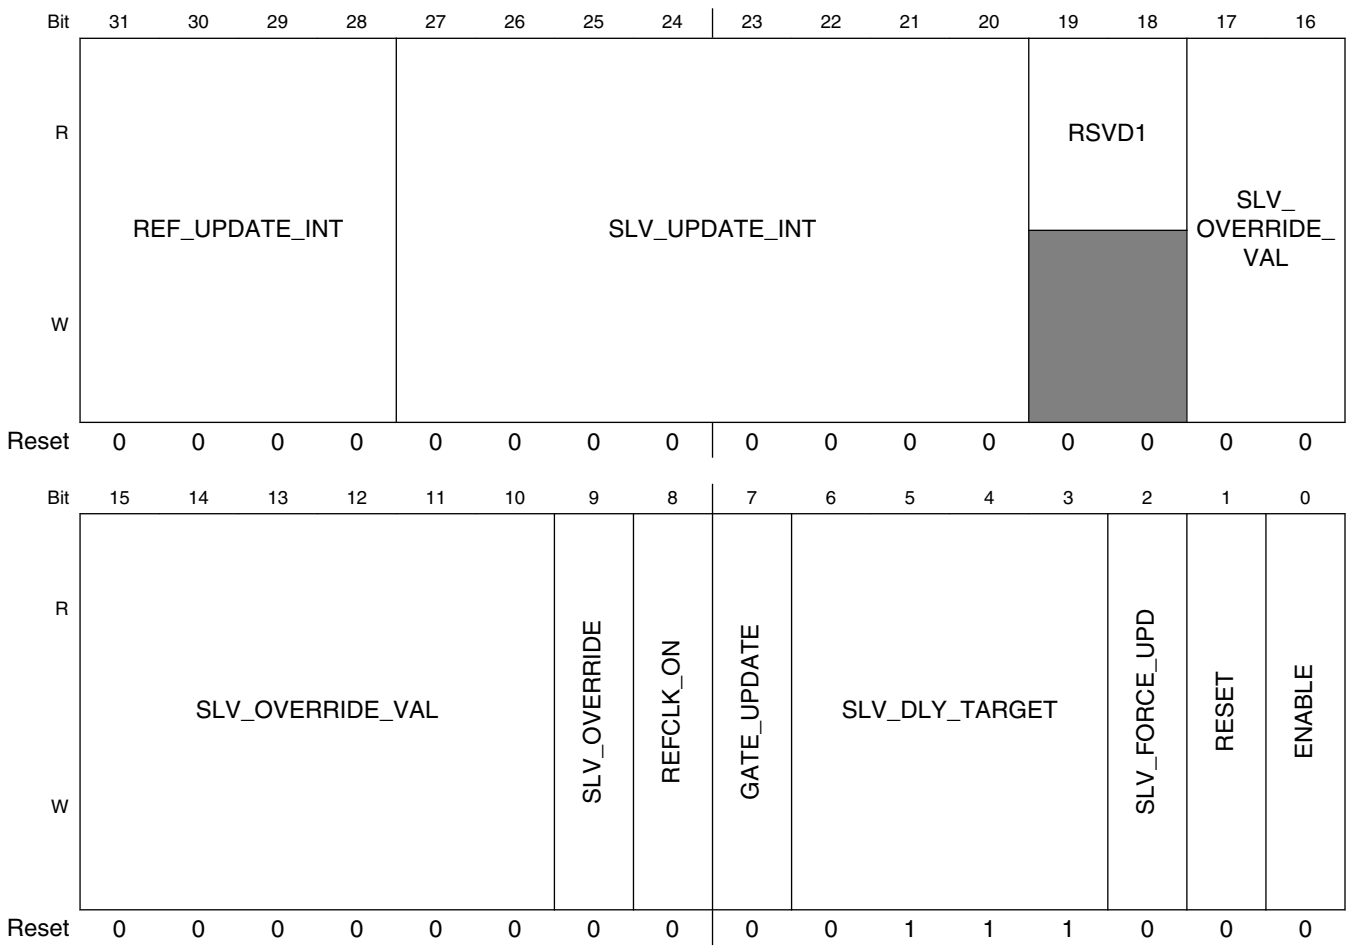
Field	Description
31–16 APB_WORD_ CNTR	Reflects the number of bytes remains to be transferred on the APB bus.
DEV_WORD_ CNTR	Reflects the number of bytes remains to be transferred on the ATA/Nand bus.

9.7.5.17 GPMI Double Rate Read DLL Control Register Description (GPMI_READ_DDR_DLL_CTRL)

GPMI DDR Read Delay Loop Lock Control Register. This register provides programmability in DDR mode for data input timing and data formats.

GPMI_READ_DDR_DLL_CTRL 0x100

Address: 3300_2000h base + 100h offset = 3300_2100h



GPMI_READ_DDR_DLL_CTRL field descriptions

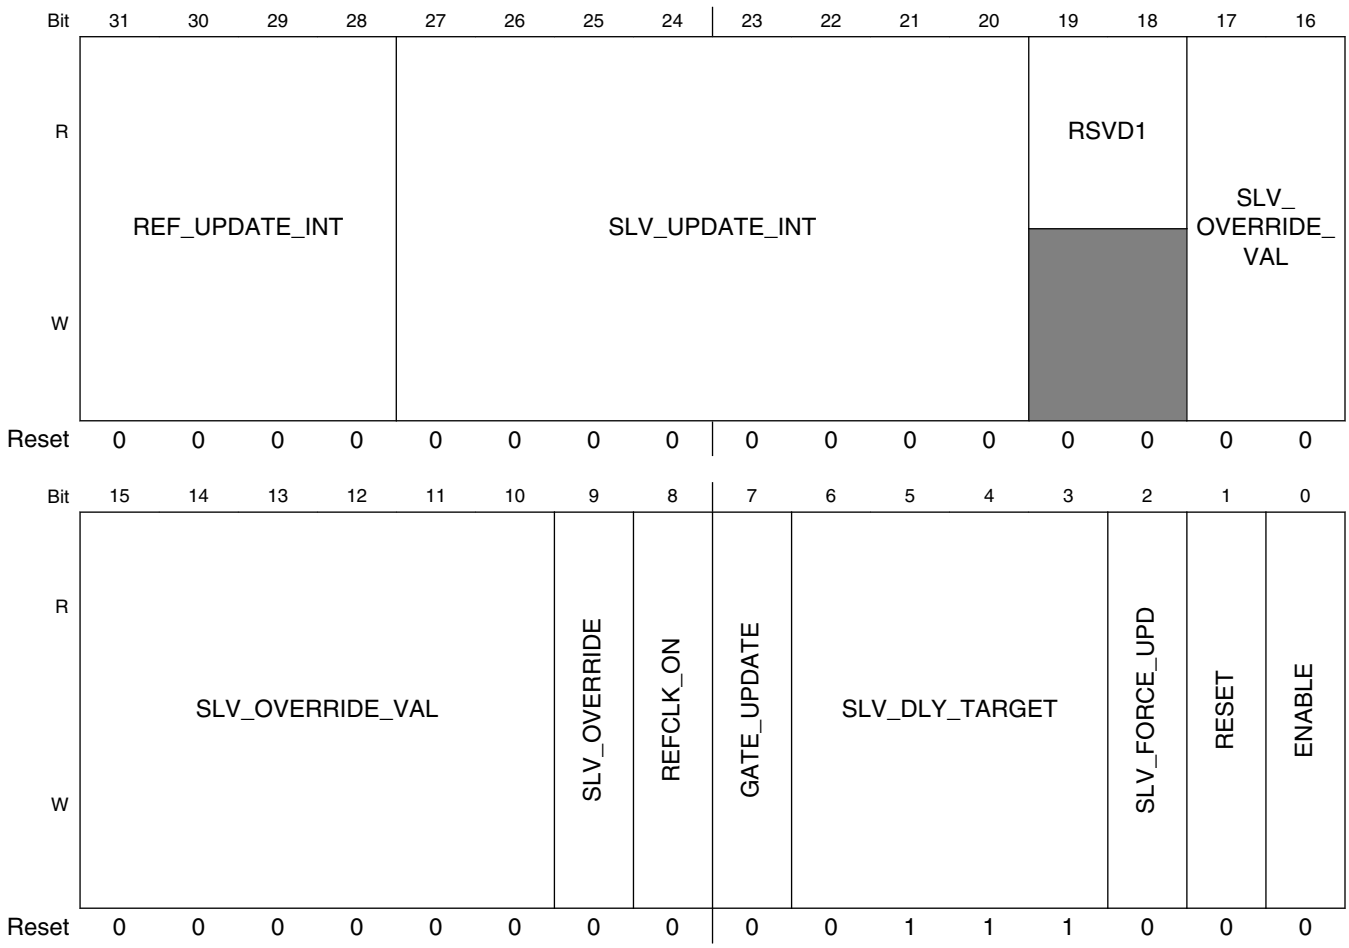
Field	Description
31–28 REF_UPDATE_INT	This field allows the user to add additional delay cycles to the DLL control loop (reference delay line control). By default, the DLL control loop shall update every two GPMICLK cycles. Programming this field results in a DLL control loop update interval of (2 + REF_UPDATE_INT) * GPMICLK. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)
27–20 SLV_UPDATE_INT	Setting a value greater than 0 in this field, shall over-ride the default slave delay-line update interval of 256 GPMICLK cycles. A value of 0 results in an update interval of 256 GPMICLK cycles (default setting). A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).
19–18 RSVD1	Reserved
17–10 SLV_OVERRIDE_VAL	When SLV_OVERRIDE=1 This field is used to select 1 of 256 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 256.
9 SLV_OVERRIDE	Set this bit to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to tbe enabled using the ENABLE bit. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE=0
8 REFCLK_ON	set this bit to 1 will turn on the reference clock
7 GATE_UPDATE	Setting this bit to 1, forces the slave delay line not update
6–3 SLV_DLY_TARGET	The delay target for the read clock is can be programmed in 1/16th increments of an GPMICLK half-period. So the input read-clock can be delayed relative input data from (GPMICLK/2)/16 to GPMICLK/2.
2 SLV_FORCE_UPD	Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line shall update automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered).
1 RESET	Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an GPMICLK half period phase shift. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, RESET must be taken low and then asserted again.
0 ENABLE	Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

9.7.5.18 GPMI Double Rate Write DLL Control Register Description (GPMI_WRITE_DDR_DLL_CTRL)

GPMI DDR Write Delay Loop Lock Control Register. This register provides programmability in DDR mode for data output timing and data formats.

GPMI_WRITE_DDR_DLL_CTRL 0x110

Address: 3300_2000h base + 110h offset = 3300_2110h



GPMI_WRITE_DDR_DLL_CTRL field descriptions

Field	Description
31–28 REF_UPDATE_ INT	This field allows the user to add additional delay cycles to the DLL control loop (reference delay line control). By default, the DLL control loop shall update every two GPMICLK cycles. Programming this field results in a DLL control loop update interval of (2 + REF_UPDATE_INT) * GPMICLK. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)
27–20 SLV_UPDATE_ INT	Setting a value greater than 0 in this field, shall over-ride the default slave delay-line update interval of 256 GPMICLK cycles. A value of 0 results in an update interval of 256 GPMICLK cycles (default setting). A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).
19–18 RSVD1	Reserved
17–10 SLV_ OVERRIDE_VAL	When SLV_OVERRIDE=1 This field is used to select 1 of 256 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 256.
9 SLV_OVERRIDE	Set this bit to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to tbe enabled using the ENABLE bit. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE=0

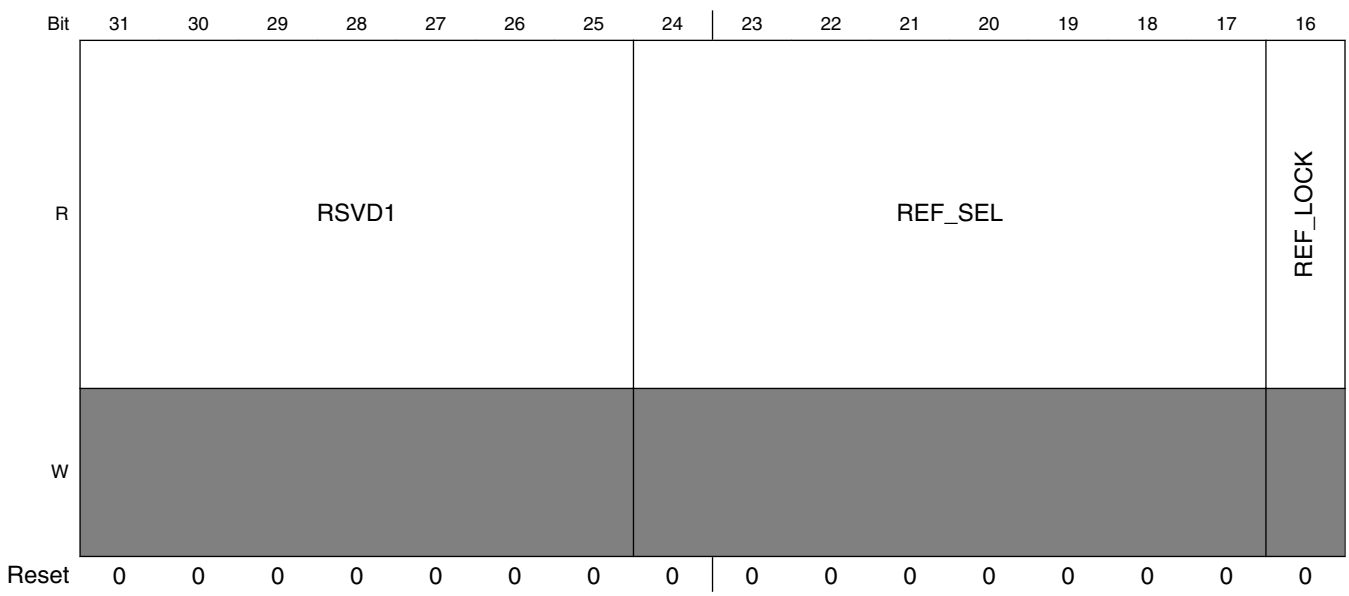
Field	Description
8 REFCLK_ON	set this bit to 1 will turn on the reference clock
7 GATE_UPDATE	Setting this bit to 1, forces the slave delay line not update
6–3 SLV_DLY_ TARGET	The delay target for the read clock can be programmed in 1/16th increments of an GPMICLK half-period. So the input read-clock can be delayed relative input data from (GPMICLK/2)/16 to GPMICLK/2.
2 SLV_FORCE_ UPD	Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line shall update automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered).
1 RESET	Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an GPMICLK half period phase shift. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, RESET must be taken low and then asserted again.
0 ENABLE	Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

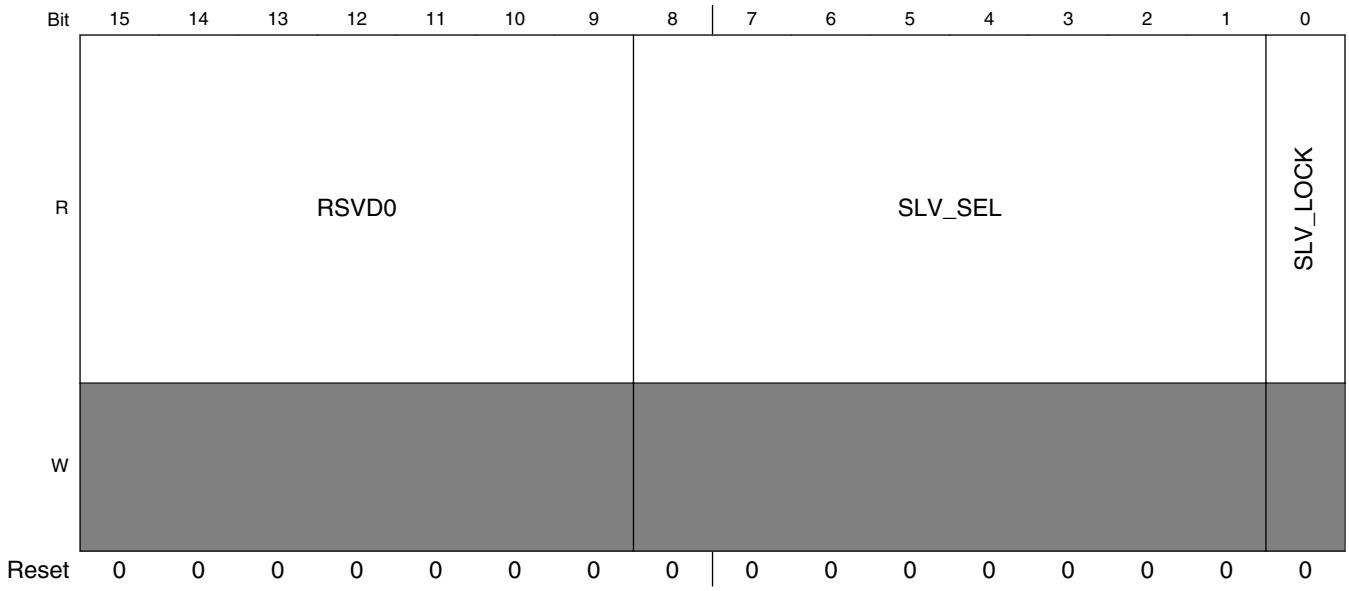
9.7.5.19 GPMI Double Rate Read DLL Status Register Description (GPMI_READ_DDR_DLL_STS)

GPMI Double Rate Read DLL Status Register, Read Only. GPMI DLL status fields are provided in this register.

GPMI_READ_DDR_DLL_STS 0x120

Address: 3300_2000h base + 120h offset = 3300_2120h





GPMI_READ_DDR_DLL_STS field descriptions

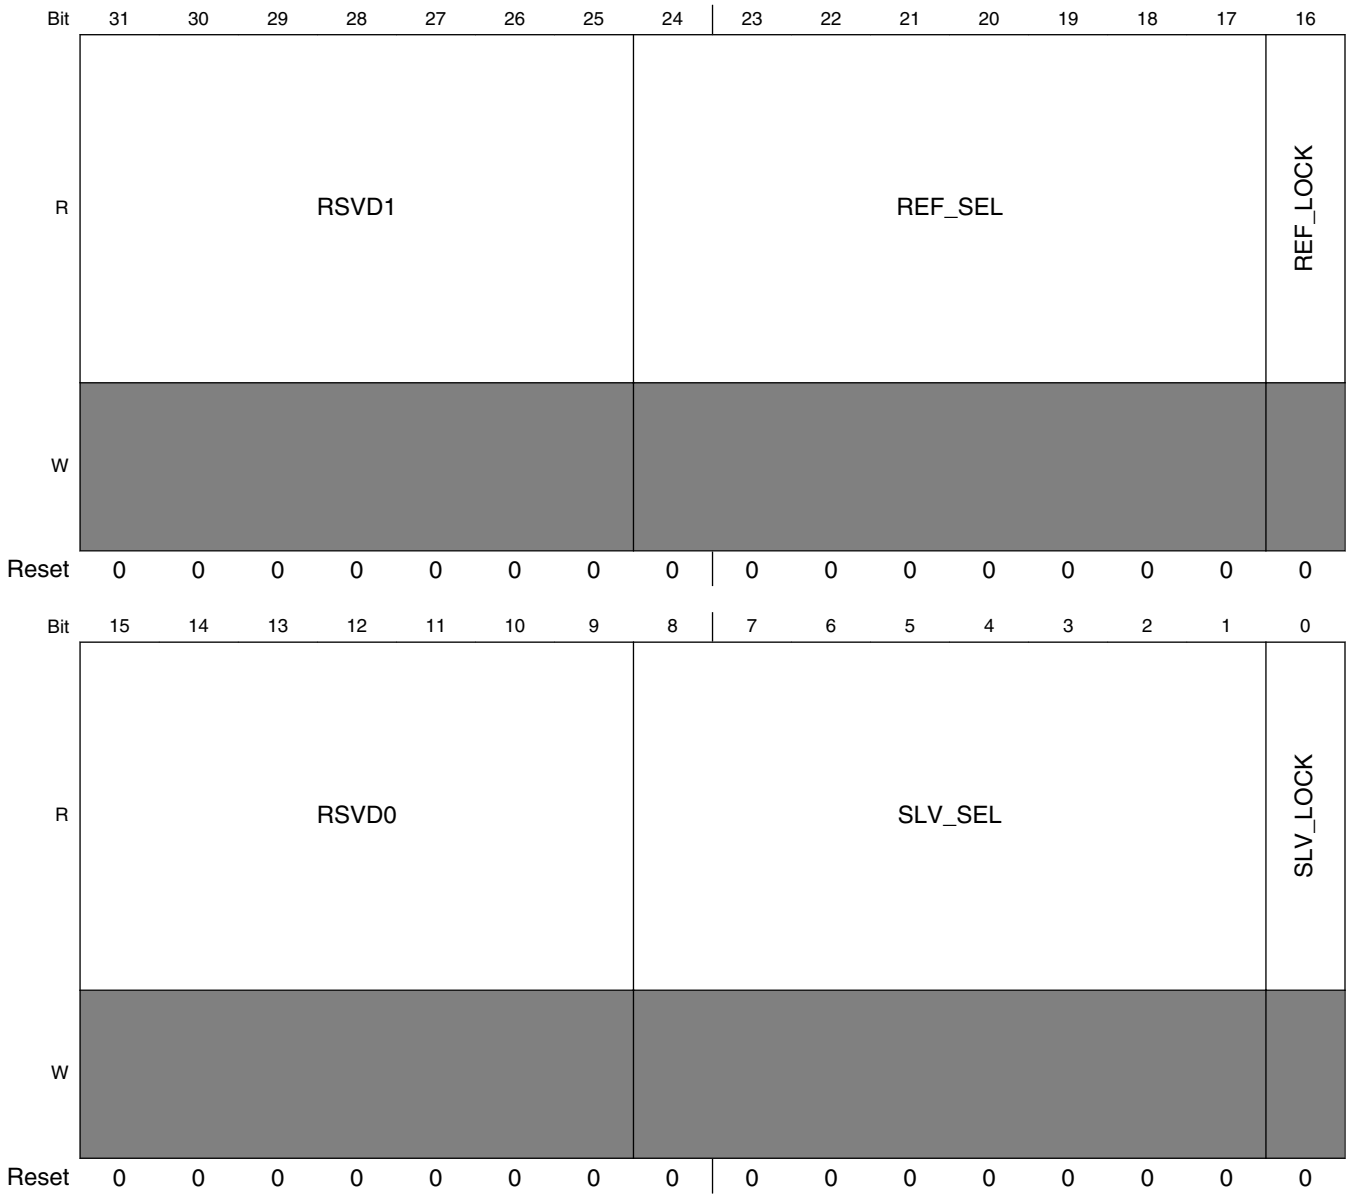
Field	Description
31–25 RSVD1	Reserved
24–17 REF_SEL	Reference delay line select status.
16 REF_LOCK	Reference DLL lock status. This signifies that the DLL has detected and locked to a half-phase GPMICLK shift, allowing the slave delay-line to perform programmed clock delays.
15–9 RSVD0	Reserved
8–1 SLV_SEL	Slave delay line select status
0 SLV_LOCK	Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value.

9.7.5.20 GPMI Double Rate Write DLL Status Register Description (GPMI_WRITE_DDR_DLL_STS)

GPMI Double Rate Write DLL Status Register, Read Only. GPMI DLL status fields are provided in this register.

GPMI_WRITE_DDR_DLL_STS 0x130

Address: 3300_2000h base + 130h offset = 3300_2130h



GPMI_WRITE_DDR_DLL_STS field descriptions

Field	Description

0 SLV_LOCK	Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value.

Chapter 10
Mass Storage

10.1 Enhanced Configurable SPI (ECSPI)

10.1.1 Overview

The Enhanced Configurable Serial Peripheral Interface (ECSPI) is a full-duplex, synchronous, four-wire serial communication block.

The ECSPI contains a 64 x 32 receive buffer (RXFIFO) and a 64 x 32 transmit buffer (TXFIFO). With data FIFOs, the ECSPI allows rapid data communication with fewer software interrupts. The figure below shows a block diagram of the ECSPI.

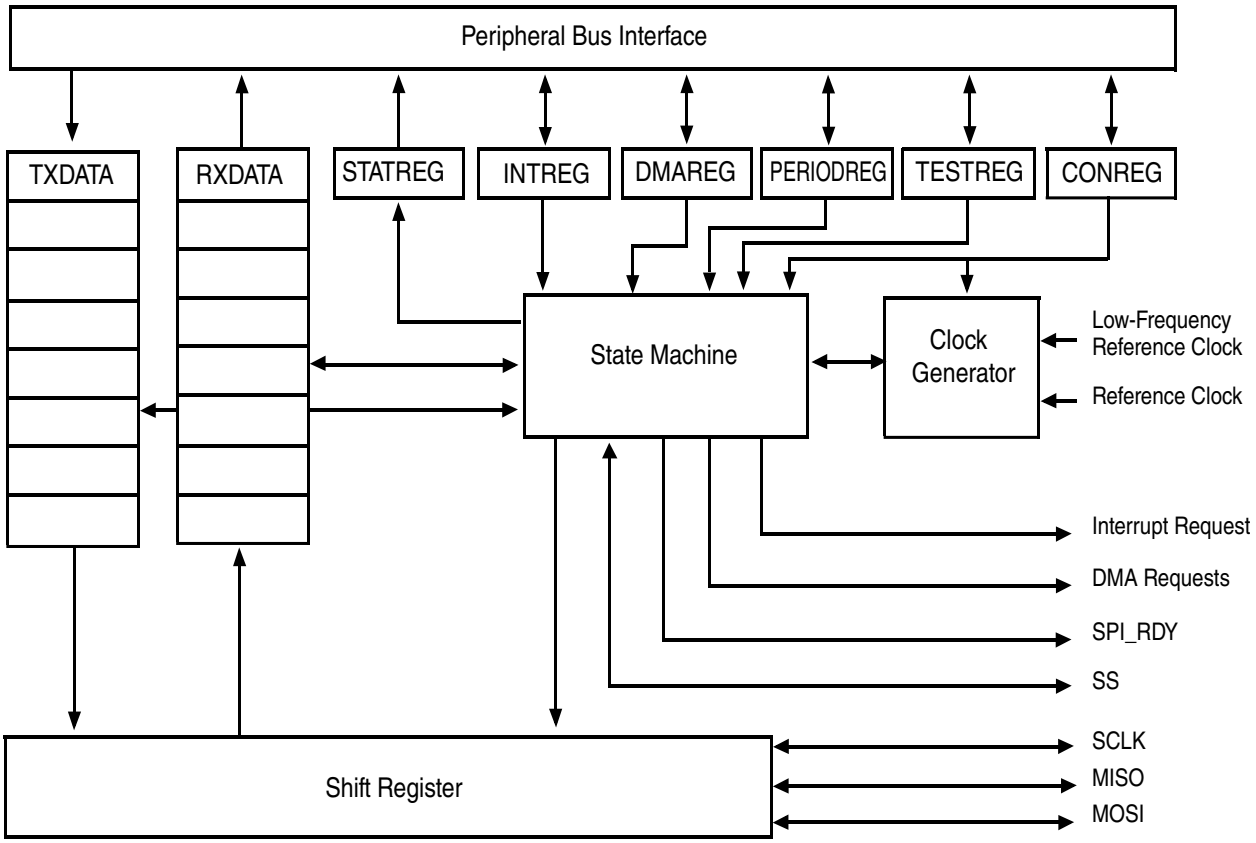

Figure 10-1. ECSPI Block Diagram

10.1.1.1 Features

Key features of the ECSPI include:

- Full-duplex synchronous serial interface
- Master/Slave configurable
- One Chip Select (SS) signal
- Transfer continuation function allows unlimited length data transfers
- 32-bit wide by 64-entry FIFO for both transmit and receive data
- Polarity and phase of the Chip Select (SS) and SPI Clock (SCLK) are configurable
- Direct Memory Access (DMA) support
- Refer to the product data sheet for the maximum operating frequency

10.1.1.2 Modes and Operations

The ECSPI supports the modes described in the indicated sections:

- Master Mode
- Slave Mode
- Low Power Modes

As described in Operations, the ECSPI supports the operations described in the indicated sections:

- Typical Master Mode
  - Master Mode with SPI_RDY
  - Master Mode with Wait States
  - Master Mode with SS_CTL[3:0] Control
  - Master Mode with Phase Control
- Typical Slave Mode

10.1.2 Clocks

The following table describes the clock sources for eCSPI. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 10-1. eCSPI Clocks

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_32k	ckil_sync_clk_root	Low-frequency reference clock (32kHz)
ipg_clk_per	ecspi_clk_root	eCSPI module clock
ipg_clk_s	ipg_clk_root	Peripheral access clock

10.1.3 Functional Description

This section provides a complete functional description of the ECSPI. The figure found here shows the relationship of SCLK and data lines while ECSPI has been configured with different POL and PHA settings.

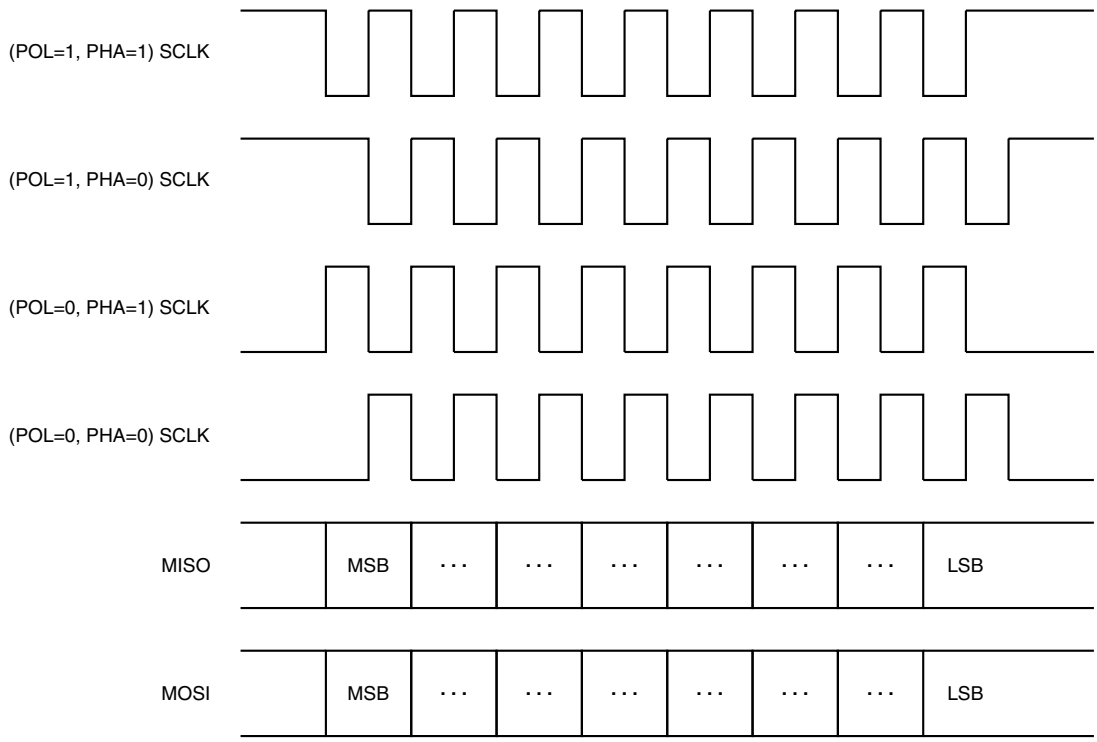

Figure 10-2. ECSPI SCLK, MISO, and MOSI Relationship

10.1.3.1 Master Mode

When the ECSPI is configured as a master, it uses a serial link to transfer data between the ECSPI and an external slave device.

The Chip Select (SS) signal and the clock signal (SCLK) are used to transfer data between two devices. If the external device is a transmit-only device, the ECSPI master's output port can be ignored and used for other purposes. In order to use the internal TXFIFO and RXFIFO, two auxiliary output signals, Chip Select (SS) and SPI_RDY, are used for data transfer rate control. Software can also configure the sample period control register to a fixed data transfer rate.

10.1.3.2 Slave Mode

When the ECSPI is configured as a slave, software can configure the ECSPI Control register to match the external SPI master's timing.

In this configuration, Chip Select (SS) becomes an input signal, and is used to control data transfers through the Shift register, as well as to load/store the data FIFO.

Slave mode only supports the case when ECSPIx_CONFIGREG[SS_CTL] is cleared. The accurate burst length should always be specified using the BURST_LENGTH parameter. ECSPIx_CONFIGREG[SS_CTL] set to 1 is not supported in slave mode.

10.1.3.3 Low Power Modes

The ECSPI does not operate under low power mode.

It holds its operation when its clock is gated off in master mode. In slave mode, the ECSPI does not respond when its clock is gated off.

10.1.3.4 Operations

The information found here describes the ECSPI's operations.

10.1.3.4.1 Typical Master Mode

The ECSPI master uses the Chip Select (SS) signal to enable an external SPI device, and uses the SCLK signal to transfer data in and out of the Shift register.

The SPI_RDY enables fast data communication with fewer software interrupts. By programming the ECSPI_PERIODREG register accordingly, the ECSPI can be used for a fixed data transfer rate.

When the ECSPI is in Master mode the SS, SCLK, and MOSI are output signals, and the MISO signal is an input.

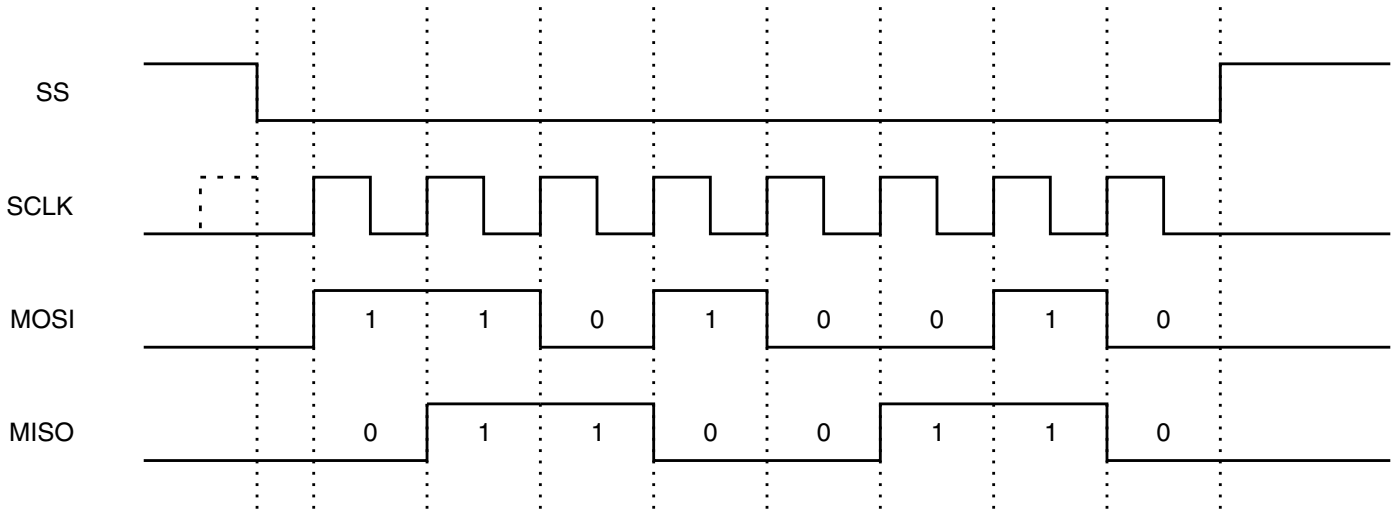

Figure 10-3. Typical SPI Burst (8-bit Transfer)

In the above figure, the Chip Select (SS) signal enables the selected external SPI device, and the SCLK synchronizes the data transfer. The MOSI and MISO signals change on rising edge of SCLK and the MISO signal is latched on the falling edge of the SCLK. The figure above shows a data of 0xD2 is shifted out, and a data of 0x66 is shifted in.

10.1.3.4.1.1 Master Mode with SPI_RDY

By default, the ECSPI does not use the SPI_RDY signal in master mode (MODE =1).

A SPI burst begins when the following events happen:

- The ECSPI is enabled, TXFIFO has data in it, and ECSPI_CONREG[XCH] bit or the ECSPI_CONREG[SMC] bit is set.
- When the SPI Data Ready Control (ECSPI_CONREG[DRCTL]) bits contains either 01 or 10, the SPI_RDY signal controls when a SPI burst starts.

A SPI burst is defined as a bus transaction that starts when the slave select is asserted and ends when the slave select is negated. The Chip Select (SS) signal will remain asserted until all the bits in a SPI burst are shifted out.

If ECSPI_CONREG[DRCTL] is set to 01, the SPI burst can be triggered only if a falling edge of the SPI_RDY signal has been detected.

The following figure shows the relationship between a SPI burst and the falling edge of SPI_RDY signal.

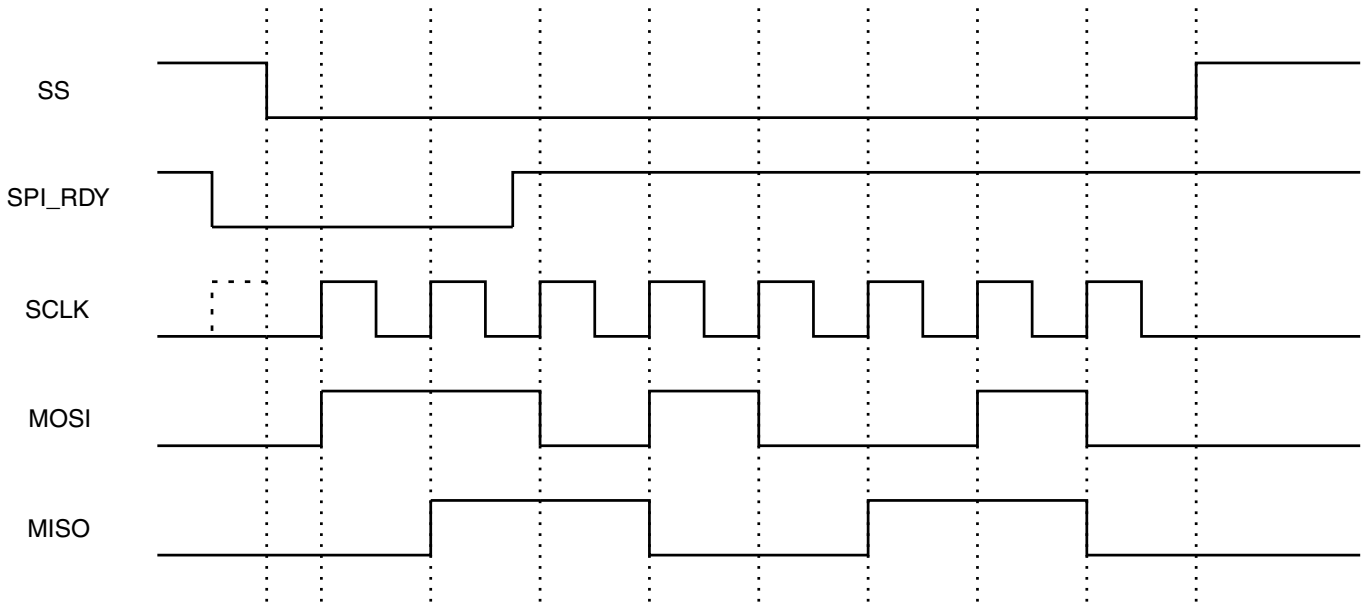

Figure 10-4. Relationship Between a SPI Burst and SPI_RDY: Falling-Edge Triggered

A SPI burst does not start until the falling edge of the SPI_RDY signal is detected. The next SPI burst starts when the next SPI_RDY falling edge is detected, after the last burst has finished.

If SPI Data Ready Control (ECSPI_CONREG[DRCTL]) is set to 10, the SPI burst can be triggered only if the SPI_RDY signal is low.

The following figure shows the relationship between a SPI burst and the SPI_RDY signal. The SPI burst does not begin until the SPI_RDY signal goes low. The ECSPI will keep transmitting SPI burst if the SPI_RDY signal remains low.

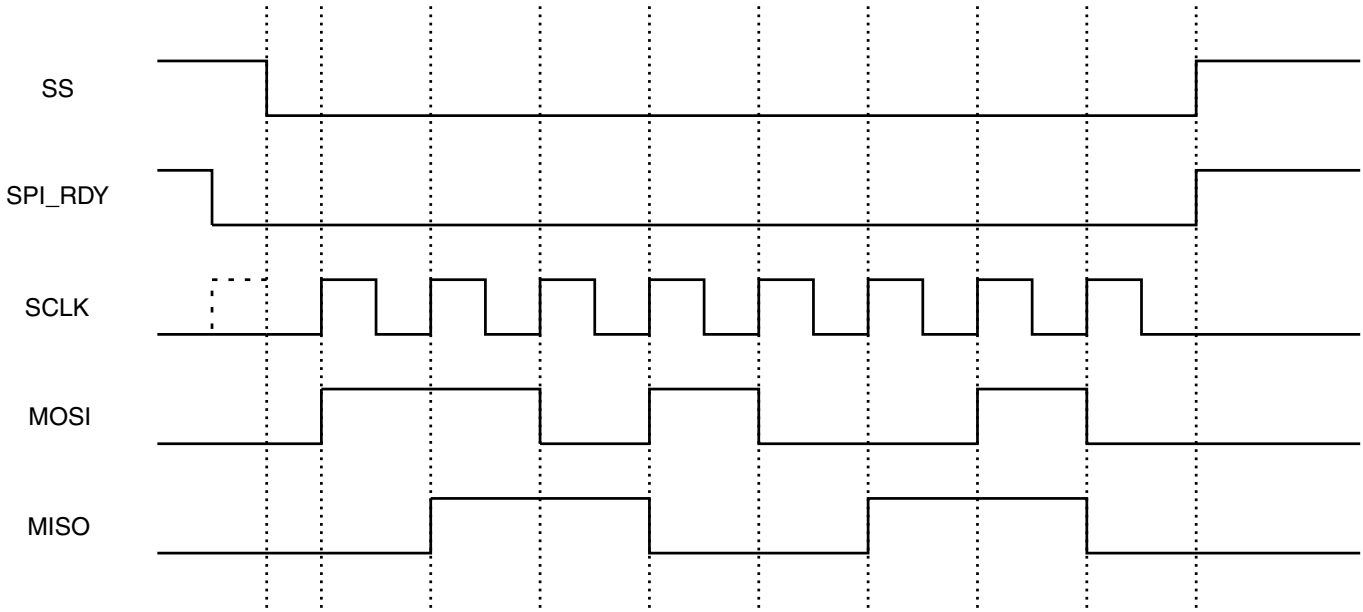

Figure 10-5. Relationship Between a SPI Burst and SPI_RDY: Low-Level Triggered

10.1.3.4.1.2 Master Mode with Wait States

Wait states can be inserted between SPI bursts. This provides a way for software to slow down the SPI burst to meet the timing requirements of a slower SPI device.

The following figure shows wait states inserted between SPI bursts.

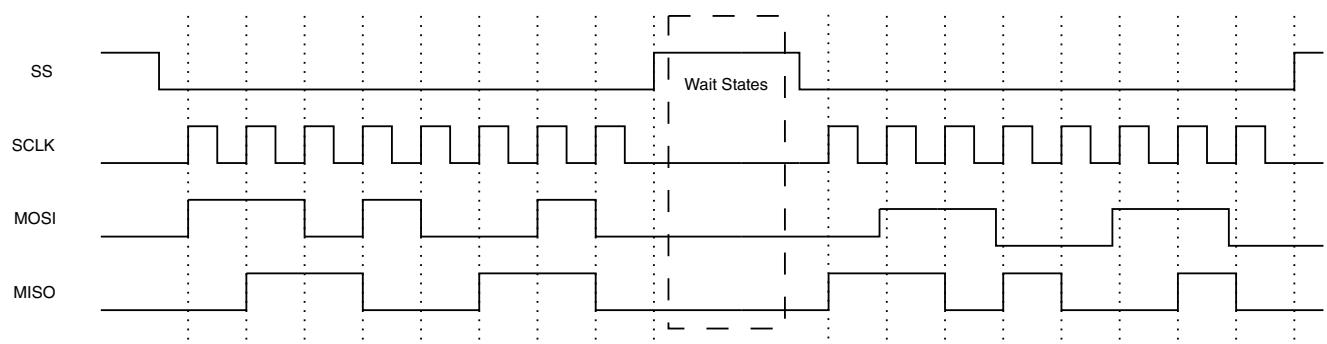

Figure 10-6. SPI Bursts with Wait States

In this case, the number of wait states is controlled by ECSPI_PERIODREG[SAMPLE PERIOD] and the wait states' clock source is selected by ECSPI_PERIODREG[CSRC].

10.1.3.4.1.3 Master Mode with SS_CTL[3:0] Control

The SPI SS Control (SS_CTL[3:0]) controls whether the current operation is single burst or multiple bursts.

When the SPI SS Wave Form Select (SS_CTL[3:0]) is set, the current operation is multiple bursts transfer. When the SPI SS Wave Form Select (SS_CTL[3:0]) bit is cleared, the current operation is single burst transfer. A SPI burst can contains multiple words as defined in the BURST LENGTH field of the ECSPI_CONREG register.

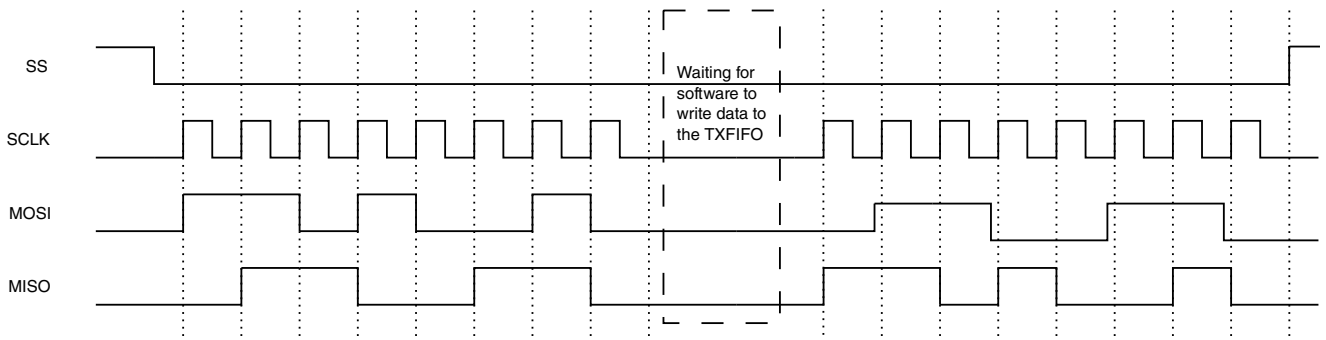

Figure 10-7. SPI Burst While SS_CTL[3:0] is Clear

In Figure 10-7, two 8-bit bursts in the TXFIFO have been combined and transmitted in one SPI burst. The maximum length of a single SPI burst is defined by the BURST LENGTH and limited by the FIFO size. (Figure 10-7 corresponds to a BURST LENGTH of 8.) This provides a way for transferring a longer SPI burst by writing data into TXFIFO while the ECSPI is transmitting.

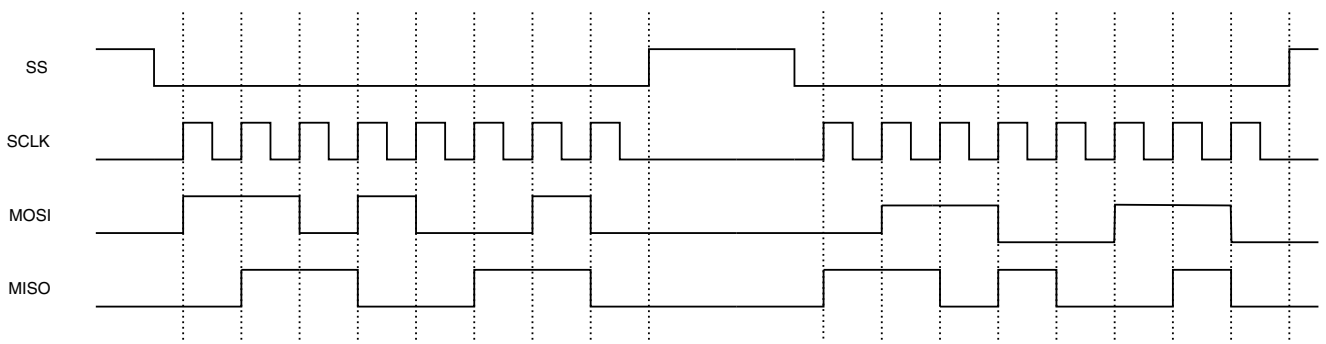

Figure 10-8. SPI Bursts While SS_CTL[3:0] is Set

In Figure 10-8, two FIFO entries are transmitted, one entry with each SPI burst. The ECSPI will continue to transmit SPI bursts until the TXFIFO is empty. When wait states can be inserted between SPI bursts, the SS will negate between SPI bursts until the wait states finish.

10.1.3.4.1.4 Master Mode with Phase Control

The Phase Control (ECSPI_CONREG[PHA]) bit controls how the transmit data shifts out and the receive data shifts in.

When the Phase control (ECSPI_CONREG[PHA]) bit is set, the transmit data will shift out on the rising edge of SCLK, and the receive data is latched on the falling edge of SCLK. The most-significant bit is output on the first rising SCLK edge.

When ECSPI_CONREG[PHA] is cleared, the transmit data is shifted out on the falling edge of SCLK and the receive data is latched on the rising edge of SCLK. The MSB is output when the host processor loads the transmitted data.

Inverting the SCLK polarity does not impact the edge-triggered operations because they are internal to the serial peripheral interface master. Figure 10-9 shows how SPI burst works with different POL and PHA configuration.

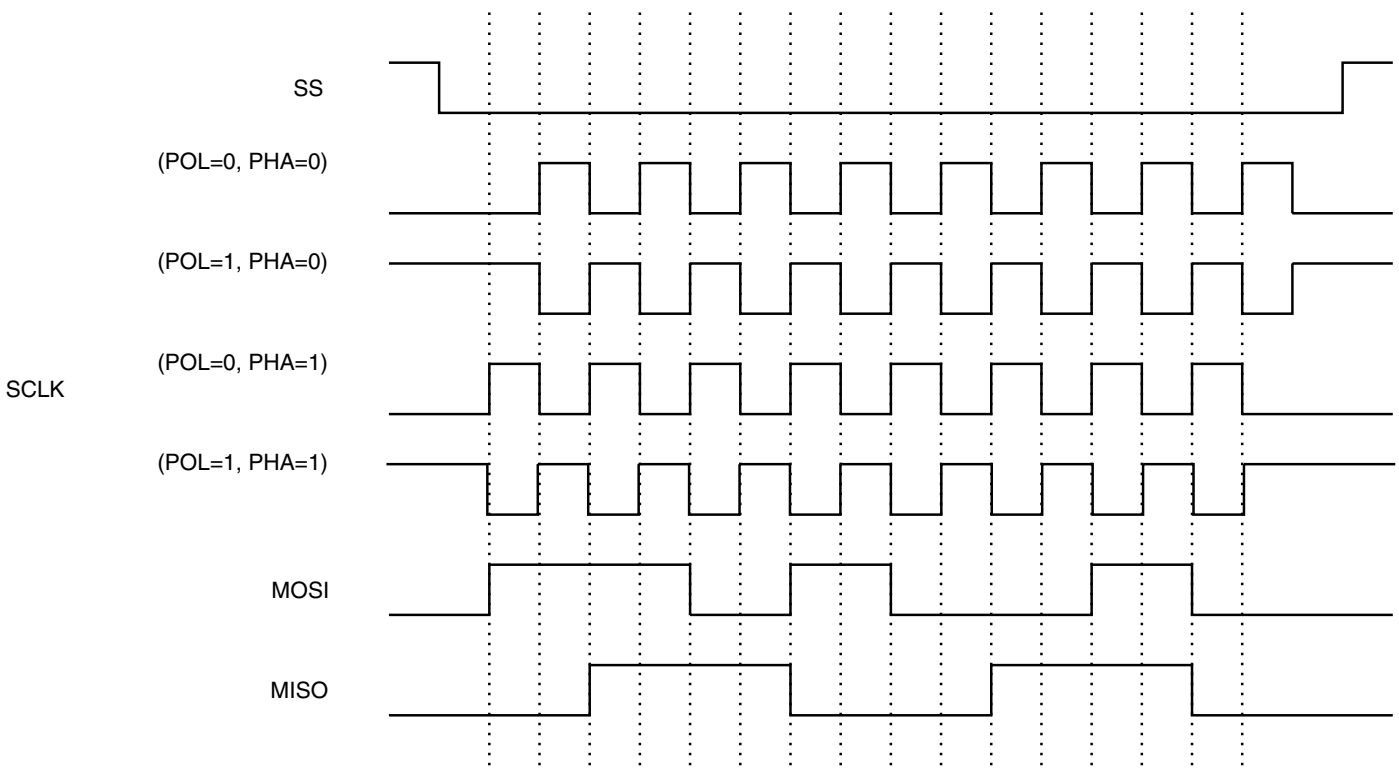

Figure 10-9. SPI Burst with Different POL and PHA Configurations

10.1.3.4.2 Typical Slave Mode

When the ECSPI is configured as a slave (Mode = 0), software can configure the ECSPI Control register to match the external SPI master's timing. In this configuration, SS becomes an input signal, and is used to latch data in and out of the internal data Shift registers, as well as to advance the data FIFO.

