13.4.10.2.24.3 Fields