The SS, SCLK, and MOSI are inputs and MISO is output. Most of the timing diagrams are similar to the diagrams shown previously for the SPI in Master mode (Mode = 1), because the inputs come from a SPI master device.

However, the timing is different when SS is used to advance the data FIFO. When the SS_POL=0 is set while the ECSPI is configured in Slave mode, the data FIFO will advance on the rising edge of the SS signal. When the polarity is reversed (SS_POL = 1), the data FIFO will advance on the falling edge of the SS signal.

The figure below shows a SPI burst in which the data FIFO is advanced by the rising edge of the SS signal.

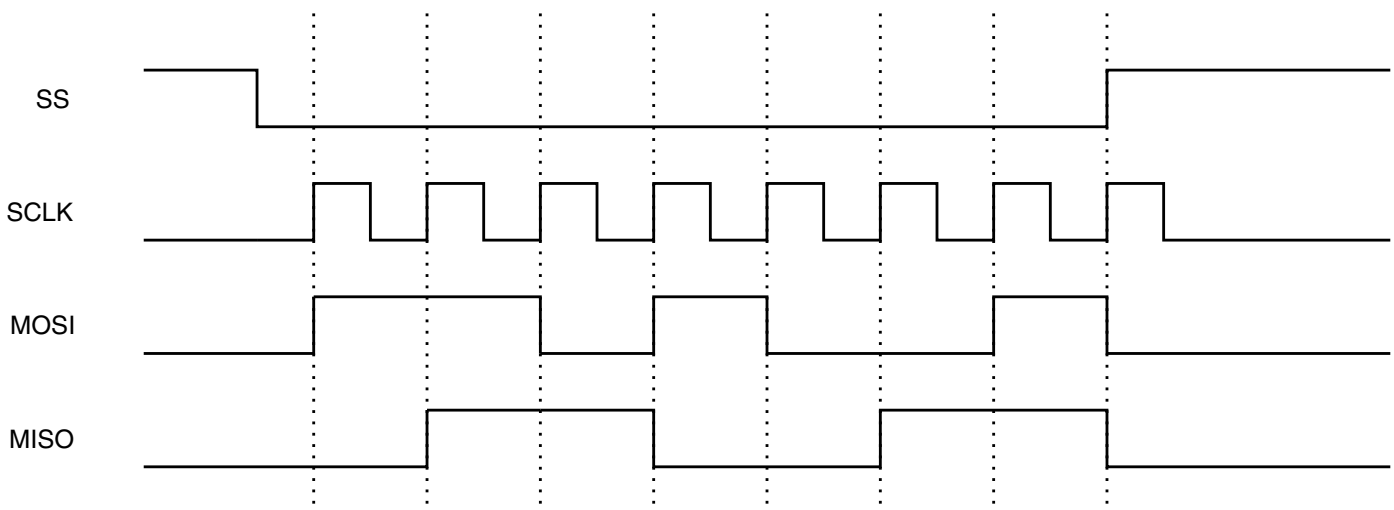

Figure 10-10. Advancing the Data FIFO on the Rising Edge of SS

In the above case, only the most significant 7 bits are loaded to the RXFIFO.

10.1.3.5 Reset

Whenever a device reset occurs, a reset is performed on the ECSPI, resetting all registers to their default values.

Software can reset the block using the CONREG[EN] bit; see ECSPI.

10.1.3.6 Interrupts

Interrupt control provides a way to manage the ECSPI FIFOs:

- For transmitting data, software can enable the TXFIFO empty, TXFIFO data request, and TXFIFO full interrupts to maintain the TXFIFO using an interrupt service routine.
- For receiving data, software can enable the RXFIFO ready, RXFIFO data request, and RXFIFO full interrupts to retrieve data from the RXFIFO using an interrupt service routine.

Other interrupt sources can be used to control or debug the SPI bursts:

- The transfer-completed interrupt means that there is no data left in the TXFIFO and that the data in the Shift register has been shifted out.
- The RXFIFO overflow interrupt means that the RXFIFO received more than 64 words and will not accept any other words.

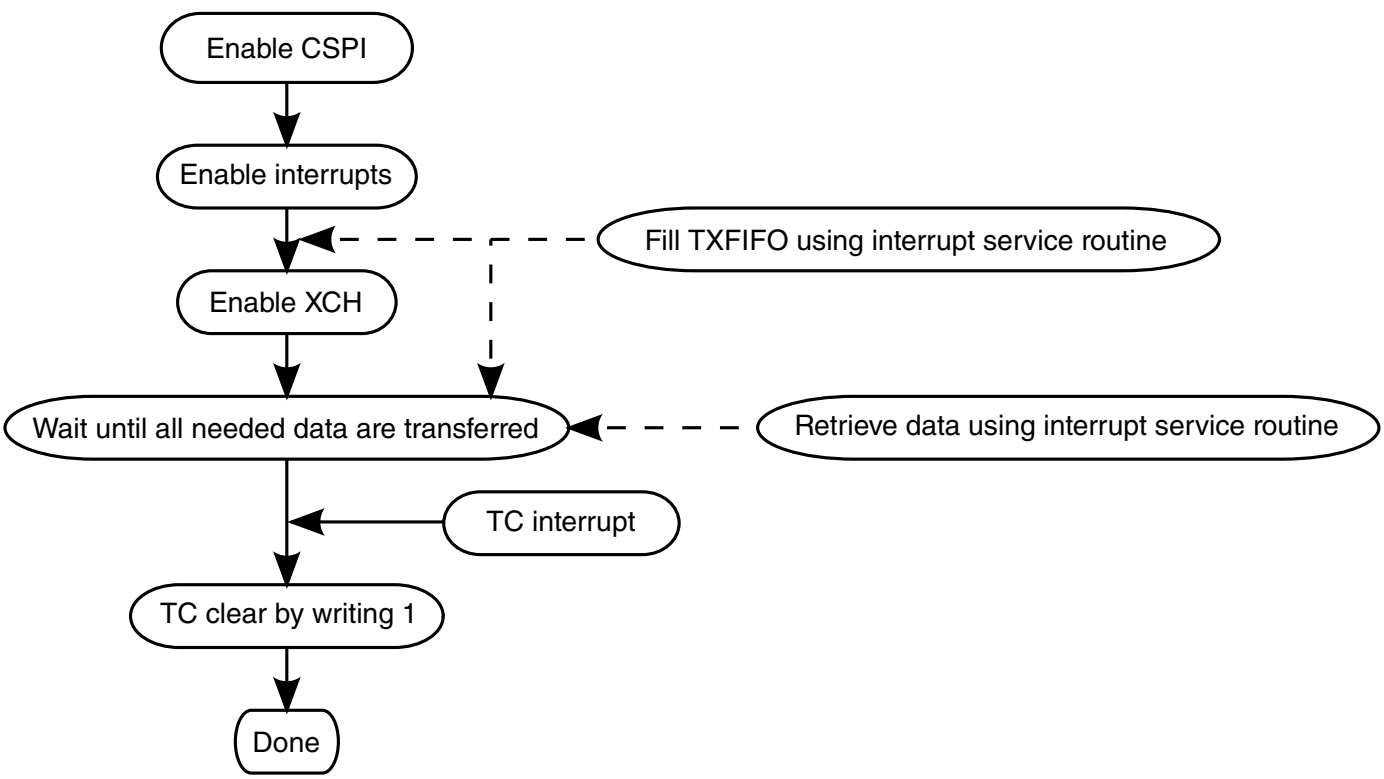

Figure 10-11. Program Sequence of SPI Burst Using Interrupt Control

NOTE

The TC bit does not provide a reliable indication that the transfer is complete. Under some conditions, the TC interrupt can occur before the transfer is completed. If the TC bit is used as an interrupt source, the XCH bit should be polled after the TC interrupt occurs to accurately confirm that the transfer is complete.

10.1.3.7 DMA

DMA control provides another method to utilize the FIFOs in the ECSPI. By using DMA request and acknowledge signals, larger amounts of data can be transferred, and will reduce interrupts and host processor loading. When the appropriate conditions are matched, the block will send out a DMA request.

The DMA can deal with the following conditions:

- TXFIFO empty
- TXFIFO data request
- RXFIFO data request
- RXFIFO full

The figure below shows a program sequence of SPI bursts using DMA control.

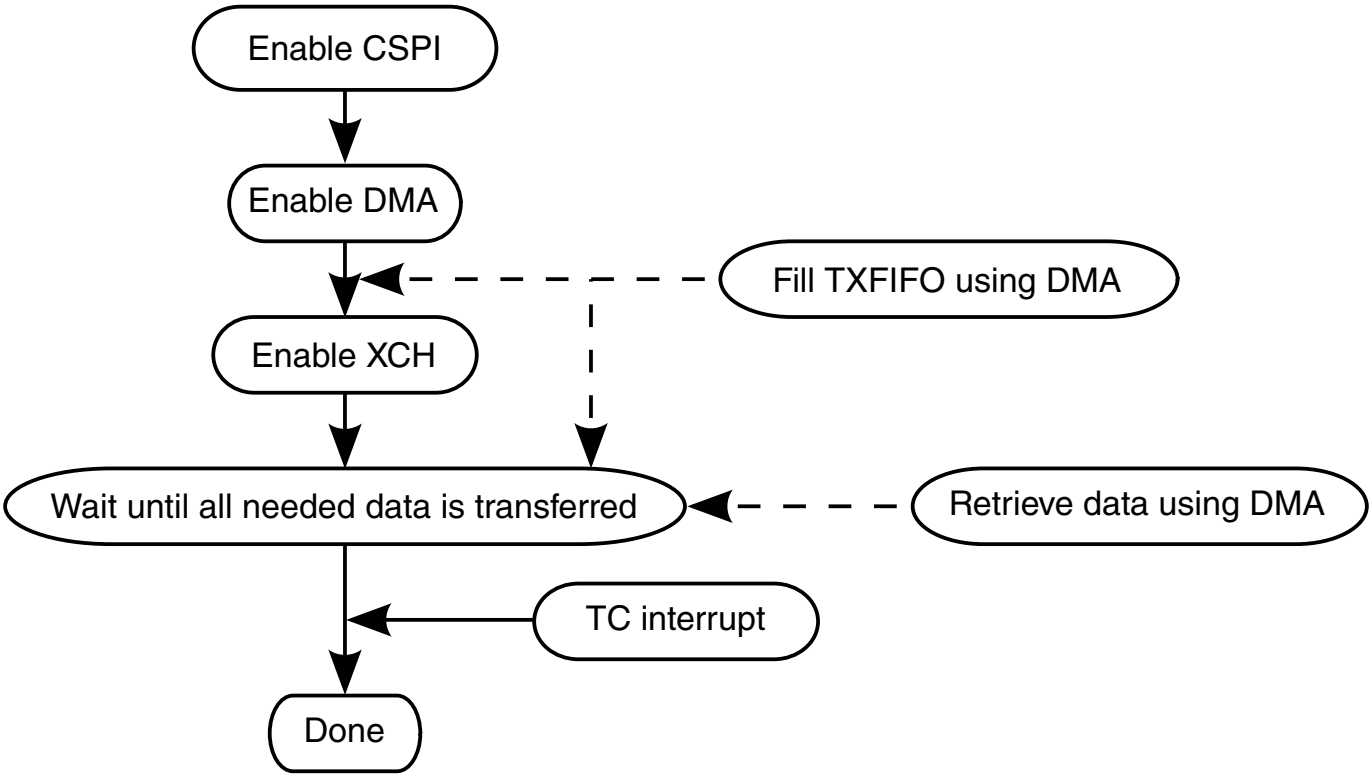

Figure 10-12. Program Sequence of SPI Burst Using DMA

NOTE

The TC bit does not provide a reliable indication that the transfer is complete. Under some conditions, the TC interrupt can occur before the transfer is completed. If the TC bit is used as an interrupt source, the XCH bit should be polled after the TC interrupt occurs to accurately confirm that the transfer is complete.

10.1.3.8 Byte Order

The ECSPI does not support byte re-ordering in hardware.

10.1.4 Initialization

This section provides initialization information for ECSPI.

To initialize the block:

1. Clear the EN bit in ECSPI_CONREG to reset the block.

2. Enable the clocks for ECSPI within the CCM.
3. Configure the Control Register and then set the EN bit in the ECSPI_CONREG to put ECSPI out of reset.
4. Configure corresponding IOMUX for ECSPI external signals.
5. Configure registers of ECSPI properly according to the specifications of the external SPI device.

10.1.5 Applications

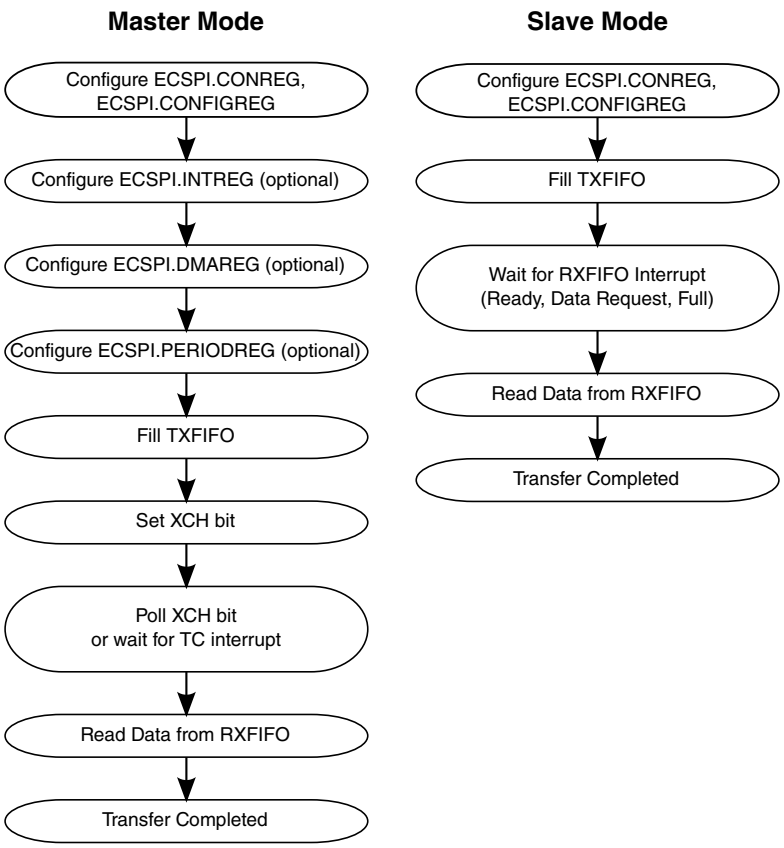

Figure 10-13. Flowchart of the ECSPI Operation

NOTE

The TC bit does not provide a reliable indication that the transfer is complete. Under some conditions, the TC interrupt can occur before the transfer is completed. If the TC bit is used as an interrupt source, the XCH bit should be polled after the TC interrupt occurs to accurately confirm that the transfer is complete.

10.1.6 ECSPI Memory Map/Register Definition

This section includes the block memory map and detailed descriptions of all registers. For the base address of a particular block instantiation, see the system memory map.

ECSPI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

10.1.6.1 Receive Data Register (ECSPIx_RXDATA)

The Receive Data register (ECSPI_RXDATA) is a read-only register that forms the top word of the 64 x 32 receive FIFO. This register holds the data received from an external SPI device during a data transaction. Only word-sized read operations are allowed.

Address: Base address + 0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ECSPIx_RXDATA field descriptions

Field	Description
ECSPI_RXDATA	Receive Data. This register holds the top word of the receive data FIFO. The FIFO is advanced for each read of this register. The data read is undefined when the Receive Data Ready (RR) bit in the Interrupt Control/Status register is cleared. Zeros are read when ECSPI is disabled.

10.1.6.2 Transmit Data Register (ECSPIx_TXDATA)

The Transmit Data (ECSPI_TXDATA) register is a write-only data register that forms the bottom word of the 64 x 32 TXFIFO. The TXFIFO can be written to as long as it is not full, even when the SPI Exchange bit (XCH) in ECSPI_CONREG is set. This allows software to write to the TXFIFO during a SPI data exchange process. Writes to this register are ignored when the ECSPI is disabled (ECSPI_CONREG[EN] bit is cleared).

Address: Base address + 4h offset

ECSPIx_TXDATA field descriptions

Field	Description
ECSPI_TXDATA	Transmit Data. This register holds the top word of data loaded into the FIFO. Data written to this register must be a word operation. The number of bits actually transmitted is determined by the BURST_LENGTH field of the corresponding SPI Control register. If this field contains more bits than the number specified by BURST_LENGTH, the extra bits are ignored. For example, to transfer 10 bits of data, a 32-bit word must be written to this register. Bits 9-0 are shifted out and bits 31-10 are ignored. When the ECSPI is operating in Slave mode, zeros are shifted out when the FIFO is empty. Zeros are read when ECSPI is disabled.

10.1.6.3 Control Register (ECSPIx_CONREG)

The Control Register (ECSPI_CONREG) allows software to enable the ECSPI , configure its operating modes, specify the divider value, and SPI_RDY control signal, and define the transfer length.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	BURST_LENGTH												CHANNEL_ SELECT		DRCTL	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	PRE_DIVIDER				POST_DIVIDER				CHANNEL_MODE				SMC	XCH	HT	EN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ECSPIx_CONREG field descriptions

Field	Description
31–20 BURST_ LENGTH	Burst Length. This field defines the length of a SPI burst to be transferred. The Chip Select (SS) will remain asserted until all bits in a SPI burst are shifted out. A maximum of 2^12 bits can be transferred in a single SPI burst. In master mode, it controls the number of bits per SPI burst. Since the shift register always loads 32-bit data from transmit FIFO, only the n least-significant (n = BURST LENGTH + 1) will be shifted out. The remaining bits will be ignored. Number of Valid Bits in a SPI burst. 0x000 A SPI burst contains the 1 LSB in a word. 0x001 A SPI burst contains the 2 LSB in a word. 0x002 A SPI burst contains the 3 LSB in a word. ... 0x01F A SPI burst contains all 32 bits in a word. 0x020 A SPI burst contains the 1 LSB in first word and all 32 bits in second word. 0x021 A SPI burst contains the 2 LSB in first word and all 32 bits in second word. ... 0xFFE A SPI burst contains the 31 LSB in first word and 2^7 -1 words. 0xFFF A SPI burst contains 2^7 words.
19–18 CHANNEL_ SELECT	SPI CHANNEL SELECT bits. Selects the external SPI Master/Slave Device. In master mode, these two bits select the external slave device by asserting the Chip Select (SS) output. 00 Channel 0 is selected. Chip Select (SS) will be asserted. 01 Reserved. 10 Reserved. 11 Reserved.
17–16 DRCTL	SPI Data Ready Control. This field selects the utilization of the SPI_RDY signal in master mode. ECSPI checks this field before it starts an SPI burst.

Table continues on the next page...

ECSPIx_CONREG field descriptions (continued)

Field	Description
	00 The SPI_RDY signal is a don't care. 01 Burst will be triggered by the falling edge of the SPI_RDY signal (edge-triggered). 10 Burst will be triggered by a low level of the SPI_RDY signal (level-triggered). 11 Reserved.
15–12 PRE_DIVIDER	SPI Pre Divider. ECSPI uses a two-stage divider to generate the SPI clock. This field defines the pre-divider of the reference clock. 0000 Divide by 1. 0001 Divide by 2. 0010 Divide by 3. ... 1101 Divide by 14. 1110 Divide by 15. 1111 Divide by 16.
11–8 POST_DIVIDER	SPI Post Divider. ECSPI uses a two-stage divider to generate the SPI clock. This field defines the post-divider of the reference clock using the equation: 2^{n} . 0000 Divide by 1. 0001 Divide by 2. 0010 Divide by 4. ... 1110 Divide by 2^{14} . 1111 Divide by 2^{15} .
7–4 CHANNEL_ MODE	SPI CHANNEL MODE selects the mode for each SPI channel. CHANNEL MODE[3] is for SPI channel 3. CHANNEL MODE[2] is for SPI channel 2. CHANNEL MODE[1] is for SPI channel 1. CHANNEL MODE[0] is for SPI channel 0. 0 Slave mode. 1 Master mode.
3 SMC	Start Mode Control. This bit applies only to channels configured in Master mode (CHANNEL MODE = 1). It controls how the ECSPI starts a SPI burst, either through the SPI exchange bit, or immediately when the TXFIFO is written to. 0 SPI Exchange Bit (XCH) controls when a SPI burst can start. Setting the XCH bit will start a SPI burst or multiple bursts. This is controlled by the SPI SS Wave Form Select (SS_CTL). Refer to XCH and SS_CTL descriptions. 1 Immediately starts a SPI burst when data is written in TXFIFO.
2 XCH	SPI Exchange Bit. This bit applies only to channels configured in Master mode (CHANNEL MODE = 1). If the Start Mode Control (SMC) bit is cleared, writing a 1 to this bit starts one SPI burst or multiple SPI bursts according to the SPI SS Wave Form Select (SS_CTL). The XCH bit remains set while either the data exchange is in progress, or when the ECSPI is waiting for an active input if SPIRDY is enabled through DRCTL. This bit is cleared automatically when all data in the TXFIFO and the shift register has been shifted out. 0 Idle. 1 Initiates exchange (write) or busy (read).

Table continues on the next page...

ECSPIx_CONREG field descriptions (continued)

Field	Description
1 HT	Hardware Trigger Enable. This bit is used in master mode only. It enables hardware trigger (HT) mode. Note, HT mode is not supported by this product. 0 Disable HT mode. 1 Enable HT mode.
0 EN	SPI Block Enable Control. This bit enables the ECSPI. This bit must be set before writing to other registers or initiating an exchange. Writing zero to this bit disables the block and resets the internal logic with the exception of the ECSPI_CONREG. The block's internal clocks are gated off whenever the block is disabled. 0 Disable the block. 1 Enable the block.

10.1.6.4 Config Register (ECSPIx_CONFIGREG)

The Config Register (ECSPI_CONFIGREG) allows software to configure each SPI channel, configure its operating modes, specify the phase and polarity of the clock, configure the Chip Select (SS), and define the HT transfer length. Note, HT mode is not supported by this product.

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved			HT_LENGTH					SCLK_CTL				DATA_CTL				SS_POL				SS_CTL				SCLK_POL				SCLK_PHA			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ECSPIx_CONFIGREG field descriptions

Field	Description
31–29 -	This field is reserved. Reserved
28–24 HT_LENGTH	HT LENGTH. This field defines the message length in HT Mode. Note, HT mode is not supported by this product. The length in bits of one message is (HT LENGTH + 1).
23–20 SCLK_CTL	SCLK CTL. This field controls the inactive state of SCLK for each SPI channel. SCLK CTL[3] is for SPI channel 3. SCLK CTL[2] is for SPI channel 2. SCLK CTL[1] is for SPI channel 1. SCLK CTL[0] is for SPI channel 0. 0 Stay low. 1 Stay high.

Table continues on the next page...

ECSPIx_CONFIGREG field descriptions (continued)

Field	Description
19–16 DATA_CTL	DATA CTL. This field controls inactive state of the data line for each SPI channel. DATA CTL[3] is for SPI channel 3. DATA CTL[2] is for SPI channel 2. DATA CTL[1] is for SPI channel 1. DATA CTL[0] is for SPI channel 0. 0 Stay high. 1 Stay low.
15–12 SS_POL	SPI SS Polarity Select. In both Master and Slave modes, this field selects the polarity of the Chip Select (SS) signal. SS POL[3] is reserved. SS POL[2] is reserved. SS POL[1] is reserved. SS POL[0] is for SPI channel 0. 0 Active low. 1 Active high.
11–8 SS_CTL	SPI SS Wave Form Select. In master mode, this field controls the output wave form of the Chip Select (SS) signal when the SMC (Start Mode Control) bit is cleared. The SS_CTL bits are ignored if the SMC bit is set. SS CTL[3] is reserved. SS CTL[2] is reserved. SS CTL[1] is reserved. SS CTL[0] is for SPI channel 0. In slave mode, this bit controls when the SPI burst is completed. An SPI burst is completed by the Chip Select (SS) signal edges. (SSPOL = 0: rising edge; SSPOL = 1: falling edge) The RXFIFO is advanced whenever a Chip Select (SS) signal edge is detected or the shift register contains 32-bits of valid data. 0 In master mode - only one SPI burst will be transmitted. 1 In master mode - Negate Chip Select (SS) signal between SPI bursts. Multiple SPI bursts will be transmitted. The SPI transfer will automatically stop when the TXFIFO is empty. 0 In slave mode - an SPI burst is completed when the number of bits received in the shift register is equal to (BURST LENGTH + 1). Only the n least-significant bits (n = BURST LENGTH[4:0] + 1) of the first received word are valid. All bits subsequent to the first received word in RXFIFO are valid. 1 Reserved
7–4 SCLK_POL	SPI Clock Polarity Control. This field controls the polarity of the SCLK signal. See Figure 10-9 for more information. SCLK_POL[3] is for SPI channel 3. SCLK_POL[2] is for SPI channel 2. SCLK_POL[1] is for SPI channel 1. SCLK_POL[0] is for SPI channel 0.

Table continues on the next page...

ECSPIx_CONFIGREG field descriptions (continued)

Field	Description
	0 Active high polarity (0 = Idle). 1 Active low polarity (1 = Idle).
SCLK_PHA	SPI Clock/Data Phase Control. This field controls the clock/data phase relationship. See Figure 10-9 for more information. SCLK PHA[3] is for SPI channel 3. SCLK PHA[2] is for SPI channel 2. SCLK PHA[1] is for SPI channel 1. SCLK PHA[0] is for SPI channel 0. 0 Phase 0 operation. 1 Phase 1 operation.

10.1.6.5 Interrupt Control Register (ECSPIx_INTREG)

The Interrupt Control Register (ECSPI_INTREG) enables the generation of interrupts to the host processor. If the ECSPI is disabled, this register reads zero.

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ECSPIx_INTREG field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
7 TCEN	Transfer Completed Interrupt enable. This bit enables the Transfer Completed Interrupt. 0 Disable 1 Enable

Table continues on the next page...

ECSPIx_INTREG field descriptions (continued)

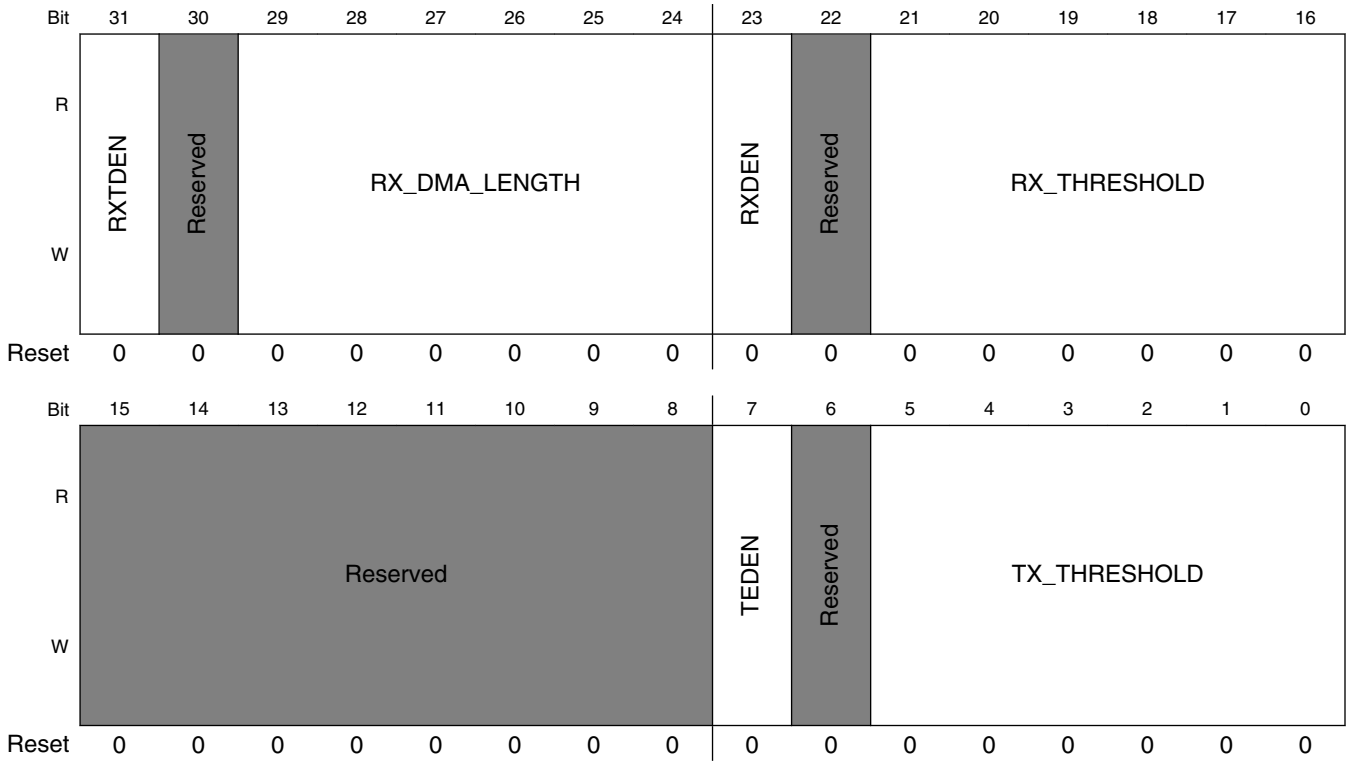
Field	Description
6 ROEN	RXFIFO Overflow Interrupt enable. This bit enables the RXFIFO Overflow Interrupt. 0 Disable 1 Enable
5 RFEN	RXFIFO Full Interrupt enable. This bit enables the RXFIFO Full Interrupt. 0 Disable 1 Enable
4 RDREN	RXFIFO Data Request Interrupt enable. This bit enables the RXFIFO Data Request Interrupt when the number of data entries in the RXFIFO is greater than RX_THRESHOLD. 0 Disable 1 Enable
3 RREN	RXFIFO Ready Interrupt enable. This bit enables the RXFIFO Ready Interrupt. 0 Disable 1 Enable
2 TFEN	TXFIFO Full Interrupt enable. This bit enables the TXFIFO Full Interrupt. 0 Disable 1 Enable
1 TDREN	TXFIFO Data Request Interrupt enable. This bit enables the TXFIFO Data Request Interrupt when the number of data entries in the TXFIFO is less than or equal to TX_THRESHOLD. 0 Disable 1 Enable
0 TEEN	TXFIFO Empty Interrupt enable. This bit enables the TXFIFO Empty Interrupt. 0 Disable 1 Enable

10.1.6.6 DMA Control Register (ECSPIx_DMAREG)

The Direct Memory Access Control Register (ECSPI_DMAREG) provides software a way to use an on-chip DMA controller for ECSPI data. Internal DMA request signals enable direct data transfers between the ECSPI FIFOs and system memory. The ECSPI sends out DMA requests when the appropriate FIFO conditions are matched.

If the ECSPI is disabled, this register is read as 0.

Address: Base address + 14h offset



ECSPIx_DMAREG field descriptions

Field	Description
31 RXTDEN	RXFIFO TAIL DMA Request/Interrupt Enable. This bit enables an internal counter that is increased at each read of the RXFIFO. This counter is cleared automatically when it reaches RX DMA LENGTH. If the number of words remaining in the RXFIFO is greater than or equal to RX DMA LENGTH, a DMA request/ interrupt is generated even if it is less than or equal to RX_THRESHOLD. 0 Disable 1 Enable
30 -	This field is reserved. Reserved
29–24 RX_DMA_ LENGTH	RX DMA LENGTH. This field defines the burst length of a DMA operation. Applies only when RXTDEN is set.
23 RXDEN	RXFIFO DMA Request Enable. This bit enables/disables the RXFIFO DMA Request. 0 Disable 1 Enable
22 -	This field is reserved. Reserved
21–16 RX_ THRESHOLD	RX THRESHOLD. This field defines the FIFO threshold that triggers a RX DMA/INT request. A RX DMA/INT request is issued when the number of data entries in the RXFIFO is greater than RX_THRESHOLD.
15–8 -	This field is reserved. Reserved

Table continues on the next page...

ECSPIx_DMAREG field descriptions (continued)

Field	Description
7 TEDEN	TXFIFO Empty DMA Request Enable. This bit enables/disables the TXFIFO Empty DMA Request. 0 Disable 1 Enable
6 -	This field is reserved. Reserved
TX_ THRESHOLD	TX THRESHOLD. This field defines the FIFO threshold that triggers a TX DMA/INT request. A TX DMA/INT request is issued when the number of data entries in the TXFIFO is not greater than TX_THRESHOLD.

10.1.6.7 Status Register (ECSPIx_STATREG)

The ECSPI Status Register (ECSPI_STATREG) reflects the status of the ECSPI's operating condition. If the ECSPI is disabled, this register reads 0x0000_0003.

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								TC	RO	RF	RDR	RR	TF	TDR	TE
W									w1c	w1c						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

ECSPIx_STATREG field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
7 TC	Transfer Completed Status bit. Writing 1 to this bit clears it. **NOTE:** The TC bit does not provide a reliable indication that the transfer is complete. Under some conditions, the TC interrupt can occur before the transfer is completed. If the TC bit is used as an interrupt source, the XCH bit should be polled after the TC interrupt occurs to accurately confirm that the transfer is complete. 0 Transfer in progress. 1 Transfer completed.
6 RO	RXFIFO Overflow. When set, this bit indicates that RXFIFO has overflowed. Writing 1 to this bit clears it.

Table continues on the next page...

ECSPIx_STATREG field descriptions (continued)

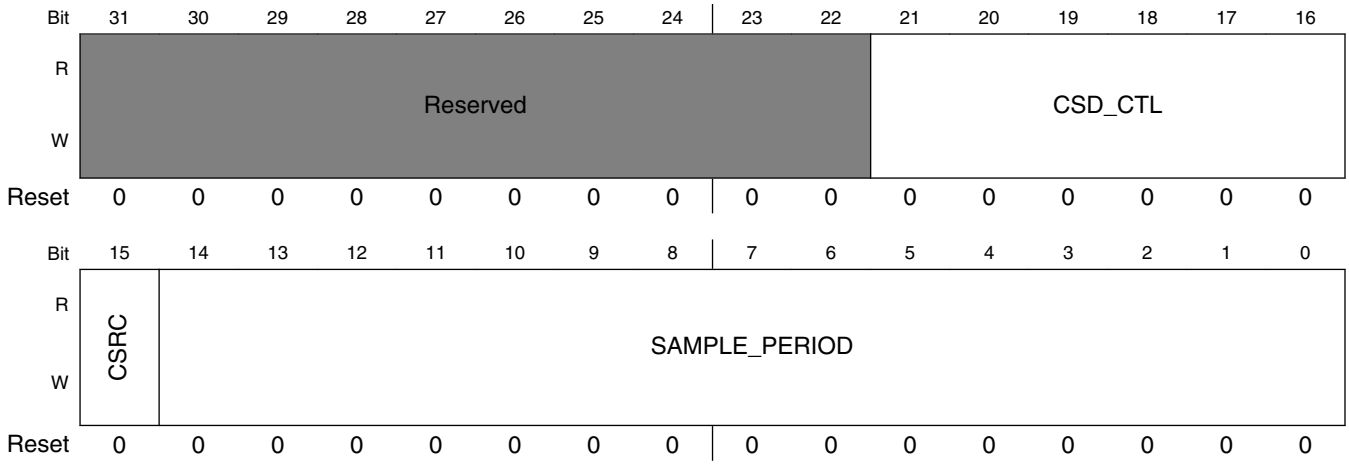
Field	Description
	0 RXFIFO has no overflow. 1 RXFIFO has overflowed.
5 RF	RXFIFO Full. This bit is set when the RXFIFO is full. 0 Not Full. 1 Full.
4 RDR	RXFIFO Data Request. 0 When RXTDE is set - Number of data entries in the RXFIFO is not greater than RX_THRESHOLD. 1 When RXTDE is set - Number of data entries in the RXFIFO is greater than RX_THRESHOLD or a DMA TAIL DMA condition exists. 0 When RXTDE is clear - Number of data entries in the RXFIFO is not greater than RX_THRESHOLD. 1 When RXTDE is clear - Number of data entries in the RXFIFO is greater than RX_THRESHOLD.
3 RR	RXFIFO Ready. This bit is set when one or more words are stored in the RXFIFO. 0 No valid data in RXFIFO. 1 More than 1 word in RXFIFO.
2 TF	TXFIFO Full. This bit is set when if the TXFIFO is full. 0 TXFIFO is not Full. 1 TXFIFO is Full.
1 TDR	TXFIFO Data Request. 0 Number of valid data slots in TXFIFO is greater than TX_THRESHOLD. 1 Number of valid data slots in TXFIFO is not greater than TX_THRESHOLD.
0 TE	TXFIFO Empty. This bit is set if the TXFIFO is empty. 0 TXFIFO contains one or more words. 1 TXFIFO is empty.

10.1.6.8 Sample Period Control Register (ECSPIx_PERIODREG)

The Sample Period Control Register (ECSPI_PERIODREG) provides software a way to insert delays (wait states) between consecutive SPI transfers. Control bits in this register select the clock source for the sample period counter and the delay count indicating the number of wait states to be inserted between data transfers.

The delay counts apply only when the current channel is operating in Master mode (ECSPI_CONREG[CHANNEL MODE] = 1).ECSPI_PERIODREG also contains the CSD CTRL field used to insert a delay between the Chip Select's active edge and the first SPI Clock edge.

Address: Base address + 1Ch offset



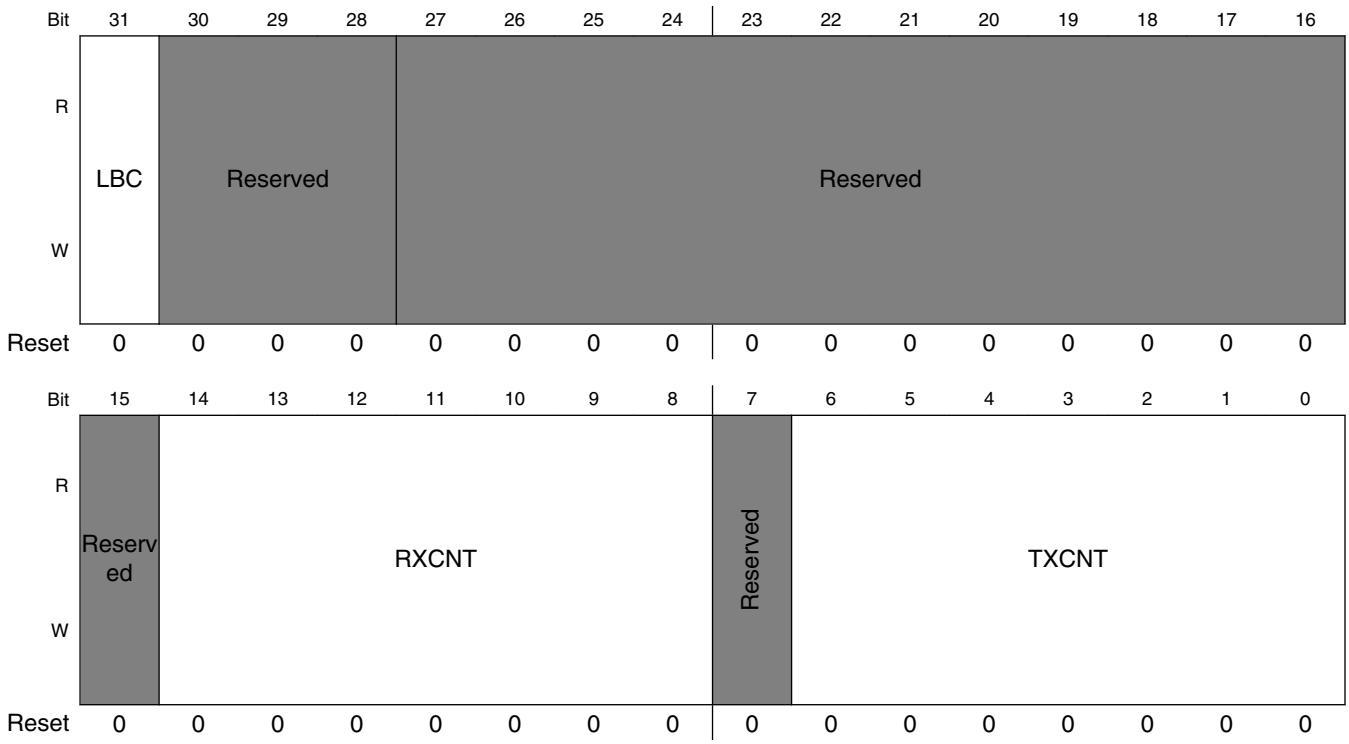
ECSPIx_PERIODREG field descriptions

Field	Description
31–22 -	This field is reserved. Reserved
21–16 CSD_CTL	Chip Select Delay Control bits. This field defines how many SPI clocks will be inserted between the chip select's active edge and the first SPI clock edge. The range is from 0 to 63.
15 CSRC	Clock Source Control. This bit selects the clock source for the sample period counter. 0 SPI Clock (SCLK) 1 Low-Frequency Reference Clock (32.768 KHz)
SAMPLE_ PERIOD	Sample Period Control. These bits control the number of wait states to be inserted in data transfers. During the idle clocks, the state of the SS output will operate according to the SS_CTL control field in the ECSPI_CONREG register. 0x0000 0 wait states inserted 0x0001 1 wait state inserted ... ... 0x7FFE 32766 wait states inserted 0x7FFF 32767 wait states inserted

10.1.6.9 Test Control Register (ECSPIx_TESTREG)

The Test Control Register (ECSPI_TESTREG) provides software a mechanism to internally connect the receive and transmit devices of the ECSPI, and monitor the contents of the receive and transmit FIFOs.

Address: Base address + 20h offset



ECSPIx_TESTREG field descriptions

Field	Description
31 LBC	Loop Back Control. This bit is used in Master mode only. When this bit is set, the ECSPI connects the transmitter and receiver sections internally, and the data shifted out from the most-significant bit of the shift register is looped back into the least-significant bit of the Shift register. In this way, a self-test of the complete transmit/receive path can be made. The output pins are not affected, and the input pins are ignored. 0 Not connected. 1 Transmitter and receiver sections internally connected for Loopback.
30–28 -	This field is reserved. Reserved, all bits should be ignored.
27–15 -	This field is reserved. Reserved
14–8 RXCNT	RXFIFO Counter. This field indicates the number of words in the RXFIFO.

Table continues on the next page...

ECSPIx_TESTREG field descriptions (continued)

Field	Description
7 -	This field is reserved. Reserved
TXCNT	TXFIFO Counter. This field indicates the number of words in the TXFIFO.

10.1.6.10 Message Data Register (ECSPIx_MSGDATA)

The Message Data Register (ECSPI_MSGDATA) forms the top word of the 16 x 32 MSG Data FIFO. Only word-size accesses are allowed for this register. Reading from this register returns zero, and writing to this register stores data in the MSG Data FIFO.

Address: Base address + 40h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W	ECSPI_MSGDATA																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ECSPIx_MSGDATA field descriptions

Field	Description
ECSPI_ MSGDATA	ECSPI_MSGDATA holds the top word of MSG Data FIFO. The MSG Data FIFO is advanced for each write of this register. The data read is zero. The data written to this register is stored in the MSG Data FIFO.

10.2 Quad Serial Peripheral Interface (QuadSPI)

10.2.1 Overview

The Quad Serial Peripheral Interface (QuadSPI) block acts as an interface to one or two external serial flash devices, each with up to four bidirectional data lines. The following figure is a block diagram of the QuadSPI module.

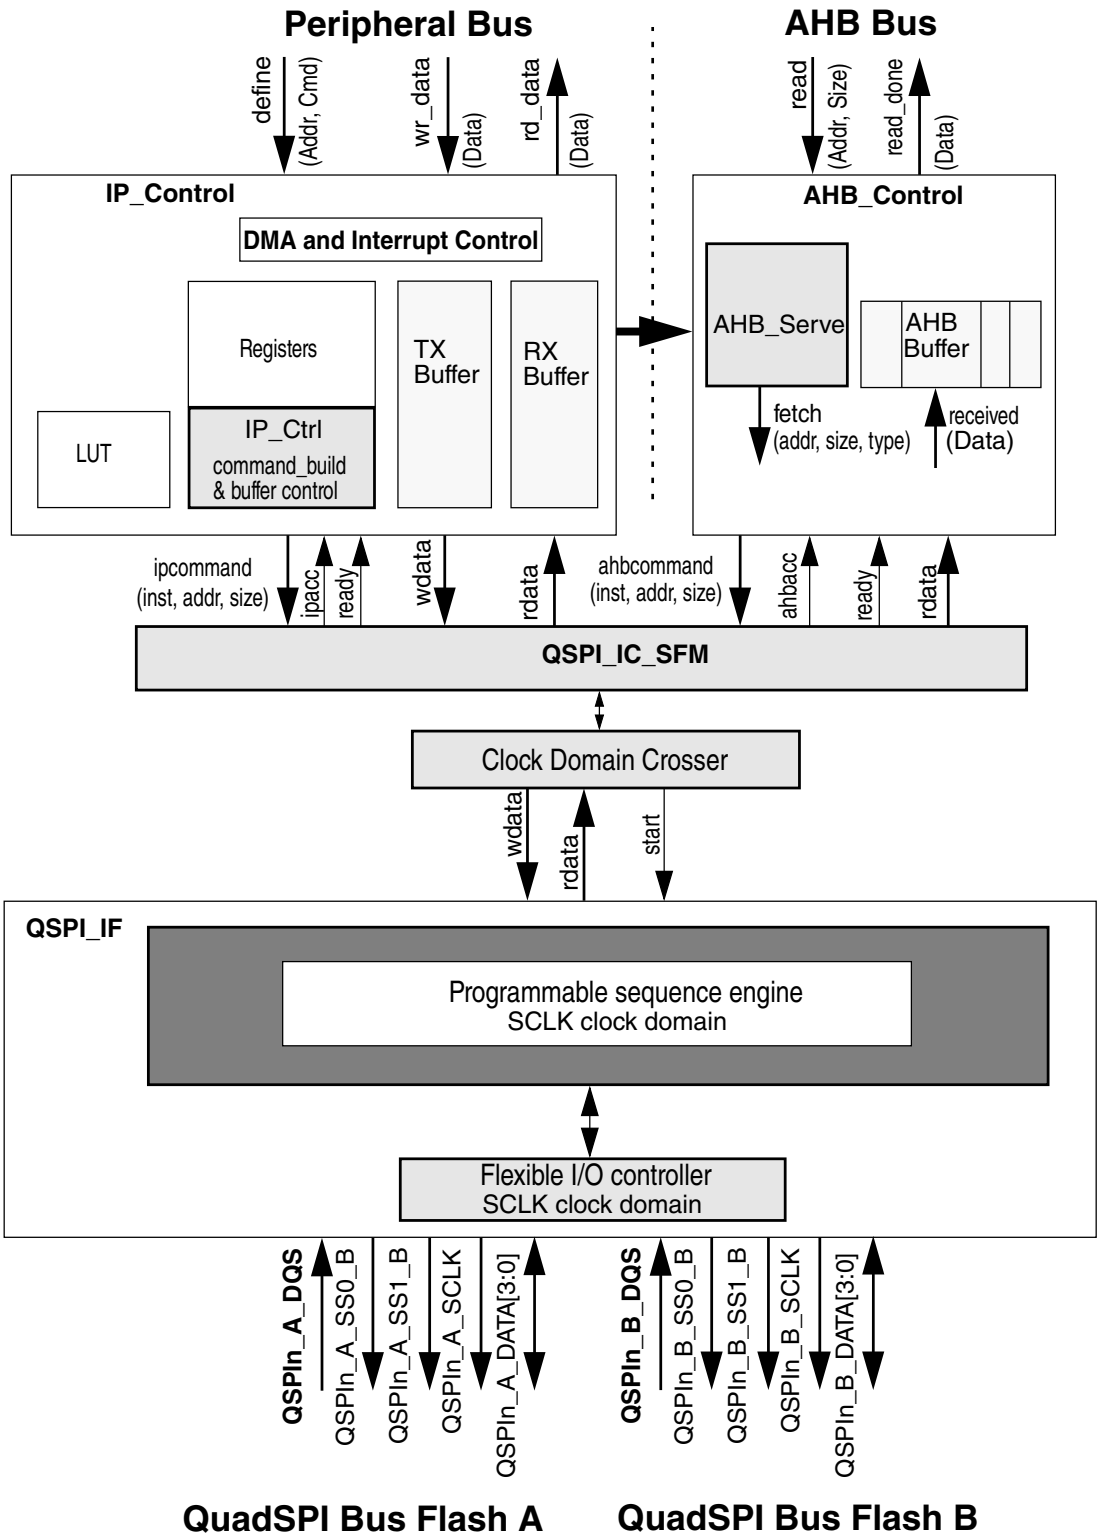


Figure 10-14. QuadSPI Block Diagram

The following figure describes the serial flash clock diagram in QuadSPI:

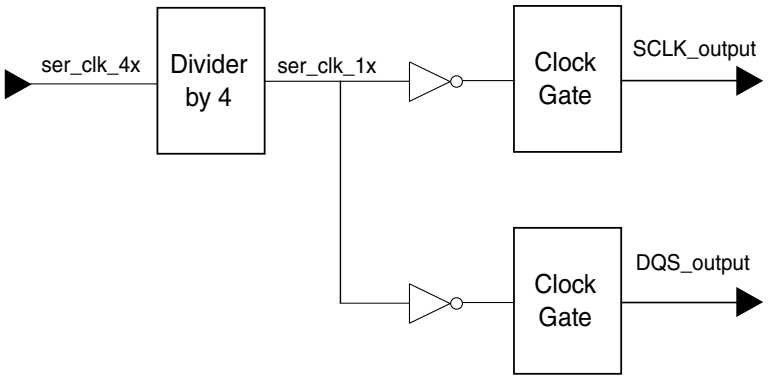

Figure 10-15. Flash Clock Diagram

ser_clk_4x is the serial clock root from CCM

ser_clk_1x' is generated clock from 'ser_clk_4x' divided by 4

SCLK_output is serial output clock generated from 'ser_clk_1x' with inverter and clock gate, it's used as Clock by external serial flash device.

DQS_output is serial flash data strobe signal generated from 'ser_clk_1x' with inverter and clock gate. This signal could be loopback from pad and used as sampling clock for serial flash data.

10.2.1.1 Features

The QuadSPI supports the following features:

- Flexible sequence engine to support various flash vendor devices.
- Single, dual, quad mode of operation.
- DDR/DTR mode wherein the data is generated on every edge of the serial flash clock.
- Support for flash data strobe signal for data sampling in DDR and SDR mode.
- Two identical serial flash devices can be connected and accessed in parallel for data read operations, forming one (virtual) flash memory with doubled readout bandwidth.
- DMA support to read RX Buffer data via AMBA AHB bus (64-bit width interface) or IP registers space (32-bit access).
    - Inner loop size of DMA access can be configured.
- Multi master accesses with priority

    - Flexible and configurable buffer for each master
- Thirteen interrupt conditions (see Table 10-10)
- Memory mapped read access to connected flash devices.
- Programmable sequence engine to cater to future command/protocol changes and able to support all existing vendor commands and operations.
    - Supports 3-byte and 4-byte addressing.
    - TXFIFO size is 512Byte
    - RXFIFO size is 512Byte
    - AHB BUF size is 1KByte

10.2.1.2 QuadSPI Modes of Operation

This section provides information about the modes in which the QuadSPI module can be used.

10.2.1.2.1 Normal Mode

In this mode, one or two external serial flash memory devices can be accessed. Further details about this mode of operation can be found in Modes of Operation (Normal Mode).

10.2.1.2.2 Module Disable Mode

This mode is used for power management of the device containing the QuadSPI module. It is controlled by signals external to the QuadSPI. The clock to the non-memory mapped logic in the QuadSPI can be stopped while in Module Disable Mode.

10.2.1.3 Acronyms and Abbreviations

The following table contains acronyms and abbreviations used in this document.

Table 10-2. Acronyms and Abbreviations

Terms	Description
AHB	Advanced High-performance Bus, version of AMBA
AMBA	Advanced Microcontroller Bus Architecture
BE	Big Endian Byte Ordering
CS	Chip Select
DMA	Direct Memory Access

Table continues on the next page...

Table 10-2. Acronyms and Abbreviations (continued)

Terms	Description
MB	Megabyte. Each MB is 1024 * 1024 bytes
IFM	Individual Flash Mode
PFM	Parallel Flash Mode
LSB	Least Significant Bit
MSB	Most Significant Bit
PCS	Peripheral Chip Select
QSPI, QuadSPI	Quad Serial Peripheral Interface
SCK	Serial Communications Clock
w1c	Write 1 to clear, writing a 1 to this field resets the flag

10.2.1.4 Glossary for QuadSPI module

Table 10-3. Glossary

Term	Definition
AHB Command	An AHB Command is a SFM Command triggered by a read access to the address range belonging to the memory mapped access defined in Table 10-7. Refer to AHB Commands for details.
Asserted	A signal that is asserted is in its active state. An active low signal changes from logic level one to logic level zero when asserted, and an active high signal changes from logic level zero to logic level one.
Clear	To clear a bit or bits means to establish logic level zero on the bit or bits.
Clock Phase	Determines when the data should be sampled relative to the active edge of SCK
Clock Polarity	Determines the idle state of the SCK signal.
Drain	To remove entries from a FIFO by software or hardware.
Endianness	Byte Ordering scheme.
Field	Two or more register bits grouped together.
Fill	To add entries to a FIFO by software or hardware.
Host	Refers to another functional block in the device containing the QuadSPI module
Instruction Code	8 bits defining the type of command to be executed.
IP Command	An IP Command is a SFM Command triggered by writing into the QSPI_IPCR[SEQID] field.
Logic level one	The voltage that corresponds to Boolean true (1) state.
Logic level zero	The voltage that corresponds to Boolean false (0) state.
Negated	A signal that is negated is in its inactive state. An active low signal changes from logic level 0 to logic level 1 when negated, and an active high signal changes from logic level 1 to logic level 0.
QSPI_AMBA_BASE	First address of QuadSPI address space on system memory map.
QSPI_ARDB_BASE	First address of QuadSPI Rx Buffer on system memory map.
Set	To set a bit or bits means to establish logic level one on the bit or bits.

Table continues on the next page...

Table 10-3. Glossary (continued)

Term	Definition
RX Buffer PUSH Event	Addition of valid entries into the RX Buffer. In the default case each Buffer PUSH Event adds 2 entries to the RX Buffer since the interface to the serial clock domain is 64 bits in width. Depending on the number of bytes read from the serial flash device it is possible for the very last Buffer PUSH Event that only one entry is added. The QSPI_RBSR[RDBFL] field is incremented by the number of entries added to the RX Buffer.
RX Buffer POP Event	Removal of valid entries from the RX Buffer. Each Buffer POP Event removes (QSPI_RBCT[WMRK] + 1) valid entries from the buffer. The QSPI_RBSR[RDBFL] field is decremented by the same number and the QSPI_RBSR[RDCTR] field is incremented accordingly.
Individual Flash Mode	Access to a single, individual serial flash device. Refer to Serial Flash Access Schemes for details.
Parallel Flash Mode	Read access to two serial flash devices attached to the QuadSPI module in parallel. Refer to Serial Flash Access Schemes for details.
SFM Command	Serial Flash Memory Command. A SFM command consists of an instruction code and all other parameters (for example, size or mode bytes) needed for that specific instruction code. Triggering a command either initiates a transaction on the external serial flash or results in an error. Refer to Table 10-20 for details on errors.
Single/Dual/Quad Instructions	Depending on the serial flash device connected to the QuadSPI module there will be instructions using a different number of data lines. • Single: Single line I/O with one data out and one data in line to/from the serial flash device. • Dual: Dual line I/O with two bidirectional I/O lines, driven alternatively by the serial flash device or the QuadSPI module • Quad: Quad line I/O with 4 bidirectional I/O lines, driven alternatively by the serial flash device or the QuadSPI
Transaction	A transaction consists of all flags, data and signals in either direction to execute a command for an attached serial flash device. It is a combination of chip select, sclk, instruction code, address, mode- and/or dummy bytes, transmit and/or receive data.
LUT	Look-up table.

10.2.2 Memory Map and Register Definition

This section provides the memory map and register definitions of the QuadSPI module.

10.2.2.1 Register Write Access

This section describes the write access restriction terms that apply to all registers, which can be one of the following:

- **Register Write Access Restriction**

For each register bit and register field, the write access conditions are specified in the detailed register description. A description of the write access conditions is given in the following table. If, for a specific register bit or field, none of the given write access conditions is fulfilled, any write attempt to this register bit or field is ignored without any notification. The values of the bits or fields are not changed.

The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled.

Table 10-4. Register Write Access Restrictions

Condition	Description
Anytime	No write access restriction.
Disabled Mode	Write access only if *QSPI_MCR[MDIS] = 1*.
Normal Mode	Write access only if the module is in *Normal Mode*.

- **Register Write Access Requirements**

  All registers can be accessed with 8-bit, 16-bit, and 32-bit wide operations. For some of the registers, at least a 16/32-bit wide write access is required to ensure correct operation. This write access requirement is stated in the detailed register description for each register affected.

10.2.2.2 Serial Flash Address Assignment

The serial flash address assignment may be modified by writing into Serial Flash A1 Top Address (QuadSPI_SFA1AD) and Serial Flash A2 Top Address (QuadSPI_SFA2AD) for device A and into Serial Flash B1Top Address (QuadSPI_SFB1AD) and Serial Flash B2Top Address (QuadSPI_SFB2AD) for device B. The following table shows how different access modes are related to the address specified for the next SFM Command. Note that this address assignment is valid for both IP and AHB commands.

Table 10-5. Serial Flash Address Assignment

Parameter	Function	Access Mode
QSPI_AMBA_BASE ((31:10) - 22 bits)	QuadSPI AHB base address	
TOP_ADDR_MEMA1(TPADA1)	Top address for the external flash A1 (first device of the dual die flash A, or the first of the two independent flashes sharing the IOFA)	Any access to the address space between TOP_ADDR_MEMA1 and QSPI_AMBA_BASE will be routed to **Serial Flash A1**

Table continues on the next page...

Table 10-5. Serial Flash Address Assignment (continued)

Parameter	Function	Access Mode
TOP_ADDR_MEMA2(TPADA2)	Top address for the external flash A2 (second device of the dual die flash A, or the second of the two independent flashes sharing the IOFA).	Any access to the address space between TOP_ADDR_MEMA2 and TOP_ADDR_MEMA1 will be routed to **Serial Flash A2**
TOP_ADDR_MEMB1(TPADB1)	Top address for the external flash B1 (first device of the dual die flash B, or the first of the two independent flashes sharing the IOFB)	Any access to the address space between TOP_ADDR_MEMB1 and TOP_ADDR_MEMA2 will be routed to **Serial Flash B1**
TOP_ADDR_MEMB2(TPADB2)	Top address for the external flash B2 (second device of the dual die flash B or the second of the two independent flashes sharing the IOFB)	Any access to the address space between TOP_ADDR_MEMB2 and TOP_ADDR_MEMB1 will be routed to **Serial Flash A2**

10.2.2.3 AMBA Bus Register Memory Map

QSPI_AMBA_BASE defines the address to be used as start address of the serial flash device as defined by the system memory map..

Table 10-6. QuadSPI AMBA Bus Memory Map

Address	Register Name
Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A	
QSPI_AMBA_BASE to (TOP_ADDR_MEMA2 - 0x01)	Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A Refer to Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A for details and to Table 10-14 and Table 10-18 for information about the byte ordering.
Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B	
TOP_ADDR_MEMA2 to (TOP_ADDR_MEMB2 - 0x01)	Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B Refer to Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B for details and to Table 10-14 and Table 10-18 for information about the byte ordering.
Parallel Flash Mode	
QSPI_AMBA_BASE to (TOP_ADDR_MEMB2 - 0x01)	Parallel Flash Mode Refer to Parallel Flash Mode for details and to Table 10-17 and Table 10-18 for information about the byte ordering.
AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)	
QSPI_ARDB_BASE to… (32 * 4 Byte) QSPI_ARDB_BASE + 0x0000_01FF	AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31) Refer to Table 10-14 and Table 10-16 for information about the byte ordering.

Note

Any read access to non-implemented addresses will provide undefined results.

In case single die flash devices, TOP_ADDR_MEMA2 and TOP_ADDR_MEMB2 should be initialized/programmed to TOP_ADDR_MEMA1 and TOP_ADDR_MEMB1 respectively- in effect, setting the size of these devices to 0. This would ensure that the complete memory map is assigned to only one flash device.

Parallel Flash Mode is valid only for commands related to data read from the serial flash. The first device of flash A has to be paired with the first device of flash B and the second device of flash A has to be paired with the second device of flash B in parallel mode. Parallel mode is selected via the QSPI_BFGENCR[PAR_EN] bit for all masters in AHB driven mode and via the QSPI_IPCR[PAR_EN] in IP driven mode. In parallel mode, the incoming address (SFAR address in case of IP initiated transactions and the incoming AHB address in case of AHB initiated transactions) is divided by 2 and sent to the two flashes connected in parallel.

Any IP Command other than data read in Parallel Flash Mode will result in the assertion of the QSPI_FR[IUEF] flag and any AHB Command other than data read in Parallel Flash Mode will result in the assertion of the QSPI_FR[ABSEF] flag.

In the Individual Flash Modes, the 3/4 address bytes (as programmed in the instruction/operand in the sequence) available for the flash address is determined by SFADR [23:0] or SFADR [31:0]as given in the table above.

In Parallel Flash Mode, both flashes are read with the same starting address of 3/4 (as programmed in the instruction/ operand in the sequence) bytes in size. This address is derived from SFADR [24:1] or SFADR [31:1] as given in the table above. The LSB of the SFADR field is used to select the appropriate bits of both flash devices to combine the byte corresponding to the selected address.

10.2.2.4 AHB Bus Register Memory Map Descriptions

This chapter contains definitions of registers in the AMBA address space.

10.2.2.4.1 AHB Bus Access Considerations

It has to be noted that all logic in the QuadSPI module implementing the AHB Bus access is designed to read the content of an external serial flash device. Therefore the following restrictions apply to the QuadSPI module with respect to accesses to the AHB bus:

- Any write access is answered with the ERROR condition according to the AMBA AHB Specification. No write occurs.
- Any AHB Command resulting in the assertion of the QSPI_FR[ABSEF] flag is answered with the ERROR condition according to the AMBA_AHB specification. The resulting AHB Command is ignored.
- AHB Bus access types fully supported are NONSEQ and BUSY.
- AHB access type SEQ is treated in the same way like NONSEQ. Refer to the AMBA AHB Specification for further details.

10.2.2.4.2 Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A

Starting with address QSPI_AMBA_BASE the content of the first external serial flash devices is mapped into the address space of the device containing the QuadSPI module. Serial flash address byte address 0x0 corresponds to bus address QSPI_AMBA_BASE with increasing order. Assuming that a dual-die flash is connected on the first set of external pads, the address space is divided into two parts, one for each device of the dual die package. Refer to the following table for the address mapping. The byte ordering for 32 bit access is given in Table 10-14 and for 64 bit read access the byte ordering is given in Table 10-18.

Table 10-7. Memory Mapped Individual Flash Mode - Flash A Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash Byte Address	Flash Device
QSPI_AMBA_BASE + 0x00	QSPI_AMBA_BASE + 0x00	0x00_0000 to 0x00_0003	A1
QSPI_AMBA_BASE + 0x04		0x00_0004 to 0x00_0007	
…	…	…	
TOP_ADDR_MEMA1 - 0x08	TOP_ADDR_MEMA1 - 0x08	(TOP_ADDR_MEMA1- 0x08) to (TOP_ADDR_MEMA1 - 0x04 -0x01)	
TOP_ADDR_MEMA1 - 0x04		(TOP_ADDR_MEMA1 - 0x04) to (TOP_ADDR_MEMA1 - 0x01)	

Table continues on the next page...

Table 10-7. Memory Mapped Individual Flash Mode - Flash A Address Scheme (continued)

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash Byte Address	Flash Device
TOP_ADDR_MEMA1 + 0x00	TOP_ADDR_MEMA1 + 0x00_0000	0x00_0000 to 0x00_0003	A2
TOP_ADDR_MEMA1 + 0x04		0x00_0004 to 0x00_0007	
…..	…	…	
TOP_ADDR_MEMA2 - 0x08	TOP_ADDR_MEMA2 - 0x08	(TOP_ADDR_MEMA2 - 0x08) to (TOP_ADDR_MEMA2 - 0x04 - 0x01)	
TOP_ADDR_MEMA2 - 0x04		(TOP_ADDR_MEMA2 - 0x04) to (TOP_ADDR_MEMA2 - 0x01)	

The available address range depends from the size of the external serial flash device. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to Flash Read.

10.2.2.4.3 Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B

Starting with address TOP_ADDR_MEMA2 the content of the first external serial flash devices is mapped into the address space of the device containing the QuadSPI module. Serial flash address byte address 0x0 corresponds to bus address TOP_ADDR_MEMA2 with increasing order. Assuming that a dual-die flash is connected on the first set of external pads, the address space is divided into two parts, one for each device of the dual die package. Refer the following table for the address mapping. The byte ordering for 32 bit access is given in Table 10-14 and for 64 bit read access the byte ordering is given in Table 10-18.

Table 10-8. Memory Mapped Individual Flash Mode - Flash B Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash Byte Address	Flash Device
TOP_ADDR_MEMA2 + 0x00	TOP_ADDR_MEMA2 + 0x00	0x00_0000 to 0x00_0003	B1
TOP_ADDR_MEMA2 + 0x04		0x00_0004 to 0x00_0007	
…	…	…	
TOP_ADDR_MEMB1 - 0x08	TOP_ADDR_MEMB1 - 0x08	(TOP_ADDR_MEMB1- TOP_ADDR_MEMA2 - 0x08) to (TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x04 -0x01)	
TOP_ADDR_MEMB1 - 0x04		(TOP_ADDR_MEMB1- TOP_ADDR_MEMA2 - 0x04) to (TOP_ADDR_MEMB1- TOP_ADDR_MEMA2- 0x01)	
TOP_ADDR_MEMB1 + 0x00	TOP_ADDR_MEMB1 + 0x00_0000	0x00_0000 to 0x00_0003	B2

Table continues on the next page...

Table 10-8. Memory Mapped Individual Flash Mode - Flash B Address Scheme (continued)

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash Byte Address	Flash Device
TOP_ADDR_MEMB1 + 0x04		0x00_0004 to 0x00_0007	
…..	…	…	
TOP_ADDR_MEMB2 - 0x08	TOP_ADDR_MEMA2 - 0x08	(TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1- 0x08) to (TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x04 - 0x01)	
TOP_ADDR_MEMB2 - 0x04		(TOP_ADDR_MEMB2- TOP_ADDR_MEMB1 - 0x04) to (TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x01)	

The available address range depends from the size of the external serial flash device. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to Flash Read.

10.2.2.4.4 Parallel Flash Mode

Any of the AHB flexible-buffers can be configured to work in parallel flash mode by programming the QSPI_BFGENCR[PAR_EN] bit to '1'. When parallel mode is set, Flash A1 is paired with Flash B1 and Flash A2 is paired with Flash B2. In parallel mode, software should ensure that the size of Flash A1(A2) is equal to the size of Flash B1(B2).

Reads from any even AHB bus address provides bits [7:4] of both serial flash devices and reads from any odd AHB bus address provides bits [3:0] of both flash devices. Refer to the following table for the address mapping. The byte ordering for 32 bit access is given in Table 10-16 and for 64 bit read access the byte ordering is given in Table 10-18.

Table 10-9. Memory Mapped Parallel Flash Mode Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash A Byte Address	Serial Flash B Byte Address
QSPI_AMBA_BASE + 0x0000_0000	QSPI_AMBA_BASE + 0x00 For details, please refer to Parallel mode and Dual Die Flashes.	0x00_0000 - 0x00_0001	0x00_0000 - 0x00_0001
QSPI_AMBA_BASE + 0x0000_0004		0x00_002 - 0x00_0003	0x00_0002 - 0x00_0003
QSPI_AMBA_BASE + 0x0000_0008	QSPI_AMBA_BASE + 0x08	0x00_0004 - 0x00_0005	0x00_0004 - 0x00_0005

Table continues on the next page...

Table 10-9. Memory Mapped Parallel Flash Mode Address Scheme (continued)

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash A Byte Address	Serial Flash B Byte Address
QSPI_AMBA_BASE + 0x0000_000C		0x00_0006 - 0x00_0007	0x00_0006 - 0x00_0007
…	…	…	…
TOP_ADDR_MEMB2 - 0x08	TOP_ADDR_MEMB2 - 0x08	(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x08)/2	(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x08)/2
TOP_ADDR_MEMB2 - 0x04		(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x04)/2 +0x01	(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE- 0x04)/2 + 0x01

The available address range covers 27 address bits, corresponding to 128 MB per flash device. The usable space depends from the size of the external serial flash devices. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to Flash Read.

10.2.3 Interrupt Signals

The interrupt request lines of the QuadSPI module are mapped to the internal flags according to the following table.

Table 10-10. Assignment of Interrupt Request Lines

IRQ/DMA line	QSPI_FR Flag	Interrupt Description
ipi_int_tfff	TBFF	TX Buffer Fill
ipi_int_tcf	TFF	Peripheral Command Transaction Finished
ipi_int_rfdf	RBDF	RX Buffer Drain
ipi_int_overrun		Buffer Overflow/Underrun Error Logical OR from:
	RBOF	RX Buffer Overrun
	TBUF	TX Buffer Underrun
	ABOF	AHB Buffer Overflow
ipi_int_cerr		Serial Flash Command Error Logical OR from:
	IPAEF	Peripheral access while AHB busy Error
	IPIEF	Peripheral Command could not be triggered Error
	IPGEF	Peripheral access while AHB Grant Error
	IUEF	Peripheral Command Usage Error

Table continues on the next page...

Table 10-10. Assignment of Interrupt Request Lines (continued)

IRQ/DMA line	QSPI_FR Flag	Interrupt Description
ipi_int_ored	DLPFF, TBFF, TFF, ILLINE, RBDF, RBOF, TBUF, ABSEF, ABOF, IPAEF, IPIEF, IPGEF, IUEF	Logical OR from all the QSPI_FR flags mentioned

10.2.4 Functional Description

This section provides the functional information of the QuadSPI module.

10.2.4.1 Serial Flash Access Schemes

The Quad Serial Peripheral Interface (QuadSPI) block acts as an interface to one single or two external serial flash devices, each with up to 4 bidirectional data lines. Depending from the serial flash devices attached to the QuadSPI module the following access schemes are possible:

Table 10-11. Access Schemes for Serial Flash Data Access

Access Scheme	One Flash Device on Port A	One Flash Device on Port B	Two identical Flash Devices connected on Port A and Port B
Individual Flash Mode: Access to Flash A	**Yes**	**N/a**	**Yes**
Individual Flash Mode: Access to Flash B	**N/a**	**Yes**	**Yes**
Parallel Flash Mode: Read from Flash A and Flash B	**N/a**	**N/a**	**Yes**

Note

If two flash devices are accessed in Parallel Flash Mode, they are accessed with identical control signals. Special alignment on per-flash basis is **not** possible. It is within the responsibility of the application to ensure that the identical signals are applicable to both flash devices.

In Parallel Flash Mode, both external serial flash devices appear logically as one single memory doubled in size with respect to one individual flash device.

If two different flash devices are attached, they can be operated only in Individual Flash Mode.

In the Parallel Flash Mode, only data read commands are supported. Any other IP Command will result in an error condition signaled by the assertion of the QSPI_FR[IUEF] flag and any other AHB Command will result in the assertion of the QSPI_FR[ABSEF] flag.

In the Individual Flash Mode, all supported commands are available.

Unless explicitly noted, all the following descriptions relate to the Individual Flash Mode.

10.2.4.2 Modes of Operation

Refer to QuadSPI Modes of Operation for an overview over the possible operational modes of the QuadSPI block.

- Normal Mode can be used for write or read accesses to an external serial flash device.
  - Serial Flash Write: Data can be programmed into the flash via the IP interface only. Refer to Flash Programming for further details.
  - Serial Flash Read: Read the contents of the serial flash device. Two separate read channels are available via RX Buffer and AHB Buffer, see Flash Read.
- Stop Mode: The mode is used for power management. When a request is made to enter Stop Mode, the QuadSPI block acknowledges the request and completes the SFM Command in progress, then the system clocks to the QuadSPI block may be shut off
- Module Disable Mode: The mode is used for power management. The clock to the non-memory mapped logic in the QuadSPI can be stopped while in Module Disable Mode. The module enters the mode by setting QSPI_MCR[MDIS].

10.2.4.3 Normal Mode

This mode is used to allow communication with an external serial flash device. Compared to the standard SPI protocol, this communication method uses up to 4 bidirectional data lines operating at high data rates. The communication to the external serial flash device consists of an instruction code and optional address, mode, dummy

and data transfers. The flexible programmable core engine described below is immune to a wide variety of command/protocol differences in the serial flash devices provided by various flash vendors.

10.2.4.3.1 Programmable Sequence Engine

The core of the QuadSPI module is a programmable sequence engine that works on "instruction-operand" pairs. The core controller executes each programmed instruction sequentially. The complete list of instructions and the corresponding operands is given in the following table.

Table 10-12. Instruction set

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
CMD	6'd1	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	8 bit command value	Provide the serial flash with operand on the number of pads specified
ADDR	6'd2		Number of address bits to be sent (for example, 8'd24 => 24 address bits required)	Provide the serial flash with address cycles according to the operand on the number of pads specified. The actual address to be provided will be derived from the incoming address in case of AHB initiated transactions and the value of SFAR in case of IPS initiated transactions .
DUMMY	6'd3		Number of dummy clock cycles (should be <= 64 cycles)	Provide the serial flash with dummy cycles as per the operand. The PAD information defines the number of pads in input mode. (for example, one pad implies that pad 1 is not driven, rest all are driven)
MODE	6'd4		8 bit mode value	Provide the serial flash with 8 bit operand on the number of pads specified
MODE2	6'd5	N=2'd{0,1}	2 bit mode value	Provide the serial flash with 2 bit operand on the number of pads[1] specified
MODE4	6'd6	N=2'd{0,1,2}	4 bit mode value	Provide the serial flash with 4 bit operand on the number of pads[2] specified
READ	6'd7	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	Read data size in bytes (for AHB transactions, the user's application should ensure that data size is a multiple of 8 bytes)	Read data from flash on the number of pads specified. The data size may be overwritten by writing to the ADATSZ field of the QSPI_BUFxCR registers for AHB initiated transactions and IDATSZ field of IP Configuration Register (QuadSPI_IPCR) for IP initiated transactions.
WRITE	6'd8		Write data size in bytes	Write data on number of pads sepcified. The data size may be overwritten by writing to the IDATSZ field of IP Configuration Register (QuadSPI_IPCR) register

Table continues on the next page...

Table 10-12. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
JMP_ON_CS	6'd9	NA	Instruction number	Every time the CS is deasserted, jump to the instruction pointed to by the operand. This instruction allows the programmer to specify the behavior of the controller when a new read transaction is initiated following a CS deassertion.
ADDR_DDR	6'd10	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	Number of address bits to be sent (for example, 8'd24 => 24 address bits required)	Provide the serial flash with address cycles according to the operand on the number of pads specified at each clock edge of serial flash clock. The actual address to be provided will be derived from the incoming address in case of AHB initiated transactions and the value of QSPI_SFAR in case of IPS initiated transactions .
MODE_DDR	6'd11		8 bit mode value	Provide the serial flash with 8 bit operand on the number of pads specified at each clock edge of serial flash.
MODE2_DDR	6'd12	N=2'd{0}	2 bit mode value	Provide the serial flash with 2 bit operand on the number of pads specified at each clock edge of serial flash[3]
MODE4_DDR	6'd13	N=2'd{0,1}	4 bit mode value	Provide the serial flash with 4 bit operand on the number of pads specified at each clock edge of serial flash[4].
READ_DDR	6'd14	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	Read data size in bytes (for AHB transactions, the user's application should ensure that data size is in multiple of 8 bytes)	Read data from flash on the number of pads specified at each clock edge of serial flash. The data size may be overwritten by writing to the ADATSZ field of the QSPI_BUFxCR registers for AHB initiated transactions and IDATSZ field of IP Configuration Register (QuadSPI_IPCR) for IP initiated transactions
WRITE_DDR	6'd15		Write data size in bytes	Write data on the number of pads specified at each clock edge of serial flash. The data size may be overwritten by writing to the IDATSZ field of IP Configuration Register (QuadSPI_IPCR) register
DATA_LEARN[5]	6'd16		8 bit Data learning pattern	Find the correct sampling point with the data learning pattern. When this instruction is encountered, the QSPI_SMPR[DDRSMP] values are ignored and the controller finds the correct sampling point on its own by sampling the data learning pattern.[6]
STOP	8'd0	NA	NA	Stop execution; deassert CS

1. For a one pad instruction, MODE2 will take 2 serial flash clock cycles on the flash interface.
2. For a one pad instruction, MODE4 will take 4 serial flash clock cycles on the flash interface. For a 4 pad instruction, MODE4 will take 1 serial flash clock cycle on the flash interface.
3. For a one pad instruction, MODE2_DDR will take 1 serial flash clock cycle on the flash interface.
4. For a one pad instruction, MODE4_DDR will take 2 serial flash clock cycles on the flash interface. For a 4 pad instruction MODE4_DDR will take half a cycle on the serial flash interface.
5. Data learning is not implemented on this chip.
6. t is not recommended to have 0x00 or 0xFF as the data learning pattern.

A sequence of such instruction-operand pairs may be pre-populated in the LUT according to the device connected on board. Each instruction-operand pair is of 16 bits (2 bytes) each. Every sequence pre-programmed in the LUT is referred to by its index.

The programmable sequence engine allows the user to configure the QuadSPI module according to the serial flash connected on board. The flexible structure is easily adaptable to new command/protocol changes from different vendors.

10.2.4.3.2 Flexible AHB buffers

In order to reduce the latency of the reads for AHB masters, the data read from the serial flash is buffered in flexible AHB buffers. There are four such flexible buffers. The size of each of these buffers is configurable with the minimum size being 0 Bytes and maximum size being the size of the complete buffer instantiated.The size of buffer 0 is defined as being from 0 to QSPI_BUF0IND. The Size of buffer 1 is from QSPI_BUF0IND to QSPI_BUF1IND, buffer2 is from QSPI_BUF1IND to QSPI_BUF2IND and buffer 3 is from QSPI_BUF2IND to the size of the complete buffer, which is given in the chip-specific QuadSPI information.

Each flexible AHB buffer is associated with the following

1. An AHB master. Optionally, buffer3 may be configured as an "all master" buffer by setting the QSPI_BUF3CR[ALLMST] bit. When buffer3 is configured in such a way, any access from a master not associated with any other buffer is routed to buffer3.
2. A datasize field representing the amount of data to be fetched from the flash on every "missed" access.

The master port number of every incoming request is checked and the data is returned/ fetched into the corresponding associated buffer. Every "missed" access to the buffer causes the controller to clear the buffer and fetch QSPI_BUFxCR[ADATSZ] amount of data from the serial flash.As such, there is no benefit in configuring a buffer size of greater than ADATSZ, as the locations greater than ADATSZ will never be used. For any AHB access, the sequence pointed to by the QSPI_BFGENCR[SEQID] field is used for the flash transaction initiated. The data is returned to the master as soon as the requested amount is read from the serial flash. The controller however, continues to prefetch the rest of the data in anticipation of a next consecutive request. Figure 10-16 shows the flexible AHB buffers.

The QSPI_BFGENCR[SEQID] field points to an index of the LUT. Refer to Look-up Table for details.

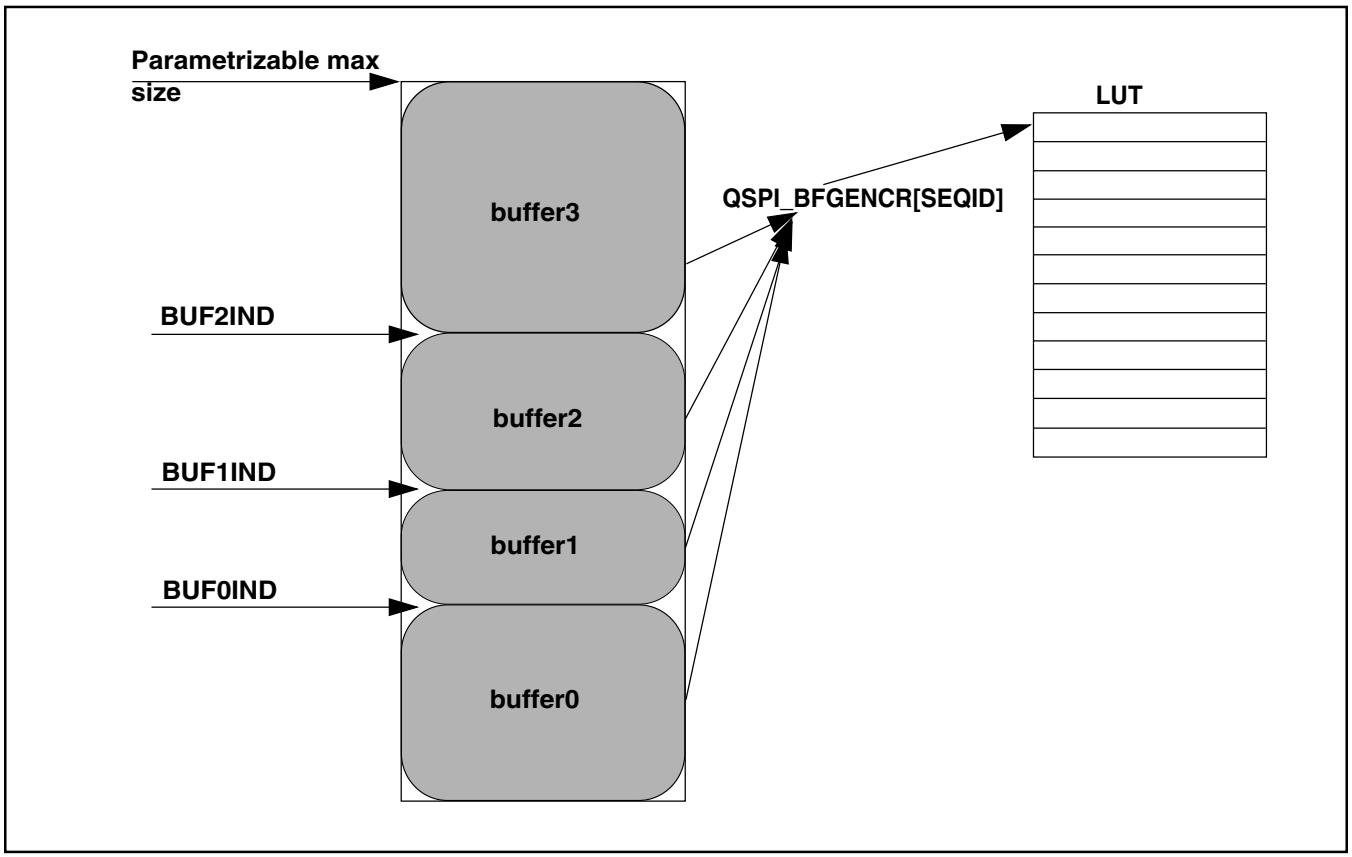

Figure 10-16. Flexible AHB Buffers

Buffer0 may optionally be configured to be associated with a high priority master by setting the QSPU_BUF0CR[HP_EN] bit. An access by a high priority master suspends any ongoing prefetch to any of the other buffers. The ongoing prefetch is suspended and the high priority master is serviced first. Once the high priority masters access completes, the suspended transaction is resumed (before any other AHB access is entertained). The status of the suspended buffer can be read from Sequence Suspend Status Register (QuadSPI_SPNDST).

10.2.4.3.3 Suspend-Abort Mechanism

Any low priority AHB access can be suspended by a high priority AHB master request. The ongoing transaction is suspended at 64 bit boundary. The suspended transaction is restarted after the high priority master is served and the high priority transaction including data prefetch is completed. While a transaction is in suspended state, it may be aborted if a transaction by the same suspended master is made to a location which is different from the location of the suspended transaction.

Any ongoing transaction is aborted if a request from the same master arrives for a location other than the location at which the transaction is going on. The abort can happen at any point of time.

10.2.4.3.4 Look-up Table

The Look-up-table or LUT consists of a number of pre-programmed sequences. Each sequence is basically a sequence of instruction-operand pairs which when executed sequentially generates a valid serial flash transaction. Each sequence can have a maximum of 8 instruction-operand pairs. The LUT can hold a maximum of 16 sequences. The figure below shows the basic structure of the sequence in the LUT.

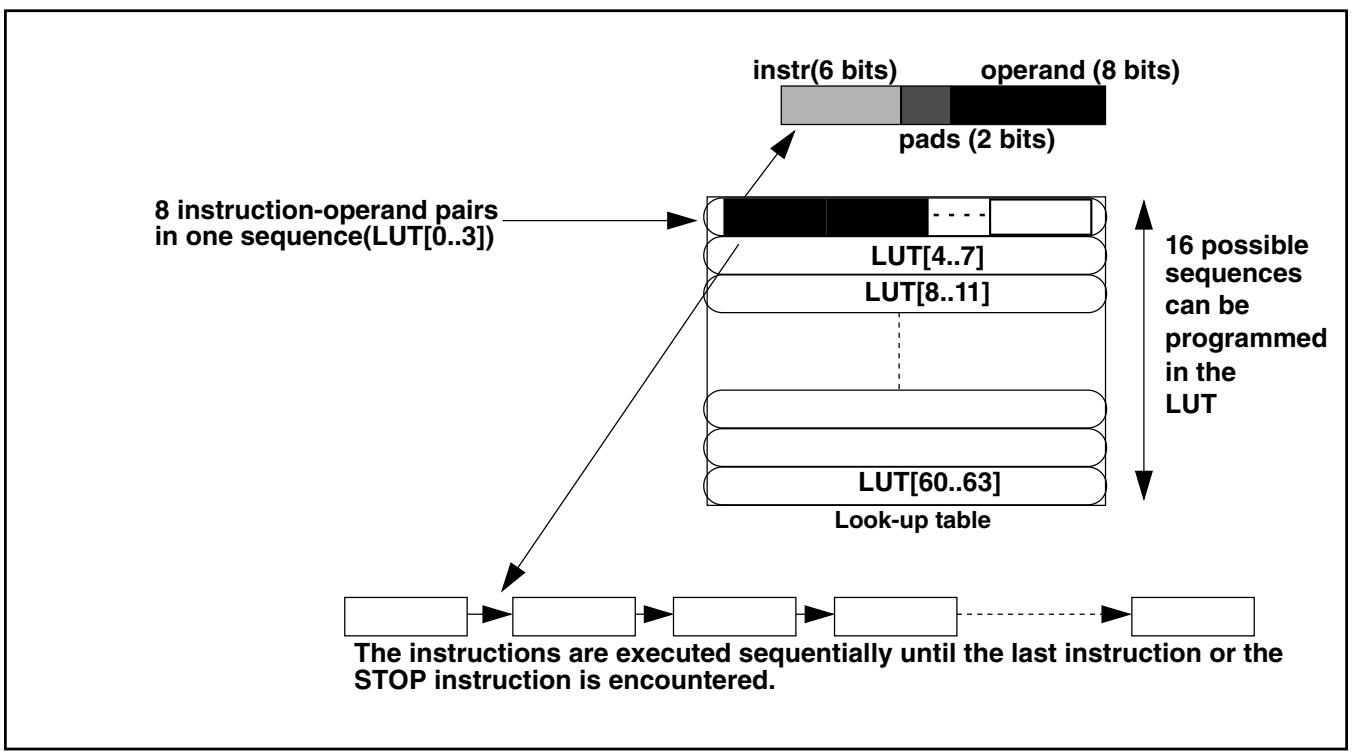

Figure 10-17. LUT and sequence structure

At reset, the index 0 of the look-up-table (LUT[0..3]) is programmed with a basic read sequence as given in Table 10-13. After reset the complete LUT may be reprogrammed according to the device connected on board.In order to protect its contents during a code runover the LUT may be locked, after which a write to the LUT will not be successful until it has been unlocked again.The key for locking or unlocking the LUT is **0x5AF05AF0**. The process for locking and un-locking the LUT is as follows:

Locking the LUT

1. Write the key **(0x5AF05AF0)** in to the LUT Key Register (QuadSPI_LUTKEY).
2. Write 0b01 to the LUT Lock Configuration Register (QuadSPI_LCKCR). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write into this register locks the LUT.

Unlocking the LUT

1. Write the key **(0x5AF05AF0)** into the LUT Key Register (QuadSPI_LUTKEY)
2. Write 0b10 to the LUT Lock Configuration Register (QuadSPI_LCKCR). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write into this register unlocks the LUT.

The lock status of the LUT can be read from QSPI_LCKCR[UNLOCK] and QSPI_LCKCR[LOCK] bit.

Some example sequences are defined in Example Sequences. The reset sequence at LUT index 0 is given in the following table.

Table 10-13. Reset sequence

Instruction	Pad	Operand	Comment
CMD	0x00	0x03	Read Data byte command on one pad
ADDR	0x00	0x18	24 Addr bits to be sent on one pad
READ	0x00	0x08	Read 64 bits
JMP_ON_CS	0x00	0x00	Jump to instruction 0 (CMD)

10.2.4.3.5 Issuing SFM Commands

Each access to the external device follows the same sequence:

1. The user must pre-populate the LUT with the serial flash command sequences that are required for the flash device being used.
2. The QuadSPI module starts executing the instructions in the sequence one by one. The transaction starts and the status bit QSPI_SR[BUSY] is set.
3. Communication with the external serial flash device is started and the transaction is executed.
4. When the transaction is finished (all transmit- and receive operations with the external serial flash device are finished) the status bit QSPI_SR[BUSY] is reset. In case of an IP Command the QSPI_FR[TFF] flag is asserted.

Further details are given in below in Flash Programming and Flash Read.

You can trigger the processing of SFM commands in the QuadSPI module in one of the following ways:

- **Using IP commands**

For IP Commands the required components need to be written into the following registers:

- Write the serial flash address to be used by the instruction into QSPI_SFAR, refer to Serial Flash Address Register (QSPI_SFAR). For IP Commands not related to specific addresses, the base address of the related flash need to be programmed.For example, for an instruction which does not require an address (i.e. write enable instruction) the SFAR should be programmed with the base address of the memory the command is to be sent to.
- Write the sequence ID and data size details in the IP Configuration Register (QSPI_IPCR).
- Note that the write into the QSPI_IPCR[SEQID] field must be the last step of the sequence. It is possible to combine all fields of the QSPI_IPCR into one single write. Refer to IP Configuration Register (QSPI_IPCR) for details.

Note that there are some conditions where no IP Command is executed after writing the QSPI_IPCR[SEQID] field and the write operation itself is ignored. They are described in Command Arbitration.

- **Using AHB commands**

  Any AHB memory mapped access is routed to one of the buffers depending on the master port number of the request. If the access is a "miss", a new serial flash transaction is started. The transaction is based on the sequence pointed to by the BFGENCR[SEQID] field as described in Flexible AHB buffers.

  An AHB access is termed memory mapped when the access is to the memory mapped serial flashes, as described in Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A and Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B.

  Again the possible error conditions are described in Command Arbitration .

10.2.4.3.6 Flash Programming

In all cases the memory sector to be written needs to be erased first. The programming sequence itself is then initiated in the following way:

1. Check that the TX Buffer is empty. If the QSPI_SR[TXEDA] bit is set then the TX Buffer must be cleared by writing 1 into the QSPI_MCR[CLR_TXF] bit.
2. Program the address related to the command in the QSPI_SFAR register.

3. Provide initial data for the program command into the circular buffer via register TX Buffer Data Register (QSPI_TBDR) . At least four word of data must be written into the TX Buffer up to a maximum of 32.
4. Program the QSPI_IPCR register to trigger the command. The QSPI_IPCR[SEQID] should point to an index of the LUT which has the flash program sequence pre-programmed.The IDATSZ field should be set to denote the size of the write.
5. Depending on the amount of data required, step 3 must be repeated until all the required data have been written into the QSPI_TBDR register.The QSPI_SR[TXFULL] can be used to check if the buffer is ready to receive more data. At any time, the QSPI_TBSR[TRCTR] field can be read to check how many words have been written actually into the TX Buffer.

Upon writing the QSPI_IPCR[SEQID] field (refer to step 4) the QuadSPI module will start to execute the programmed sequence. It is the responsibility of the software to ensure that a correct sequence is programmed into the LUT in accordance with the flash memory connected to the module. The data is fetched from the TX Buffer. It consists of **32** entries of 32-bits and is organized as a circular FIFO, whose read pointer is incremented by four after each fetch. When all data are transmitted, the QuadSPI module will return from 'busy' to 'idle'. However, this is not true for the external device since the internal programming is still ongoing. It is up to the user to monitor the relevant status information available from the serial flash device and to ensure that the programming is finished properly.

10.2.4.3.7 Flash Read

Host access to the data stored in the external serial flash device is done in two steps. First, the data must be read into the internal buffers and in the second step these internal buffers can be read by the host.

1. **Reading Serial Flash Data into the QuadSPI Module Internal Buffers**

   A read access to the external serial flash device can be triggered in two different ways:

   - **IP Command Read**: For **reading flash data into the RX Buffer** the user must provide the correct sequence ID in the QuadSPI_IPCR[SEQID] register. The sequence ID points to a sequence in the LUT. It is the responsibility of the software to ensure that a correct read sequence is programmed in the LUT in accordance with the serial flash device connected on board. The user should program the Serial Flash Address Register (QSPI_SFAR) and the IP Configuration Register (QSPI_IPCR) registers. All available read commands supported by the external serial flash are possible.

Optionally it is possible to clear the RX Buffer pointer prior to triggering the IP Command by writing a 1 into the QuadSPI_MCR[CLR_RXF] field.

From these inputs, the complete transaction is built when the QSPI_IPCR[SEQID] field is written. The transaction related to the read access starts and the requested number of bytes is fetched from the external serial flash device into the RX Buffer. Since the read access is triggered by an IP command, the IP_ACC status bit and the BUSY bit are both set (both are located in the Status Register (QSPI_SR)). A count of the number of entries currently in the Rx Buffer can be obtained from QSPI_RBCT[RXBRD].

The communication with the external serial flash is stopped when the specified number of bytes has been read (successful completion of the transaction).

- **AHB Command Read**: For **reading flash data into the AHB Buffer** the user must set up a read access by a master to the address range in the system memory map which the external serial flash devices are mapped to. The user should also program the buffer registers corresponding to the AHB master initiating the request, this is depends on the configuration of the QSPI_RBCT[RXBRD]. The user should provide the correct sequence ID into the buffer generic configuration register (QSPI_BFGENCR). It is the responsibility of the software to ensure that a correct read sequence in programmed in the LUT in accordance with the serial flash device connected on board. Flash device selection and access mode are determined by the address accessed in the AHB address space associated to the QuadSPI module (refer to Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A, Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B and Parallel Flash Mode.)

  On each AHB read access to the memory mapped area the valid data in the AHB Buffer is checked against the address requested in the actual read. When the AHB read request can't be served from the content of the AHB Buffer, the buffer is flushed and the sequence pointed to by the sequence ID is executed by the controller. The requested number of buffer entries defined in the QSPI_BUFxCR[ADATSZ] field is then fetched from the external serial flash device into the internal AHB Buffer. Since the read access is triggered via the AHB bus, the QSPI_SR[AHB_ACC] status bit is set driving in turn the QSPI_SR[BUSY] bit until the transaction is finished. The communication with the external serial flash is stopped when the specified number of entries has been filled.

2. **Data Transfer from the QuadSPI Module Internal Buffers**

The data read out from the external serial flash device by the QuadSPI module is stored in the internal buffers.The means of accessing the data from the buffer differs depending on which buffer the data has been loaded to. Refer to Block Diagram for details about the two available buffers, the RX Buffer and the AHB Buffer, in the QuadSPI module:

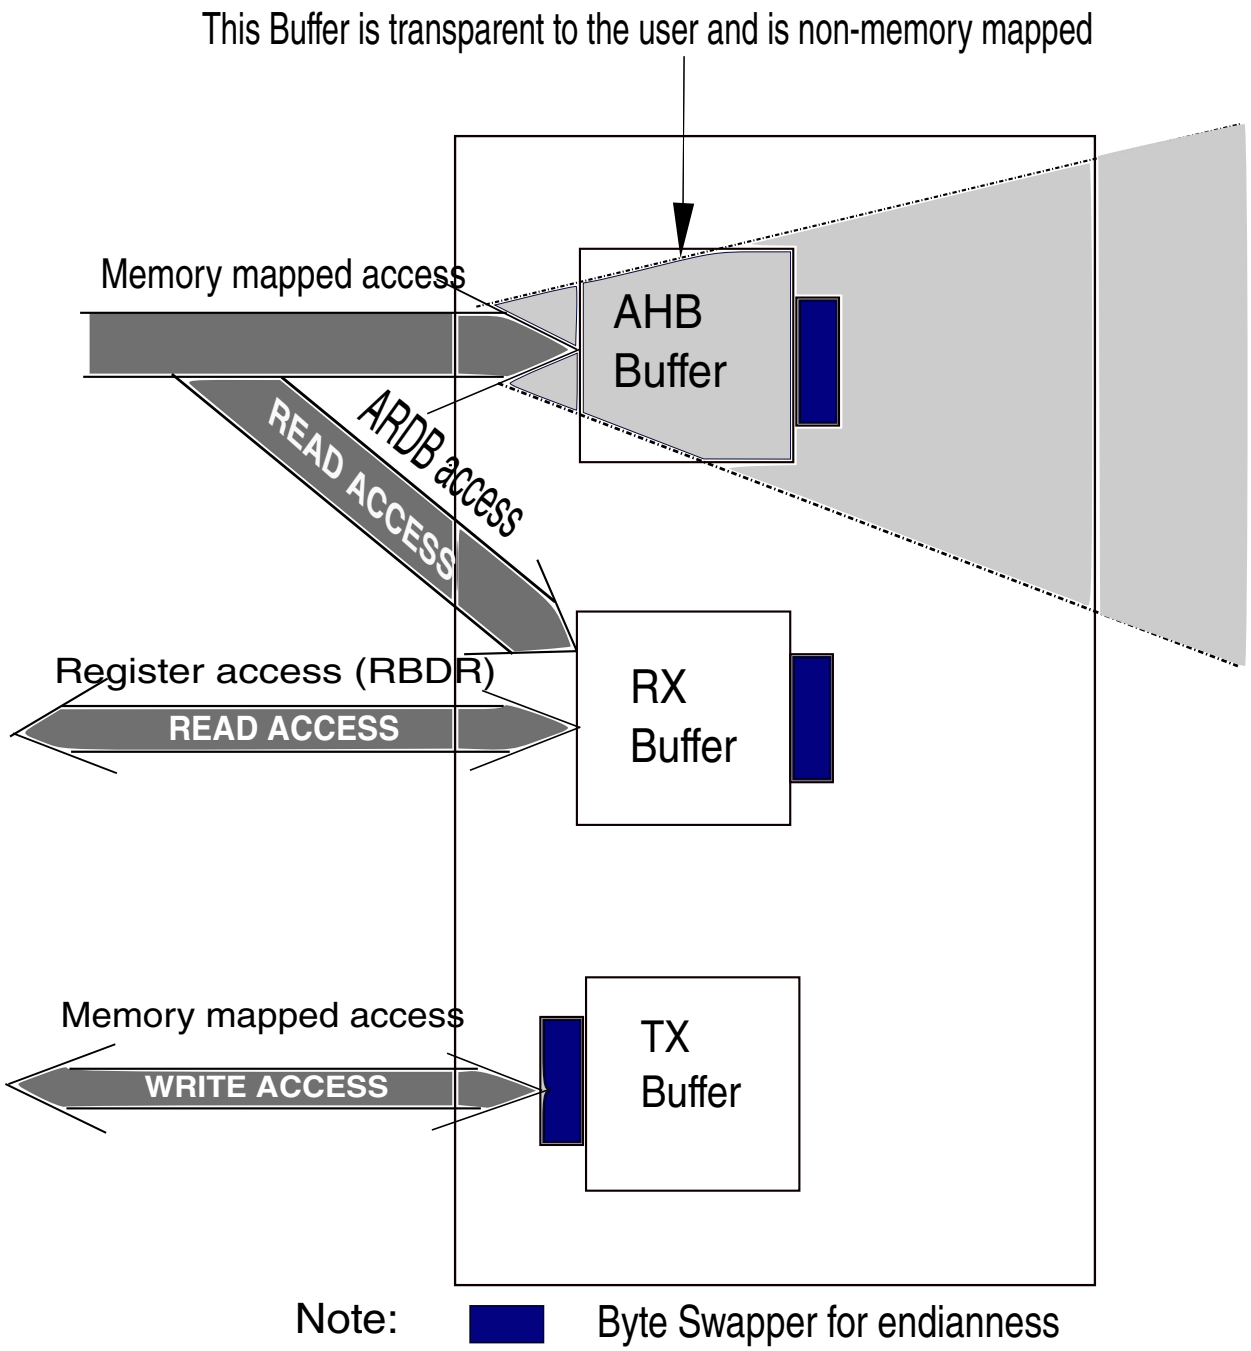

Figure 10-18. QuadSPI memory map

- The RX Buffer is implemented as FIFO of depth 32 entries of 4 bytes. Its content is accessible in two different address areas both referring to the identical data and the same physical memory.

  In the IPS address space in the area associated to QSPI_RBDR0 to QSPI_RBDR31

  In the AHB address space in the area associated to QSPI_ARDB0 to QSPI_ARDB31. Two successive entries are accessed with one single 64 bit AHB read operation.

  RX Buffer operation can be summarized as follows: The QSPI_RBCT[WMRK] field determines at which fill level the RXWE bit is asserted and how many entries are removed from the RX Buffer on each Buffer POP operation. So the QSPI_SR[RXWE] bit indicates that the configured number of data entries is available in the RX Buffer and the QSPI_RBSR[RDBFL] field indicates how many valid entries are available in total. Note that the first entry (QSPI_RBDR0 or QSPI_ARDB0) always corresponds to the first valid entry in the RX Buffer. The software needs to manage the number of valid data bytes itself.

  Further details can be found in RX Buffer Data Register (QuadSPI_RBDR*n*) and in AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31).

- **Flag-based Data Read of the RX Buffer** is done by polling the QSPI_SR[RXWE] bit. When it is asserted the valid entries can be read either via the IPS address space (QSPI_RBDRn) or the AHB address space (QSPI_ARDBn). A Buffer POP operation must be triggered by the application by writing a 1 into the QSPI_FR[RBDF] bit - this automatically updates the FIFO to point to the next entry as defined by RBCT[WMRK]. For example, if WMRK is set to 3, then the buffer will discard 16 bytes of data.

- **DMA controlled Data Read of the RX Buffer** is done by using the DMA module.The application must ensure that the DMA controller of the related device is programmed appropriately like it is described in DMA Usage.

  DMA controlled read out is triggered fully automatically by the assertion of the QSPI_SR[RXWE] bit. The related Buffer POP operation is also handled completely inside the QuadSPI module. Like in the case above, accessing the RX Buffer content either on QSPI_RBDRn or QSPI_ARDBn related addresses is equivalent.

- **AHB Buffer data read via memory mapped access:** This kind of access is done by reading one of the addresses assigned to the external serial flash device(s) within the range given in Table 10-6 table *under the condition that the data requested are already present in the AHB Buffer or it is currently being read from the serial flash device by the instruction in progress.* If this is not the

case a memory mapped AHB command read is triggered as described above. If the requested data is already available in the AHB Buffer they are provided directly to the host.

When AHB access are made to the flash memory mapped address, the data will be fetched and returned to the AHB interface. Till the data is being fetched the AHB interface would be stalled. As soon as the data from the requested address has been read by the QuadSPI module the AHB read access is served. So it is possible to run sequential reads from the AHB buffer at arbitrary speed without the need to monitor any information about the availability of the data. Nevertheless this access scheme stalls the AHB bus for the time required to read the data from the serial flash device. A better way is (when it is known the access is sequential) to have a prefetch enabled (by programming the ADATSZ field) such that before the next sequential AHB access come, the data is already fetched into the buffer.

As long as the host restricts its accesses to the data already in the buffer and the data currently fetched from the serial flash, it is possible to run the host read from the AHB Buffer in parallel to the serial flash read into the AHB Buffer.

10.2.4.3.8 Byte Ordering of Serial Flash Read Data

In this paragraph the byte ordering of the serial flash data is given. The basic scheme is that the **first** byte read out of the serial flash device - which is addressed by the QSPI_SFAR[SFADR] field - corresponds to bit position QSPI_RBDR0[31:24] register for IP Command read. In contrast to that for AHB Command read the bytes are always positioned according to the byte ordering of the AHB bus.

- **Byte Ordering in Individual Flash Mode**

  The following table gives the byte ordering scheme of how the byte oriented data space of the serial flash device is mapped into one single 32 bit entry of the RX Buffer or the AHB Buffer. The table is valid within the following context:

  - Flash A or Flash B in Individual Flash Mode
  - All AHB data read commands with access size of 32 bit

Table 10-14. Byte Ordering in Individual Flash Mode

Serial Flash Byte Numbering	3	2	1	0
Buffer Entry Bit Position [31:0] (32 Bit data width)	[31:24]	[23:16]	[15:8]	[7:0]

Note

For IP Commands the read size can be given in number of bytes. If this number is not a multiple of 4, then the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

For AHB Commands, reads, starting from an address not aligned to 32 bit boundaries, the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

- **Byte Ordering in Parallel Flash Mode**

  In Parallel Flash Mode each byte is combined out of 2 half bytes which are read in parallel from the two serial flash devices. The following tables shows how the flash content is separated into the half bytes and how the half bytes are assembled to the content of the QSPI_RBDR0 register.

Table 10-15. Serial Flash Device Half Byte Ordering

Serial Flash Device Byte #	Flash A Bit Position		Flash B Bit Position	
	[7:4]	[3:0]	[7:4]	[3:0]
0	fah0	fal0	fbh0	fbl0
1	fah1	fal1	fbh1	fbl1
2	fah2	fal2	fbh2	fbl2
3	fah3	fal3	fbh3	fbl3
4	fah4	fal4	fbh4	fbl4
5	fah5	fal5	fbh5	fbl5
6	fah6	fal6	fbh6	fbl6
7	fah7	fal7	fbh7	fbl7
8	fah8	fal8	fbh8	fbl8

The table entry naming reflects the half byte positioning in the serial flash devices:

- **<fa>**h0 means **Flash A**, <fb>h0 means Flash B.

- fa**<h>**0 means half byte in **high position**, fa<l>o means half byte in low position.
- fah**<0>** means **physical byte address 0** in the serial flash device, fal<1> means physical byte address 1 in the serial flash device.

Table 10-16. Byte Ordering in Parallel Flash Mode - RX Buffer

QSPI_SFAR[SFADR] set to 0x000_0000								
QSPI_RBDR0 **QSPI_ARDB0**	fal1	fbl1	fah1	fbh1	fal0	fbl0	fah0	fbh0
QSPI_RBDR1 **QSPI_ARDB1**	fal3	fbl3	fah3	fbh3	fal2	fbl2	fah2	fbh2
QSPI_SFAR[SFADR] set to 0x000_0001								
QSPI_RBDR0 **QSPI_ARDB0**	fal2	fbl2	fah2	fbh2	fal1	fbl1	fah1	fbh1
QSPI_RBDR1 **QSPI_ARDB1**	fal4	fbl4	fah4	fbh4	fal3	fbl3	fah3	fbh3

Note

For IP Commands the read size can be given in number of bytes. If this number is not a multiple of 4 the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

* Appicable only for single io mode.

Table 10-17. Byte Ordering in Parallel Flash Mode - AHB Buffer

AHB Address **(32 Bit Access)**	fal1	fbl1	fah1	fbh1	fal0	fbl0	fah0	fbh0
AHB Address 0x800_0004 **(32 Bit Access)**	fal3	fbl3	fah3	fbh3	fal2	fbl2	fah2	fbh2

Note

For AHB Command read starting from an address not aligned to 32 bit boundaries or AHB access size smaller than 32 bit the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

- **Buffer Entry Ordering for 64 Bit Read Access**

  For read access via the AHB interface 64 bit access is possible. Each 64 bit access reads 2 32 bit entries simultaneously. The ordering of these 32 bit entries within the 64 bit word is given in the following table.

Table 10-18. 64 Bit Read Access Buffer Entry Ordering

AHB Read Data Bit Position [63:0]	[63:32]	[31:0]
Buffer Entry #	Odd (1, 3, 5, ...)	Even (0, 2, 4, ...)

10.2.4.3.9 Normal Mode Interrupt and DMA Requests

The QuadSPI module has different flags that can only generate interrupt requests and one flag that can generate interrupt as well as DMA requests. The following table lists the eight conditions. Note that the flags mentioned in the table are related to the Flag Register (QSPI_FR).

Table 10-19. Interrupt and DMA Request Conditions

Condition	Flag(QSPI_FR)	DMA
Data Learn patttern Failure	DLPFF	-
TX Buffer Fill	TBFF	-
TX Buffer Underrun	TBUF	-
Illegal Instruction Error	ILLINE	-
RX Buffer Drain	RBDF	X
RX Buffer Overflow	RBOF	-
AHB Buffer Overflow	ABOF	-
AHB Sequence Error	ABSEF	-
IP Command Usage Error	IUEF	-
IP Command Trigger during AHB Access Error	IPAEF	-
IP Command Trigger could not be executed Error	IPIEF	-
IP Access during AHB Grant Error	IPGEF	-

Table continues on the next page...

Table 10-19. Interrupt and DMA Request Conditions (continued)

Condition	Flag(QSPI_FR)	DMA
IP Command related Transaction Finished	TFF	-

Each condition has a flag bit in the Flag Register (QSPI_FR) and a Request Enable bit in the DMA Request Select and Enable Register (QSPI_RSER) . The RX Buffer Drain Flag (RBDF) has separate enable bits for generating IRQ and DMA requests. Note that not all flags have an individual IRQ line. Check the devices Interrupt Vector Table for more details.

- Transmit Buffer Fill Interrupt Request:

  The Transmit Buffer Fill IRQ indicates that the TX Buffer can accept new data. It is asserted if the QSPI_FR[TBFF] flag is asserted and if the corresponding enable bit (QSIP_RSER[TBFIE]) is set. Refer to TX Buffer Operation, for details about the assertion of the QSPI_FR[TBFF] flag.

- Receive Buffer Drain Interrupt or DMA Request:

  The Receive Buffer Drain IRQ derived from the QSPI_FR[RBDF] flag indicates that the RX Buffer of the QuadSPI module has data available from the serial flash device to be read by the host. It remains set as long as the QSPI_RBSR[RXWE] bit is set. The QSPI_RSER[RBDIE] bit enables the related IRQ.

  Aside from the IRQ it is possible to handle RX Buffer drain by DMA. If the QSPI_RSER[RBDDE] bit is set, a DMA request will be triggered when the RX Buffer contains more than QSPI_RBCT[WMRK] valid entries.The application must set the environment appropriately (for example, the DMA controller) for the DMA transfers.

- Buffer Overflow/Underrun Interrupt Request:

  The Buffer Overflow/Underrun IRQ is a combination of the following flags (all located in the QSPI_FR register with the related enable bits in the QSPI_RSER register):

  - TBUF - TX Buffer Underrun, enabled by TBUIE
  - RBOF - RX Buffer Overflow, enabled by RBOIE
  - ABOF - AHB Buffer Overflow, enabled by ABOIE

    The Transmit Buffer Underrun indicates that an underrun condition in the TX Buffer has occurred. It is generated when a write instruction is triggered whilst the Tx Buffer is empty and the QSPI_RSER[TFUFIE] bit is set.

The Receive Buffer Overflow indicates that an overflow condition in the RX Buffer has occurred. It is generated when the RX Buffer is full, an additional read transfer attempts to write into the RX Buffer and the QSPI_RSER[RBOIE] bit is set.

The AHB Buffer Overflow indicates that an overflow condition in the AHB Buffer has occurred. It is generated when the AHB Buffer is full, an additional read transfer attempts to write into the AHB Buffer and the QSPI_RSER[ABOIE] bit is set.

The data from the transfers that generated the individual overflow conditions is ignored.

- Serial Flash Command Error Interrupt Request

  If the IPAEF, IPIEF, IPGEF or IUEF flags in the QSPI_FR are set, and the related interrupt enable bits in the QSPI_RSER are also set, then an interrupt is requested.

- Transaction Finished Interrupt Request

  The IP Command Transaction Finished IRQ indicates the completion of the current IP Command.It is triggered by the QSPI_FR[TFF] flag and is masked by the QSPI_RSER[TFIE] bit.

10.2.4.3.10 TX Buffer Operation

The TX Buffer provides the data used for page programming. For proper operation it is required to provide at least four entry in the TX Buffer prior to starting the execution of the page programming command. The application must ensure that the required number of data bytes is written into the TX Buffer fast enough as long as the command is executed without a TX Buffer overflow or underrun.

The QuadSPI module sets the QSPI_FR[TBFF] flag so long as the TX Buffer is not full and can accept more data.

When the QuadSPI module tries to pull data out of an empty TX Buffer the TX Buffer underrun is signaled by the QSPI_FR[TBUF] flag.The TX buffer underrun flag is also asserted when TX buffer contains less than 128 bits of data and QuadSPI module tries to pull out data from it. The current IP Command leading to the underrun condition is continued until the specified number of bytes has been sent to the serial flash device, in the underrun condition when QuadSPI module tries to pull out data of empty TX buffer, the data transferred is all F's i.e. once the underrun flag is set under this condition, it will return F's until the required number of bytes are not sent. This has been done to ensure that the software need not to erase whole sector after underrun, just reprogramming from

failure point will serve the purpose. When this Sequence Command is finished, the QSPI_FR[TBFF] flag is asserted indicating that the Tx Buffer is ready to be written again.

The TX Buffer overflow isn't signaled explicitly, but the TX Buffer fill level can be monitored by the QSPI_TBSR[TRBFL] field.

Refer to TX Buffer Status Register (QuadSPI_TBSR) and Flag Register (QuadSPI_FR) for details about the TX Buffer related registers.

10.2.4.3.11 Address scheme

Earlier serial flash memories supported only 24-bit address space hence restricting the maximum memory size of the serial flash as 16 MB. The new memory specification supports two types of 32-bit addressing mode in addition to legacy 24-bit address mode.

- **Extended Address Mode**

  In this mode, the legacy 24-bit commands are converted to accept 32-bit address commands. The flash memory needs to be configured for 32-bit address mode. Also, while programming the LUT sequence in QuadSPI for 32-bit mode, the ADDR and ADDR_DDR command should be programmed with 8’d32 as the operand value. By default, the QuadSPI is in 24-bit legacy address mode. Each of the memory vendors have a different way of enabling this mode (Refer to the memory specification from memory vendors). For example, the command B7h sent to Macronix flash will enable it for 32-bit address mode.

- **Extended Address register**

  In this mode, the upper 8-bit of the 32-bit address is provided by the Extended address register in the memory itself. The memory provides a specific register which is updated according to the address to be accessed. This effectively converts the legacy 24-bit address command into 32-bit address commands. The memories greater in size than 16 MB, consists of banks of 16 MB. The 8-bit written in the extended address register effectively enables a bank. For example in Spansion memory, when the extended address register is updated with a value of 0x01 with the help of the command 17h, it will open Bank1 of the memory. The consequent 24-bit address commands will lead to Bank1. The extended address register needs to be update with the respective value for access to other banks. This effectively converts the legacy 24-bit address command into 32-bit address commands.

10.2.5 Initialization/Application Information

This section provides the initialization and application information of the QuadSPI module.

10.2.5.1 Power Up and Reset

Note that the serial flash devices connected to the QuadSPI module may require special voltage characteristics of their inputs during power up or reset. It is the responsibility of the application to ensure this.

10.2.5.2 Available Status/Flag Information

This paragraph gives an overview of the different status and flag information available and their interdependencies for different use cases. Related registers are QSPI_SR and QSPI_FR. Refer to the related descriptions how to set up the QuadSPI module appropriately.

10.2.5.2.1 IP Commands

Refer to IP Configuration Register (QuadSPI_IPCR) for additional details not explicitly covered in this paragraph.

- **IP Commands - Normal Operation**

  Writing the QSPI_IPCR[SEQID] field triggers the execution of a new IP Command. Given that this is a legal command the QSPI_SR[IPACC] and the QSPI_SR[BUSY] bits are asserted simultaneously, immediately after the execution is started.

  When the instruction on the serial flash device has been finished these bits are de-asserted and the QSPI_FR[TFF] flag is set.

- **IP Commands - Error Situations**

  Refer to Table 10-20 below.

10.2.5.2.2 AHB Commands

Refer to Section 1, Reading Serial Flash Data into the QuadSPI Module, in Flash Read for additional details not explicitly covered in this paragraph.

- **AHB Commands - Normal Operation**

  Memory mapped read access to a serial flash address not contained in the AHB Buffer, triggers the execution of an AHB Command. Given that this is a legal command the QSPI_SR[AHBACC] and the QSPI_SR[BUSY] bits are asserted simultaneously immediately after the execution is started. When the instruction on the serial flash device has been finished these bits are de-asserted.

- **IP Commands - Error Situations**

  Refer to Table 10-20 below.

10.2.5.2.3 Overview of Error Flags

The following table gives an overview of the different error flags in the QSPI_FR register and additional error-related details.

Table 10-20. Overview of QSPI_FR Error Flags

Error Category	Error Flag in QSPI_FR	Command Execution on Serial Flash Device TFF Behavior (in case of IP commands only)	Description
AHB Error Flag	ABSEF	Flash transaction is aborted	AHB sequence contains • WRITE instruction • WRITE_DDR instruction
AHB Error Flag	ABOF	Flash transaction continues until it finishes	Set when the module tried to push data into the AHB buffer that exceeded the size of the AHB buffer. Only occurs due to wrong programming of the QSPI_BUFxCR[ADATSZ].
Miscellaneous Error Flag	DLPFF[1]	Flash transaction continues until it finishes	Set when DATA_LEARN instruction was encountered in a sequence but no sampling point was found for the data learning pattern.
Miscellaneous Error Flag	ILLINE	Flash transaction aborted	Illegal instruction Error Flag – Set when an illegal instruction is encountered by the controller in any of the sequences.
Command Arbitration Error	IPIEF	TFF not asserted in conjunction with that command	IP Command Error - caused when IP access is currently in progress (IP_ACC set) and • write attempt to QSPI_IPCR register.

Table continues on the next page...

Table 10-20. Overview of QSPI_FR Error Flags (continued)

Error Category	Error Flag in QSPI_FR	Command Execution on Serial Flash Device TFF Behavior (in case of IP commands only)	Description
			• write attempt to QSPI_SFAR register. • write attempt to QSPI_RBCT register.
Command Arbitration Error	IPAEF		• AHB Command already running, another IP Command could not be executed. • AHB Command already running, write attempt to QSPI_IPCR[SEQID] field.
Command Arbitration Error	IPGEF		• Exclusive access to the serial flash granted for AHB Commands, write attempt to QSPI_IPCR[SEQID] field.
IP Command Error	IUEF	—	• IP Command Usage Error
Buffer Related Error	RBOF	TFF is asserted on completion	• RX Buffer Overrun
Buffer Related Error	TBUF		• TX Buffer Underrun

1. Data learning is not implemented on this chip.

Note that only the buffer related errors are related to a transaction on the external serial flash. All the other errors do not trigger an actual transaction.

10.2.5.2.4 IP Bus and AHB Access Command Collisions

There are two flags related to this topic, the QSPI_FR[IPAEF] and QSPI_FR[IPIEF]. Refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of Flash Read section, for a description of the flags and Command Arbitration , for details about possible command collisions.

10.2.5.3 Exclusive Access to Serial Flash for AHB Commands

It is possible that several masters need to access the serial flash device connected to the QuadSPI module separately, one master by triggering IP Commands and reading the RX Buffer (via RBDR*n* register) and the other masters by triggering AHB Commands (via ARDB*n* Registers). These two set of buffer (RBDR and ARDB Buffer) points to the same physical buffer.Refer to Figure 10-18 To avoid command collisions resulting in

excessive latencies the QuadSPI module implements a request-handshake mechanism between the master triggering AHB Commands and the QuadSPI module allowing this specific master to request exclusive access to the serial flash device for AHB Commands. If this exclusive access is granted the execution of IP Commands is blocked. This resolves command collisions and excessive times where the AHB interface may be blocked.

If this capability is used in the device there is additional status and flag information available related to this mechanism. The QSPI_SR[AHBGNT] bit reflects the module-internal state that the exclusive access mentioned above is granted, any attempt to trigger an IP Command is rejected and results in the assertion of the QSPI_FR[IPGEF] flag. Refer to the descriptions of the related bit and flag for details.

It is within the responsibility of the application to set up the master using this mechanism appropriately, if used incorrectly no IP Commands at all can be triggered.

Two different cases can be distinguished:

10.2.5.3.1 RX Buffer Read via QSPI_ARDB Registers

In this case all masters share the AHB bus for RX Buffer as well as for AHB Buffer read. In this case the access to the AHB interface by the master triggering AHB Commands must be deferred until any pending IP Command has been finished **and** the RX Buffer readout has been finished as well. The QSPI ARDB Buffers access the Rx buffer i.e the data from the Rx Buffer is returned and no data from AHB Buffer is touched. This is the conservative use case, corresponding to the reset value 0 of the QSPI_RBCT[RXBRD] bit.

In this case the QSPI_SR[AHBGNT] bit is asserted not earlier than any running IP Command has been finished (QSPI_SR[IP_ACC] is 0), the RX Buffer has been read out completely (QSPI_RBSR[RDBFL] equal to 0) or no DMA read is pending (QSPI_SR[RXDMA] equal to 0 and Rx Buffer readout is via AHB(QSPI_RBCT[RXBRD]) equal to 1.

10.2.5.3.2 RX Buffer Read via QSPI_RBDR Registers

This is the preferred use case as an access to the AHB buffer (memory mapped flash) does not interfere with any IPS access to read the RBDR buffer. It is not possible that a pending AHB bus access triggered by an AHB Command stalls the AHB bus and blocks the RX Buffer readout since the RX Buffer is read via the IP bus based registers QSPI_RBDR0 to QSPI_RBDR31.

For this case it is recommended to program the QSPI_RBCT[RXBRD] bit to 1. The QSPI_SR[AHBGNT] bit is asserted immediately after any running IP Command has been finished (QSPI_SR[IP_ACC] is 0), the RX Buffer has been read out completely (QSPI_RBSR[RDBFL] equal to 0) or no DMA read is pending (QSPI_SR[RXDMA] equal to 0, allowing the master triggering AHB Commands to trigger AHB Commands as soon as possible without the need to wait for the RX Buffer readout to be finished.

10.2.5.4 Command Arbitration

In case of overlapping commands, the arbitration scheme is described in the following paragraphs under the assumption that the priority mechanism described in Exclusive Access to Serial Flash for AHB Commands is **not** used:

- During the execution of an IP Command, the running IP Command can't be terminated by issuing another IP Command or AHB Command. The QSPI_FR[IPIEF] flag is asserted when the host tries to write into the QSPI_IPCR register. When the host triggers an AHB Command (refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of Flash Read section, for details), this command is stalled until the currently running IP Command is finished.
- During the execution of an AHB Command, the running AHB Command can't be terminated by issuing an IP Command. The command is ignored and the QSPI_FR[IPAEF] flag is asserted. Refer to Flag Register (QuadSPI_FR) for the description of these flags.

  When another AHB Command is triggered the address of the memory mapped access is considered. If the requested address is currently read from the serial flash device, the running command is continued. If this is not the case the currently running command is terminated and another AHB Command related to the requested address is executed. Refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of Flash Read section, for further details.

In case of coinciding commands the IP Command is triggered and the AHB Command is stalled until the IP Command has been finished (QSPI_SR[IP_ACC] has been deasserted).

The IP Commands ignored in case of command collision will not result in the assertion of the QSPI_FR[TFF] flag.

10.2.5.5 Flash Device Selection

Regardless of the SFM Command (IP or AHB) the access mode is selected by specifying the 32 bit address value for the following SFM Command.

For IP Commands the access mode is selected with the address programmed into the QSPI_SFAR register. Refer to Serial Flash Address Register (QuadSPI_SFAR) for details.

For AHB Commands the access mode is determined by the memory mapped address which is accessed Refer to AMBA Bus Register Memory Map for details.

10.2.5.6 DMA Usage

For the complete description of the DMA module refer to the related DMA Controller chapter. In this paragraph only the details specific to the DMA usage related to the QuadSPI module are given.

10.2.5.6.1 DMA Usage in Normal Mode

10.2.5.6.1.1 Bandwidth considerations

Careful consideration of the throughput rate of the entire chain (serial flash -> AHB bus / IP Bus -> DMA controller) involved in the read data process is essential for proper operation. Such analysis must take into account not only the data rate provided by the serial flash but also the data rate of the AHB bus and the performance of the DMA controller in reading data from the RX buffer.

Two figures must match for proper operation, that means that the data rate provided by the serial flash device must not exceed the average RX Buffer readout data rate. Otherwise, the longer this state persists, a RX Buffer overflow will result.

AHB Bus Side (data read):

The total number of bus cycles for each DMA Minor Loop completion is added from the following components:

- Overhead for each minor loop, given by DMA controller: Assume 10 cycles
- Overhead due to clock domain crossing: Assume 2 cycles
- Number of bus clock cycles required for 8 bytes (64 bit read size): Assume 2 cycles (read/write sequence of DMA controller)

Note that the size of the minor loop is determined by the size of the QSPI_RBCT[WMRK] field, therefore the overhead given above distributes among (QSPI_RBCT[WMRK]+1)/2 read accesses of 64 bit each.

The following table gives some examples for typical use cases:

Table 10-21. Access Duration Examples - Bus Clock Side

QSPI_RBCT[WMRK]	Number of Bytes per DMA Loop [1]	Number of Bus Clock cycles for DMA Minor Loop	Time Duration of DMA Minor Loop for 120Mhz Bus clock Frequency
0	4	12+2 = 14	~117ns
1	8	12+2 = 14	~117ns
3	16	12+4 = 16	~133ns
7	32	12+8 = 20	~167ns
11	48	12+12 = 24	~200ns

1. DMA Loop means one Minor Loop Completion which is equivalent to one.

NOTE

The table figure represents ideal scenario, actual performance will depend on how the system is integrated.

Serial Flash Device Side (data read):

The number of serial flash cycles can be determined in the following way:

- Number of serial flash clock cycles required to read 4 bytes, corresponding to one RX Buffer entry (setup of command and address not considered): 2 cycles for Quad DDR mode instructions in Parallel Flash Mode, 4 cycles for Quad (SDR) mode instruction in parallel flash mode or Dual IO DDR mode instruction in parallel flash mode, 8 cycles for Quad Mode (SDR) instructions in Individual Flash Mode etc.
- Overhead due to clock domain crossing : 1 cycle.

The following table lists the number of clock cycles required to read the data from the serial flash corresponding to the different settings of the QSPI_RBCT[WMRK] field:

Table 10-22. Access Duration Examples - Serial Flash side

QSPI_RBCT[WMRK] setting	Num Bytes per DMA Loop [1]	Num SCKFx for 60MHz SCKFx			Time duration of Flash data readout for 60MHz SCKFx (~16.6ns period)		
		IFM [2] Quad	IFM Quad DDR	PFM [3] Quad DDR	IFM Quad	IFM Quad DDR	PFM Quad DDR
0	4	9	5	3	~150ns	~83ns	~50ns
1	8	17	9	5	~282ns	~150ns	~83ns
3	16	33	17	9	~548ns	~282ns	~150ns
7	32	65	33	17	~1079ns	~548ns	~282ns

Table continues on the next page...

Table 10-22. Access Duration Examples - Serial Flash side (continued)

QSPI_RBCT[WMRK] setting	Num Bytes per DMA Loop [1]	Num SCKFx for 60MHz SCKFx			Time duration of Flash data readout for 60MHz SCKFx (~16.6ns period)		
		IFM [2] Quad	IFM Quad DDR	PFM [3] Quad DDR	IFM Quad	IFM Quad DDR	PFM Quad DDR
11	48	97	49	25	~1610ns	~813ns	~415ns

1. DMA Loop means one Minor loop completion which is equivalent to one Major Loop iteration.
2. Individual flash mode.
3. Parallel flash mode.

From the examples given in the two tables above, it can be seen that depending on the relationship between the Bus clock and Serial flash clock frequencies, there are settings possible where the serial flash provides the read data faster than the AHB bus can read out the RX buffer. In the above tables, it is the case of PFM Quad DDR mode with Watermark up to 3 and other cases. In these cases, the RX buffer data keeps accumulating over time and will eventually overflow. To avoid RX Buffer overflow, the data transaction size should be small enough.

A complementary example would be when the watermark is set to be too high. In such a case, the time taken by the DMA to read out the RX buffer entries should be smaller than the time taken by the controller to push in the remaining entries in the buffer.

NOTE

The tables mentioned above are only examples which must be correlated with the DMA in the system.

10.2.5.7 Parallel mode

QuadSPI can access two flashes in parallel. This increases the throughput of the QuadSPI by two times. Both write and read operations are supported in parallel mode. When dual die flashes are accessed in parallel mode, it is mandatory for flash A1 to be of the same size as B1 and A2 to be of the same size as B2. The following figure shows how QuadSPI maps the incoming addresses to the different flashes connected on board.

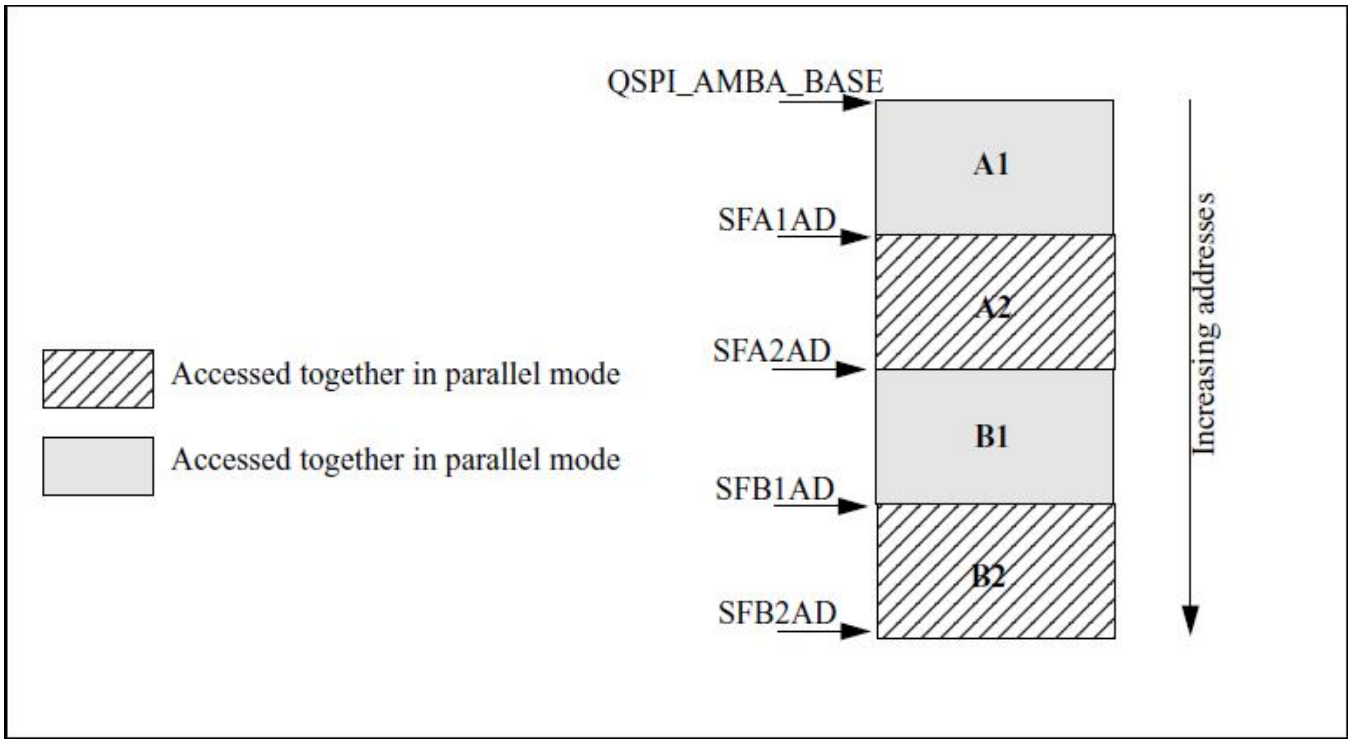

Figure 10-19. Flash addressing

An example programming for parallel mode access is given below (flash sizes are assumed to be 256MB):

- QSPI_AMBA_BASE - 0x10000000
- QSPI_SFA1AD[TPADA1] - 0x20000000
- QSPI_SFA2AD[TPADA2] - 0x30000000
- QSPI_SFB1AD[TPADB1] - 0x40000000
- QSPI_SFB2AD[TPADB2] - 0x50000000

In order to access the first location of A1/B1 pair, the incoming address should be 0x10000000. QSPI_AMBA_BASE is subtracted from this address and the result is divided by two. Therefore, address provided to flash A1 and B1

Flash Address = (Memory mapped address - QSPI_AMBA_BASE)/2

For Memory Mapped address:

- 0x10000000, flash address: 0x0 (Or, the first address of flash A1 and B1)
- 0x10000004, flash address: 0x2
- 0x10000008, flash address: 0x4 etc.

Similarly, in order to access the first location of A2/B2 pair, the incoming address should be 0x30000000.

Flash Address = (Memory mapped address - SFA2AD)/2

For Memory Mapped address:

- 0x30000000, flash address: 0x0 (Or, the first address of flash A2 and B2)
- 0x30000004, flash address: 0x2
- 0x30000008, flash address: 0x4 etc.

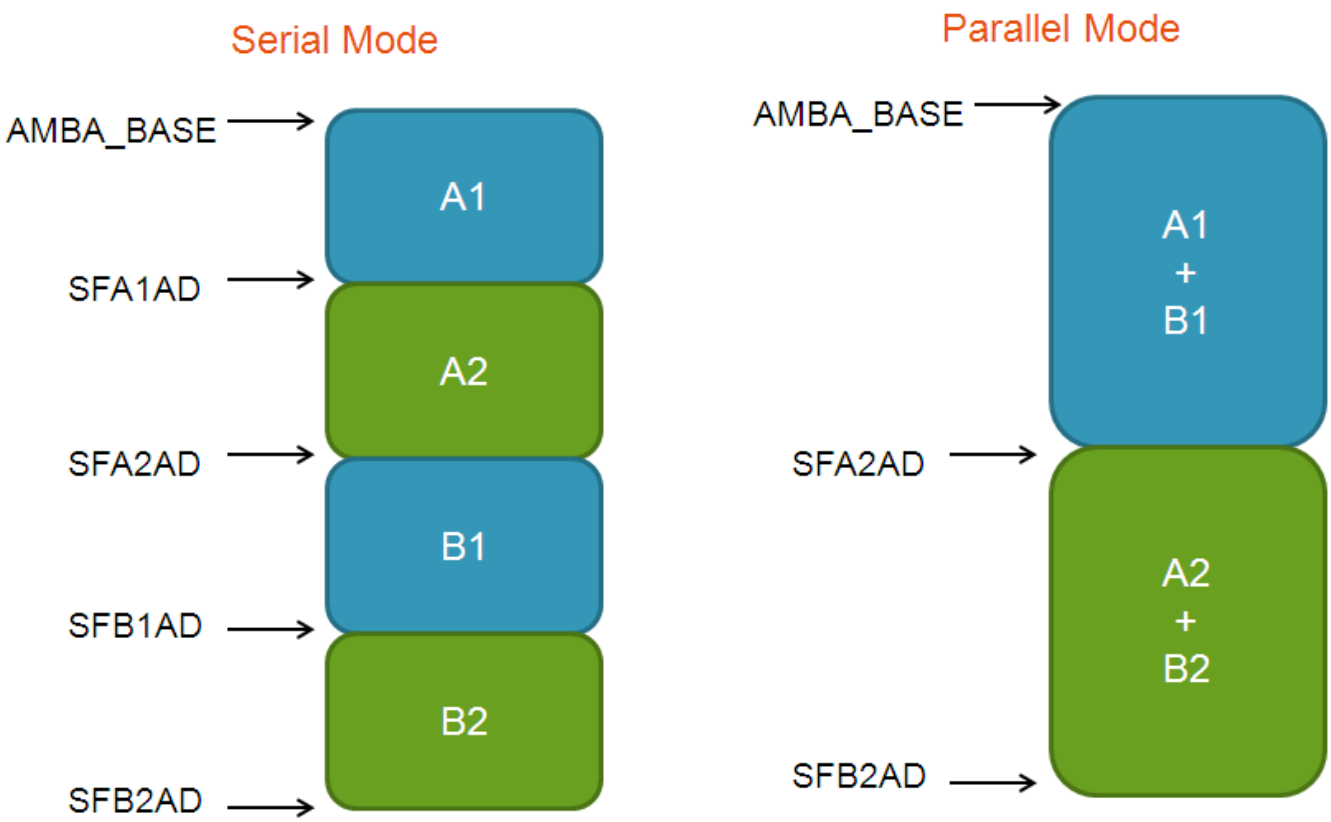

Figure 10-20. Memory map - Serial and Parallel

10.2.6 Byte Ordering - Endianness

QuadSPI provides support for swapping the flash read/write data based on the configuration of the QSPI_MCR[END_CFG]. By default the data is always returned in 64 bit LE format on the AHB bus and 32 bit LE format on the IPS interface when read via the RX buffer and written in 32 bit LE format when written via the TX buffer.

The table(QSPI_MCR[END_CFG]) below shows the complete bit ordering. BE signifies Big Endian which means the high order bits of the associated data vectors are associated with low order address positions. LE signifies Little Endian which means the lower order bits of the associated data vectors are associated with low order address positions.Refer to figure Figure 10-18

Table 10-23. QSPI_MCR[END_CFG]

00	64 bit BE
01	32 bit LE
10	32 bit BE
11	64 bit LE

The tables below (Byte ordering configuration in AHB) and (Byte ordering configuration in IPS) show how this configuration is implemented in QSPI AHB and IPS interfaces respectively. B in the table signifies Byte and the index 1-8 refers to the byte position i.e. 1 refer to bits[7:0], 8 refer to bits[63:56] and so on.

Table 10-24. Byte ordering configuration in AHB

64 bit BE	B1	B2	B3	B4	B5	B6	B7	B8
64 bit LE	B8	B7	B6	B5	B4	B3	B2	B1
32 bit BE	B5	B6	B7	B8	B1	B2	B3	B4
32 bit LE	B4	B3	B2	B1	B8	B7	B6	B5

Table 10-25. Byte ordering configuration in IPS

32BE	B1	B2	B3	B4
32LE	B4	B3	B2	B1

The examples below show the byte ordering in 64 bit BE configuration for AHB Buffer and 32 bit BE for TX/RX Buffer:

10.2.6.1 Programming Flash Data

CPU write instructions to the QSPI_TBDR register like

- Write QSPI_TBDR -> 0x01_02_03_04
- Write QSPI_TBDR -> 0x05_06_07_08

result in the following content of the TX Buffer:

Table 10-26. Example of QuadSPI TX Buffer

TX Buffer Entry	Content
0	32'h01_02_03_04
1	32'h05_06_07_08

Programming the TX Buffer into the external serial flash device results in the following byte order to be sent to the serial flash:

- 01…02…03…04…05…06…07…08

10.2.6.2 Reading Flash Data into the RX Buffer

Reading the content from the same address provides the following sequence of bytes, identical to the write case:

- 01…02…03…04…05…06…07…08

This results in the RX Buffer filled with:

Table 10-27. Resulting RX Buffer Content

RX Buffer Entry	Content
0	32'h01_02_03_04
1	32'h05_06_07_08

10.2.6.2.1 Readout of the RX Buffer via QSPI_RBDRn

The RX Buffer content appears at CPU read access via the Peripheral bus interface in the following order:

- Read QSPI_RBDR0 <- 0x01_02_03_04
- Read QSPI_RBDR1 <- 0x05_06_07_08

10.2.6.2.2 Readout of the RX Buffer via ARDBn

The RX Buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- (1a): 32 Bit Access: Read QSPI_ARDB0 <- 0x01_02_03_04

- (2a): 32 Bit Access: Read QSPI_ARDB1 <- 0x05_06_07_08
- (1b/2b): 64 Bit Access: Read QSPI_ARDB0 <- 0x01_02_03_04_05_06_07_08

10.2.6.3 Reading Flash Data into the AHB Buffer

Reading the content from the same address as it was written to provides the following sequence of bytes, identical to the write case:

- 01…02…03…04…05…06…07…08

This results in the AHB Buffer filled with:

Table 10-28. Resulting AHB Buffer Content

AHB Buffer Entry	Content
0	64'h01_02_03_04_05_06_07_08

10.2.6.3.1 Readout of the AHB Buffer via Memory Mapped Read

The AHB Buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- (1a): 32 Bit Read Access: <- 0x01_02_03_04
- (2a): 32 Bit Read Access: <- 0x05_06_07_08
- (1/2): 64 Bit Read Access: <- 0x01_02_03_04_05_06_07_08

10.2.7 Serial Flash Devices

Several different vendors make flash devices with a QuadSPI interface. At present there is no set standard for the QuadSPI instruction set. Most common commands currently have the same instruction code for all vendors, however some commands are unique to specific vendors. Some example sequences are provided below.

10.2.7.1 Example Sequences

This section provides the example sequences of the QuadSPI module.

Table 10-29. Exit 4 x I/O Read Enhance Performance Mode (XIP) (Macronix) and Read Status

INSTR	PAD	OPERAND	COMMENT
CMD	0x0	0xEB	4xIO Read Command
ADDR	0x2	0x18	24 Bit address to be send on 4 pads
MODE	0x2	0x00	2 mode cycles (exit XIP)
DUMMY	0x0	0x04	4 dummy cycles
READ	0x2	0x08	Read 64 bits
CMD	0x0	0x05	Read Status register
READ	0x0	0x01	Status register data
STOP	0x0	0x00	STOP, Instruction over

10.2.7.1.1 Fast Read Sequence (Macronix/Numonyx/Spansion/Winbond)

The following table shows the fast read sequence for Macronix/Numonyx/Spansion/ Winbond flashes.

Table 10-30. Fast Read sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x0B	Fast Read command = 0x0B
ADDR	0x0	0x18	24 Addr bits to be sent on one pad
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x0	0x04	Read 32 Bits on one pad
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

10.2.7.1.2 Fast Dual I/O DT Read Sequence (Macronix)

The following table shows the Fast Dual I/O DT read sequence for Macronix flashes.

Table 10-31. Fast Dual I/O DT Read sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xBD	Fast Dual I/O DT read command = 0xBD
ADDR_DDR	0x1	0x18	24 Addr bits to be sent on 2 pads in DDR mode
MODE4_DDR	0x1	0x00	P2=P0 or P3=P1 is necessary. Refer to Macronix datasheet for details. One clock cycle for mode.
DUMMY	0x0	0x06	6 Dummy cycles

Table continues on the next page...

Table 10-31. Fast Dual I/O DT Read sequence (continued)

Instruction	Pad	Operand	Comment
READ_DDR	0x1	0x04	Read 32 Bits on 2 pads in DDR mode
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

10.2.7.1.3 Fast Read Quad Output (Winbond)

The following table shows the Fast read quad output sequence for Winbond memories

Table 10-32. Fast Read Quad output sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x6B	Fast read quad output command = 0x6B
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

10.2.7.1.4 4 x I/O Read Enhance Performance Mode (XIP) (Macronix)

The following table shows the 4 x I/O Read Enhance Performance Mode for Macronix flashes. The enhanced performance mode is also known as XIP mode.

Table 10-33. Fast Read Quad output sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xEB	4xI/O Read command = 0xEB
ADDR	0x2	0x18	24 Addr bits to be sent on 4 pads
MODE	0x2	0xA5	2 mode cycles
DUMMY	0x0	0x04	4 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x01	Jump to instruction 1 (ADDR)

When in XIP mode the software should ensure that all the flashes connected to the controller are in XIP mode. As a part of initializing the controller, all the flashes may be enabled with XIP by carrying out dummy reads.

10.2.7.1.5 Dual Command Page Program (Numonyx)

The following table shows the Dual command page program sequence for Numonyx flashes.

Table 10-34. Dual Command Page Program sequence

Instruction	Pad	Operand	Comment
CMD	0x1	0x02	Dual command page program = 0x02 on 2 pads
ADDR	0x1	0x18	24 Addr bits to be sent on 2 pads
WRITE	0x1	0x20	Write 32 Bytes on 2 pads
STOP	0x0	0x00	STOP, Instruction over

10.2.7.1.6 Sector Erase (Macronix/Spansion/Numonyx)

The following table shows the Sector erase sequence for Macronix/Spansion/Numonyx flashes

Table 10-35. Sector Erase sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xD8	Sector erase command = 0xD8
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
STOP	0x0	0x00	STOP, Instruction over

10.2.7.1.7 Read Status Register (Macronix/Spansion/Numonyx/Winbond)

The following table shows the Read status register sequence for Macronix/Spansion/ Numonyx/Winbond flashes.

Table 10-36. Read Status Register Sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x05	Read status register command = 0x05
READ	0x0	0x01	Read status register data
STOP	0x0	0x00	STOP, Instruction over

10.2.7.2 Dual Die Flashes

Certain serial flash vendors provide dual-die packages which are essentially two devices (dies) stacked within the same package to increase the memory capacity of a single package. These two devices within a package share the same data and clock pins, but have individual Chip Selects. QuadSPI controller provides support for two dual-die packages to be connected simultaneously. The figure below shows the two dual-die packages and the naming conventions used in this document. For simplicity, the data pins are shown to be unidirectional.

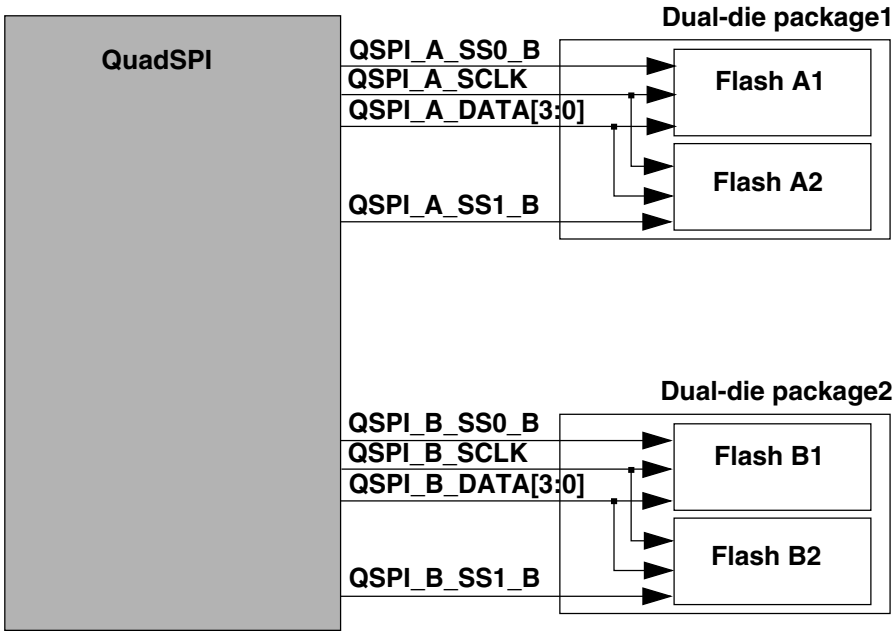

Figure 10-21. Dual-die support

Since the two devices within one package share the same i/o pads, they cannot function in parallel mode. Software should ensure that when QuadSPI is configured in parallel mode the two selected flash devices are from different dual-die packages.

10.2.7.3 Boot initialization sequence

The following are the recommended sequence of steps for booting from QuadSPI:

- System out of reset and flash available (300us)
- Clocks still at very low frequency. Clock tree configured, I/O pins configured. First request sent to QuadSPI for address 0x0 of flash.
- The reset command sequence in QuadSPI has 0x03 (basic read command) which is applicable to all flashes at < 50MHz serial flash clock
- The first few bytes of data is read from the flash which contains the following information:
  - The total sizes of all the flashes connected on board
  - Whether DDR mode supported
  - Frequency of DDR operation

- Continuous mode entry sequence
- 24bit or 32bit addressing (assuming 24bit for first accesses)

- All the serial flashes are configured
  - Quad Mode enabled
  - Dummy reads to enter into XIP
- QuadSPI is configured
  - Parallel enable set
  - LUT configured for highest performance reads
  - DDR mode enabled (if applicable)
  - Buffers configured
- Serial flash clock frequency increased.
- Boot reads happen in parallel, DDR enabled, quad output mode @66MHz.

10.2.8 Sampling of Serial Flash Input Data

10.2.8.1 Internal Sampling of Serial Flash Input Data

Depending from the actual implementation there is a delay between the internal clocking in the QuadSPI module and the external serial flash device.Refer to the following figure for an overview of this scheme.

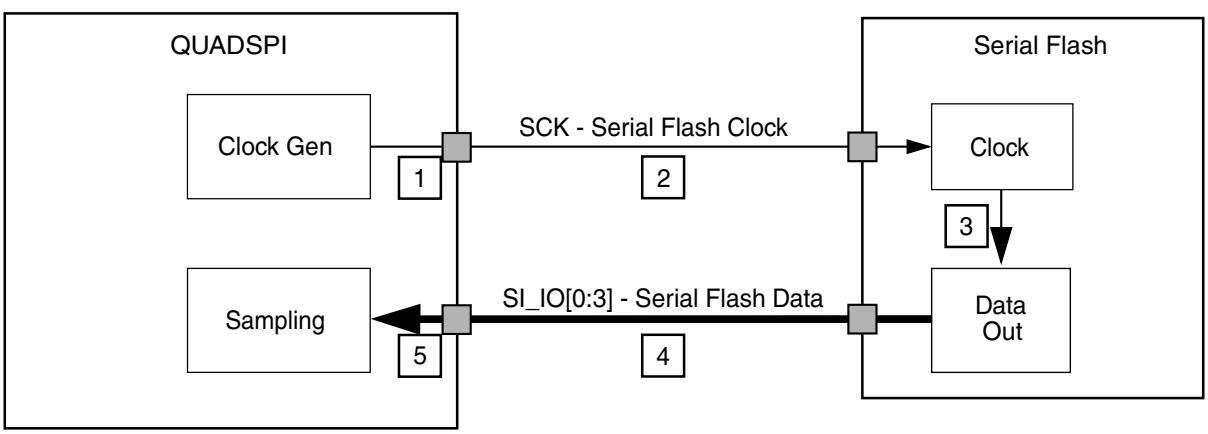

Figure 10-22. Serial Flash Sampling Clock Overview

Note

The arrival of the serial flash data in the sampling stage of the QuadSPI module are given in the following figure. Note that the amount of the total delay $t_{Del,total}$ is very specific to the characteristics of the actual implementation.

Note also that the serial flash device clock SCK is inverted with respect to the QuadSPI internal reference clock.

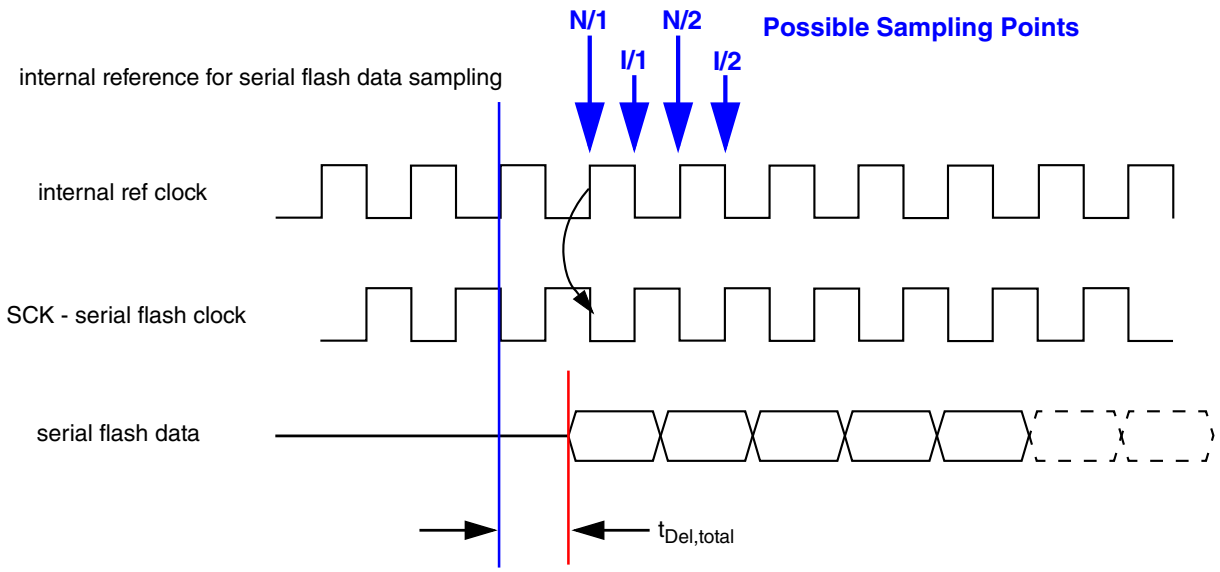

Figure 10-23. Serial Flash Sampling Clock Timing

The rising edge of the internal reference clock is taken as timing reference for the data output of the serial flash. After a time of $t_{Del,total}$ the data arrive at the internal sampling stage of the QuadSPI module.

According to the Serial Flash Sampling Clock Overview figure, the following parts of the delay chain contribute to $t_{Del,total}$:

1. Output delay of the serial flash clock output of the device containing the QuadSPI module
2. Wire delay of application/PCB from the device containing the QuadSPI module to the external serial flash device
3. Clock to data out delay of the external serial flash device, including input and output delays
4. Wire delay of application/PCB from the external serial flash device to the device containing the QuadSPI module
5. Input delay belonging to the data in input

The possible points in time for the sampling of the incoming data are denoted as N/1, I/1, N/2 and I/2 above. The sampling point relevant for the internal sampling is configured in the QSPI_SMPR register, refer to Sampling Register (QuadSPI_SMPR) for details. Note that the falling edges of the reference clock are not actually used, instead the inverted clock is used for sampling at these positions. The following table gives an overview of the available configurations for the commands running at regular (full) speed:

Table 10-37. Sampling Configuration

Sampling Point	Description	Delay [FSDLY] [HSDLY]	Phase [FSPHS] [HSPHS]	QSPI_SMPR for Full Speed Setting[1]
N/1	sampling with non-inverted clock, 1 sample delay	0	0	0x0000000x
I/1	sampling with inverted clock, 1 sample delay	0	1	0x0000002x
N/2	sampling with non-inverted clock, 2 samples delay	1	0	0x0000004x
I/2	sampling with inverted clock, 2 samples delay	1	1	0x0000006x

1. 'x' is not considered here

Depending from the actual delay and the serial flash clock frequency the appropriate sampling point can be chosen. The following remarks should be considered when selecting the appropriate setting:

- Theoretically there should be 2 settings possible to capture the correct data since the serial flash output is valid for 1 clock cycle, disregarding rise and fall times and timing uncertainties.
- Depending from the timing uncertainties it may turn out in actual applications that only one possible sample positions remains. This is subject to careful consideration depending from the actual implementation.
- The delay $t_{Del,total}$ is an absolute size to shift the point in time when the serial flash date get valid at the QuadSPI input.
- For decreasing frequency of the serial flash clock the distance between the edges increases. So for large differences in the frequency the required setting may change.
- For commands running at half of the regular serial flash clock (QSPI_SMPR[HSENA] bit set) the sampling point must be figured separately to allow for the compensation of the absolute shift in time with respect to the sample-relative setting in the QSPI_SPMPR register.

10.2.8.2 DDR Mode

The increasing requirement of improved throughput has introduced the double data rate (DDR) mode. In DDR mode, the data is transferred on both the rising and falling edges of the serial flash clock. The DDR serial flashes sample as well as drive the data on both rising and falling edges of serial flash clock.

10.2.9 Serial Flash Data Input Timing

There are sampling modes for input flash data:

- Internal sampling - Input serial flash data is captured by internal serial clock. In SDR mode, serial data is sampled by serial clock 1x (ser_clk_1x) rise edge. In DDR mode, serial data is sampled by serial clock 4x (ser_clk_4x) rise edge.
- Loopback DQS sampling - Soc will output serial data strobe with internal serial clock. This serial data strobe would be loopback from pad and used to sample input serial data. In SDR mode, serial data is sampled by loopback DQS rise edge. In DDR mode, serial data is sampled by loopback DQS both edge

NOTE

DQS pad need to be set to force input for loopback.

- Flash DQS sampling - Some serial Flash device provide the data strobe output together with serial data. This strobe signal is used to sample input serial data directly. In SDR mode, serial data is sampled by Flash DQS rise edge. In DDR mode, serial data is sampled by Flash DQS both edge

Following table shows selection for sampling mode:

Sampling mode	DQS_EN	DQS_LOOPBACK_EN
Internal sampling	0	doesn't matter
Loopback DQS sampling	1	1
Flash DQS sampling	1	0

Serial flash data and clock path for input timing is shown in the following figure.

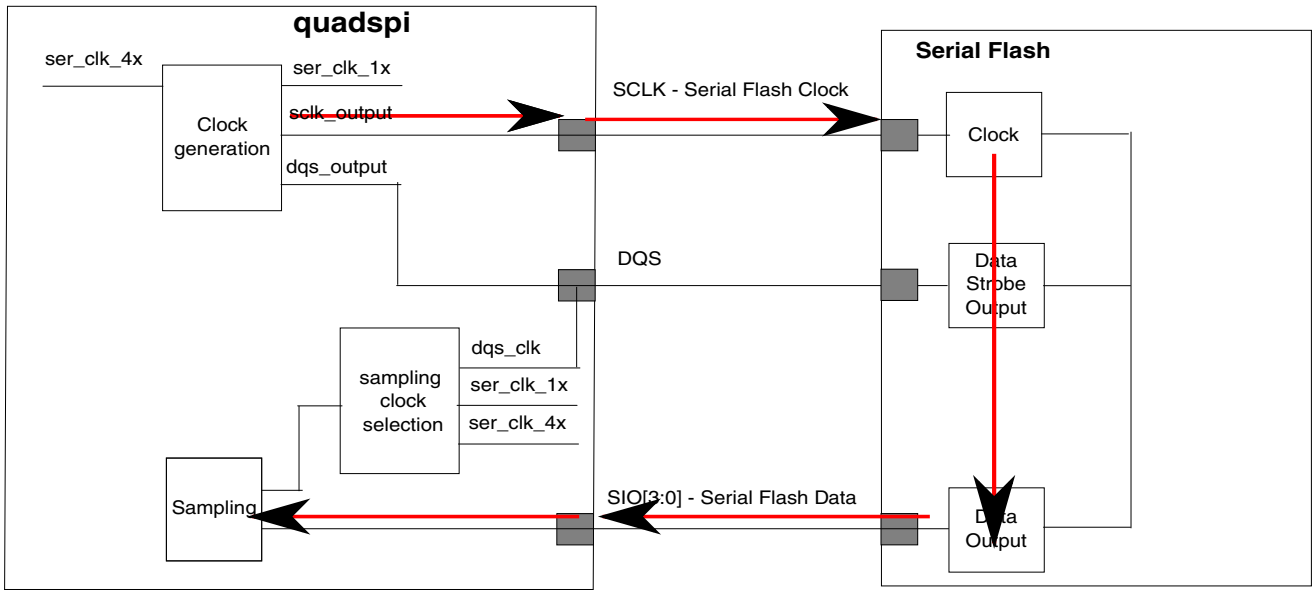

Figure 10-24. Serial flash data and clock path

NOTE

The red line is for data input path, the blue line is for DQS loopback path, and the purple line is for DQS input path from Serial Flash.

Total delay (Ttotal_delay_data) for serial flash data input is the sum of following delay:

1. Output delay of serial flash clock from internal serial clock to SCLK pad inside SOC
2. Wire delay of serial flash clock (SCLK) from SOC to external Serial Flash Device
3. Clock to Output Valid time of external Serial Flash Device
4. Wire delay of serial flash data (SIO) from external serial Flash Device to SOC
5. Input delay of serial flash data from SIO pad to internal sample register

Total delay (Ttotal_delay_loopback_dqs) for loopback DQS clock is the sum of following delay:

1. Output delay of DQS clock from internal serial clock to DQS pad inside SOC
2. Input delay of DQS clock from DQS pad to internal sample register

Total delay (Ttotal_delay_flash_dqs) for Flash DQS clock is the sum of following delay:

1. Output delay of serial flash clock from internal serial clock to SCLK pad inside SOC
2. Wire delay of serial flash clock (SCLK) from SOC to external Serial Flash Device
3. Clock to DQS Output time of external Serial Flash Device
4. Wire delay of serial flash data strobe (DQS) from external serial Flash Device to SOC
5. Input delay of DQS clock from DQS pad to internal sample register

10.2.9.1 Input timing in SDR mode with internal sampling

Input Timing diagram in SDR mode with internal sampling is show in the figure below.

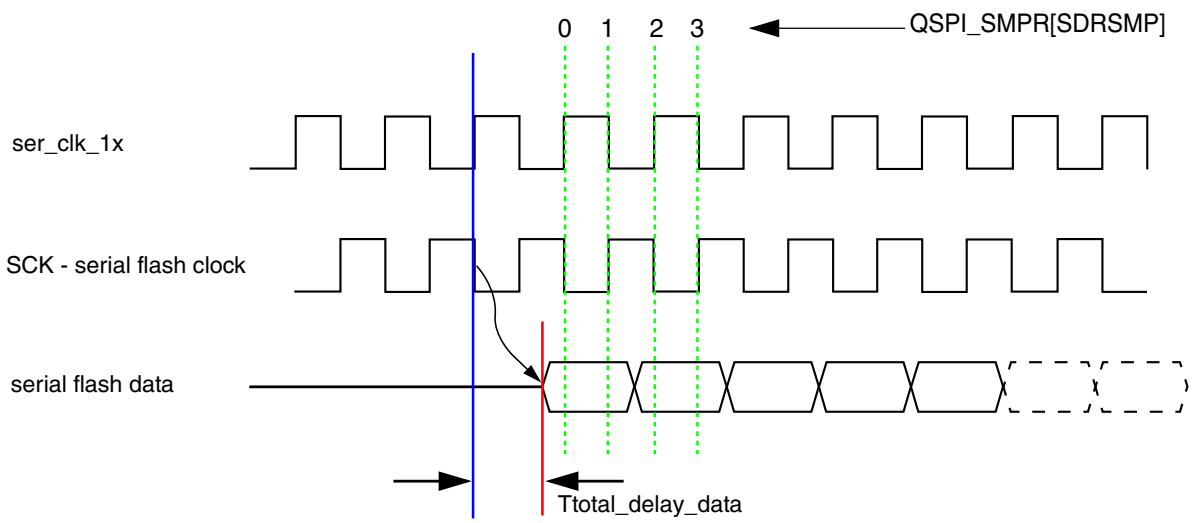

Figure 10-25. Internal sample SDR

There are four sample points for this sampling mode, which is determined by register field QSPI_SMPR.SDRSMP.

Sampling point need to be select correctly to meet both Setup and Hold timing for internal sample registers:

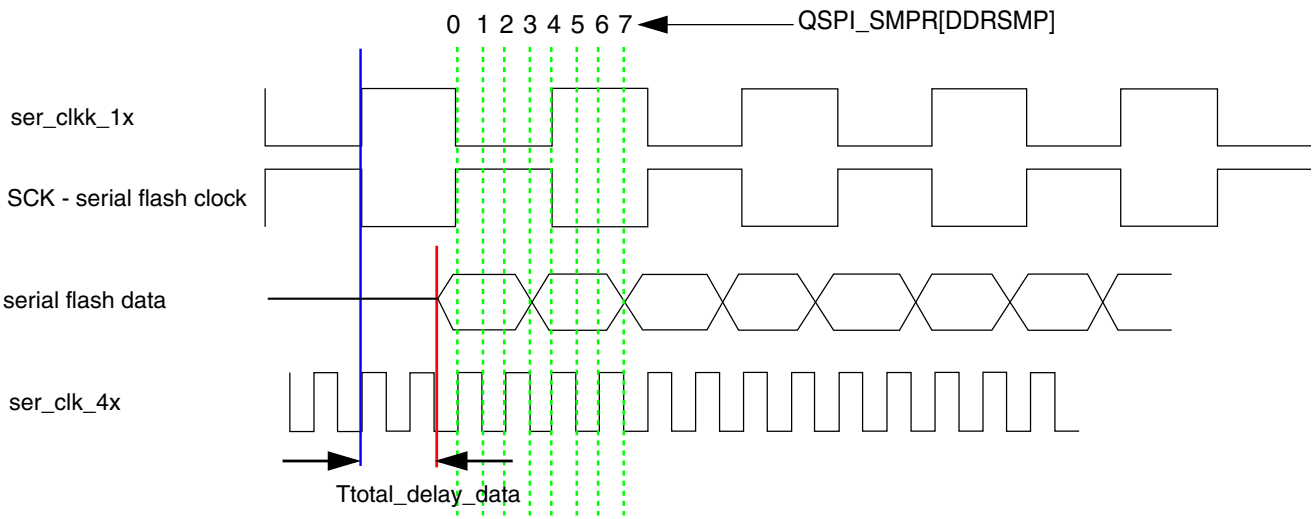
- For sample point N, Setup requirement is: Tcycle*(N+2)/2>Ttotal_delay_data,max
- For sample point N, Hold requirement is: Ttotal_delay_data,min>Tcycle*N/2

NOTE

Tcycle is the cycle of ser_clk_1x. Ttotal_delay_data,max is maximum delay of serial data input path. Ttotal_delay_data,min is the minimum delay of serial data input path. N=0,1,2,3

10.2.9.2 Input timing in DDR mode with internal sampling

Input Timing diagram in SDR mode with internal sampling is show in the following figure.



There are 8 sample points for this sampling mode, which is determined by register field DDRSMP.

Sampling point need to be select correctly to meet both Setup and Hold timing for internal sample registers:

- For sample point N, Setup requirement is: Tcycle * (N+2)/8 >Ttotal_delay_data,max
- For sample point N, Hold requirement is: Ttotal_delay_data,min> Tcycle * N/8

10.2.9.3 Input timing in SDR mode with loopback DQS sampling

Input Timing diagram in SDR mode with internal sampling is show in the following figure.

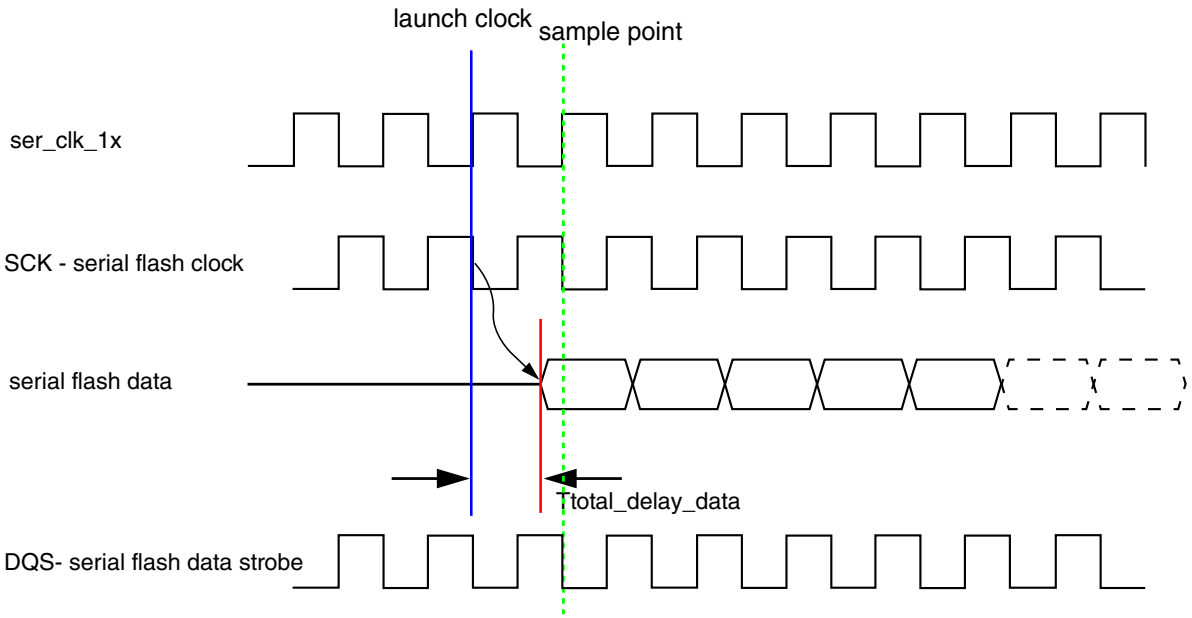


Figure 10-26. Input timing in SDR mode with loopback DQS sampling

In SDR mode and loopback sampling mode, DQS_PHASE_EN should be set 1.

For this sample point, the Setup requirement is: Tcycle >max(Ttotal_delay_data-Ttotal_delay_loopback_dqs). The Hold requirement is: min(Ttotal_delay_data-Ttotal_delay_loopback_dqs)> 0.

10.2.9.4 Input timing in DDR mode with loopback DQS sampling

Input Timing diagram in DDR mode with internal sampling is show in the following figure.

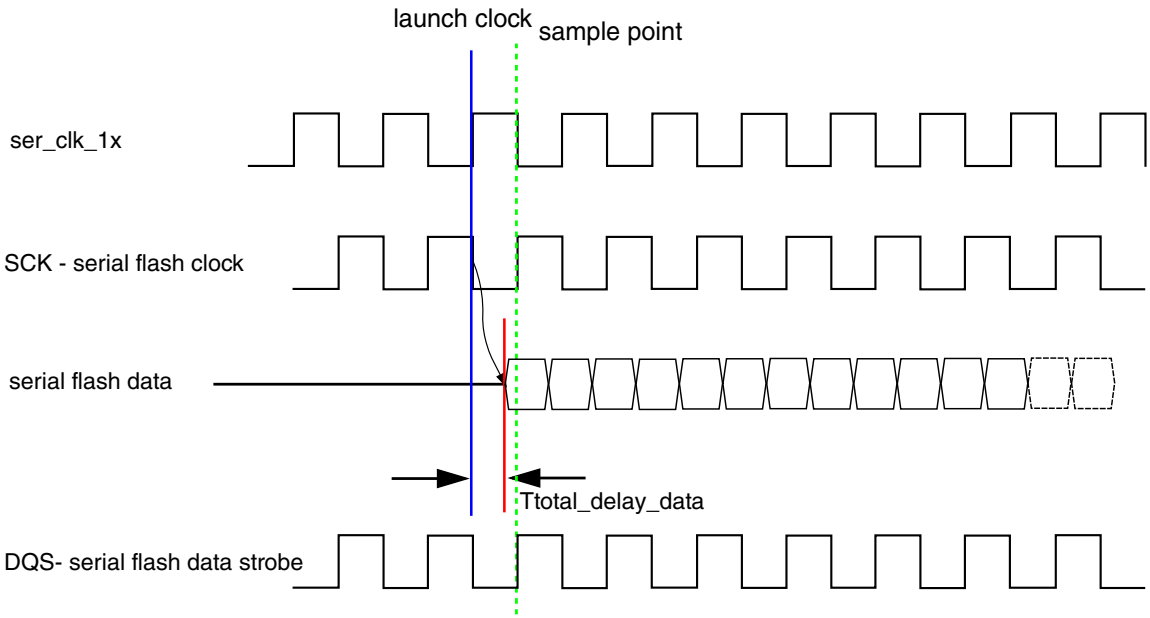

Figure 10-27. Input timing in DDR mode with loopback DQS sampling

In DDR mode and loopback sampling mode, DQS_PHASE_EN should be set 0.

For this sample point, the Setup requirement is: Tcycle >max(Ttotal_delay_data-Ttotal_delay_loopback_dqs). The Hold requirement is: min(Ttotal_delay_data-Ttotal_delay_loopback_dqs)> 0.

10.2.9.5 Input timing in SDR mode with flash DQS sampling

Input Timing diagram in SDR mode with internal sampling is show in the following figure.

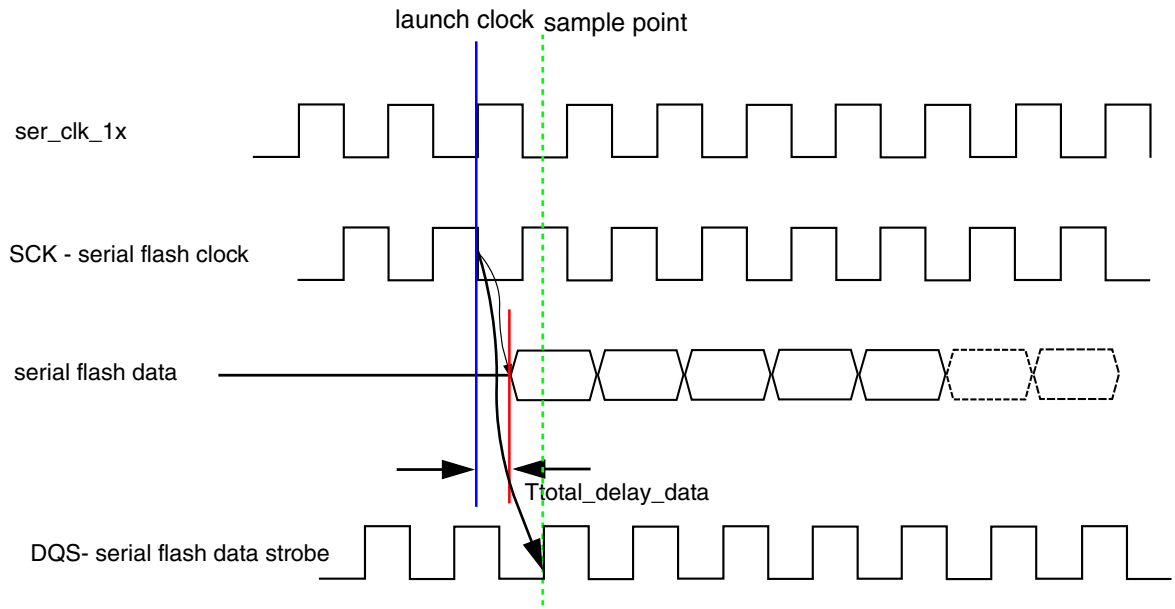

Figure 10-28. Input timing in SDR mode with flash DQS sampling

In this sampling mode, there will be a setup/hold requirement on Flash serial Data and Flash serial Data Strobe. This value will be specified in the data sheet.

10.2.9.6 Input timing in DDR mode with flash DQS sampling

Input Timing diagram in DDR mode with internal sampling is show in the following figure.

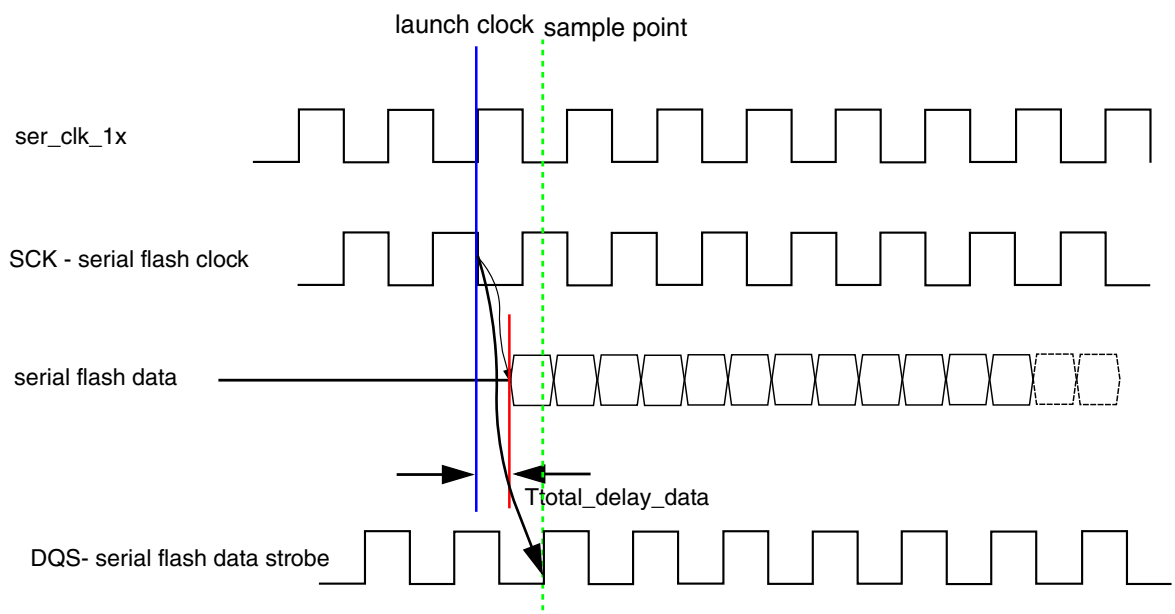

Figure 10-29. Input timing in DDR mode with flash DQS sampling

In this sampling mode, there will be a setup/hold requirement on Flash serial Data and Flash serial Data Strobe. This value will be specified in the data sheet.

10.2.9.7 Data Strobe Signal functionality

Some external serial flashes provide the data strobe (DQS/RDS) output which is fed directly to the QuadSPI module. The strobe (DQS/RDS) signal needs to be delayed to have the edges aligned to the data valid period. QuadSPI internally samples the incoming data at posedge of the strobe signal for SDR and on both the edges of the strobe signal for DDR. Refer to the figure for more detail.

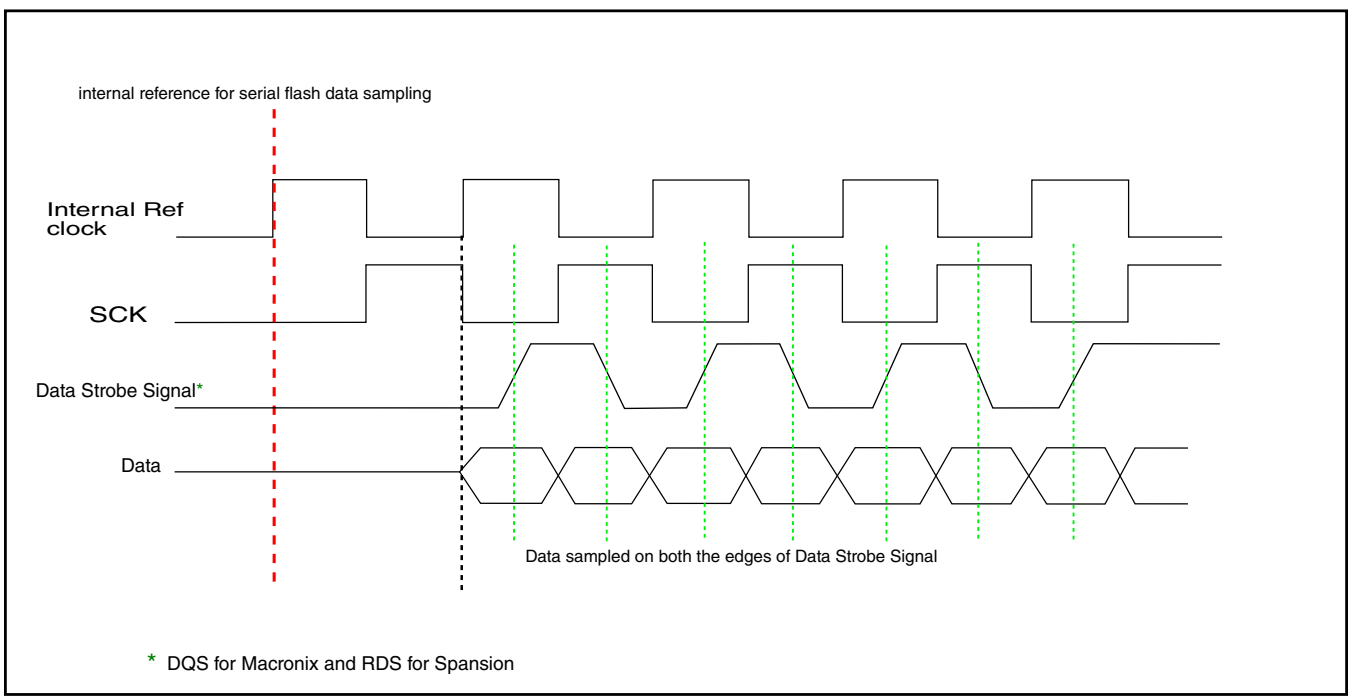

Figure 10-30. Data strobe signal functionality

10.2.10 Output timing in SDR mode

Output timing diagram in SDR mode is show in the following figure.

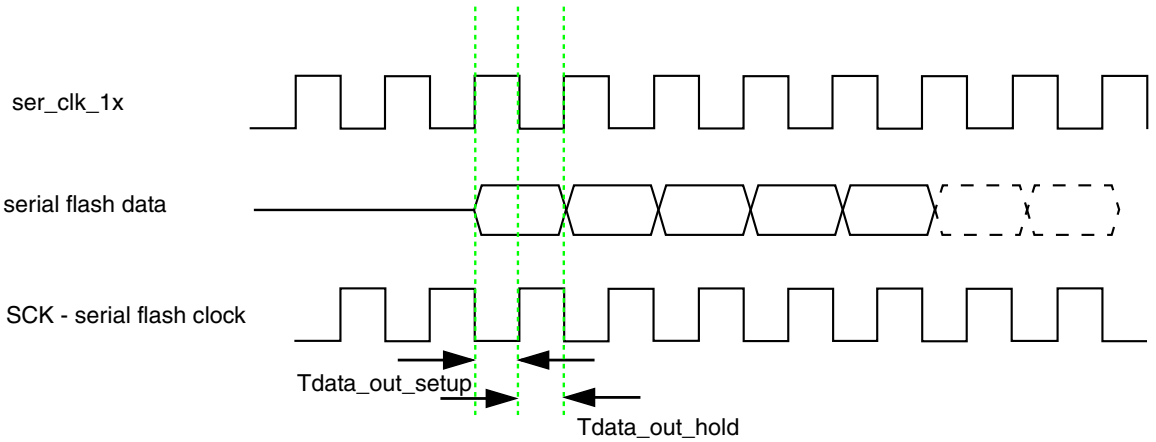

Figure 10-31. Output timing in SDR mode

In SDR mode, quadspi output serial data with internal serial clock rise edge 1x (ser_clk_1x). Flash Device has requirement on Data and Clock setup and hold timing.

10.2.11 Output timing in DDR mode

Output Timing diagram in DDR mode is show in the following figure.

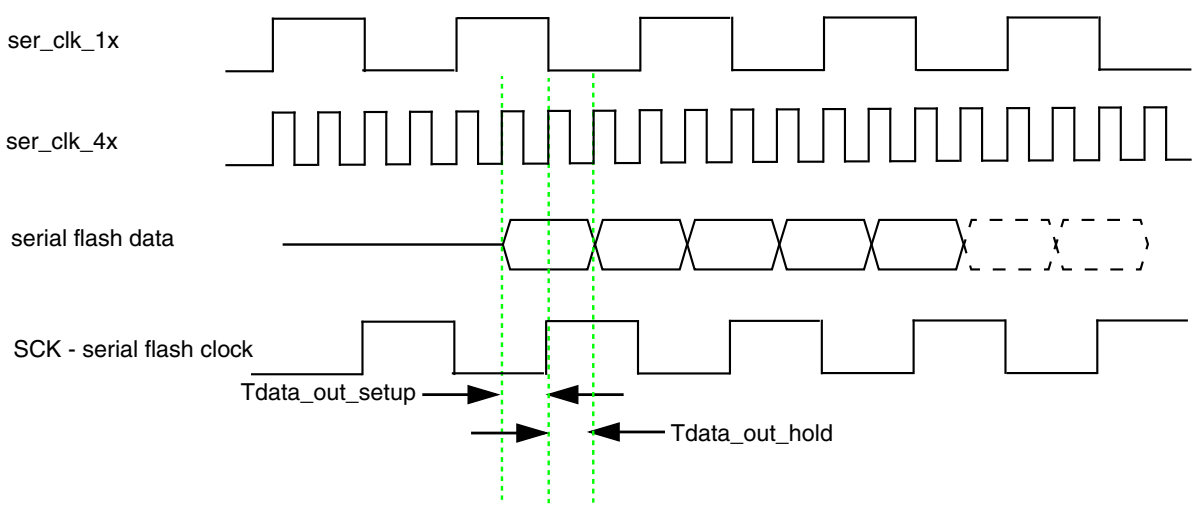

Figure 10-32. Output timing in DDR mode

In DDR mode, quadspi output serial data with internal serial clock both edge 1x (ser_clk_1x) and then delay one ser_clk_4x cycle for hold timing.

NOTE

TX_DDR_DELAY_EN should be set to 1 for DDR mode.

10.2.12 AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)

10.2.12.1 AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)

NOTE

See the System Memory map in this document for the base address of the QSPI AHB RX Data Buffer.

10.2.12.1.1 AHB RX Data Buffer register (ARDB*n*)

The AHB RX Data Buffer register 0 to 31 can be used to read the buffer content of the RX Buffer from successive addresses. QSPI_ARDB0 corresponds to the RX Buffer register entry corresponding to the current value of the read pointer with increasing order.

The increment of the read pointer depends from the access scheme (DMA or flag-driven). Refer to "Data Transfer from the QuadSPI Module Internal Buffers" section in Flash Read section, RX Buffer, data read via register interface and AHB read, for the description of successive accesses to the RX Buffer content. Refer also to Byte Ordering of Serial Flash Read Data for the byte ordering scheme.

Valid address range accessible in the QSPI_ARDBn range depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

- Example 1, RX Buffer filled completely with 32 words: In this case the address range for valid read access extends from QSPI_ARDB0 to QSPI_ARDB31.
- Example 2, RX Buffer filled with 5 valid words, RX Buffer fill level QSPI_RBSR[RDBFL] is 5. In this case an access to QSPI_ARDB4 provides the last valid entry.

Address: 0h base + 0h offset + (4d × i), where i=0d to 31d

ARDB*n* field descriptions

Field	Description
ARXD	ARDB provided RX Buffer Data. Byte order (endianness) is identical to the RX Buffer Data Registers.

10.2.13 Peripheral Bus Register Descriptions

This section provides the peripheral bus register information of the QuadSPI module.

This section provides the memory map and register definitions of the QuadSPI module.

QuadSPI memory map

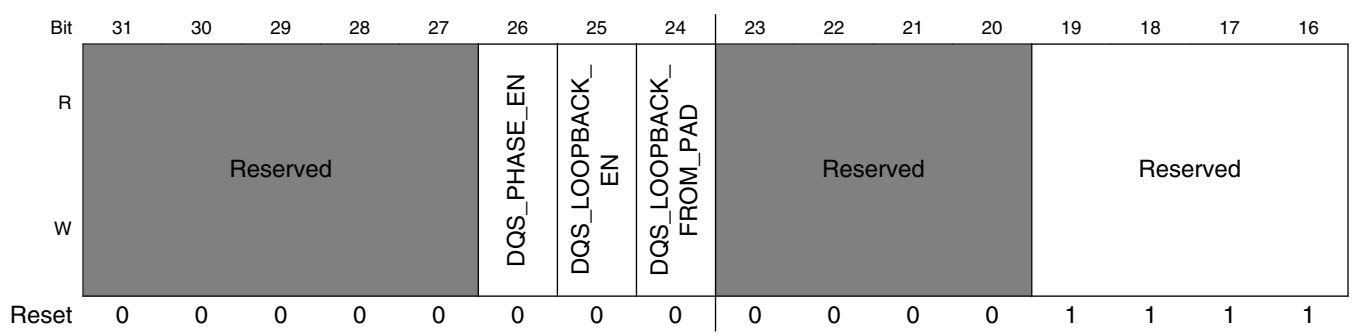
10.2.13.1 Module Configuration Register (QuadSPI_MCR)

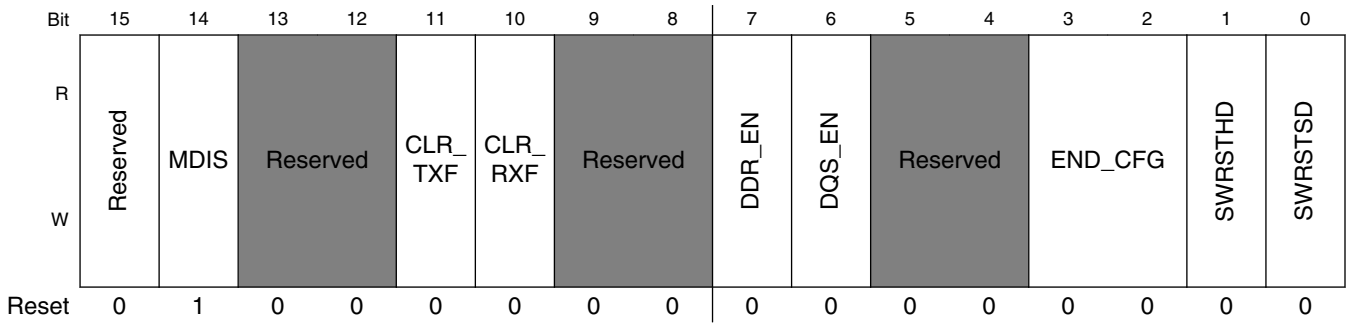
The QuadSPI_MCR holds configuration data associated with QuadSPI operation.

Write:

- *All other fields: Anytime*

Address: 30BB_0000h base + 0h offset = 30BB_0000h





QuadSPI_MCR field descriptions

Field	Description
31–27 Reserved	This field is reserved.
26 DQS_PHASE_ EN	This bit controls internal DQS output phase. If DQS_EN and DQS_LOOPBACK_EN are both set to 1, this bit should be set in SDR mode, and cleared in DDR mode. If either DQS_EN or DQS_LOOPBACK_EN is set to 0, this bit is ignored.
25 DQS_ LOOPBACK_EN	Quadspi will output serial data strobe signal which will be loopback from pad to sample input flash serial data. Please note pad should be force input for loopback.Quadspi will output serial data strobe signal which will be loopback from pad to sample input flash serial data. Please note pad should be force input for loopback. This bit is a don't care when DQS_EN is set to 0. 1'b1 DQS loopback sampling enabled 1'b0 DQS loopback sampling disabled
24 DQS_ LOOPBACK_ FROM_PAD	This bit should always be set to '1' when DQS_LOOPBACK_EN is set to '1'. When DQS_LOOPBACK_EN is set to '1', this bit is ignored.
23–20 Reserved	This field is reserved.
19–16 Reserved	This field is reserved. This field is reserved and should always be set to 0xF.
15 Reserved	This field is reserved. This field is reserved.
14 MDIS	Module Disable. The MDIS bit allows the clock to the non-memory mapped logic in the QuadSPI to be stopped, putting the QuadSPI in a software controlled power-saving state. Please refer to , for more information. 0 Enable QuadSPI clocks. 1 Allow external logic to disable QuadSPI clocks.
13–12 Reserved	This field is reserved.
11 CLR_TXF	Clear TX FIFO/Buffer. Invalidate the TX Buffer content. 0 No action. 1 Read and write pointers of the TX Buffer are reset to 0. QSPI_TBSR[TRCTR] is reset to 0.

Table continues on the next page...

QuadSPI_MCR field descriptions (continued)

Field	Description
10 CLR_RXF	Clear RX FIFO. Invalidate the RX Buffer. 0 No action. 1 Read and write pointers of the RX Buffer are reset to 0. QSPI_RBSR[RDBFL] is reset to 0.
9–8 Reserved	This field is reserved.
7 DDR_EN	DDR mode enable: 0 2x and 4x clocks are disabled for SDR instructions only 1 2x and 4x clocks are enabled supports both SDR and DDR instruction.
6 DQS_EN	DQS enable: This field is valid for both SDR and DDR mode. For more details Refer Data Strobe Signal Functionality 0 DQS disabled. 1 DQS enabled- When enabled, the incoming data is sampled on both the edges of DQS input when QSPI_MCR[DDR_EN] is set, else, on only one edge when QSPI_MCR[DDR_EN] is 0. The QSPI_SMPR[DDR_SMP] values are ignored.
5–4 Reserved	This field is reserved.
3–2 END_CFG	Defines the endianness of the QSPI module.For more details refer to Byte Ordering Endianess
1 SWRSTHD	Software reset for AHB domain **NOTE:** Please keep other fields value when write to SWRSTHD and SWRSTSD **NOTE:** These software reset don't reset register setting but only reset internal flip-flops in quadspi controller **NOTE:** To remove the reset, need to write 0 to SWRSTHD and SWRSTSD 0 No action 1 AHB domain flops are reset. Does not reset configuration registers. It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects.
0 SWRSTSD	Software reset for Serial Flash domain **NOTE:** Please keep other fields value when write to SWRSTHD and SWRSTSD **NOTE:** These software reset don't reset register setting but only reset internal flip-flops in quadspi controller **NOTE:** To remove the reset, need to write 0 to SWRSTHD and SWRSTSD 0 No action 1 Serial Flash domain flops are reset. Does not reset configuration registers. It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects.

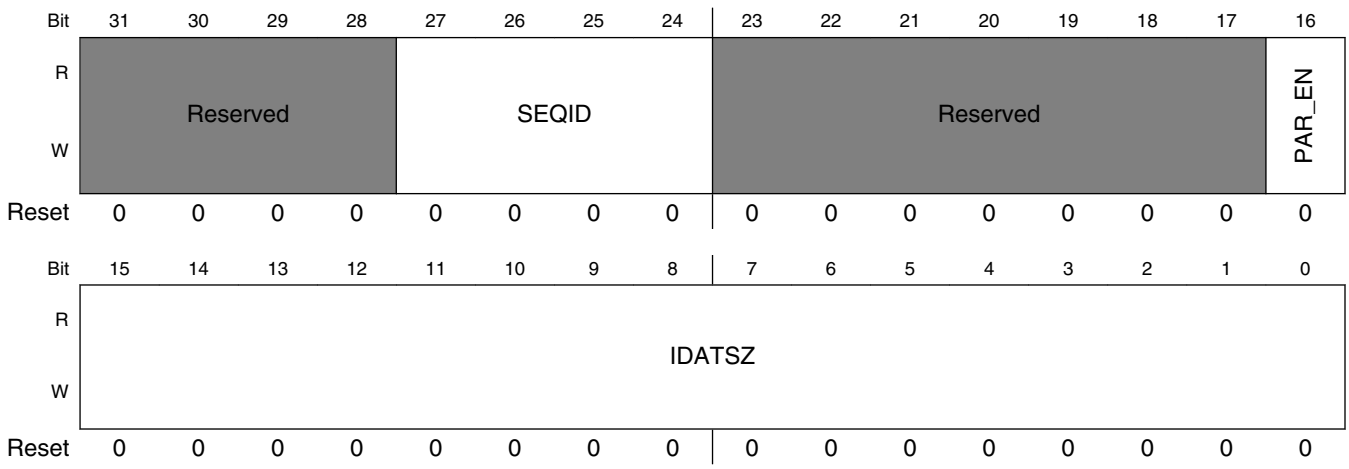
10.2.13.2 IP Configuration Register (QuadSPI_IPCR)

The IP configuration register provides all the configuration required for an IP initiated command. An IP command can be triggered by writing in the SEQID field of this register. If the SEQID field is written successfully, a new command to the external serial flash is started as per the sequence pointed to by the SEQID field. Refer to Normal Mode, for details about the command triggering and command execution.

Write:

- *QSPI_SR[IP_ACC]=0*

Address: 30BB_0000h base + 8h offset = 30BB_0008h



QuadSPI_IPCR field descriptions

Field	Description
31–28 Reserved	This field is reserved.
27–24 SEQID	Points to a sequence in the Look-up-table. The SEQID defines the bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to Look-up Table for more details. A write to this bit -field triggers a transaction on the serial flash interface.
23–17 Reserved	This field is reserved.
16 PAR_EN	When set, a transaction to two serial flash devices is triggered in parallel mode. Refer to Parallel Flash Mode for more details.
IDATSZ	IP data transfer size: Defines the data transfer size in bytes of the IP command.

10.2.13.3 Flash Configuration Register (QuadSPI_FLSHCR)

The Flash configuration register contains the flash device specific timings that must be met by the QuadSPI controller for the device to function correctly.

Write:

- *QSPI_SR[AHB_ACC] = 0*
- *QSPI_SR[IP_ACC] = 0*

Address: 30BB_0000h base + Ch offset = 30BB_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved														TDH		Reserved				TCSH				Reserved				TCSS			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	1	1

QuadSPI_FLSHCR field descriptions

Field	Description
31–18 Reserved	This field is reserved.
17–16 TDH	Serial flash Data In hold time: This helps in meeting the Data In Hold time requirement of a Flash. This is valid only in DDR mode. Refer to Data input hold requirement of Flash for details. **NOTE:** This field should be set to 01 in DDR mode (DDR_EN=1) and set to 00 in SDR mode (DDR_EN=0). Other value are reserved. 00 Data aligned with the posedge of Internal reference clock of QuadSPI 01 Data aligned with 2x serial flash half clock 10 Reserved 11 Reserved
15–12 Reserved	This field is reserved.
11–8 TCSH	Serial flash CS hold time in terms of serial flash clock cycles. **NOTE:** The actual delay between chip select assertion and clock fall edge is defined as: • 1 SCK cycle if TCSH is set 0 or 1 • N SCK cycle if TCSH is set N (N>1)
7–4 Reserved	This field is reserved. Reserved.
TCSS	Serial flash CS setup time in terms of serial flash clock cycles. **NOTE:** 1. The actual delay between chip select assertion and clock fall edge is defined as: • 0.5 SCK cycle if TCSS is set 0 or 1 • N+0.5 SCK cycle if TCSS is set N (N>1) 2. Any update to TCSS register bits is visible on the flash interface only from the second transaction following the update.

10.2.13.4 Buffer0 Configuration Register (QuadSPI_BUF0CR)

This register provides the configuration for any access to buffer0. An access is routed to buffer0 when the master port number of the incoming AHB request matches the MSTRID field of the BUF0CR. Any buffer "miss" leads to a serial flash transaction being triggered as per the sequence pointed to the SEQID field. Buffer0 may also be configured as a high priority buffer by setting the HP_EN field of this register.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: 30BB_0000h base + 10h offset = 30BB_0010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	HP_EN	Reserved														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADATSZ								Reserved				MSTRID			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPI_BUF0CR field descriptions

Field	Description
31 HP_EN	High Priority Enable: When set, the master associated with this buffer is assigned a priority higher than the rest of the masters. An access by a high priority master will suspend any ongoing prefetch by another AHB master and will be serviced on high priority. Refer to Flexible AHB Buffers for details.
30–16 Reserved	This field is reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash. For example,a value of 0x2 will set transfer size to 16bytes.When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved. Reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER0. Any AHB access with this master port number is routed to this buffer.

10.2.13.5 Buffer1 Configuration Register (QuadSPI_BUF1CR)

This register provides the configuration for any access to buffer1. An access is routed to buffer1 when the master port number of the incoming AHB request matches the MSTRID field of the BUF1CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: 30BB_0000h base + 14h offset = 30BB_0014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved																ADATSZ								Reserved				MSTRID			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPI_BUF1CR field descriptions

Field	Description
31–16 Reserved	This field is reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash.For example, a value of 0x2 will set transfer size to 16bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER1. Any AHB access with this master port number is routed to this buffer.

10.2.13.6 Buffer2 Configuration Register (QuadSPI_BUF2CR)

This register provides the configuration for any access to buffer2. An access is routed to buffer2 when the master port number of the incoming AHB request matches the MSTRID field of the BUF2CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: 30BB_0000h base + 18h offset = 30BB_0018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved																ADATSZ								Reserved				MSTRID			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPI_BUF2CR field descriptions

Field	Description
31–16 Reserved	This field is reserved. Reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 Bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16bytes.When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved. Reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER2. Any AHB access with this master port number is routed to this buffer.

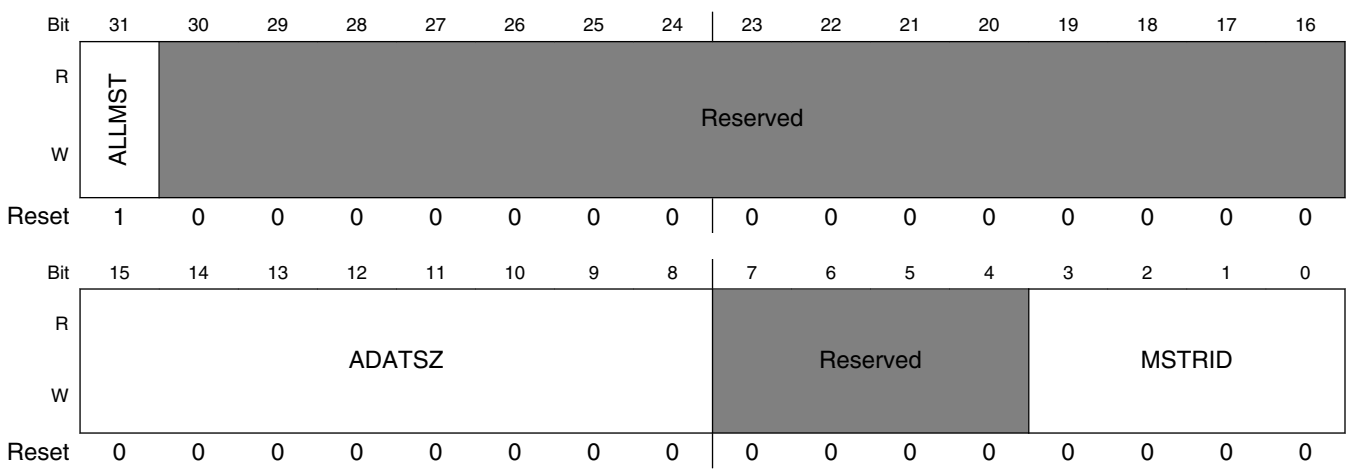
10.2.13.7 Buffer3 Configuration Register (QuadSPI_BUF3CR)

This register provides the configuration for any access to buffer3. An access is routed to buffer3 when the master port number of the incoming AHB request matches the MSTRID field of the BUF3CR. Any buffer "miss" leads to the buffer being flushed a serial flash transaction being triggered as per the sequence pointed to by the SEQID field. If the ALLMST field is set, any transaction where the master port number does not match any of the buffer MSTRID fields will be routed to this buffer. In the case that the ALLMST field is not set, any such transaction (where master port number does not match any of the MSTRID fields) will be returned an ERROR response.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: 30BB_0000h base + 1Ch offset = 30BB_001Ch



QuadSPI_BUF3CR field descriptions

Field	Description
31 ALLMST	All master enable: When set, buffer3 acts as an all-master buffer. Any AHB access with a master port number not matching with the master ID of buffer0 or buffer1 or buffer2 is routed to buffer3. When set, the MSTRID field of this register is ignored.
30–16 Reserved	This field is reserved. Reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 Bytes of an AHB triggered access to serial flash. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER3. Any AHB access with this master port number is routed to this buffer.

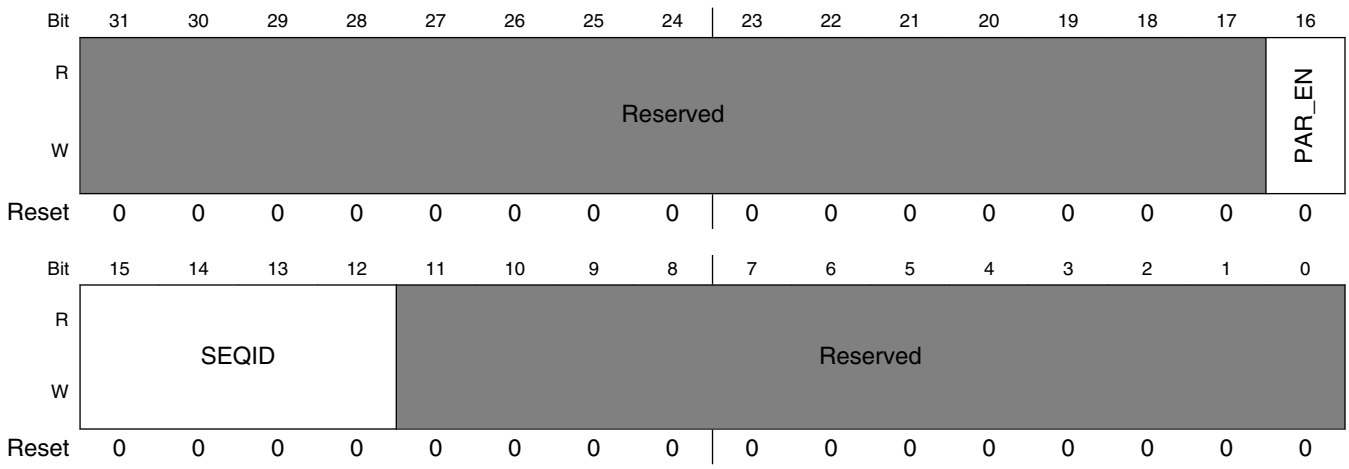
10.2.13.8 Buffer Generic Configuration Register (QuadSPI_BFGENCR)

This register provides the generic configuration to any of the buffer accesses. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field. If the PAR_EN field is set, all the buffer accesses result in parallel accesses to the flashes.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: 30BB_0000h base + 20h offset = 30BB_0020h



QuadSPI_BFGENCR field descriptions

Field	Description
31–17 Reserved	This field is reserved.
16 PAR_EN	When set, a transaction to two serial flash devices is triggered in parallel mode. Refer to Parallel Flash Mode for more details.
15–12 SEQID	Points to a sequence in the Look-up-table. The SEQID defines the bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to Look-up Table. **NOTE:** If the sequence pointer differs between the new and previous sequence then the user should reset this. See QSPI_SPTRCLR for more information.
Reserved	This field is reserved.

10.2.13.9 Buffer0 Top Index Register (QuadSPI_BUF0IND)

This register specifies the top index of buffer0, which defines its size. Note that that the 3 LSBs of this register are set to zero - this ensures that the buffer is 64bit aligned, as each buffer entry is 64bits long.

The register value should be set to the desired number of bytes less 8. For example, setting BUF0IND to 0 gives 8 bytes, 1 give 16bytes etc.

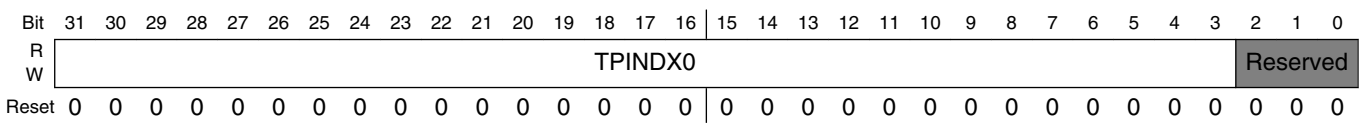
The size of buffer0 is the difference between the BUF0IND+8 and 0.

It is the responsibility of the software to ensure that BUF0IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: 30BB_0000h base + 30h offset = 30BB_0030h



QuadSPI_BUF0IND field descriptions

Field	Description
31–3 TPINDX0	Top index of buffer 0.
Reserved	This field is reserved. Reserved.

10.2.13.10 Buffer1 Top Index Register (QuadSPI_BUF1IND)

This register specifies the top index of buffer1, which defines its size. Note that the 3 LSBs of this register are set to zero - this ensures that the buffer is 64bit aligned as each buffer entry is 64bits long.

The register value should be set to the desired number of bytes less. The size of buffer1 is the difference between the BUF1IND and BUF0IND.

It is the responsibility of the software to ensure that BUF1IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: 30BB_0000h base + 34h offset = 30BB_0034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TPINDX1																													Reserved

QuadSPI_BUF1IND field descriptions

Field	Description
31–3 TPINDX1	Top index of buffer 1.
Reserved	This field is reserved.

10.2.13.11 Buffer2 Top Index Register (QuadSPI_BUF2IND)

This register specifies the top index of buffer2, which defines its size. Note that that the 3 LSBs of this register are set to zero - this ensures that the buffer is 64bit aligned as each buffer entry is 64bits long.

The register value should be set to the desired number of bytes less 8. The size of buffer2 is the difference between the BUF2IND and BUF1IND.

It is the responsibility of the software to ensure that BUF2IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: 30BB_0000h base + 38h offset = 30BB_0038h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPI_BUF2IND field descriptions

Field	Description
31–3 TPINDX2	Top index of buffer 2.
Reserved	This field is reserved.

10.2.13.12 Serial Flash Address Register (QuadSPI_SFAR)

The module automatically translates this address on the memory map to the address on the flash itself. When operating in 24bit mode, only bits 23-0 are sent to the flash, in 32bit mode, bits 27-0 are used with bits 31-28 driven to 0 Refer to Table 10-5 for the mapping between the access mode and the QSPI_SFAR content and to Normal Mode for details about the command triggering and command execution. The software should ensure that the serial flash address provided in the QSPI_SFAR register lies in the valid flash address range as defined in Table 10-5.

Write:

- *QSPI_SR[IP_ACC] = 0*

Address: 30BB_0000h base + 100h offset = 30BB_0100h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPI_SFAR field descriptions

Field	Description
SFADR	Serial Flash Address. The register content is used as byte address for all following IP Commands.

10.2.13.13 Sampling Register (QuadSPI_SMPR)

The Sampling Register allows configuration of how the incoming data from the external serial flash devices are sampled in the QuadSPI module.

Write:Disabled Mode

Address: 30BB_0000h base + 108h offset = 30BB_0108h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

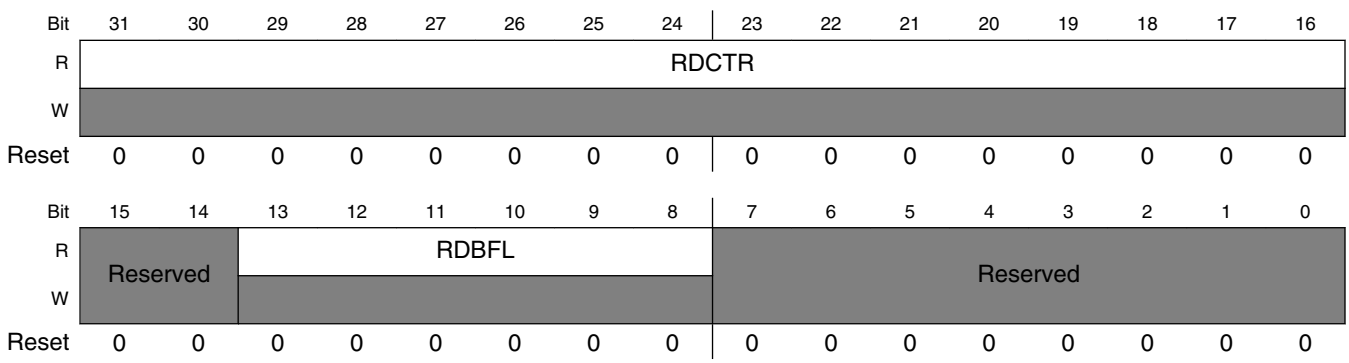
QuadSPI_SMPR field descriptions

Field	Description
31–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–16 DDRSMP	DDR Sampling point. Select the sampling point for incoming data when serial flash is executing a DDR instruction. Refer to Input timing in DDR mode with internal sampling , for details on the sampling points.
15–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–5 SDRSMP	SDR sampling point.
4–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

10.2.13.14 RX Buffer Status Register (QuadSPI_RBSR)

This register contains information related to the receive data buffer.

Address: 30BB_0000h base + 10Ch offset = 30BB_010Ch



QuadSPI_RBSR field descriptions

Field	Description
31–16 RDCTR	Read Counter, indicates how many entries of 4 bytes have been removed from the RX Buffer.For example a value of 0x2 would indicate 8bytes have been removed It is incremented by the number (QSPI_RBCT[WMRK] + 1) on RX Buffer POP event. The RX Buffer can be popped using DMA or pop flag QSPI_FR[RBDF]. The QSPI_RSER[RBDDE] defines which pop has to be done. For further details please refer to AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31) and "Data Transfer from the QuadSPI Module Internal Buffers section in Flash Read section.
15–14 Reserved	This field is reserved.
13–8 RDBFL	RX Buffer Fill Level, indicates how many entries of 4 bytes are still available in the RX Buffer.For example a value of 0x2 would indicate 8bytes are available.
Reserved	This field is reserved.

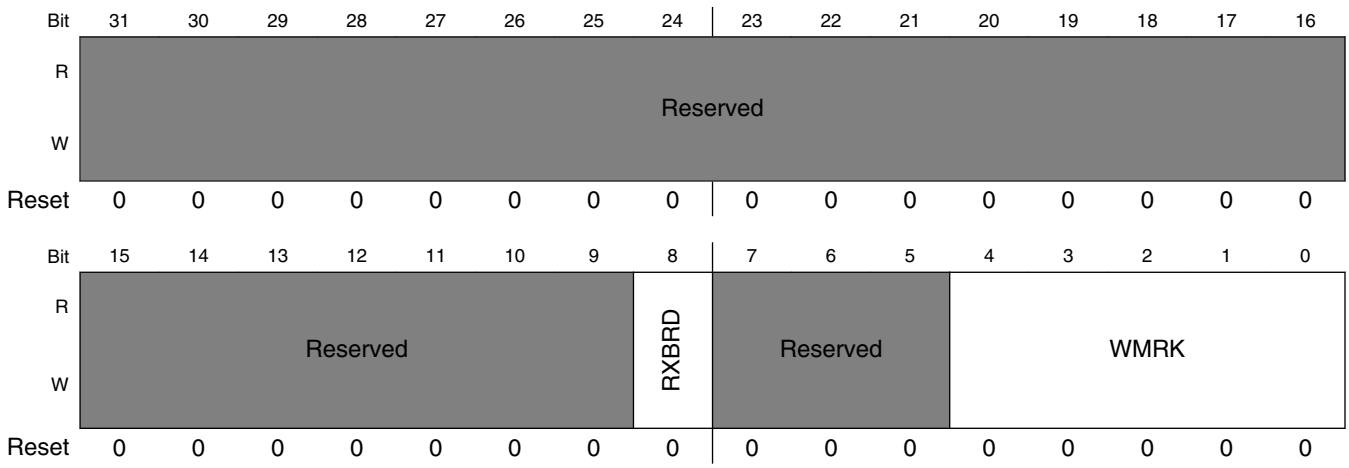
10.2.13.15 RX Buffer Control Register (QuadSPI_RBCT)

This register contains control data related to the receive data buffer.

Write:

- *QSPI_SR[IP_ACC] = 0*

Address: 30BB_0000h base + 110h offset = 30BB_0110h



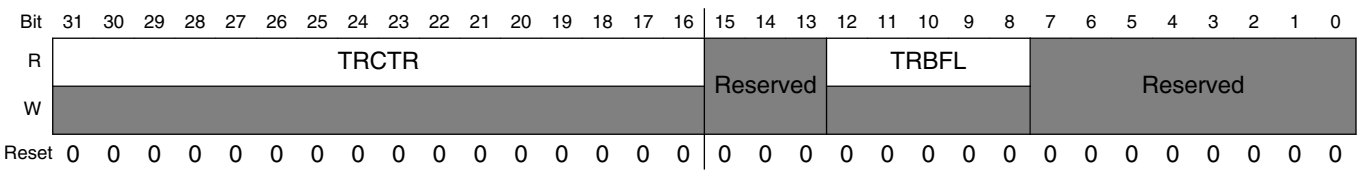
QuadSPI_RBCT field descriptions

Field	Description
31–9 Reserved	This field is reserved.
8 RXBRD	RX Buffer Readout: This bit specifies the access scheme for the RX Buffer readout. 0 RX Buffer content is read using the AHB Bus registers QSPI_ARDB0 to QSPI_ARDB31. For details, refer to Exclusive Access to Serial Flash for AHB Commands. 1 RX Buffer content is read using the IP Bus registers QSPI_RBDR0 to QSPI_RBDR31.
7–5 Reserved	This field is reserved.
WMRK	RX Buffer Watermark: This field determines when the readout action of the RX Buffer is triggered. When the number of valid entries in the RX Buffer is equal to or greater than the number given by (WMRK+1) the QSPI_SR[RXWE] flag is asserted.The value should be entered as the number of 4byte entries minus 1. For example a value of 0x0 would set the watermark to 4bytes, 1 to 8bytes, 2 to 12bytes etc. For details, refer to DMA Usage.

10.2.13.16 TX Buffer Status Register (QuadSPI_TBSR)

This register contains information related to the transmit data buffer.

Address: 30BB_0000h base + 150h offset = 30BB_0150h



QuadSPI_TBSR field descriptions

Field	Description
31–16 TRCTR	Transmit Counter. This field indicates how many entries of 4 bytes have been written into the TX Buffer by host accesses. It is reset to 0 when a 1 is written into the QSPI_MCR[CLR_TXF] bit. It is incremented on each write access to the QSPI_TBDR register when another word has been pushed onto the TX Buffer. When it is not cleared the TRCTR field wraps around to 0. Refer to TX Buffer Data Register (QuadSPI_TBDR) for details.
15–13 Reserved	This field is reserved.
12–8 TRBFL	TX Buffer Fill Level. The TRBFL field contains the number of entries of 4 bytes each available in the TX Buffer for the QuadSPI module to transmit to the serial flash device.
Reserved	This field is reserved.

10.2.13.17 TX Buffer Data Register (QuadSPI_TBDR)

The QSPI_TBDR register provides access to the circular TX Buffer of depth 128 bytes. This buffer provides the data written into it as write data for the page programming commands to the serial flash device. Refer to Table 10-14 for the byte ordering scheme. A write transaction on the flash with data size of less than 32 bits will lead to the removal of four data entry from the TX buffer. The valid bits will be used and the rest of the bits will be discarded.

Write:

- *QSPI_SR[TXFULL] = 0*

32-bit write access required

NOTE

There is no limitation on Flash programming size. But the data size written to TX Buffer should be 64 Byte aligned. If flash programming size is not 64 bytes aligned, please write redundant data to TX Buffers. The redundant data will be ignored by QuadSPI controller.

Address: 30BB_0000h base + 154h offset = 30BB_0154h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TXDATA																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

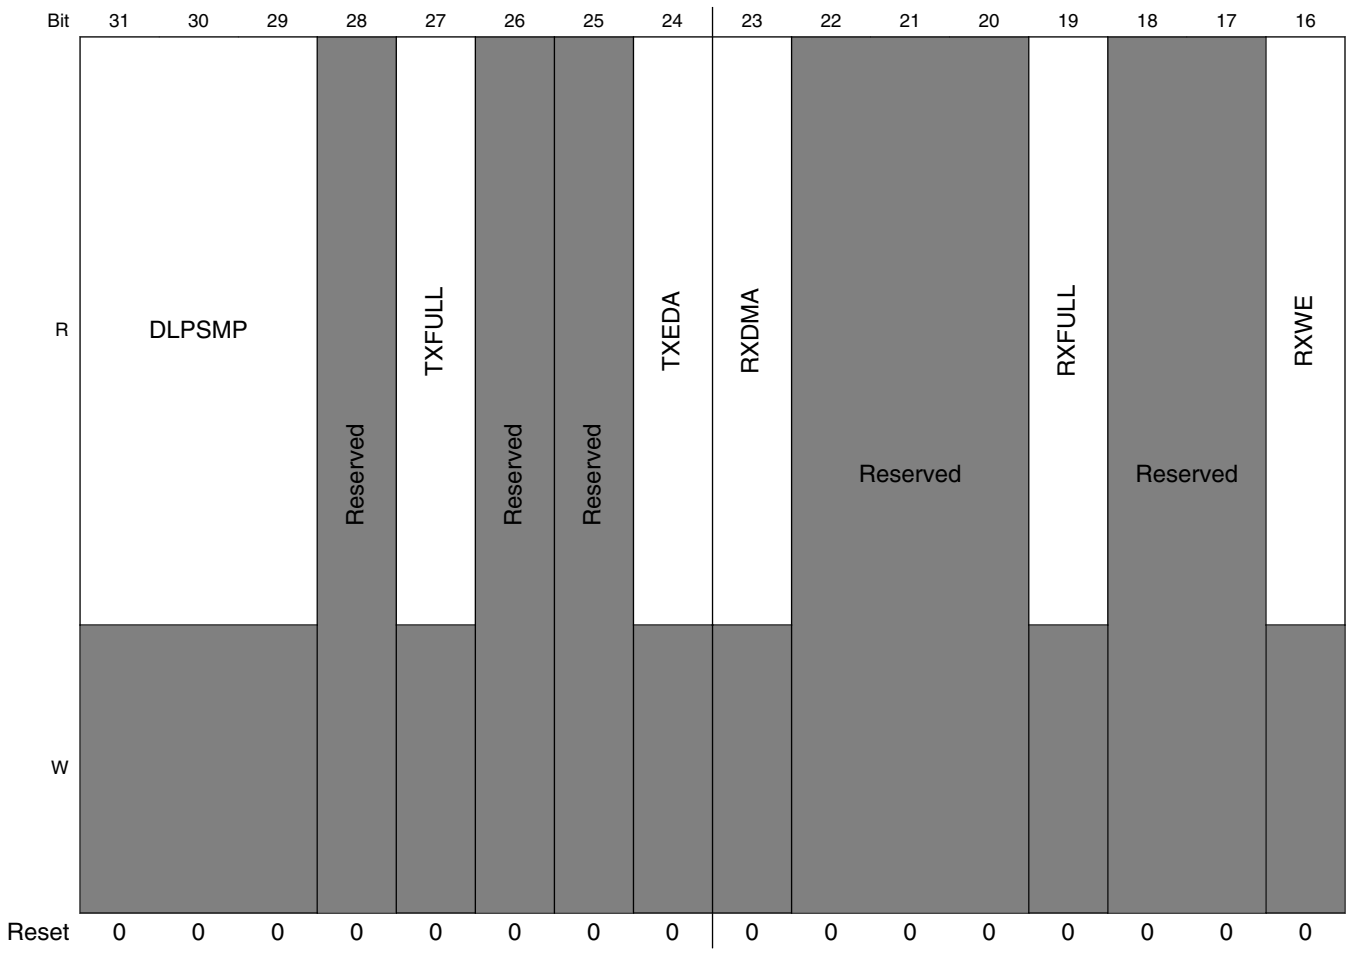
QuadSPI_TBDR field descriptions

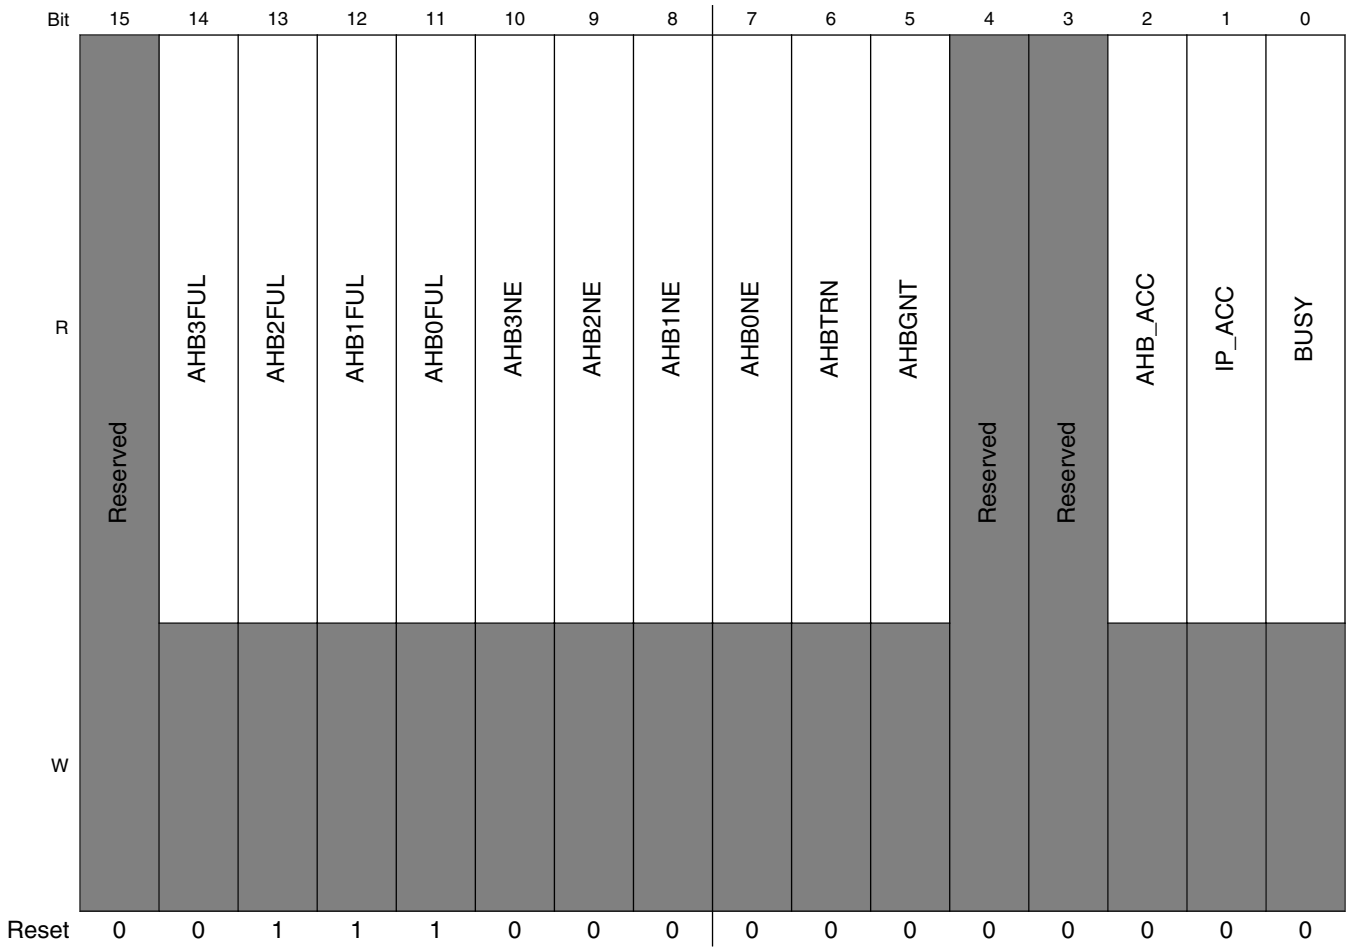
Field	Description
TXDATA	TX Data On write access the data is written into the next available entry of the TX Buffer and the QPSI_TBSR[TRBFL] field is updated accordingly. On a read access, the last data written to the register is returned.

10.2.13.18 Status Register (QuadSPI_SR)

The QSPI_SR register provides all available status information about SFM command execution and arbitration, the RX Buffer and TX Buffer and the AHB Buffer.

Address: 30BB_0000h base + 15Ch offset = 30BB_015Ch





QuadSPI_SR field descriptions

Field	Description
31–29 DLPSMP	**NOTE:** Data learning is not implemented on this chip. Data learning pattern sampling point: The sampling point found by the controller with the data learning pattern. • This is used for DDR only. • If the learning fails, this field will return garbage and DLPFF bit will be set.
28 Reserved	This field is reserved.
27 TXFULL	TX Buffer Full: Asserted when no more data can be stored.
26 Reserved	This field is reserved.
25 Reserved	This field is reserved.
24 TXEDA	Tx Buffer Enough Data Available Asserted when TX Buffer contains enough data for any pop operation to take place. There must be atleast 128bit data available in TX FIFO for any pop operation otherwise QSPI_FR[TBUF] will be set.

Table continues on the next page...

QuadSPI_SR field descriptions (continued)

Field	Description
23 RXDMA	RX Buffer DMA: Asserted when RX Buffer read out via DMA is active i.e DMA is requested or running.
22–20 Reserved	This field is reserved.
19 RXFULL	RX Buffer Full: Asserted when the RX Buffer is full, i.e. that QSPI_RBSR[RDBFL] field is equal to 32.
18–17 Reserved	This field is reserved.
16 RXWE	RX Buffer Watermark Exceeded: Asserted when the number of valid entries in the RX Buffer exceeds the number given in the QSPI_RBCT[WMRK] field.
15 Reserved	This field is reserved.
14 AHB3FUL	AHB 3 Buffer Full: Asserted when AHB 3 buffer is full.
13 AHB2FUL	AHB 2 Buffer Full: Asserted when AHB 2 buffer is full.
12 AHB1FUL	AHB 1 Buffer Full: Asserted when AHB 1 buffer is full.
11 AHB0FUL	AHB 0 Buffer Full: Asserted when AHB 0 buffer is full.
10 AHB3NE	AHB 3 Buffer Not Empty: Asserted when AHB 3 buffer contains data.
9 AHB2NE	AHB 2 Buffer Not Empty: Asserted when AHB 2 buffer contains data.
8 AHB1NE	AHB 1 Buffer Not Empty: Asserted when AHB 1 buffer contains data.
7 AHB0NE	AHB 0 Buffer Not Empty: Asserted when AHB 0 buffer contains data.
6 AHBTRN	AHB Access Transaction pending: Asserted when there is a pending request on the AHB interface. Refer to the AMBA specification for details.
5 AHBGNT	AHB Command priority Granted: Asserted when another module has been granted priority of AHB Commands against IP Commands. For details refer to Command Arbitration.
4 Reserved	This field is reserved.
3 RESERVED	This field is reserved.
2 AHB_ACC	AHB Access: Asserted when the transaction currently executed was initiated by AHB bus.
1 IP_ACC	IP Access: Asserted when transaction currently executed was initiated by IP bus.
0 BUSY	Module Busy: Asserted when module is currently busy handling a transaction to an external flash device.

10.2.13.19 Flag Register (QuadSPI_FR)

The QSPI_FR register provides all available flags about SFM command execution and arbitration which may serve as source for the generation of interrupt service requests. Note that the error flags in this register do not relate directly to the execution of the transaction in the serial flash device itself but only to the behavior and conditions visible in the QuadSPI module.

Write:Enabled Mode

Address: 30BB_0000h base + 160h offset = 30BB_0160h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

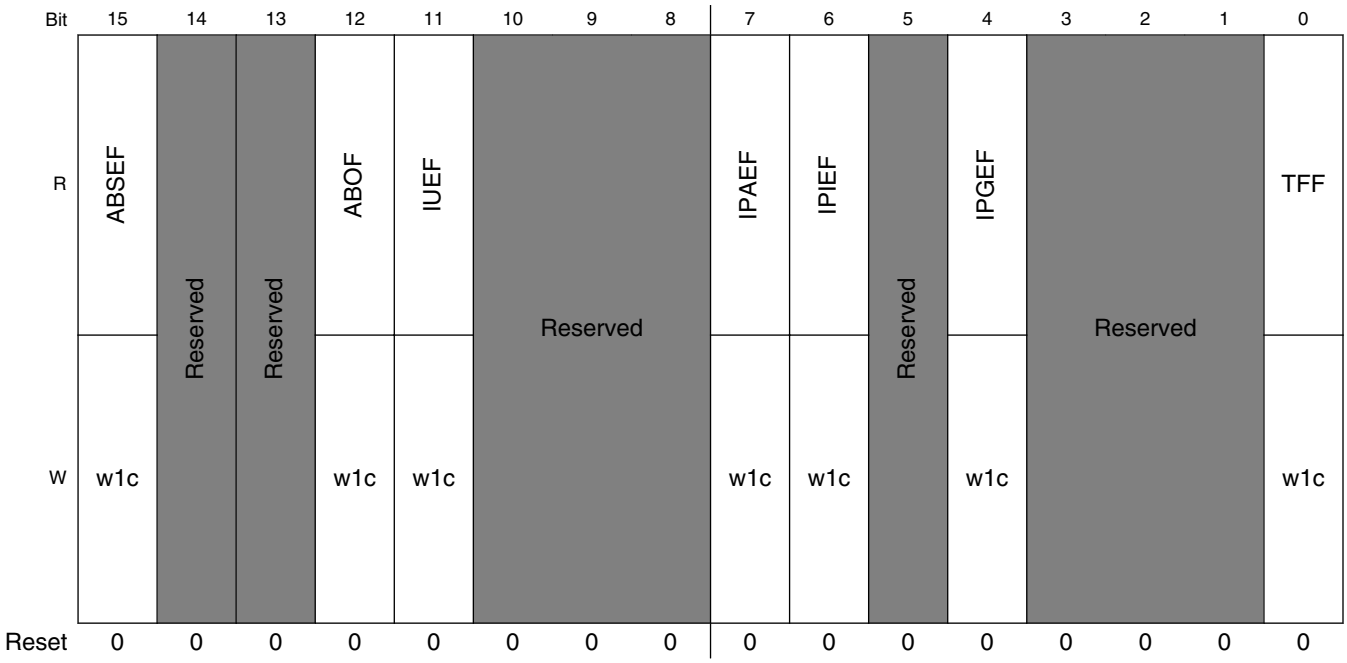
Reset	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0



QuadSPI_FR field descriptions

Field	Description
31 DLPFF	**NOTE:** Data learning is not implemented on this chip. Data Learning Pattern Failure Flag: Set when DATA_LEARN instruction was encountered in a sequence but no sampling point was found for the data learning pattern The controller automatically starts sampling using the value in QSPI_SMPR[DDRSMP].
30 Reserved	This field is reserved.
29–28 Reserved	This field is reserved.
27 TBFF	TX Buffer Fill Flag: Before writing to the TX buffer, this bit should be cleared. Then this bit has to be read back. If the bit is set, the TX Buffer can take more data. If the bit remains cleared, the TX buffer is full. Refer to Tx Buffer Operation for details.
26 TBUF	TX Buffer Underrun Flag: Set when the module tried to pull data although TX Buffer was emptyor the buffer contains less than 128bits of data. The application must ensure that the buffer never goes empty during a transaction expect for the last data fetch. The IP Command leading to the TX Buffer underrun is continued (data sent to the serial flash device is all F in case of valid tx underrun. The application must clear the TX Buffer in response to this event by writing a 1 into the QSPI_MCR[CLR_TXF] bit.
25–24 Reserved	This field is reserved.
23 ILLINE	Illegal Instruction Error Flag: Set when an illegal instruction is encountered by the controller in any of the sequences. Refer to Table 10-12 for a list of legal instructions.
22–18 Reserved	This field is reserved.
17 RBOF	RX Buffer Overflow Flag: Set when not all the data read from the serial flash device could be pushed into the RX Buffer. The IP Command leading to this condition is continued until the number of bytes according to the QSPI_IPCR[IDATSZ] field has been read from the serial flash device.

Table continues on the next page...

QuadSPI_FR field descriptions (continued)

Field	Description
	The content of the RX Buffer is not changed.
16 RBDF	RX Buffer Drain Flag: Will be set if the QuadSPI_SR[RXWE] status bit is asserted. Writing 1 into this bit triggers one of the following actions: • If the RX Buffer has up to QuadSPI_RBCT[WMRK] valid entries then the flag is cleared. • If the RX Buffer has more than QuadSPI_RBCT[WMRK] valid entries and the QuadSPI_RSER[RBDDE] bit is not set (flag driven mode) a RX Buffer POP event is triggered. The flag remains set if the RX Buffer contains more than QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished. The flag is cleared if the RX Buffer contains less than or equal to QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished. Refer to "Receive Buffer Drain Interrupt or DMA Request" section in Normal Mode Interrupt and DMA Requests, for details.
15 ABSEF	AHB Sequence Error Flag: Set when the execution of an AHB Command is started with an WRITE or WRITE_DDR Command in the sequence pointed to by the QSPI_BUFxCR register Communication with the serial flash device is terminated before the execution of WRITE/WRITE_DDR command by the QuadSPI module. The AHB bus request which triggered this command is answered with an ERROR response.
14 Reserved	Reserved This field is reserved.
13 Reserved	Reserved This field is reserved.
12 ABOF	AHB Buffer Overflow Flag: Set when the size of the AHB access exceeds the size of the AHB buffer. This condition can occur only if the QSPI_BUFxCR[ADATSZ] field is programmed incorrectly. The AHB Command leading to this condition is continued until the number of entries according to the QSPI_BUFxCR[ADATSZ] field has been read from the serial flash device. The content of the AHB Buffer is not changed.
11 IUEF	IP Command Usage Error Flag: Set when in parallel flash mode the execution of an IP Command is started and the sequence pointed to by the sequence ID contains a WRITE or a WRITE_DDR command. Refer to Table 10-12 table for the related commands. Communication with the serial flash device is terminated before the execution of WRITE/WRITE_DDR command by the QuadSPI module.
10–8 Reserved	This field is reserved.
7 IPAEF	IP Command Trigger during AHB Access Error Flag. Set when the following condition occurs: • A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHB_ACC] bit is set. Any command leading to the assertion of the IPAEF flag is ignored.
6 IPIEF	IP Command Trigger could not be executed Error Flag. Set when the QSPI_SR[IP_ACC] bit is set (i.e. an IP triggered command is currently executing) and any of the following conditions occurs: • Write access to the QSPI_IPCR register. Any command leading to the assertion of the IPIEF flag is ignored • Write access to the QSPI_SFAR register. • Write access to the QSPI_RBCT register.
5 Reserved	This field is reserved.

Table continues on the next page...

QuadSPI_FR field descriptions (continued)

Field	Description
4 IPGEF	IP Command Trigger during AHB Grant Error Flag: Set when the following condition occurs: • A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHBGNT] bit is set. Any command leading to the assertion of the IPGEF flag is ignored.
3–1 Reserved	This field is reserved.
0 TFF	IP Command Transaction Finished Flag: Set when the QuadSPI module has finished a running IP Command. If an error occurred the related error flags are valid, at the latest, in the same clock cycle when the TFF flag is asserted.

1. QSPI_BUFxCR implies anyone of QSPI_BUF0CR/QSPI_BUF1CR/QSPI_BUF2CR/QSPI_BUF3CR

10.2.13.20 Interrupt and DMA Request Select and Enable Register (QuadSPI_RSER)

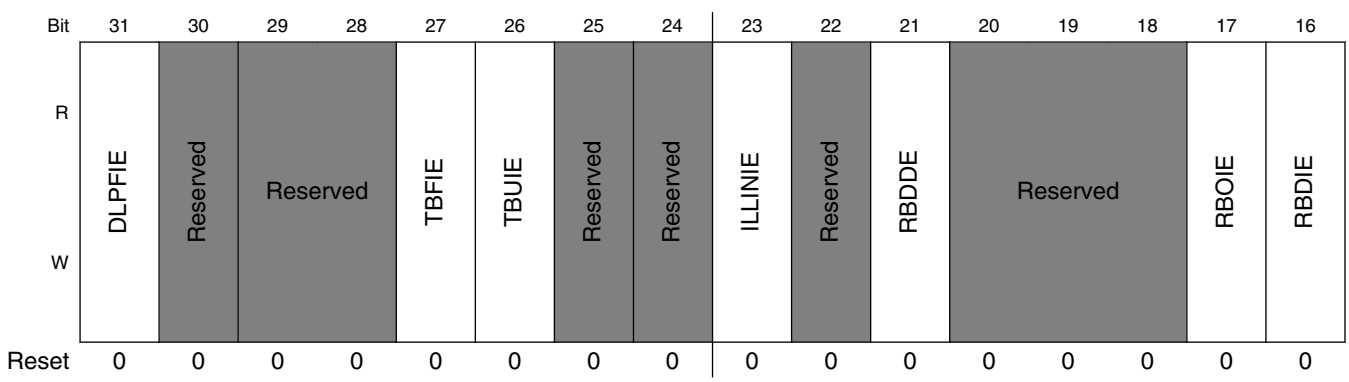
The QuadSPI_RSER register provides enables and selectors for the interrupts in the QuadSPI module.

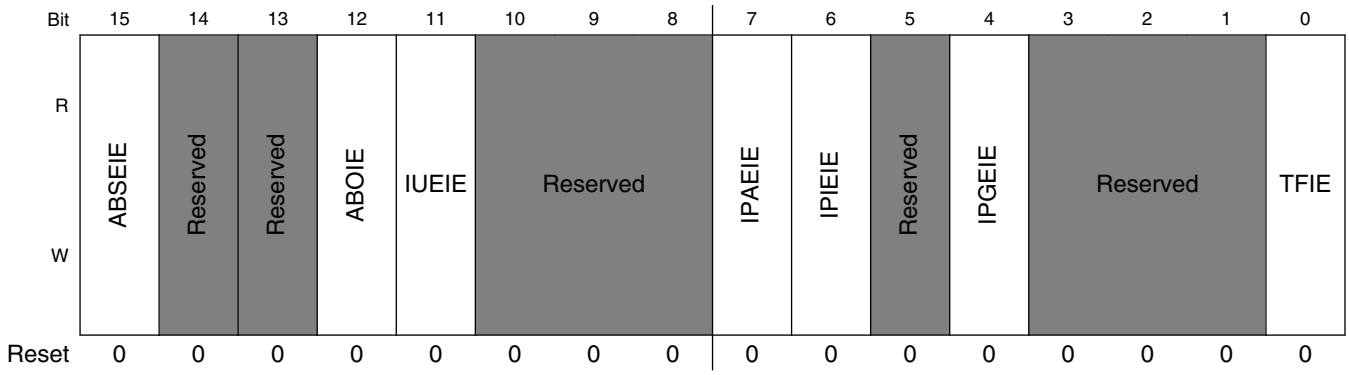
NOTE

Each flag of the QuadSPI_FR register enabled as source for an interrupt prevents the QuadSPI module from entering Stop Mode or Module Disable Mode when this flag is set.

Write:Anytime

Address: 30BB_0000h base + 164h offset = 30BB_0164h





QuadSPI_RSER field descriptions

Field	Description
31 DLPFIE	**NOTE:** Data learning is not implemented on this chip. Data Learning Pattern Failure Interrupt enable. Triggered by DLPFF flag in QSPI_FR register 0 No DLPFF interrupt will be generated 1 DLPFF interrupt will be generated
30 Reserved	This field is reserved.

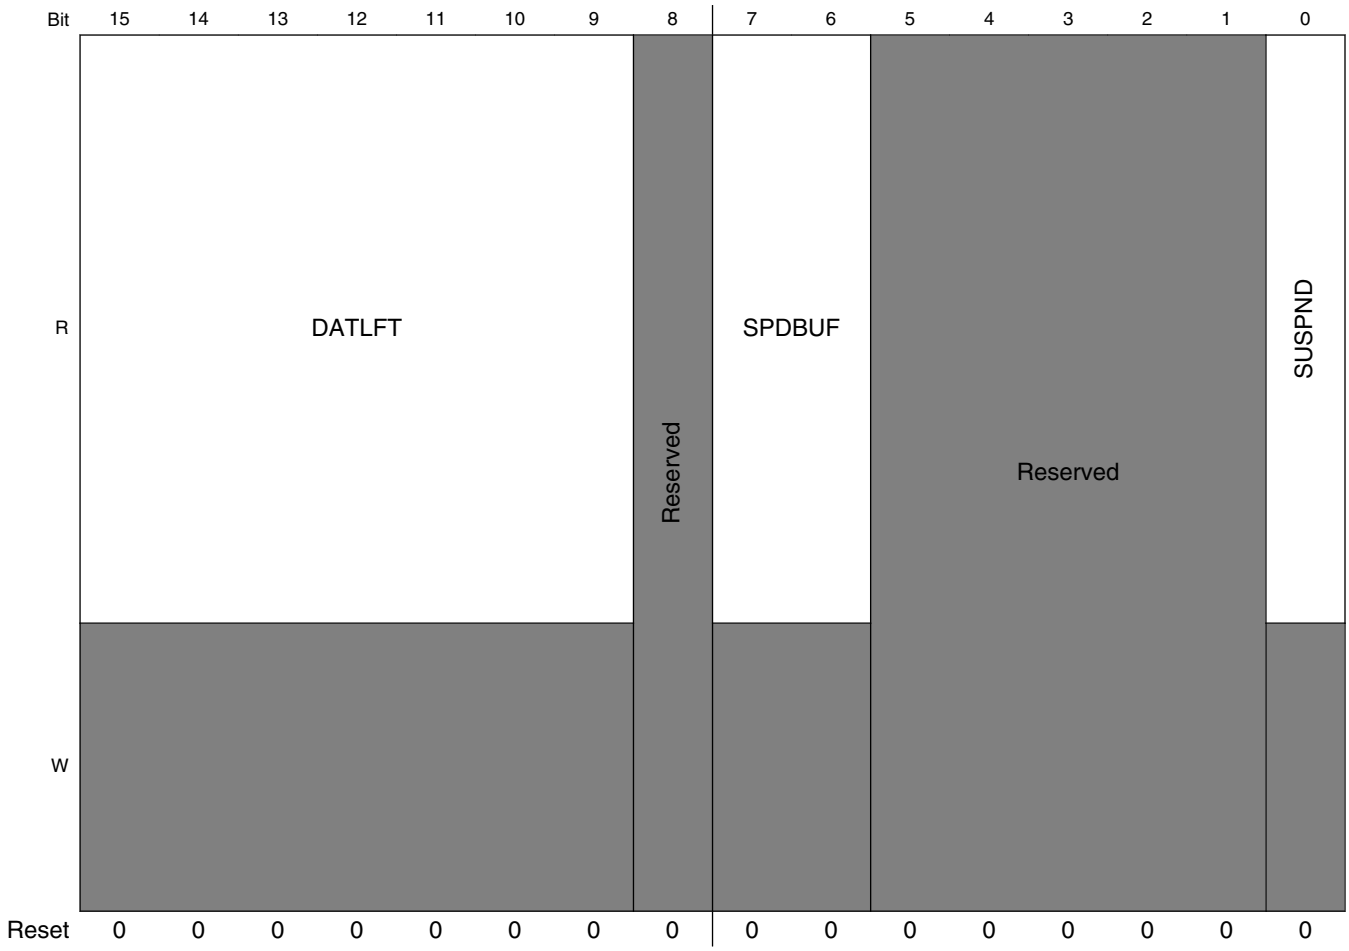
10.2.13.21 Sequence Suspend Status Register (QuadSPI_SPNDST)

The sequence suspend status register provides information specific to any suspended sequence. An AHB sequence may be suspended when a high priority AHB master makes an access before the AHB sequence completes the data transfer requested.

Address: 30BB_0000h base + 168h offset = 30BB_0168h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



QuadSPI_SPNDST field descriptions

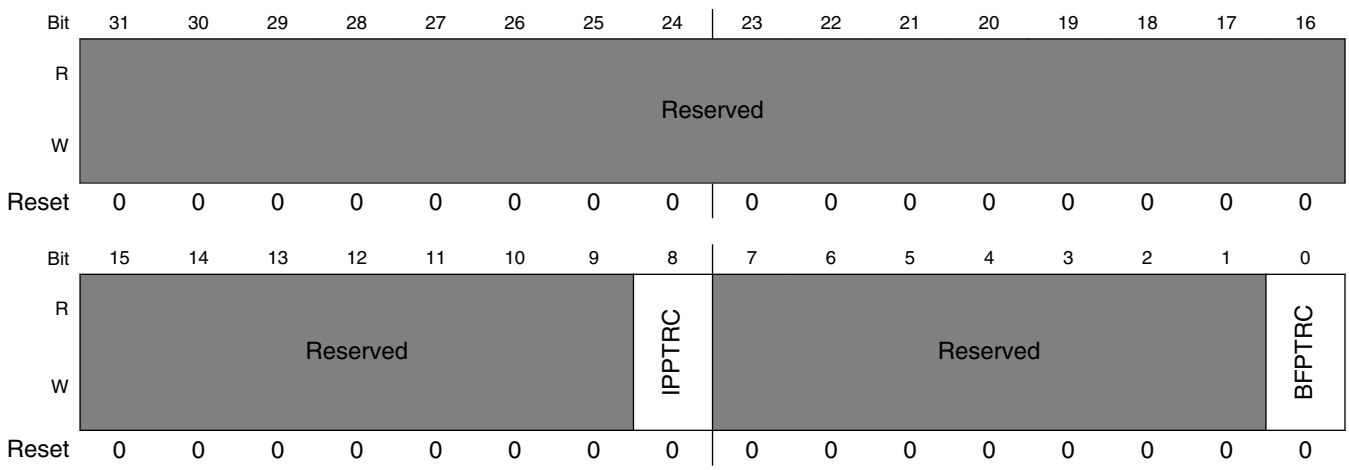
Field	Description
31–16 Reserved	This field is reserved.
15–9 DATLFT	Data left: Provides information about the amount of data left to be read in the suspended sequence. Valid only when SUSPND is set to 1'b1. Value in terms of 64 bits or 8 bytes
8 Reserved	This field is reserved.
7–6 SPDBUF	Suspended Buffer: Provides the suspended buffer number. Valid only when SUSPND is set to 1'b1
5–1 Reserved	This field is reserved.
0 SUSPND	When set, it signifies that a sequence is in suspended state

10.2.13.22 Sequence Pointer Clear Register (QuadSPI_SPTRCLR)

The sequence pointer clear register provides bits to reset the IP and Buffer sequence pointers. The sequence pointer contains the index of which instruction within the LUT entry is to be executed next. For example, if the LUT entry ends on a JMP_ON_CS value of 2, the index will be stored as 2.

The software should reset the sequence pointers whenever the sequence ID is changed by updating the SEQID field in QSPI_IPCR or QSPI_BFGENCR.

Address: 30BB_0000h base + 16Ch offset = 30BB_016Ch



QuadSPI_SPTRCLR field descriptions

Field	Description
31–9 Reserved	This field is reserved.
8 IPPTRC	IP Pointer Clear: 1: Clears the sequence pointer for IP accesses as defined in QuadSPI_IPCR
7–1 Reserved	This field is reserved. Reserved.
0 BFPTRC	Buffer Pointer Clear: 1: Clears the sequence pointer for AHB accesses as defined in QuadSPI_BFGENCR.

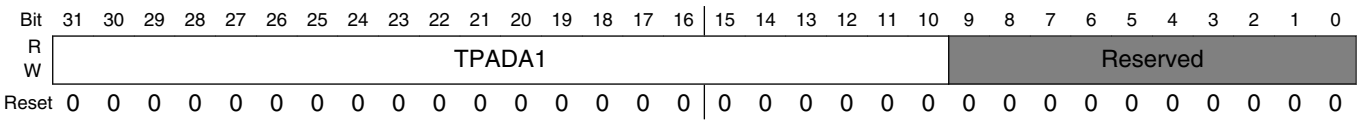
10.2.13.23 Serial Flash A1 Top Address (QuadSPI_SFA1AD)

The QSPI_SFA1AD register provides the address mapping for the serial flash A1.The difference between QSPI_SFA1AD[TPADA1] and QSPI_AMBA_BASE defines the size of the memory map for serial flash A1.

Write:

- *QSPI_SR[IP_ACC] = 0*
- *QSPI_SR[AHB_ACC] = 0*

Address: 30BB_0000h base + 180h offset = 30BB_0180h



QuadSPI_SFA1AD field descriptions

Field	Description
31–10 TPADA1	Top address for Serial Flash A1. In effect, TPADxx is the first location of the next memory.
Reserved	This field is reserved.

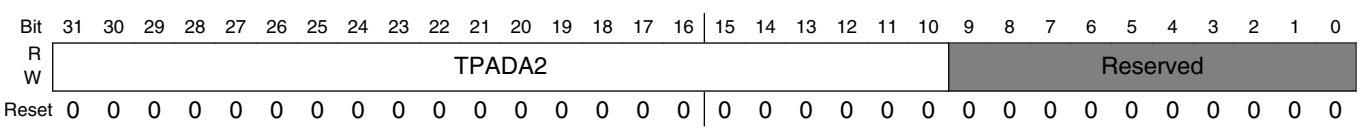
10.2.13.24 Serial Flash A2 Top Address (QuadSPI_SFA2AD)

The QSPI_SFA2AD register provides the address mapping for the serial flash A2.The difference between QSPI_SFA2AD[TPADA2] and QSPI_SFA1AD[TPADA1] defines the size of the memory map for serial flash A2.

Write:

- *QSPI_SR[IP_ACC] = 0*
- *QSPI_SR[AHB_ACC] = 0*

Address: 30BB_0000h base + 184h offset = 30BB_0184h



QuadSPI_SFA2AD field descriptions

Field	Description
31–10 TPADA2	Top address for Serial Flash A2. In effect, TPxxAD is the first location of the next memory.
Reserved	This field is reserved.

10.2.13.25 Serial Flash B1Top Address (QuadSPI_SFB1AD)

The QSPI_SFB1AD register provides the address mapping for the serial flash B1.The difference between QSPI_SFB1AD[TPADB1] and QSPI_SFA2AD[TPADA2] defines the size of the memory map for serial flash B1.

Write:

- *QSPI_SR[IP_ACC] = 0*
- *QSPI_SR[AHB_ACC] = 0*

Address: 30BB_0000h base + 188h offset = 30BB_0188h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

10.2.13.26 Serial Flash B2Top Address (QuadSPI_SFB2AD)

The QSPI_SFB2AD register provides the address mapping for the serial flash B2.The difference between QSPI_SFB2AD[TPADB2] and QSPI_SFB1AD[TPADB1] defines the size of the memory map for serial flash B2.

Write:

- *QSPI_SR[IP_ACC] = 0*
- *QSPI_SR[AHB_ACC] = 0*

Address: 30BB_0000h base + 18Ch offset = 30BB_018Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
31–10 TPADB2	Top address for Serial Flash B2. In effect, TPxxAD is the first location of the next memory.
Reserved	This field is reserved.

10.2.13.27 RX Buffer Data Register (QuadSPI_RBDR*n*)

The QuadSPI_RBDR registers provide access to the individual entries in the RX Buffer. Refer to Table 10-14 for the byte ordering scheme.

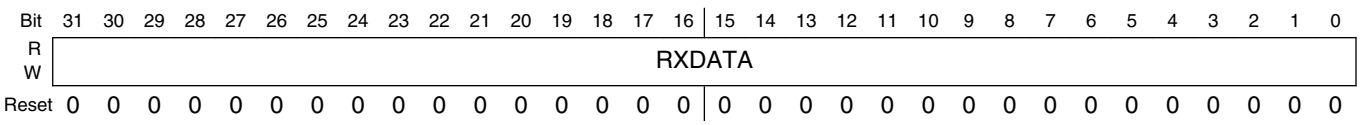
QuadSPI_RBDR0 corresponds to the actual position of the read pointer within the RX Buffer. The number of valid entries available depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

Example 1, RX Buffer filled completely with 32 words: In this case the address range for valid read access extends from QuadSPI_RBDR0 to QuadSPI_RBDR31.

Example 2, RX Buffer filled with 5 valid words: RX Buffer fill level QuadSPI_RBSR[RDBFL] is 5. In this case an access to QuadSPI_RBDR4 provides the last valid entry.

Any access beyond the range of valid RX Buffer entries provides undefined results.

Address: 30BB_0000h base + 200h offset + (4d × i), where i=0d to 31d



QuadSPI_RBDR*n* field descriptions

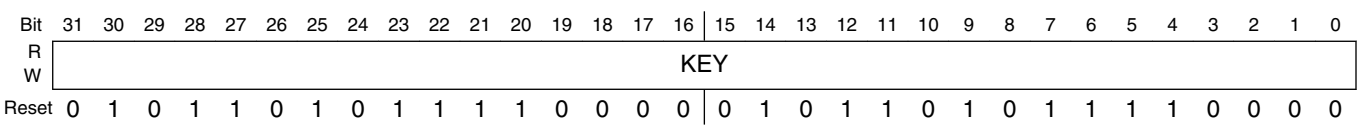
Field	Description
RXDATA	RX Data. The RXDATA field contains the data associated with the related RX Buffer entry. Data format and byte ordering is given in Byte Ordering of Serial Flash Read Data.

10.2.13.28 LUT Key Register (QuadSPI_LUTKEY)

The LUT Key register contains the key to lock and unlock the Look-up-table. Refer to Look-up Table for details.

Write:Anytime

Address: 30BB_0000h base + 300h offset = 30BB_0300h



QuadSPI_LUTKEY field descriptions

Field	Description
KEY	The key to lock or unlock the LUT. The KEY is 0x5AF05AF0. The read value is always 0x5AF05AF0

10.2.13.29 LUT Lock Configuration Register (QuadSPI_LCKCR)

The LUT lock configuration register is used along with QSPI_LUTKEY register to lock or unlock the LUT. This register has to be written immediately after QSPI_LUTKEY register for the lock or unlock operation to be successful. Refer to Look-up Table for details. Setting both the LOCK and UNLOCK bits as "00" or "11" is not allowed.

Write:Just after writing the LUT Key Register

(QSPI_LUTKEY)

Address: 30BB_0000h base + 304h offset = 30BB_0304h

1 UNLOCK	Unlocks the LUT when the following two conditions are met: 1. This register is written just after the LUT Key Register (QuadSPI_LUTKEY) 2. The LUT key register was written with 0x5AF05AF0 key
0 LOCK	Locks the LUT when the following condition is met: 1. This register is written just after the LUT Key Register (QuadSPI_LUTKEY) 2. The LUT key register was written with 0x5AF05AF0 key

10.2.13.30 Look-up Table register (QuadSPI_LUT0)

The LUT registers are a look-up-table for sequences of instructions. The programmable sequence engine executes the instructions in these sequences to generate a valid serial flash transaction. There are a total of 64 LUT registers. These 64 registers are divided into groups of 4 registers that make a valid sequence. Therefore, QSPI_LUT[0], QSPI_LUT[4], QSPI_LUT[8] ..... QSPI_LUT[60] are the starting registers of a valid sequence. Each of these sets of 4 registers can have a maximum of 8 instructions. A maximum of 16 sequences can be defined at one time. Look-up Table describes the LUT registers in detail.

Write:Once the LUT is unlocked

Address: 30BB_0000h base + 310h offset = 30BB_0310h

10.3 Ultra Secured Digital Host Controller (uSDHC)

10.3.1 Introduction

The uSDHC provides the interface between the host system and the SD/SDIO/MMC cards, as depicted in Figure 10-33. It acts as a bridge, passing host bus transactions to the SD/SDIO/MMC cards by sending commands and performing data accesses to/from the cards. It handles the SD/SDIO/MMC protocols at the transmission level. The following are brief descriptions of the cards supported by uSDHC:

The Multi Media Card (MMC) is a universal low-cost data storage and communication media designed to cover a wide array of applications including mobile video and gaming. Previous MMC cards were based on a 7-pin serial bus with a single data pin, while the new high speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low-voltage range.

The Secure Digital Card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environmental requirements inherent in newly emerging audio and video consumer electronic devices. The physical form factor, pin assignment, and data transfer protocol are forward compatible with the old MMC (with some additions).

Under the SD protocol, it can be categorized into memory card, I/O card, and combo card, which have both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low-power consumption for mobile electronic devices. For the sake of simplicity, the next figure does not show cards with reduced size or mini cards.

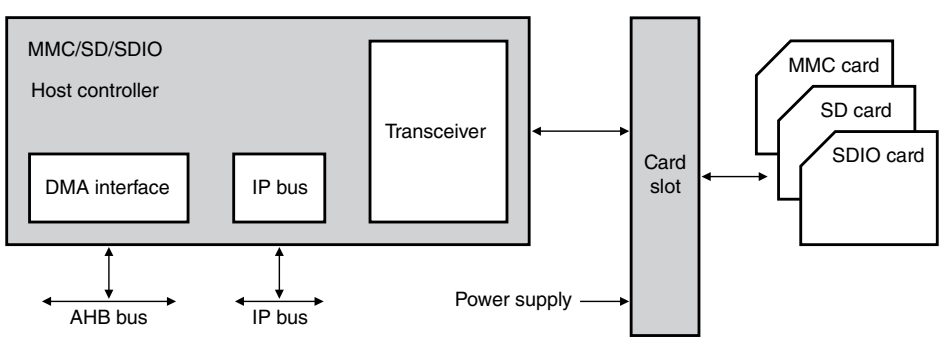

Figure 10-33. System connection of uSDHC

The following figure illustrates the block diagram of uSDHC.

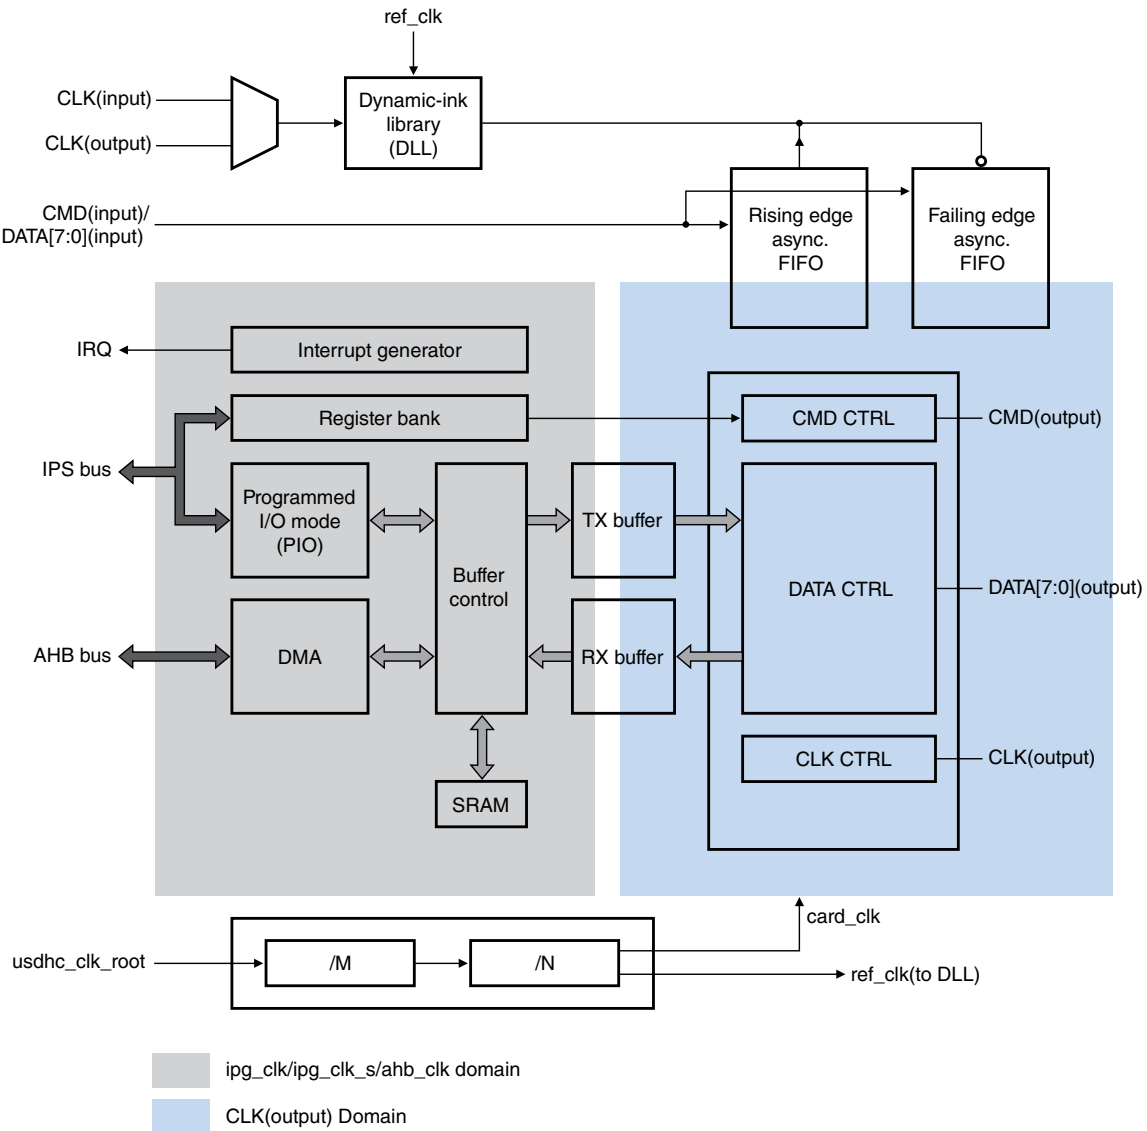

Figure 10-34. uSDHC block diagram

10.3.1.1 Features

The features of the uSDHC module include the following:

- Conforms to the SD Host Controller Standard Specification version 2.0/3.0
- Compatible with the MMC System Specification version 4.2/4.3/4.4/4.41/5.0/5.1
- Compatible with the SD Memory Card Specification version 3.0 and supports the Extended Capacity SD Memory Card
- Compatible with the SDIO Card Specification version 2.0/3.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards
- Card bus clock frequency up to 208 MHz

- Supports 1-bit/4-bit SD and SDIO modes, and 1-bit/4-bit/8-bit MMC modes
  - Up to 832 Mbps of data transfer for SDIO cards using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDIO card using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 832 Mbps of data transfer for SDXC cards using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDXC card using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 416 Mbps of data transfer for MMC cards using eight parallel data lines in the Single Data Rate (SDR) mode
  - Up to 3200 Mbps of data transfer for MMC cards using eight parallel data lines in the Dual Data Rate (DDR) mode
- Supports a single block/multi-block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes; also supports interrupt period
- Embodies two fully configurable 128x32-bit FIFO for read/write data
- Supports internaland external DMA capabilities
- Support voltage selection by configuring vendor-specific register bit
- Supports Advanced DMA to perform linked memory access
- support Command queue mechanism

10.3.1.2 Modes and operations

10.3.1.2.1 Data transfer modes

The uSDHC module can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit
- MMC 4-bit
- MMC 8-bit
- Identification mode (up to 400 kHz)

- MMC full-speed mode (up to 26 MHz)
- MMC high-speed mode (up to 52 MHz)
- MMC HS400 mode (200 MHz both edges)
- MMC DDR mode (52 MHz both edges)
- SD/SDIO full-speed mode (up to 25 MHz)
- SD/SDIO high-speed mode (up to 50 MHz)
- SD/SDIO UHS-I mode(up to 208 MHz in SDR mode, up to 50 MHz in the DDR mode)

10.3.2 External signals

The following table describes the external signals of uSDHC:

Table 10-38. uSDHC external signals

Signal	Description	Direction
CLK	Clock for MMC/SD/SDIO card	O
CMD	CMD line connect to card	I/O
DATA7	DATA7 line in the 8-bit mode — Not used in other modes	I/O
DATA6	DATA6 line in the 8-bit mode — Not used in other modes	I/O
DATA5	DATA5 line in the 8-bit mode — Not used in other modes	I/O
DATA4	DATA4 line in the 8-bit mode — Not used in other modes	I/O
DATA3	DATA3 line in the 4/8-bit mode or configured as card detection pin. The bit may be configured as card detection pin in the 1-bit mode.	I/O
DATA2	DATA2 line or Read Wait in the 4-bit mode Read Wait in 1-bit mode	I/O
DATA1	DATA1 line in the 4/8-bit mode Also, used to detect interrupt in 1/4-bit mode	I/O
DATA0	DATA0 line in all the modes Also, used to detect busy state	I/O
CD_B	Card detection pin If not used (for the embedded memory), tie low to indicate that there is a card attached.	I
WP	Card write protect detect If not used (for the embedded memory), tie low to indicate that it is not write protected.	I

Table continues on the next page...

Table 10-38. uSDHC external signals (continued)

Signal	Description	Direction
LCTL	LED control used to drive an external LED active high, fully controlled by the driver Optional output	O
RESET_B	Card hardware reset signal, active low	O
VSELECT	IO power voltage selection signal	O
STROBE	Input clock for eMMC HS400 mode	I

10.3.2.1 Signals overview

uSDHC has 15 associated I/O signals.

- The CLK is an internally generated clock used to drive the MMC, SD, and SDIO cards.
- The CMD I/O is used to send commands and receive responses to and from the card. Eight data lines (DATA7~DATA0) are used to perform data transfers between the uSDHC module and the card.
- The CD_B and WP are card detection and write protection signals directly routed from the socket. These two signals are active low (0). A low on CD_B means that a card is inserted, and a high on WP means that the write protect switch is active.
- LCTL is an output signal used to drive an external LED to indicate that the SD interface is busy.
- RESET_B is an output signal used to reset the MMC card.
- VSELECT is an output signal used to change the voltage of the external power supplier.
- STROBE is input clock signal for eMMC HS400 mode.

CD_B, WP, LCTL, RESET_B, and VSELECT are all optional for system implementation. If uSDHC needs to support a 4-bit data transfer, DATA7~DATA4 can also be optional and tied to high. If the uSDHC does not support the HS400 mode, STROBE can also be optional and tied to low.

10.3.3 Functional description

The following sections provide a brief functional description of the major system blocks, including the data buffer, DMA AHB interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock and reset manager, and clock generator.

10.3.3.1 Data buffer

The uSDHC module uses one configurable data buffer to transfer data between the system bus (IP bus or advanced high-performance bus (AHB) bus) and the SD card in an optimized manner, maximizing throughput between the two clock domains (IP peripheral clock and the master clock).

The buffer is used as a temporary storage for transferring data between the host system and the card. The watermark levels for read and write are both configurable and can range between 1 to 128 words. The burst lengths for read and write are also configurable and can range between 1 to 31 words. The next figure provides the uSDHC buffer scheme.

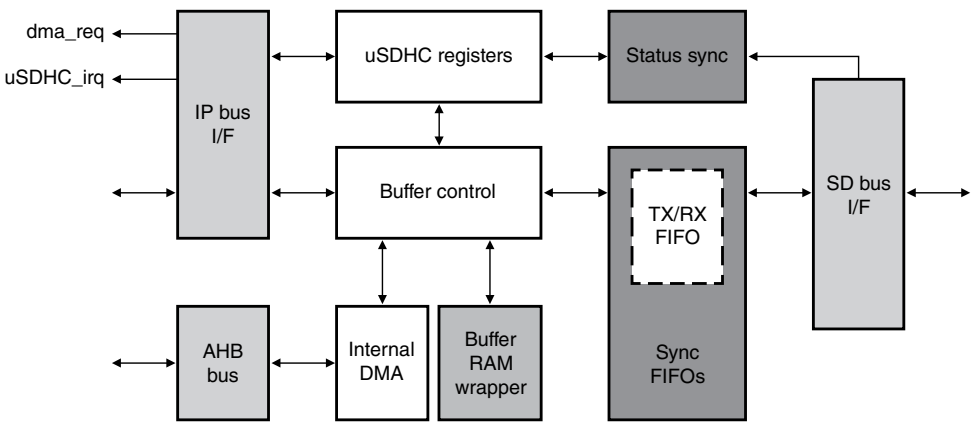

Figure 10-35. uSDHC buffer scheme

Here are 3 the two transfer modes to access the data buffer:

- CPU polling mode:
  - For a host-read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, by polling the BRR bit, the host driver can read the Buffer Data Port register to fetch the amount of words set in the RD_WML register from the buffer. The write operation is similar. For more information on the process of writing operation, see Write operation sequence.
- External DMA mode:
  - For a read operation, when there are more words received in the buffer than the amount set in the RD_WML register, a DMA request is sent out to inform the external DMA to fetch the data. The request will be immediately de-asserted when there is an access on the Buffer Data Port register. If the number of words in the buffer after the current burst meets or exceeds RD_WML value, the DMA request is asserted again. For instance, if there are twice as many words in the

buffer as there are in the RD_WML value, there are two successive DMA requests with only one cycle of de-assertion between. The write operation is similar. Note the accesses CPU polling mode and external DMA mode both use the IP bus, and if the external DMA is enabled, in both modes an external DMA request is sent when the buffer is ready.

- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AHB bus. For internal DMA access mode, the external DMA request will never be sent out.

For a read operation, when there are more words in the buffer than the amount set in the RD_WML register, the internal DMA starts fetching data over the AHB bus. Except for INCR4 and INCR8, the burst type is always the INCR mode and the burst length depends on the shortest of the following factors:

- Burst length configured in the burst length field of the Watermark Level register
- Watermark level boundary
- Block size boundary
- Data boundary configured in the current descriptor (if the ADMA is active)
- 1 KB address boundary defined in the AHB protocol

The Write operation functions in a similar manner—sequential and contiguous access is necessary to ensure that the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actual byte order is swapped inside the buffer, according to the endian mode configured by software (see the following figures). For a host write operation, the byte order is swapped after the data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, the byte order is swapped before the data is stored in the buffer.

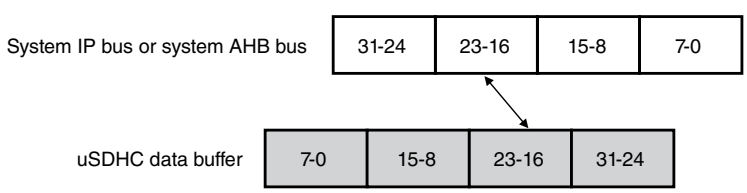

Figure 10-36. Data swap between system bus and uSDHC data buffer in the byte little endian mode

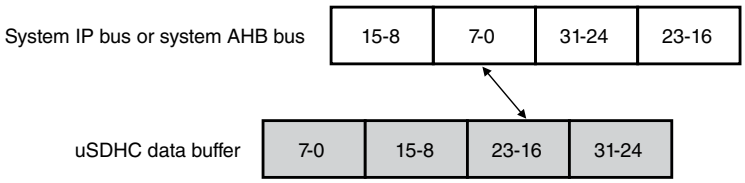

Figure 10-37. Data swap between system bus and uSDHC data buffer in half word big endian mode

10.3.3.1.1 Write operation sequence

There are 3 ways to write data into the buffer when the user transfers data to the card:

- External DMA through the uSDHC DMA request signal
- Processor core polling through the BWR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When the internal DMA is not used, the DMAEN bit in the Transfer Type register is not set when the command is sent, uSDHC asserts a DMA request when the amount of buffer space exceeds the value set in the WR_WML register and is ready for receiving new data. At the same time, uSDHC sets the BWR bit. The buffer write ready interrupt is generated if it is enabled by software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC aborts the data transfer and abandons the current block. The host driver should read the contents of the DMA System Address register to obtain the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the write operation from that address. It is recommended that a software reset for Data be applied before the transfer is restarted.

The uSDHC module does not start data transmission until the number of words set in the WR_WML register can be held in the buffer. If the buffer is empty and the host system does not write data in time, uSDHC stops the CLK to avoid the data buffer underrun situation.

10.3.3.1.2 Read operation sequence

There are 3 ways to read data from the buffer when the user transfers data to the card:

- External DMA through uSDHC DMA request signal

- Processor core polling through the BRR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When internal DMA is not used (DMAEN bit in Transfer Type register is not set when the command is sent), uSDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register, which is available and ready for system fetching data. At the same time, uSDHC sets the BRR bit. The buffer read ready interrupt is generated if it is enabled by the software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC aborts the data transfer and abandons the current block. The host driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the read operation from that address. It is recommended that a software reset for data be applied before the transfer is restarted.

For any write transfer mode, uSDHC does not start data transmission until the number of words set in the RD_WML register are in buffer. If the buffer is full and the host system does not read data in time, uSDHC stops the CLK to avoid the data buffer overrun situation.

10.3.3.1.3 Data buffer and block size

The user needs to know the buffer size for the buffer operation during a data transfer to utilize it in the most optimized way. In the uSDHC module, the only data buffer can hold up to 128 words (32-bit) and the watermark levels for write and read can be configured accordingly.

For both read and write, the watermark level can range between 1 to 128 words. For both read and write, the burst length can range between from 1 to 31 words. The host driver may configure the value according to the system situation and requirement.

During a multi-block data transfer, the block length can be set to any value between 1 and 4096 bytes, satisfying the requirements of the external card. The only restriction is from the external card, which can be limited in size or support of a partial block access (which is not the integer times of 512 bytes).

As uSDHC treats each block individually, for block sizes which are not multiples of four (not word-aligned), stuffed bytes are required at the end of each block. For example, if the block size is 7 bytes and there are 12 blocks to write, the system side must write twice

for each block. For each block, the ending byte is abandoned by uSDHC because it only sends 7 bytes to the card and picks data from the following system write, resulting in 24 beats of write access in total.

10.3.3.1.4 Dividing large data transfer

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in block size units. If the total data length cannot be divided evenly into a multiple of the block size, then there are two ways to transfer the data. These two ways depend on the function and the card design. Option 1 is for the host driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

See the figure below for an example showing the division of large data transfers, assuming a kind of WLAN SDIO card that only supports a block size of up to 64 bytes. Although uSDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size of less than 64 bytes, so the data must be divided (see the example below).

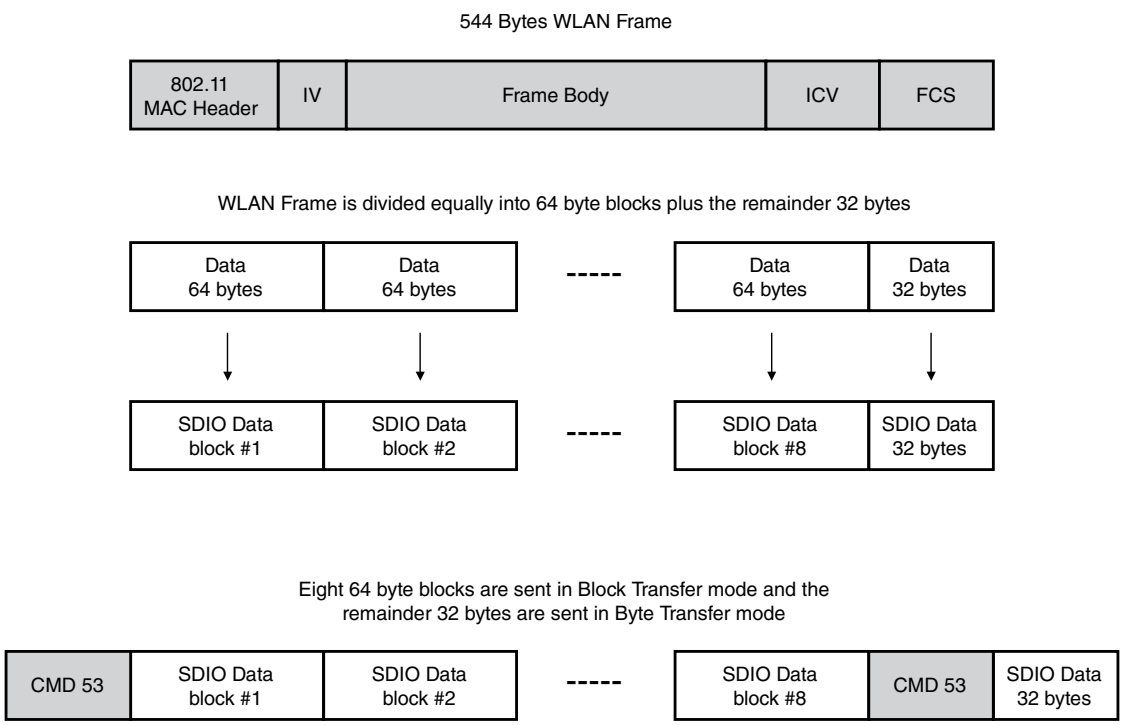

Figure 10-38. Example for dividing large data transfers

10.3.3.1.5 External DMA Request

When the internal DMA is not in use and external DMA is enabled, the Data Buffer will generate a DMA request to the system. During a write operation, when the number of WR_WML words can be held in the buffer free space, the signal uSDHC_dreq_b is asserted to 0, informing the Host System of a DMA write.

The BWR bit in the Interrupt Status register is also set, as long as the BWRSEN bit in the Interrupt Status Enable register is set. The DMA request is de-asserted after several accesses to the Data Port register are made while the buffer's free space can't meet the watermark condition (free space> write watermark level).

On read operation, when the number of RD_WML words are already in the buffer, the signal uSDHC_dreq_b is asserted to 0, informing the Host System for a DMA read. The BRR bit in the Interrupt Status register is also set, as long as the BRRSEN bit in the Interrupt Status Enable register is set. The DMA request is de-asserted after several accesses to the Data Port register are made while the buffer's data can't meet the watermark condition (the number of data in buffer > read watermark level).

If the DMA burst length can't change during a data transfer for an external DMA transfer, the watermark level (read or write) must be a divisor of the block size. If it is not, transferring the block may cause buffer under-run (read operation) or over-run (write operation). For example, if the block size is 512 bytes, the watermark level of read (or write) must be a power of two between 1 and 128. For processor core polling access there is no such issue, as the last access in the block transfer can be controlled by software. The watermark level can be any value, even larger than the block size (but no greater than 128 words) because the actual number of bytes transferred by the software can be controlled and does not exceed the block size in each transfer.

The uSDHC also supports non-word aligned block size, as long as the card supports that block size. In this case, the watermark level should be set as the number of words. For example, if the block size is 31 bytes, the watermark level can be set to any number of words. For this case, the BLKSIZE bits of the Block Attribute register will be set as 1fh. For the CPU polling access, the burst length can be 1 to 128 words, without restriction. This is because the software will transfer 8 words, and the uSDHC will also set the BWR or BRR bits when the remaining data does not violate data buffer. See DMA burst length for more details about the dynamic watermark level of the data buffer.

For the above example, even though 8 words are transferred via the Data Port register, the uSDHC will transfer only 31 bytes over the SD Bus, as required by the BLKSIZE bits. In this data transfer, with non-word aligned block size, the endian mode should be set cautiously or invalid data will be transferred to and from the card.

10.3.3.2 DMA AHB interface

The internal DMA implements a DMA engine and the AHB master. When the internal DMA is enabled, the uSDHC_dreq_b is not asserted during the transfer, but the BWR and BRR bits are set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register.

See the figure below for an illustration of the DMA AHB interface block.

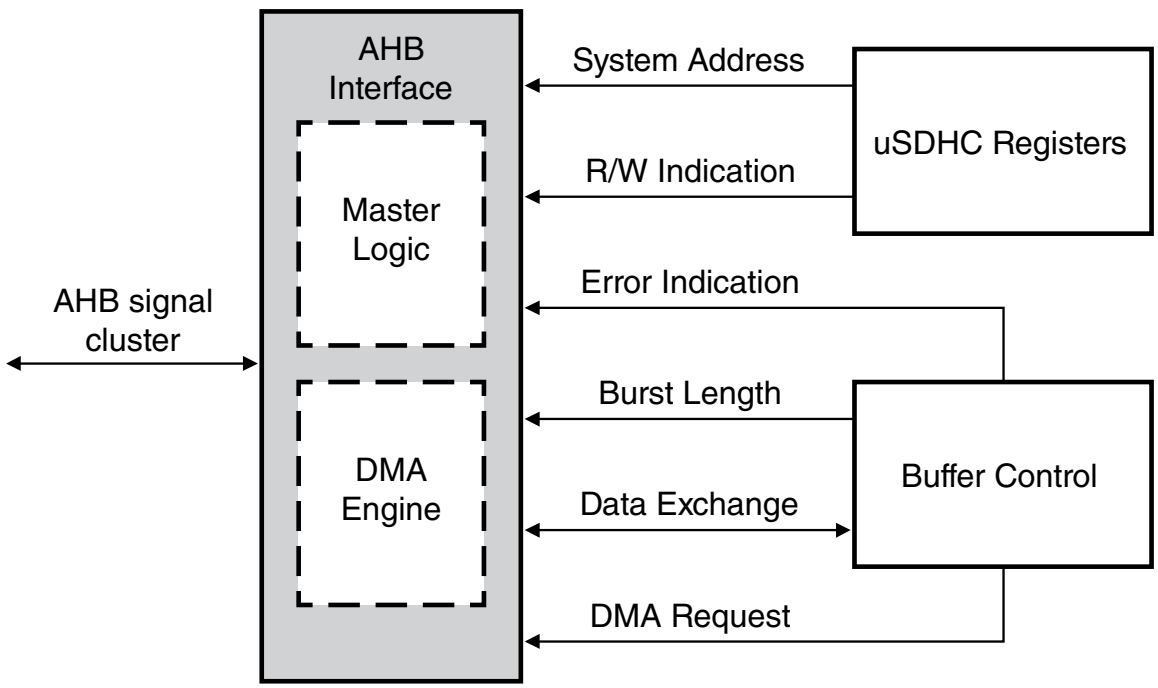

Figure 10-39. DMA AHB interface block

10.3.3.2.1 Internal DMA request

If the watermark level requirement is met in data transfer or if the last data of current block is ready in the data buffer, and the Internal DMA is enabled, the data buffer block sends a DMA request to AHB interface.Meanwhile, the external DMA request signal (uSDHC_dreq_b) is disabled.

The delay in response from the internal DMA engine depends on the system AHB bus loading and the priority assigned to uSDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The data buffer de-asserts the request if the data buffer space (for write) or bytes in data buffer is

smaller than the watermark level. Upon access to the buffer by internal DMA, the data buffer updates its internal buffer pointer, and when the watermark level is satisfied or the last data of the current block is ready in the data buffer, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the burst length set to six words. After the first burst transfer, if there are more than two words in the buffer, which might contain some data of the next block), another DMA request is sent. This is because the remaining number of words to send for the current block is (31 - 6 * 4) / 4 = 2. The uSDHC module reads two words out of the buffer, with seven valid bytes and one stuffed byte.

10.3.3.2.2 DMA burst length

Just like a CPU polling access, the DMA burst length for the internal DMA engine can range between 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block. See the example in Internal DMA request. After six words are read, the burst length is two words, then the next burst length is six words. This is because the next block starts, which is 31 bytes, more than six words. The host driver may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length is the same.

10.3.3.2.3 AHB master interface

It is possible that the internal AHB DMA engine could fail during the data transfer. Upon detection of an AHB bus error during DMA transfer, the DMA engine stops the transfer and goes to the idle state. At that point, the internal data buffer stops receiving incoming data and sending out data. The DMAE bit in the Interrupt Status register is generated to host CPU to report a bus error condition.

After the DMAE interrupt is received, the software sends a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and restart the transfer from this address to recover the corrupted block. DMA operation resumes when the interrupt is serviced by the software.

10.3.3.2.4 ADMA engine

In the SD host controller standard, a new DMA transfer algorithm called the Advanced DMA (ADMA) is defined. For simple DMA, after the page boundary is reached, a DMA interrupt is generated and the new system address is programmed by the host driver.

The ADMA defines the programmable descriptor table in the system memory. The host driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized because the host MCU intervention is not be needed during long DMA-based data transfers.

There are two types of ADMA in host controller: ADMA1 and ADMA2. ADMA1 can support data transfer of 4KB aligned data in system memory, and ADMA2 improves the restriction so that the data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA can recognize all kinds of descriptors defined in SD host controller Standard, and if the "End" flag is detected in the descriptor, ADMA stops after this descriptor is processed.

10.3.3.2.4.1 ADMA concept and descriptor format

ADMA1 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Set data length descriptor
- Set data address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA2 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Rsv descriptor
- Set data length and address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA starts read/write operation after it reaches the tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last set type descriptor before the tran type descriptor. Every tran type triggers a transfer, and the transfer data length is extracted from the most recent set type descriptor. If there is no set type descriptor after the previous Trans descriptor, the data length is the value for previous transfer, or 0 if no set descriptor is ever met.

For ADMA2, the tran type descriptor contains both data length and transfer data address, so only a tran type descriptor can start a data transfer.

See the figure below for the format of the descriptor table for ADMA1.

Address/ Page Field		Address/ Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 10-40. Format of the ADMA1 descriptor table

See the figure below for the concept and access method of the descriptor table for ADMA1.

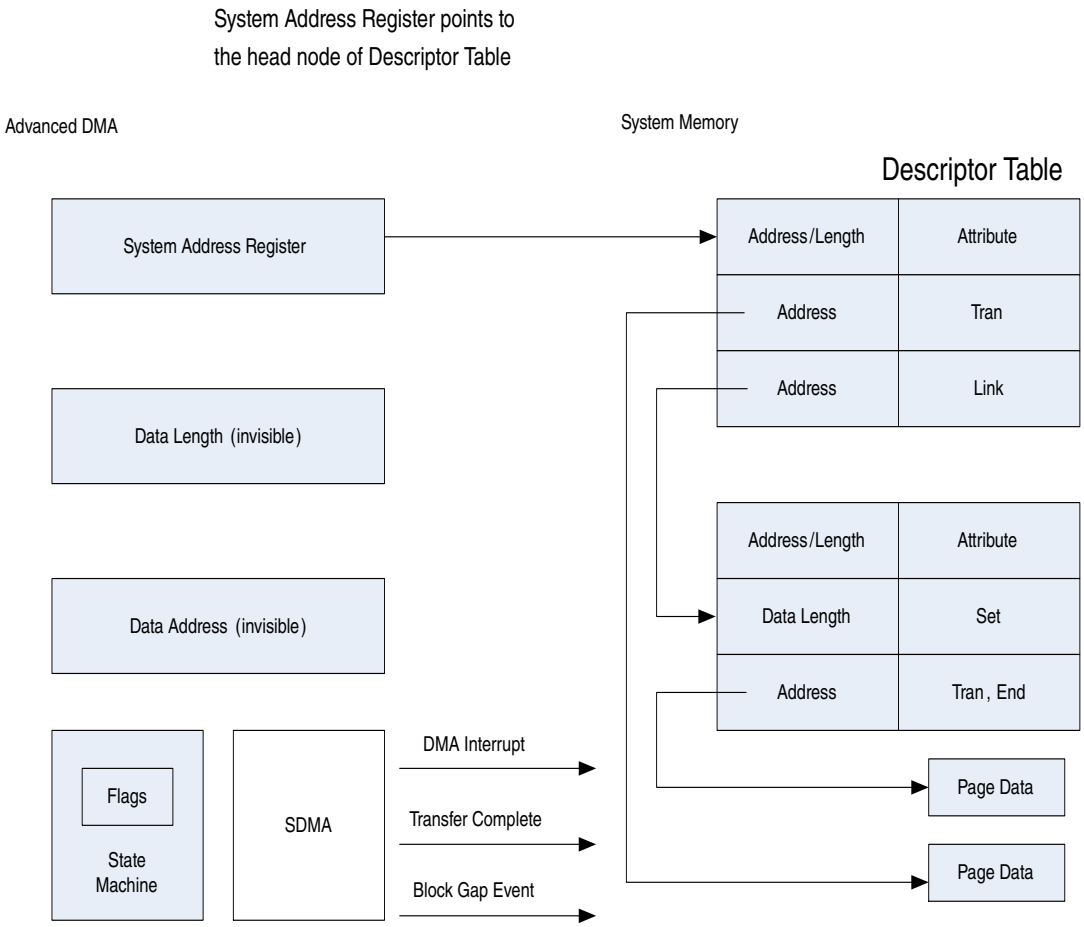

Figure 10-41. Concept and access method of the ADMA1 descriptor table

The figure below explains the ADMA2 format. ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it ignores the higher 32-bit. The Address field should be set to word aligned (lower 2-bit is always set to 0). Data length is in byte unit.

Address Field		Length		Reserved		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 10-42. Format of the ADMA2 descriptor table

See the figure below for the concept and access method of the descriptor table for ADMA2.

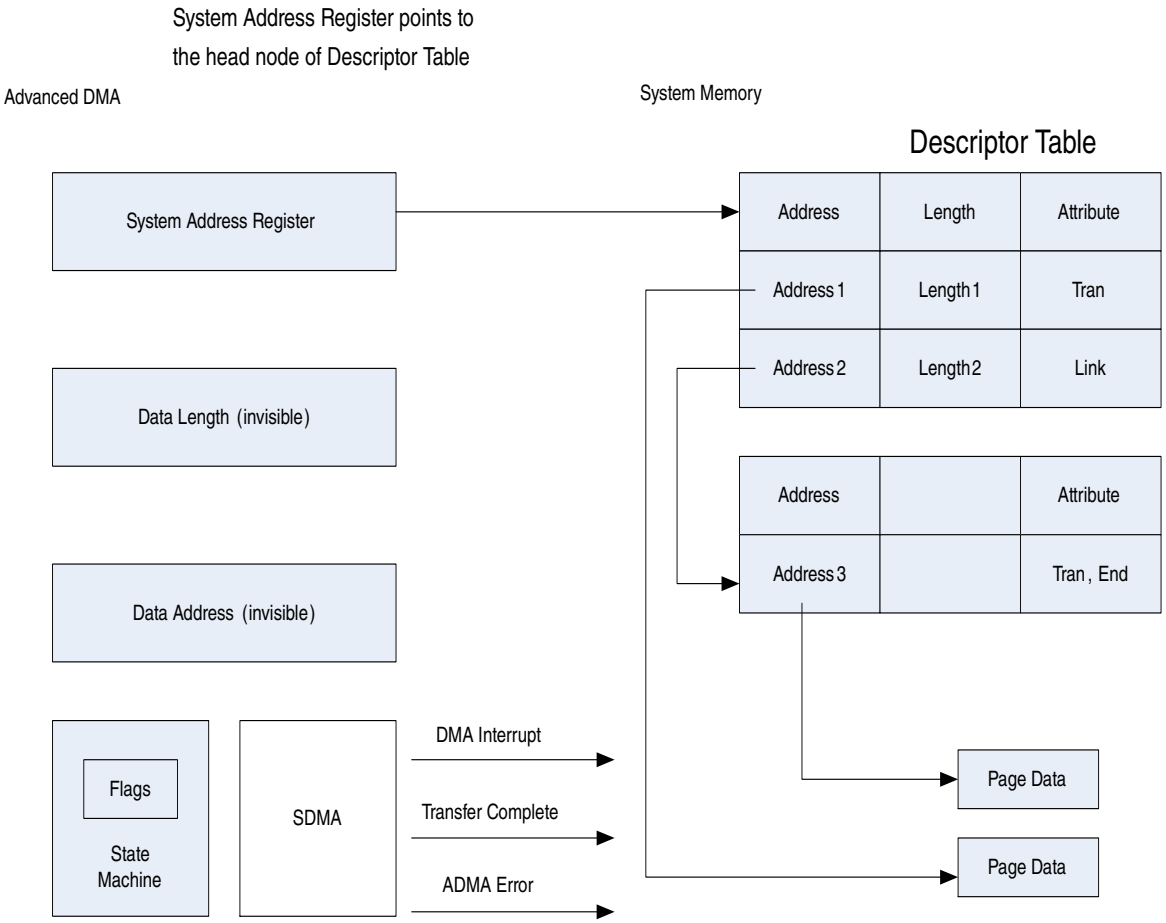

Figure 10-43. Concept and access method of the ADMA2 descriptor table

10.3.3.2.4.2 ADMA interrupt

If the interrupt flag descriptor is set, ADMA generates an interrupt according to various types of descriptors.

For ADMA1:

- Set type of descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop type of descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type of descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type of descriptor: interrupt is generated just after this descriptor is fetched.

10.3.3.2.4.3 ADMA error

The ADMA stops whenever an error is encountered. These errors include:

- Fetching descriptor error
- AHB response error
- Data length mismatch error

An ADMA descriptor error is generated when it fails to detect a "valid" flag in the descriptor. If an ADMA descriptor error occurs, the interrupt is not generated even if the "Interrupt" flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in buffer must be equal to the whole data length set in descriptor nodes, otherwise data length mismatch error is generated.

When BLKCNTEN bit is not set, then the whole data length set in descriptor is a multiple of block lengths; otherwise, when data set in the descriptor nodes are not performed at block boundaries, then data mismatch errors occur.

10.3.3.3 Register bank with IP bus interface

Register accesses through the IP bus interface are on the register bank.

See the figure below for the block diagram.

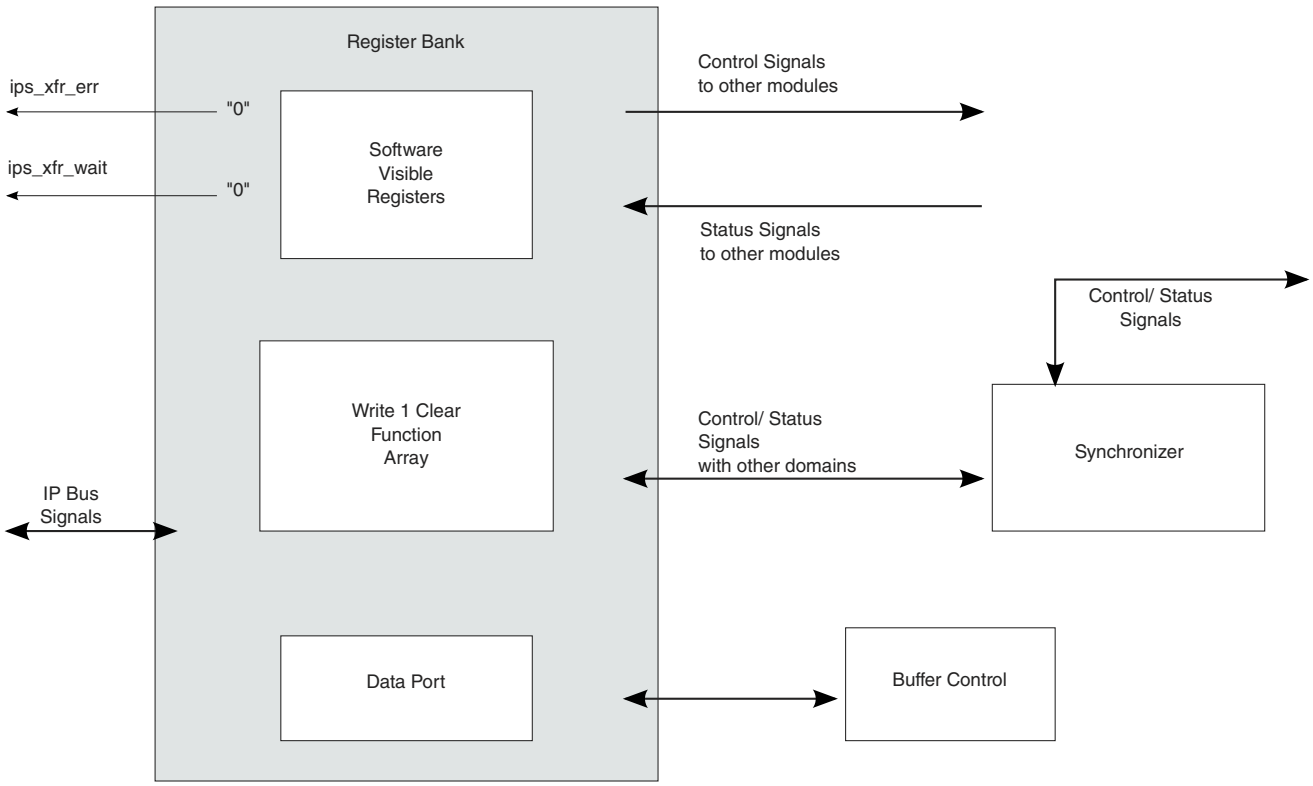

Figure 10-44. Register bank diagram

Only a 32-bit access is allowed, and no partial read/write is supported; therefore, all accesses are word aligned.

10.3.3.3.1 SD protocol unit

The SD protocol unit deals with all SD protocol affairs.

The SD protocol unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the CMD/DATA lines
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD protocol unit consists of four submodules:

- SD control misc
- Command control

- Data control
- Clock control

10.3.3.3.2 SD control misc

In the SD control misc unit, the card detection (including the CD_B and DATA3 used for card detection), write protection, and card interrupt are implemented.

This module monitors the signal level on all the eight data lines and the command lines. It directly routes the level values into the register bank.

The module also detects the Write Protect (WP) line. If WP is active, writes to the register bank are ignored.

This module also drives the LCTL output signal when the LCTL bit is set by the driver.

10.3.3.3.3 SD clock control

If the internal data buffer is near full (for read) or near empty (for write), the SD clock must be gated off to avoid buffer over/under-run. This module asserts the gate of the output SD clock to shut the clock off. After the buffer has space (for read) or has data (for write), the clock gate of this module opens, and the SD clock is active again.

10.3.3.3.4 Command control

The Command Control module deals with the transactions on the CMD line.

See the figure below for an illustration of the structure for the Command CRC shift register.

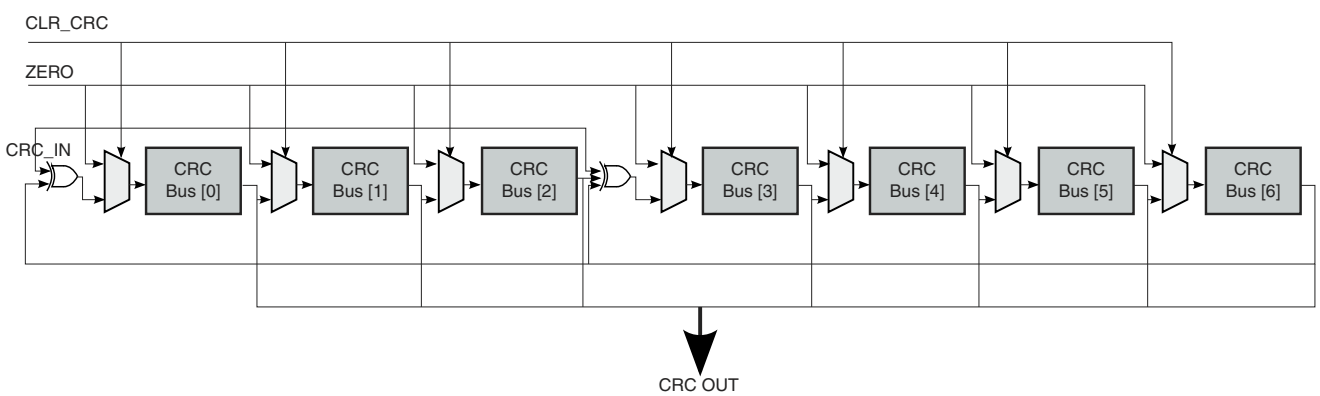

Figure 10-45. Command CRC shift register

The CRC polynomials for the CMD are as follows:

Generator polynomial: $G(x) = x^7 + x^3 + 1$
$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \ldots + (\text{last bit}) * x^0$
$CRC[6:0] = \text{Remainder } [(M(x) * x^7) / G(x)]$

10.3.3.3.5 Data control

The data agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DATA0 line, and generates the read wait state by the request from the transceiver.

The CRC polynomials for the data are as follows:

Generator polynomial: $G(x) = x^{16} + x^{12} + x^5 + 1$

$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \ldots + (\text{last bit}) * x^0$

$CRC[15:0] = \text{Remainder } [(M(x) * x^{16}) / G(x)]$

10.3.3.4 Clock and reset manager

This module controls all four kinds reset signals within uSDHC:

- Hardware reset
- Software reset for all logic
- Software reset for the data logic
- Software reset for the command logic

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

10.3.3.5 Clock generator

The clock generator generates the card CLK by peripheral source clock in two stages. The clock divisor can be configured through register SYS_CTRL [SDCLKFS] is for prescaler configuration while the [DVS] is for divisor configuration. Details can be found in the register function description. See the following figure for the structure of the divider. The term "Base" represents the frequency of peripheral source clock.

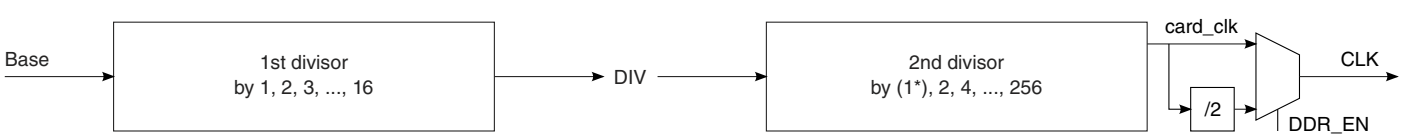

Figure 10-46. Two stages of the clock divider

The first stage outputs an intermediate clock (DIV) that can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler and outputs the actual internal working clock (card_clk). This clock is the driving clock for all the sub modules of the SD protocol unit, and helps in syncing FIFOs (see Figure 10-35) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage can be DIV, DIV/2, DIV/4,..., or DIV/256. Therefore, the highest frequency of the card_clk is base, and the next highest is Base/2, while the lowest frequency is Base/4096. If the duty cycle of the base clock is 50%, the duty cycle of card_clk is also 50%, even when the compound divisor is an odd value.

NOTE

CLK is different for the SDR and DDR modes.

- In the SDR mode, CLK is equal to the internal working clock (card_clk).

- In the DDR mode, CLK is equal to card_clk/2.

10.3.3.6 SDIO card interrupt

Information on interrupts in 1-bit mode, interrupts in 4-bit mode, and card interrupt handling are detailed in the sections below.

10.3.3.6.1 Interrupts in 1-bit mode

In this case, the DATA1 pin provides the interrupt function. An interrupt is asserted by pulling the DATA1 low from the SDIO card, until the interrupt service is finished to clear the interrupt.

10.3.3.6.2 Interrupt in 4-bit mode

As the interrupt and data line 1 share pin 8 in a 4-bit mode, an interrupt is only sent by the card and recognized by the host during a specific time. This is known as the interrupt period. The uSDHC module only provides sample the level on pin 8 during the interrupt period. At all other times, the host ignores the level on pin 8 and treats it as the data signal. The definition of the interrupt period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the interrupt period becomes active two clock cycles after the completion of a data packet. This interrupt period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in a 4-bit mode, there is only a limited period of time that the interrupt period can be active because of the limited period of data line availability between the multiple blocks of data. This requires stricter definition of the interrupt period. For this case, the interrupt period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DATA1 line holds low for one clock cycle with the last clock cycle pulling DATA1 high. On completion of the interrupt period, the card releases the DATA1 line into the high Z state. The uSDHC module provides sample of the DATA1 during the interrupt period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Card Specification v1.10 for further information about the SDIO card interrupt.

10.3.3.6.3 Card interrupt handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, uSDHC clears the interrupt request to the host system. The host driver should clear this bit before servicing the SDIO interrupt and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Card Interrupt Status can be cleared by writing 1 to this bit. But as the interrupt source from the SDIO card does not clear, this bit is set again. To clear this bit, it is required to reset the interrupt source from the external card followed by writing 1 to this bit. In a 1-bit mode, uSDHC detects the SDIO interrupt with or without the SD clock (to support wakeup). In a 4-bit mode, the interrupt signal is sampled during the interrupt period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the SDIO status is set and the host driver needs to service this interrupt, the SDIO bit in the Interrupt Control Register of SDIO card is cleared. This is required to clear the SDIO interrupt status latched in uSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The host driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Status Enable bit is set to 1 and uSDHC starts sampling the interrupt signal again.

See the figure below for an illustration of the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

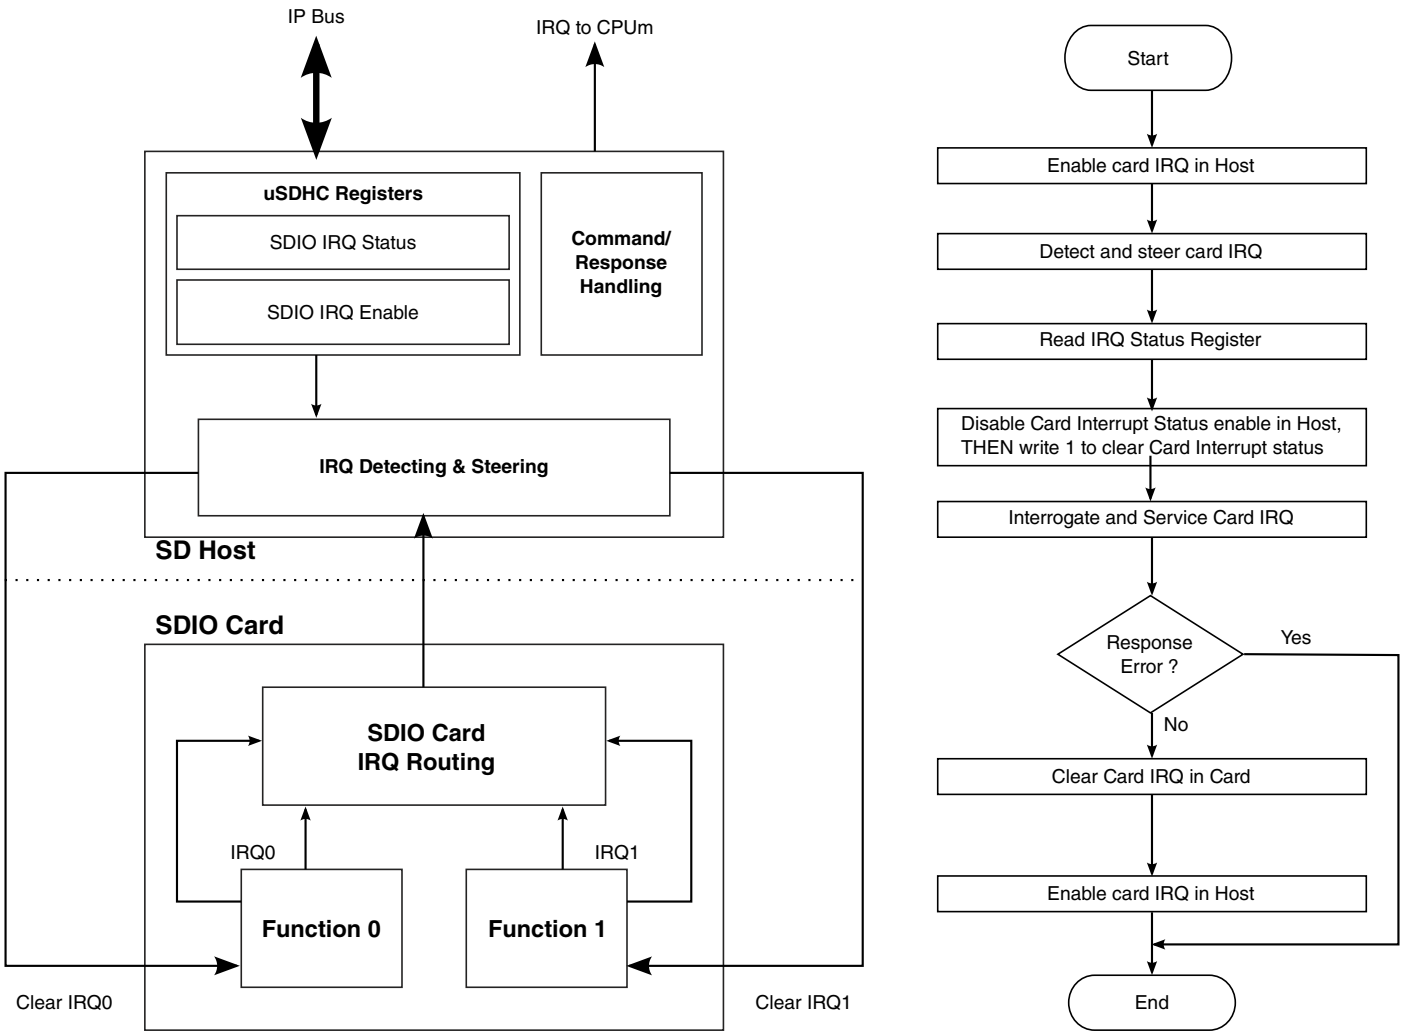

Figure 10-47. Card interrupt scheme, card interrupt detection, and handling procedure

10.3.3.7 Card insertion and removal detection

The uSDHC module uses either the DATA3 pin or the CD_B pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DATA3 is pulled to a low voltage level by default.

When any card is inserted to or removed from the socket, uSDHC detects the logic value changes on the DATA3 pin and generates an interrupt. When the DATA3 pin is not used for card detection (for example, it is implemented in GPIO), the CD_B pin must be connected for card detection. Whether DATA3 is configured for card detection or not, the CD_B pin is always a reference for card detection. Whether the DATA3 pin or the CD_B pin is used to detect card insertion, uSDHC sends an interrupt (if enabled) to inform the Host system that a card is inserted.

10.3.3.8 Power management and wakeup events

When there is no operation between uSDHC and the card through the SD bus, the user can completely disable the peripheral clock and base clock in the chip-level clock control module to save power. When the user needs to use uSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to uSDHC are disabled, for instance, when the system is in low-power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The uSDHC module can generate these interrupts even when there are no clocks enabled. The three interrupts that can be used as wakeup events are these:

- Card removal interrupt
- Card insertion interrupt
- Interrupt from SDIO card

The uSDHC module offers a power management feature. By clearing the clock enabled bits in the System Control register, the clocks are gated in the low position to uSDHC. For maximum power saving, the user can disable all the clocks to uSDHC when there is no operation in progress.

These three wakeup events (or wakeup interrupts) can also be used to wakeup the system from low-power modes.

NOTE

To make the interrupt a wakeup event, when all the clocks to uSDHC are disabled or when the entire system is in low power mode, the corresponding wakeup enabled bit needs to be set. Refer to Protocol Control (PROT_CTRL) for more information on the uSDHC Protocol Control register.

10.3.3.8.1 Setting wakeup events

For uSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters the sleep mode.

Before the software disables the host clock, it should ensure that all the following conditions have been met:

- No read or write transfer is active
- Data and command lines are not active
- No interrupts are pending
- Internal data buffer is empty

10.3.3.9 MMC fast boot

The Embedded MultiMediaCard (eMMC4.3) specification adds a fast boot feature that requires hardware support. There are two types of fast boot modes in the eMMC4.3 specification: boot operation and alternative boot operation in the eMMC4.3 specification. Each type also has with-acknowledge and without-acknowledge modes.

In the boot operation mode, the master (MultiMediaCard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFA (optional for slave), before issuing CMD1.

NOTE

For the eMMC4.3 card setting, please see the eMMC4.3 specification.

10.3.3.9.1 Boot operation

If the CMD line is held low for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after the CMD line goes low, the slave starts to send the first boot data to the master on the DATA line(s). The master must keep the CMD line low to read all of the boot data.

NOTE

For the purposes of this documentation, fast boot is called "normal fast boot mode".

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes low. If boot acknowledge is disabled, the slave does not send out acknowledge pattern '010'.

The master can terminate the boot mode with the CMD line high.

The boot operation is terminated when all the contents of the enabled boot data are sent to the master. After the boot operation is executed, the slave gets ready for the CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

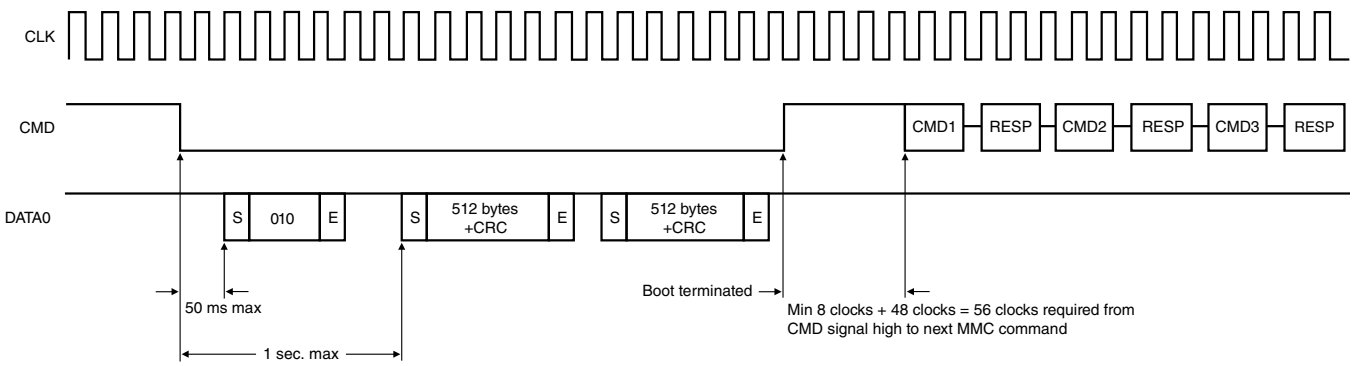

Figure 10-48. MultiMediaCard state diagram (normal boot mode)

10.3.3.9.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

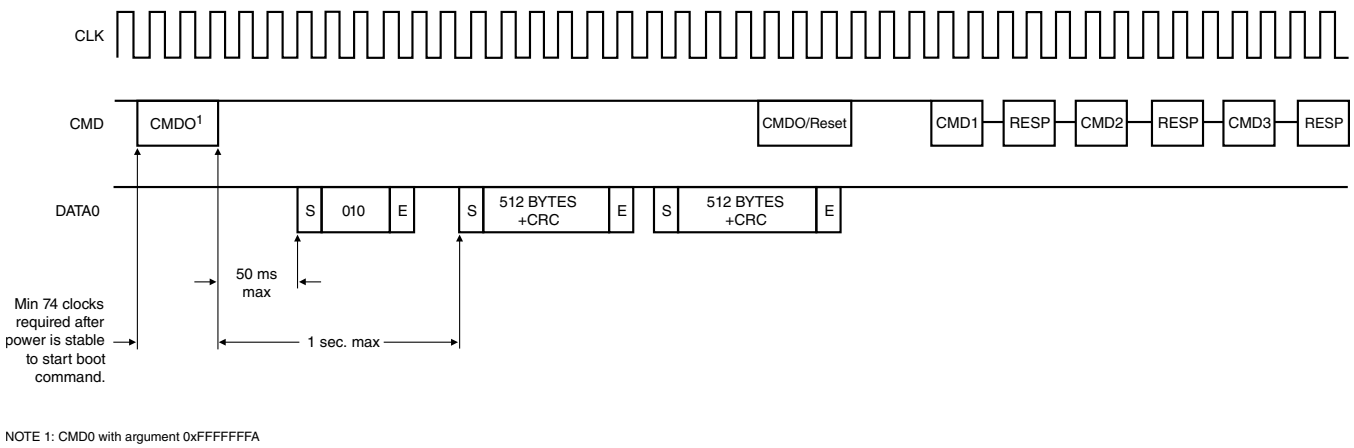
After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFA after 74 clock cycles, before CMD1 is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after CMD0 with the argument of 0xFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DATA line(s).

If boot acknowledge is enabled, the slave has to send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFA is received. If boot acknowledge is disabled, the slave does not send out acknowledge pattern '010'.

The master can terminate the boot mode by issuing CMD0 (Reset).

Boot operation is terminated when all the contents of the enabled boot data are sent to the master. After the boot operation is executed, the slave gets ready for the CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.



NOTE 1: CMD0 with argument 0xFFFFFFFA

Figure 10-49. MultiMediaCard state diagram (alternative boot mode)

10.3.4 Initialization/application of uSDHC

All communication between the system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as GO_IDLE_STATE, SEND_OP_COND, and ALL_SEND_CID. In the Broadcast mode, all cards are in the open-drain mode to avoid bus contention. Refer to Commands for MMC/SD/SDIO for the commands of bc and bcr categories.

After the broadcast command CMD3 is issued, the cards enter the standby mode. Addressed type commands are used from this point. In this mode, the CMD/DATA I/O pads turns to the push-pull mode to have the driving capability for maximum frequency operation. Refer to Commands for MMC/SD/SDIO for the commands of ac and adtc categories.

10.3.4.1 Command send & response receive basic operation

Assuming that the data type WORD is an unsigned 32-bit integer, the flow indicated below presents a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as '00'+<cmd_index>
set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL accorind to the command index;
if (internal DMA is used) wCmd |= 0x1;
if (multi-block transfer) {
          set MSBSEL bit;
          if (finite block number) {
                    set BCEN bit;
                    if (auto12 command is to use) set AC12EN bit;
          }
```

```
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits about Command are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function wait_for_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. When doing this, make sure that the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and move to the Standby state no response to the Host when CMD2 is sent. The host driver deals with "fake" errors like this with caution.

10.3.4.2 Card identification mode

When a card is inserted to the socket or the card is reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for MMC cards.

10.3.4.2.1 Card detect

See the figure below for a flow diagram showing the detection of MMC, SD, and SDIO cards using uSDHC.

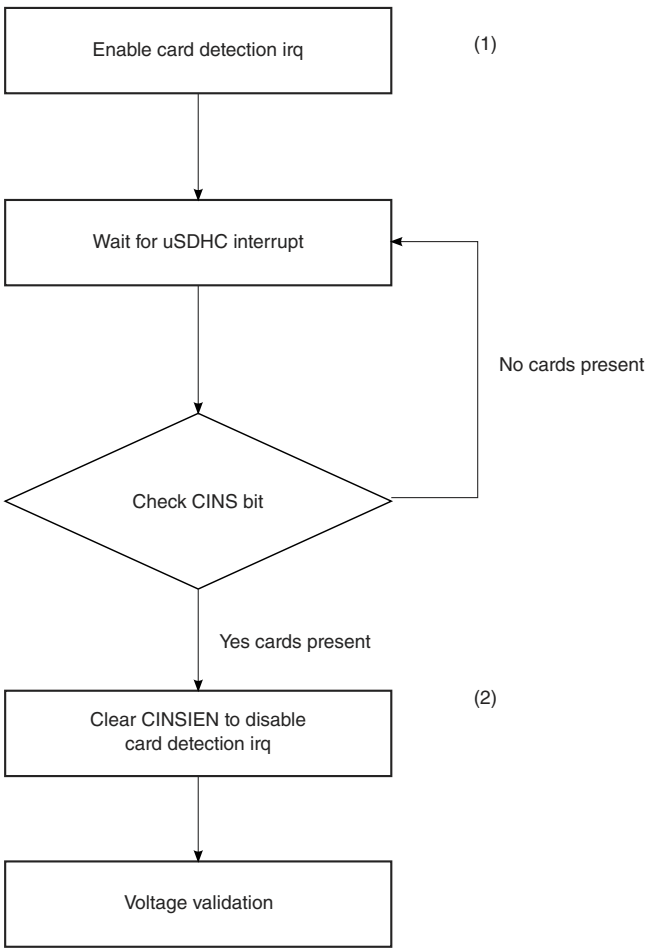


Figure 10-50. Flow diagram for card detection

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt.
- When an interrupt from uSDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion.
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards.

10.3.4.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) that is driven by Power On Reset (POR).

- Software reset (Host only) is initiated by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the host controller, respectively.
- Card reset (Card only): The command, "Go_Idle_State" (CMD0), is the software reset command for all types of MMC cards and SD memory cards. This command sets each card into the idle state regardless of the current card state. For an SD I/O card, CMD52 is used to write an I/O reset in CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See the figure below for the software flow to reset both uSDHC and the card.

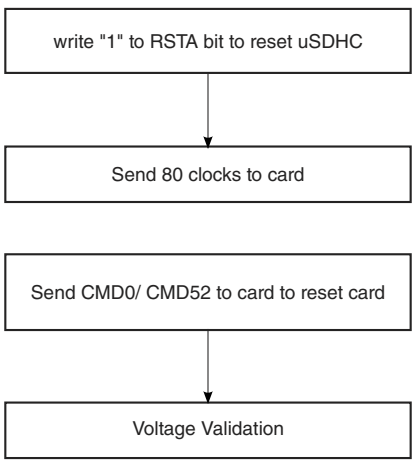

Figure 10-51. Flow chart for resetting uSDHC and SD I/O card

```
software_reset()
{
set_bit(SYSCTRL, RSTA); // software reset the Host
set DTOCV and SDCLKFS bit fields to get the CLK of frequency around 400kHz
configure IO pad to set the power voltage of external card to around 3.0V
poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
```

10.3.4.2.3 Voltage validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for VDD are defined in the Operation Conditions Register (OCR) and may not cover the whole range.

Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer VDD conditions. This means that if the host and card have non-common VDD ranges, the card is neither able to complete the identification cycle nor able to send CSD data.

Therefore, special commands Send_Op_Cont (CMD1 for MMC), SD_Send_Op_Cont (ACMD41 for SD Memory), and IO_Send_Op_Cont (CMD5 for SD I/O) are used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards that do not match the VDD range(s) desired by the host. This is accomplished when the host sends the desired VDD voltage window as the operand of this command. Cards that cannot perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive state. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive state. This query should be used if the host is able to select a common voltage range or if a notification is sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_arguement)
{
label the card as UNKNOWN;
send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
operation voltage, command argument is zero
if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
          if (0 < number of IO functions) {
                    label the card as SDIO;
                    IORDY = 0;
                    while (!(IORDY in IO OCR response)) { // set voltage range for each IO
function
                              send_command(IO_SEND_OP_COND, <voltage range>, <other
parameter>);
                              wait_for_response(IO_SEND_OP_COND);
                    } // end of while ...
          } // end of if (0 < ...
          if (memory part is present inside SDIO card) Label the card as SDCombo; // this is
an
SD-Combo card
} // end of if (RESP_TIMEOUT ...
if (the card is labelled as SDIO card) return; // card type is identified and voltage range
is
set, so exit the function;
send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific
CMD
prefix
if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
          send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage
range
for memory part or SD card
          wait_for_response(SD_APP_OP_COND); // voltage range is set
          if (card type is UNKNOWN) label the card as SD;
          return; //
} // end of if (no error ...
else if (errors other than time-out occur) { // command/response pair is corrupted
          deal with it by program specific manner;
} // of else if (response time-out
else { // CMD55 is refuse, it must be MMC card  if (card is already labelled as SDCombo)
{ //
change label
```

```
                    re-label the card as SDIO;
                    ignore the error or report it;
                    return; // card is identified as SDIO card
          } // of if (card is ...
          send_command(SEND_OP_COND, <voltage range>, <...>);
          if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted,
either
                    label the card as UNKNOWN;
                    return;
          } // of if (RESP_TIMEOUT ...
} // of else
}
```

10.3.4.2.4 Card registry

Card registry for the MMC and SD/SDIO/SD combo cards are different. For the SD card, the identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the card spec). Currently, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host requests the card to send their valid operation conditions.

The response to ACMD41 is the operation condition register of the card. The same command is sent to all the new cards in the system. Incompatible cards are put into the Inactive state. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready state), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification state.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA is used to address the card for future data transfer operations. After the RCA is received, the card changes its state to the Standby state. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in the system.

For MMC operation, the host starts the card identification process in the open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line to allow parallel card operation during card identification. After the bus is activated, the host requests the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired OR" operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive state. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards (the cards in the Ready state) simultaneously start sending their CID

numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. As the CID is unique for each card, only one card can be successfully sent its full CID to the host. This card then goes into the Identification state. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign a relative card address (RCA) to the card. After the RCA is received, the state of the card changes to standby, and the card does not react in further identification cycles. Also, its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

The following steps show how to perform an operation using MMC cards:

```
card_registry()
{
do { // decide RCA for each card until response time-out
          if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
                    send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to
publish its
RCA
                    retrieve RCA from response;
          } // end if (card is labelled as SDCombo ...
          else if (card is labelled as SD) { // for SD card
                    send_command(ALL_SEND_CID, <...>);
                    if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
                    send_command(SET_RELATIVE_ADDR, <...>);
                    retrieve RCA from response;
          } // else if (card is labelled as SD ...
          else if (card is labelled as MMC) {
                    send_command(ALL_SEND_CID, <...>);
                    rca = 0x1; // arbitrarily set RCA, 1 here for example
                    send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper
16
bits
          } // end of else if (card is labelled as MMC ...
} while (response is not time-out);
}
```

10.3.4.3 Card access

Information about Block Write, Block Read, Suspense Resume, ADMA Usage, Transfer Error, and Card Interrupt are detailed in the sections below.

10.3.4.3.1 Block write

Information on Normal Write, DDR Write, and Write with Pause are detailed in the sections below.

10.3.4.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card indicates that the failure on the DATA line. The transferred data is discarded and not written, and all further transmitted blocks (in multiple block write mode) are ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write-protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card reports an error and does not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card begins writing and holds the DATA line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO cards at any time, and the card responds with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby state and release the DATA line without interrupting the write operation. When re-selecting the card, it reactivates the busy indication by pulling data to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other two methods (by means of external DMA orCPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:

- For SD/MMC cards, use SET_BLOCKLEN (CMD16).
- For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).

3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or another error that occurred during the auto12 command sending and response receiving.

10.3.4.3.1.2 DDR write

uSDHC supports the dual data rate mode.

The software flow to write to a card in the DDR mode is described as below:

1. Check the card status and wait until the card is ready for data.

NOTE

For eMMC4.4 card, block length only can be set to 512byte.

2. Set the uSDHC number block register (NOB), where nob is 5, for instance.
3. Set the eMMC4.4 card to high-speed mode and use SWITCH(CMD6).
4. Set the eMMC4.4 card bus with 4-bit/8-bit DDR mode and use SWITCH(CMD6).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN and AC12EN bits should be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred or another error that occurred during the auto12 command sending and response receiving.

10.3.4.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set the Stop At Block Gap Request (SABGREQ) bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition in a write

operation during the data blocks, a write to all types of cards can be paused in this way, and if the DATA0 line is not required to de-assert to release the busy state, no suspend command is needed.

Similar to the flow described in Normal Write, the write with pause is shown with the same kind of write operation:

1. Check the card status and wait until the card is ready for data.
2. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred or some another error that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The host driver reads the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible that the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is the end of the transfer. These types of requests are ignored, the driver should treat these as a non-pause transfer, and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the host system is not stopped, and the transfer is active until the data buffer is full. Because of this, it is recommended to avoid using the Suspend command for the SDIO card. This is because when such a command is sent, uSDHC interprets the system that switches to another

function on the SDIO card and flush the data buffer. uSDHC takes the Resume command as a normal command with data transfer, and it is left for the host driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the uSDHC module automatically sends a CMD12 to mark the end of the multi-block transfer.

10.3.4.3.2 Block read

Information about Normal read, DDR read, Read with Pause, and Delay Line (DLL) in Read Path are detailed in the sections below.

10.3.4.3.2.1 Normal read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer state. For multi blocks read, data blocks are continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other two methods (by means of external DMA orCPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status and wait until card is ready for data.
2. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer read ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.

7. Check the status bit to see if a read CRC error occurred, or another error occurred during the auto12 command sending and response receiving.

10.3.4.3.2.2 DDR read

The uSDHC module supports dual data rate mode.

The software flow to write to a card in the DDR mode is described below:

1. Check the card status ans wait until the card is ready for data.
2. For eMMC4.4 card, block length can be set to only 512 bytes.
3. Set the uSDHC number block register (NOB) where nob is 5, for instance.
4. Set the eMMC4.4 card to high-speed mode and use SWITCH (CMD6).
5. Set the eMMC4.4 card bus with 4-bit /8-bit DDR mode and use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN and AC12EN bits should be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or another error that occurred during the auto12 command sending and response receiving.

10.3.4.3.2.3 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If the SDIO card supports Read Wait (SRW bit in CCCR register is 1), the host driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks.

Before setting the SABGREQ bit, ensure that the RWCTL bit in the Protocol Control register is set, otherwise uSDHC does not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended to set the RWCTL bit after the Read Wait capability of the SDIO card is recognized.

Similar to the flow described in Normal read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm that the card supports the Read Wait mode.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:

- For SD/MMC, use SET_BLOCKLEN (CMD16).
- For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).

5. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
6. Set the uSDHC number block register (NOB), where nob is 5, for instance.
7. Disable the buffer read ready interrupt, configure the DMA setting, and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or another error occurred during the auto12 command sending and response receiving.

Similar to the Write operation, it is possible to meet the ending block of the transfer when paused. In this case, uSDHC ignores the Stop At Block Gap Request and treats it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause is transferred to the host system. No matter if the Suspend command is sent or not, the internal data buffer is not flushed.

If the Suspend command is sent and the transfer is later resumed by means of a Resume command, uSDHC takes the command as a normal one accompanied with data transfer. It is left for the host driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the uSDHC automatically sends CMD12 to mark the end of multi-block transfer.

10.3.4.3.2.4 Delay Line (DLL) in Read Path

The DLL is newly added to assist in sampling read data. The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage, and temperature (PVT).

The reasons why DLL is needed for uSDHC are these:

- The path of read data traveling from card to host varies.
- In the SD/MMC DDR mode, the minimum input setup and hold time are both at 2.5 ns.

The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided card_clk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in the override mode. The override value set is the number of delay cells. In the override mode, there is no need to set the DLL_enable. Another DLL mode is target value mode. In this mode, the DLL automatically adjusts the number of delay cells according to the target value set by the user and PVT changes. Be aware that the target value is in units of 1/32 of the clock reference period. If the card_clk is 100Mhz, then the reference clock period is 10ns; setting target value of 16 means 5ns =(16/32)*10ns. The software can disable automatic update by the setting dll_gate_update bit.

As the user may change the frequency of card_clk from time to time by changing SDCLKFS[7:0]/DVS[3:0], the software must adjust the delay value to ensure it works correctly when the reference clock (card_clk) is changed. The following is the correct flow, which should be ignored if DLL_CTRL_ENABLE is not set.

Step 1: Set the DLL_CTRL_RESET bit

Step 2: Configure the SDCLKFS[7:0] and DVS[3:0]

Step 3: Wait until SDSTB is asserted

Step 4: Clear the DLL_CTRL_RESET bit

Step 5: Wait until both the DLL_STS_SLV_LOCK and DLL_STS_REF_LOCK are asserted

Step 6: Set the DLL_CTRL_SLV_FORCE_UPD

Step 7: Clear the DLL_CTRL_SLV_FORCE_UPD

NOTE

The software should make sure that the DLL_CTRL_SLV_FORCE_UPD lasts for at least one card_clk. So, the software may need to add some delay between step 6 and step 7.

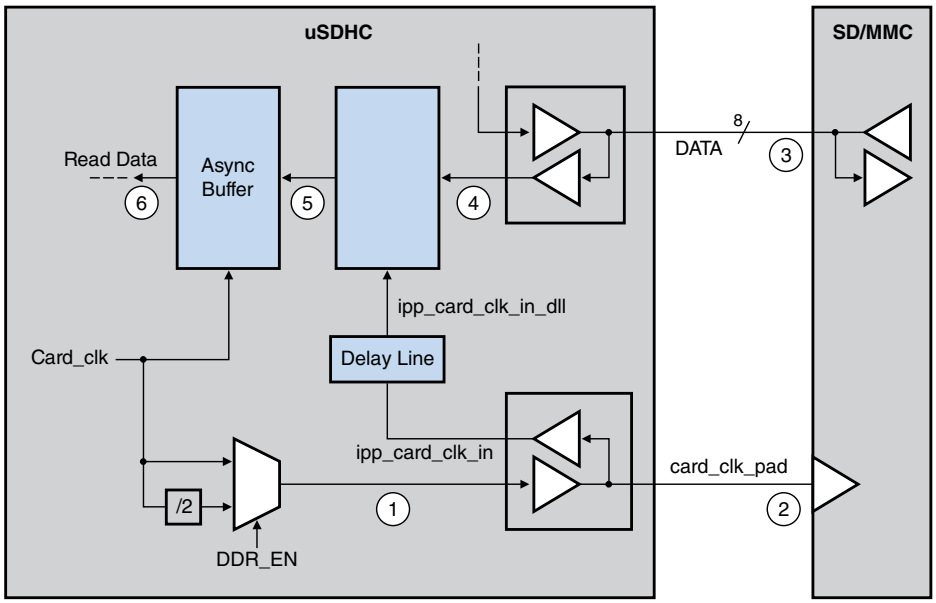

Figure 10-52. DLL in read path

10.3.4.3.3 Suspend Resume

The uSDHC module supports the Suspend Resume operations of SDIO cards, although slightly different than the suggested implementation of Suspend in the SDIO card specification.

10.3.4.3.3.1 Suspend

After setting the SABGREQ bit, the host driver may send a Suspend command to switch to another function of the SDIO card. The uSDHC module does not monitor the content of the response, so it does not know if the Suspend command succeeded or not. Accordingly, it does not de-assert Read Wait for read pause. To solve this problem, the host driver does not mark the Suspend command as "Suspend", (that is, setting the CMDTYP bits to 01). Instead, the driver sends this command as if it were a normal command, and only when the command succeeds, and the BS bit is set in the response, can the Driver send another command marked as "Suspend" to inform uSDHC that the current transfer is suspended. Here is the sequence for the Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.

4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so uSDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, uSDHC stops driving DATA2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on the SDIO card.

10.3.4.3.3.2 Resume

To resume the data transfer, a Resume command is issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation.
2. Send the Resume command: In the Transfer Type register, all the bit fields are set to the value as if this were another ordinary data transfer instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the Resume command has responded, the data transfer is resumed.

10.3.4.3.4 ADMA usage

To use the ADMA in a data transfer, the host driver must prepare the correct descriptor chain prior to sending the read/write command.

The steps to prepare the correct descriptor chain are these:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4KB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.
4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors match the product of the block size and block number configured in the Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

10.3.4.3.5 Transfer error

Information about CRC, Internal DMA, Transfer ADMA, and Auto CMD12 errors are detailed in the sections below.

10.3.4.3.5.1 CRC error

It is possible at the end of a block transfer that a write CRC status error or read CRC error occurs. For this type of error, the latest block received is discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one.

For a multi-block transfer, the host driver issues a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, uSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 is sent by uSDHC. In this case, the host driver re-sends or re-obtains the last block with a single block transfer.

10.3.4.3.5.2 Internal DMA error

During the data transfer with internal Simple DMA, if the DMA engine encounters an error on the AHB bus, the DMA operation is aborted, and the DMA error interrupt is sent to the host system. When acknowledged by such an interrupt, the host driver calculates the start address of data block in which the error occurs.

The start address can be calculated by either:

- Reading the DMA System Address register: The error occurs during the previous burst. Considering the block size, the previous burst length and the start address of the next burst transfer, it is straight forward to obtain the start address of the corrupted block.
- Reading the BLKCNT field of the Block Attribute register: Considering the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined. When the BCEN bit is not set, the contents of the Block Attribute register do not change, so this method does not work.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and restart the transfer from the corrupted block to recover from the error.

10.3.4.3.5.3 Transfer ADMA error

There are three kinds of possible ADMA errors: The AHB transfer, invalid descriptor, and data-length mismatch. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set.

For acknowledging the status, the host driver should recover the error as shown below and re-transfer from the place of interruption.

- AHB transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or to the next block if no block is corrupted.
- Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and recreate the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
- Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

10.3.4.3.5.4 Auto CMD12 error

After the last block of the multi-block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, uSDHC automatically sends a CMD12 to the card to stop the transfer.

When errors with this command occur, it is recommended to the host driver to deal with the situations in the following manner:

- Auto CMD12 response time-out: It is not certain whether the command is accepted by the card or not. The host driver clears the auto CMD12 error status bits and re-send CMD12 until it is accepted by the card.

- Auto CMD12 response CRC error: As the card responds to CMD12, it aborts the transfer. The host driver may ignore the error and clear the error status bit.
- Auto CMD12 conflict error or not sent: The command is not sent; therefore, the host driver sends a CMD12 manually.

10.3.4.3.6 Card interrupt

The external cards can inform the host controller by means of some special signals. For the SDIO card, it can be the low-level on the DATA1 line during some special period. The uSDHC module only monitors the DATA1 line and supports the SDIO interrupt.

When the SDIO interrupt is captured by uSDHC, and the host system is informed by uSDHC asserting the uSDHC interrupt line, the interrupt service from the host driver is called.

As the interrupt source is controlled by the external card, the interrupt from the SDIO card must be serviced before the CINT bit is cleared by written. Refer to Card interrupt handling for the card interrupt handling flow.

10.3.4.4 Switch function

A switch command is issued by the host driver to enable new features added to the SD/MMC spec. The SD/MMC cards can transfer data at bus widths other than 1-bit. Different speed modes are also defined. To enable these features, a switch command is issued by the host driver.

For SDIO cards, the high-speed mode/DDR50/SDR50/SDR104 are enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high-speed mode/DDR50/SDR50/SDR104 are queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For MMC cards, the high-speed mode/HS200/HS400 are queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The SDR4-bit, SDR8-bit, DDR4-bit, and DDR8-bit width of MMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO cards, it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following pseudocode examples do not show current capability check, which is recommended in the function switch process.

10.3.4.4.1 Query, enable, and disable SDIO high-speed mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
cleared;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

10.3.4.4.2 Query, enable, and disable SD high-speed mode/DDR50/SDR50/ SDR104

```
enable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
wait data transfer done bit is set;
check if the bit x of received 512 bits is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
if (bit 402 is '0') report the SD card does not support SDR50 mode and return;
if (bit 403 is '0') report the SD card does not support SDR104 mode and return;
if (bit 404 is '0') report the SD card does not support DDR50 mode and return;
send CMD6, with argument 0x80FFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104 x=3; DDR50 x=4;)
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz for high speed mode, 100MHz for SDR50, 200MHz for SDR104, 50MHz for
DDR50;
(data transactions like normal peers)
}
disable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

10.3.4.4.3 Query, enable, and disable MMC high-speed mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
```

```
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

10.3.4.4.4 Set MMC bus width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
return;
send CMD6 with argument 0x3B70x00; (8-bit(dual data rate), x=6; 4-bit(dual data rate), x=5;8-
bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

10.3.4.5 ADMA operation

Here are the codes for the ADMA1 and ADMA2 operations.

10.3.4.5.1 ADMA1 operation

```
Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
Set 'Set' type descriptor;
{
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
```

```
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB aligned);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}
```

10.3.4.5.2 ADMA2 operation

```
Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is a 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}
```

10.3.4.6 Fast boot operation

10.3.4.6.1 Normal fast boot flow

Here are the steps of normal fast boot flow:

1. Software must configure the init_active bit (system control register bit 27) to make sure that 74 card clocks are finished.
2. Software must configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode. If the data is sent through the DMA mode, the software should configure bit 7 to enable the automatic stop at block gap feature, and configure bit 3-bit 0 to select the ack timeout value according to the SD CLK frequency.

3. Software then needs to configure the Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software must configure the Protocol control register to set Data Transfer Width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure the Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure the Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN retain the default value, where DPSEL bit is set to 1, DTDSEL is set to 1 and MSBSEL is set to 1.
7. DMAEN should be configured as 0 in the polling mode and if BCEN is configured as 1, it is recommended to configure the number of blocks in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
8. When step 6 is configured, the boot process begins. The software needs to poll the data buffer ready status to read the data from the buffer in time. If a boot timeout happens (ack times out or the first data read times out), an interrupt is triggered, and the software must configure MMC Boot Register to bit 6 to 0 to disable boot. This makes CMD high, then after at least 56 clocks, it is ready to begin a normal initialization process.
9. If there is no timeout, software needs to determine when the data read is finished and then configure MMC Boot Register bit 6 to 0 to disable boot. This render CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin the normal initialization process.
10. Reset the host and then can begin the normal process.

10.3.4.6.2 Alternative fast boot flow

Here are the steps of alternative fast boot flow:

1. Software needs to configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If data needs to be sent through the DMA mode, then configure bit 7 to enable the automatic stop at block gap feature. Software should also configure bit 3-bit 0 to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in the DDR fast boot mode, the block size only can be configured to 512 bytes.

4. Software needs to configure the Protocol control register to set the data transfer width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFA.
6. Software needs to configure the Transfer Type Register to start the boot process by CMD0 with the 0xFFFFFFFA argument. In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. Note DMAEN should be configured as 0 in the polling mode, and if BCEN is configured as 1 in polling mode, it is recommended to configure the block count in the Block Attributes Register to the maximum value. If in the DDR fast boot mode, DDR_EN needs to be set to 1.
7. When step 6 is configured, the boot process begins. Software needs to poll the data buffer ready status to read the data from the buffer in time. If there is a boot timeout (ack data timeout in 50ms or data timeout in 1s), the host sends out the interrupt and the software needs to send CMD0 with reset and then configure the boot enable bit to 0 to stop this process.
8. If there is no time out, the software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after the command is completed, configure the MMC Boot Register bit 6 to stop the process. After 8 clocks from the command completion, the slave (card) is ready for the identification step.
9. Reset the host and then begin the normal process.

10.3.4.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the beginning of the image, it is necessary to switch DMA parameters on the fly during MMC fast boot.

In fast boot, the host can use Advanced DMA2 (ADMA2) with two destinations.

The detailed flow is described below:

1. The software needs to configure INIT_ACTIVE bit (system control register bit 27) to make sure that 74 card clocks are finished.
2. The software needs to configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot) or 1 (alternative boot); and bit 4 to select the ack mode. In DMA mode, configure bit 7 to 1 to enable the automatic stop at block gap feature. Also configure bits[31-16] to set the (BLK_CNT - VALUE1). Here VALUE1 is the value of the block count that needs to transfer the first time, so that the host stops at the block gap when the uSDHC controller gets VAULE1 blocks

from the device. Also, configure bits[3-0] to select the ack timeout value according to the SD clock frequency.

3. The software then needs to configure the Block Attributes Register to set block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes. In DMA mode, it is recommended to set the block count (BLK_CNT) to the max value (16'hffff).
4. The software needs to configure Protocol Control Register to set DTW (data transfer width). If in DDR fast boot mode, the DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software enable ADMA2 by configuring Protocol Control Register bits [9-8].
6. The software needs to set at least three pairs of ADMA2 descriptor in boot memory (that is, in IRAM, at least six words). The first pair descriptor defines the start address (that is, IRAM) and data length (that is,512byte*VALUE1) of the first part boot code. The software also needs to set the second pair descriptor, the second start address (any value that is writable), and data length is suggested to set 1~2word (record as VALUE2). Note that the second couple desc also transfers useful data even at lease 1 word, because our ADMA2 cannot support 0 data_length data transfer descriptor.
7. The software needs to configure Command Argument Register to set argument to 0xFFFFFFFA in alternative fast boot and do not need to be set in normal fast boot.
8. The software needs to configure Transfer Type Register to start the boot process. CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. DMAEN is configured as 1 in the DMA mode. And, if BCEN is configured as 1, then configure blk no in Bock Attributes Register to the max value. And, if in the DDR fast boot mode, DDR_EN needs to be set to 1.
9. When step 8 is configured, boot process begins, the first VALUE1 block number data gets transferred. The software needs to poll the TC bit (bit1 in Interrupt Status Register) to determine first transfer is ended. Also, the software needs to polling the BGE bit (bit2 in Interrupt Status Register) to determine if the first transfer stops at the block gap.
10. When TC and BGE bits are set to 1, the software can analyze the first code of VALUE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of the boot code (VALUE3, the remain boot code block). Remember to set the last descriptor with END.
11. The software needs to configure the MMC Boot Register (offset 0xc4) again. Set bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot), to 1 (alternative boot); and bit 4 to select the ack mode or not. In the DMA mode, configure bit 7 to 1 for enabling the automatically stop at block gap feature. Also, configure bit31-bit16 to set the (BLK_CNT - (VALUE1+1+VALUE3)), that host stops at block gap when the

uSDHC controller gets (VALUE1+1+VALUE3)) blocks from device totally include the blocks received in step 9. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequency. Note that the software does not need to configure the BLK_CNT again, because it is counted down automatically by the uSDHC controller.

12. The software needs to clear the TC and BGE bits and the software needs to clear SABGREQ (bit 16 in the Protocol control register) and set CREQ (bit17 in the Protocol control register) to 1 to resume the data transfer. Host transfers the VALUE2 and VALUE3 data to the destination that is set by descriptor.
13. The software needs to do poll BGE bit to determine if the fast boot is over.

Note:

1. When ADMA boot flow starts, for uSDHC, it is like a normal ADMA read operation. So, set ADMA2 descriptor as the normal ADMA2 transfer.
2. Need a few words length memory to keep descriptor.
3. For the 1~2-word data in second descriptor setting, it is a useful data, so the software needs to deal the data because of the application case.

10.3.5 Commands for MMC/SD/SDIO

A table containing the list of commands for the MMC/SD/SDIO cards is provided here.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the MultiMediaCard:

1. Broadcast commands (bc), no response
2. Broadcast commands with response (bcr), response from all cards simultaneously
3. Addressed (point-to-point) commands (ac), no data transfer on the DATA
4. Addressed (point-to-point) data transfer commands (adtc)

Response: A response is a token that is sent from the card to the host as an answer to a previously received command. A response is transferred serially on the CMD line.

Table 10-39. Commands for MMC/SD/SDIO cards

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all MMC and SD memory cards to idle state.

Table continues on the next page...

Table 10-39. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all MMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3[1]	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send them operation conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.

Table continues on the next page...

Table 10-39. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	adtc	[31:0] reserved bits(all 0)	R1	SEND_TUNING_BLOCK	64 bytes tuning pattern is sent for SDR50 and SDR104.
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows.
CMD21	Reserved				
CMD22-23	Reserved				
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command is issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.

Table continues on the next page...

Table 10-39. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				

Table continues on the next page...

Table 10-39. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather that a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57-59	Reserved				
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 is used to read and write these registers.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.
CMD62-63	Reserved				
ACMD6[4]	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[4]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22[4]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.

Table continues on the next page...

Table 10-39. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
ACMD23[4]	ac	[31:23] stuff bits [22:0] Number of blocks	R1	SET_WR_BLK_ERASE_COUNT	Set the number of write blocks to be pre-erased before writing (to be used for fast Multiple Block WR command). "1"=default(one write block).
ACMD41[4]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42[4]	ac	[31:1] stuff bits [0] set_cd	R1	SET_CLR_CARD_DETECT	Connect(1)/Disconnect(0) the 50KOhm pull-up resistor on CD_B/DATA3 of the card.
ACMD51[4]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high-speed SD cards. Command SWITCH_FUNC is for high-speed SD cards.
3. Command SWITCH is for high speed MMC cards. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 2.
4. ACMDs is preceded with the APP_CMD command. Commands listed are used for SD only, other SD commands not listed are not supported on this module.

The access bits for the EXT_CSD access modes are shown below.

Table 10-40. EXT_CSD access modes

Bits	Access name	Operation
00	Command set	The command set is changed according to the Cmd Set field of the argument.
01	Set bits	The bits in the pointed byte are set, according to the bits set to 1 in the Value field.
10	Clear bits	The bits in the pointed byte are cleared, according to the bits set to 1 in the Value field.
11	Write byte	The Value field is written into the pointed byte.

10.3.6 Software restrictions

10.3.6.1 Initialization active

The driver cannot set INITA bit in System Control register when any of the command line or data lines are active, so the driver must ensure both CDIHB and CIHB bits are cleared.

10.3.6.2 Software polling procedure

For polling read or write, after the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not a multiple of the value in the Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block.

For example, for a read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

10.3.6.3 Suspend operation

To suspend the data transfer, the software must inform uSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform uSDHC that the transfer is suspended.

If software needs to resume the suspended transfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending such a 'suspend' command, uSDHC treats the current transfer is aborted and change the BLKCNT register to its original value, instead of retaining the remaining number of blocks.

10.3.6.4 Data length setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

10.3.6.5 (A)DMA address setting

To configure the ADMA1/ADMA2/DMA address register, when TC bit is set, the register always updates itself with the internal address value to support dynamic address synchronization, so the software must ensure that the TC bit is cleared prior to configuring the ADMA1/ADMA2/DMA address register.

10.3.6.6 Data port access

Data port does not support parallel access. For example, during an internal DMA access, it is not allowed to write any data to the data port by CPU; or during a CPU read operation, it is also prohibited to write any data to the data port, by either CPU or internal DMA. Otherwise the data is corrupted inside the uSDHC buffer.

10.3.6.7 Change clock frequency

The uSDHC module does not automatically gate off the card clock when the host driver changes the clock frequency. To prevent possible glitch on the card clock, clear the FRC_SDCLK_ON bit when changing the clock divisor value (SDCLKFS or DVS in System Control Register) or setting the RSTA bit.

Also, before changing the clock divisor value, the host driver should make sure that the SDSTB bit is high.

10.3.6.8 Multi-block read

For pre-defined multi-block read operation, that is, the number of blocks to read has been defined by previous CMD23 for MMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by uSDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode.

In this case, the card may not respond to this extra abort command and uSDHC gets response timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

10.3.7 uSDHC memory map/register definition

10.3.7.1 uSDHC register descriptions

This section includes the module memory map and detailed descriptions of all registers.

See the table below for the register memory map of uSDHC. All these registers only support 32-bit accesses.

NOTE

The uSDHC registers are 32-bit wide and only support 32-bit access.

10.3.7.1.1 uSDHC memory map

uSDHC1 base address: 30B4_0000h

uSDHC2 base address: 30B5_0000h

uSDHC3 base address: 30B6_0000h

10.3.7.1.2.4 Fields

Field	Function
31-0 DS_ADDR	System address **DMA system address / argument 2**

Field	Function
	When ACMD23_ARGU2_EN is set to 0, SDMA uses this register as system address and supports only 32-bit addressing mode. Auto CMD23 cannot be used with SDMA. When ACMD23_ARGU2_EN is set to 1, SDMA uses ADMA System Address register (05Fh – 058h) instead of this register to support both 32-bit and 64-bit addressing. This register is used only for Argument2 and SDMA may use Auto CMD23. 1. **SDMA system address** Because the address must be word (4 bytes) aligned, the least 2 bits are reserved, always 0. When uSDHC stops a DMA transfer, this register points out the system address of the next contiguous data position. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operation during transfers may return an invalid value. The host driver initializes this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, write to this register is ignored. The host driver waits until the DLA bit in the Present State register is cleared, before writing to this register. The uSDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. And due to AHB burst limitations, if the burst must cross the 1 KB boundary, uSDHC automatically changes SEQ burst type to NSEQ. Because this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC bit is set. Such restriction is also listed in Software restrictions. 2. **Argument 2** This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23. If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without ADMA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.

10.3.7.1.3 Block Attributes (BLK_ATT)

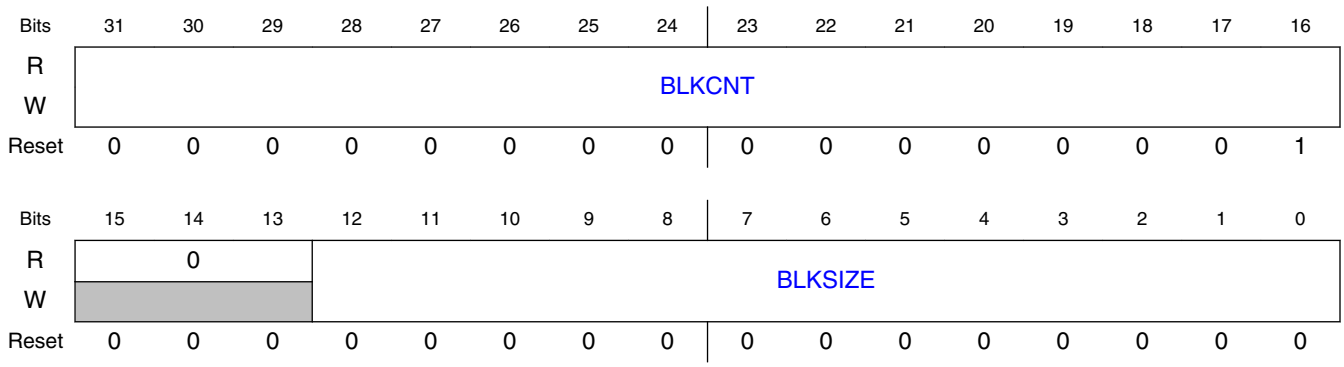
10.3.7.1.3.1 Offset

Register	Offset
BLK_ATT	4h

10.3.7.1.3.2 Function

This register is used to configure the number of data blocks and the number of bytes in each block.

10.3.7.1.3.3 Diagram



10.3.7.1.3.4 Fields

Field	Function
31-16 BLKCNT	Blocks count for current transfer This register is enabled when the Block Count Enable field in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. For single block transfer, this register always reads as 1. The host driver sets this register to a value between 1 and the maximum block count. The uSDHC module decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to zero results in no data blocks being transferred. This register should be accessed only when no transaction is executing (that is, after transactions are stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored. When saving transfer content because of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register. The reading of this register should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when the Suspend command is sent out, uSDHC treats the current transfer as aborted and change the BLKCNT register back to its original value instead of keeping the dynamical indicator of the remaining block count. When restoring transfer content prior to issuing a Resume command, the host driver restores the previously saved block count. **NOTE:** Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when MSBSEL field is indicating a single block transfer, the read value of BLKCNT is always 1. 0000000000000000b - Stop count 0000000000000001b - 1 block 0000000000000010b - 2 blocks 1111111111111111b - 65535 blocks
15-13 —	Reserved
12-0 BLKSIZE	Transfer block size This register specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations are ignored. 0000000000000b - No data transfer 0000000000001b - 1 byte

Field	Function
	0000000000010b - 2 bytes 0000000000011b - 3 bytes 0000000000100b - 4 bytes 0000111111111b - 511 bytes 0001000000000b - 512 bytes 0100000000000b - 2048 bytes 1000000000000b - 4096 bytes

10.3.7.1.4 Command Argument (CMD_ARG)

10.3.7.1.4.1 Offset

Register	Offset
CMD_ARG	8h

10.3.7.1.4.2 Function

This register contains the SD/MMC command argument.

10.3.7.1.4.4 Fields

Field	Function
31-0 CMDARG	Command argument The SD/MMC command argument is specified as bits 39-8 of the command format in the SD or MMC specification. This register is write protected when the Command Inhibit (CMD) field in the Present State register is set.

10.3.7.1.5 Command Transfer Type (CMD_XFR_TYP)

10.3.7.1.5.1 Offset

Register	Offset
CMD_XFR_TYP	Ch

10.3.7.1.5.2 Function

This register is used to control the operation of data transfers. The host driver sets this register before issuing a command followed by a data transfer or before issuing a Resume command. To prevent data loss, uSDHC prevents writing to the bits, which are involved in the data transfer of this register, when data transfer is active. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

The host driver checks the Command Inhibit DAT field (PRES_STATE[CDIHB]) and the Command Inhibit CMD field (PRES_STATE[CIHB]) in the Present State register before writing to this register. When the CDIHB field in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB field is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Block count must also be non-zero, or indicated as a single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise uSDHC ignores the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (PRES_STATE[WPSPL] field of Present State register is '1'); otherwise, uSDHC also ignores the command.

If the commands with data transfer do not receive the response in 64 clock cycles, that is, if response time-out happens, uSDHC treats the external device, does not accept the command, and aborts the data transfer. In this scenario, the driver should issue the command again to retry the transfer. It is also possible that for some reason the card responds to the command but uSDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The table below shows the summary of how register settings determine the type of data transfer.

Table 10-41. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

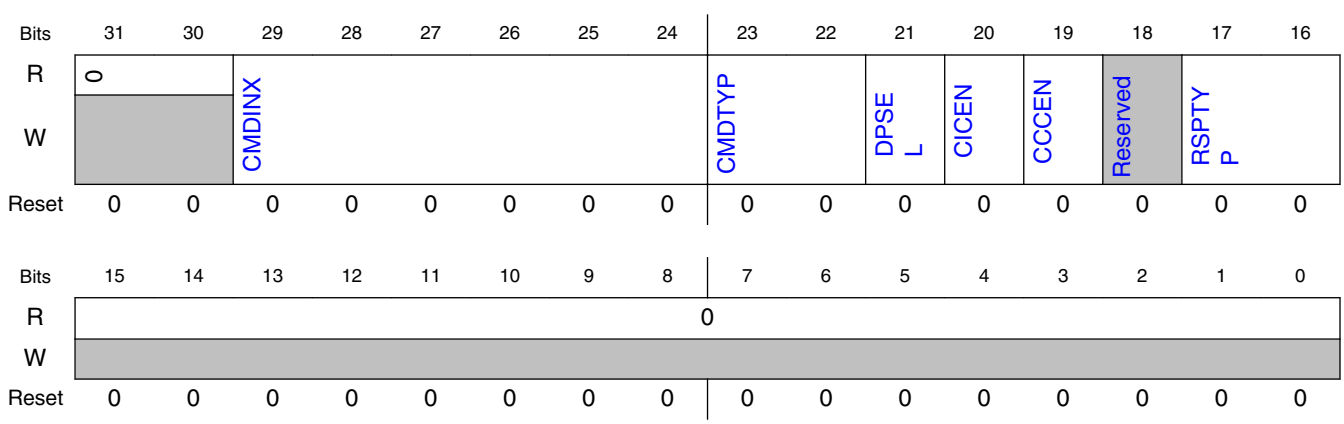
The table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, regarding the Response Type bits as well as the name of the response type.

Table 10-42. Relationship between parameters and the name of the response type

Response type	Index check enable	CRC check enable	Name of response type
00	0	0	No response
01	0	1	R2
10	0	0	R3, R4
10	1	1	R1, R5, R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification, but R5b is defined in this specification to specify that uSDHC checks the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command is used with R5b.
- The CRC fields for R3 and R4 are expected to be all 1 bits. The CRC check is disabled for these response types.

10.3.7.1.5.3 Diagram



10.3.7.1.5.4 Fields

Field	Function
31-30 —	Reserved
29-24 CMDINX	Command index These bits are set to the command number that is specified in bits 45-40 of the command-format in the SD Memory Card Physical Layer Specification and SDIO Card Specification.
23-22 CMDTYP	Command type There are three types of special commands: Suspend, Resume, and Abort. These bits are set to 00b for all other commands. • Suspend command: If the Suspend command succeeds, uSDHC assumes that the card bus has been released and that it is possible to issue the next command that uses the DATA line. Because uSDHC does not monitor the content of command response, it does not know if the Suspend command succeeded or not. It is the host driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform uSDHC that a Suspend command was successfully issued. See Suspend Resume for more details. After the end bit of command is sent, uSDHC deasserts Read Wait for read transactions and stops checking busy for write transactions. In a 4-bit mode, the interrupt cycle starts. If the Suspend command fails, uSDHC maintains its current state, and the host driver restarts the transfer by setting the Continue Request field in the Protocol Control register. • Resume command: The host driver re-starts the data transfer by restoring the registers saved before sending the Suspend command and then sends the Resume command. The uSDHC module checks for a pending busy state before starting write transfers. • Abort command: If this command is set when executing a read transfer, uSDHC stops reads to the buffer. If this command is set when executing a write transfer, uSDHC stops driving the DATA line. After issuing the Abort command, the host driver should issue a software reset (Abort Transaction). 00b - Normal other commands 01b - Suspend CMD52 for writing bus suspend in CCCR 10b - Resume CMD52 for writing function select in CCCR 11b - Abort CMD12, CMD52 for writing I/O Abort in CCCR
21 DPSEL	Data present select This field is set to 1 to indicate that data is present and is transferred using the DATA line. It is set to 0 for the following: • Commands using only the CMD line (for example, CMD52) • Commands with no data transfer, but using the busy signal on DATA0 line (R1b or R5b (for example, CMD38)) **NOTE:** In resume command, this field is set, and other bits in this register is set the same as when the transfer was initially launched. When the write protect switch is on, (that is, the WPSPL field is active as '0'), any command with a write operation ignored. When this field is set, while the DTDSEL field is 0, writes to the register Transfer Type are ignored. 0b - No data present 1b - Data present
20 CICEN	Command index check enable If this field is set to 1, uSDHC checks the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this field is set to 0, the Index field is not checked. 0b - Disable command index check 1b - Enables command index check

Table continues on the next page...

Field	Function
19 CCCEN	Command CRC check enable If this field is set to 1, uSDHC checks the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this field is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. See RSPTYP[1:0] and Command Transfer Type (CMD_XFR_TYP). 0b - Disables command CRC check 1b - Enables command CRC check
18 —	Reserved
17-16 RSPTYP	Response type select 00b - No response 01b - Response length 136 10b - Response length 48 11b - Response length 48, check busy after response
15-0 —	Reserved
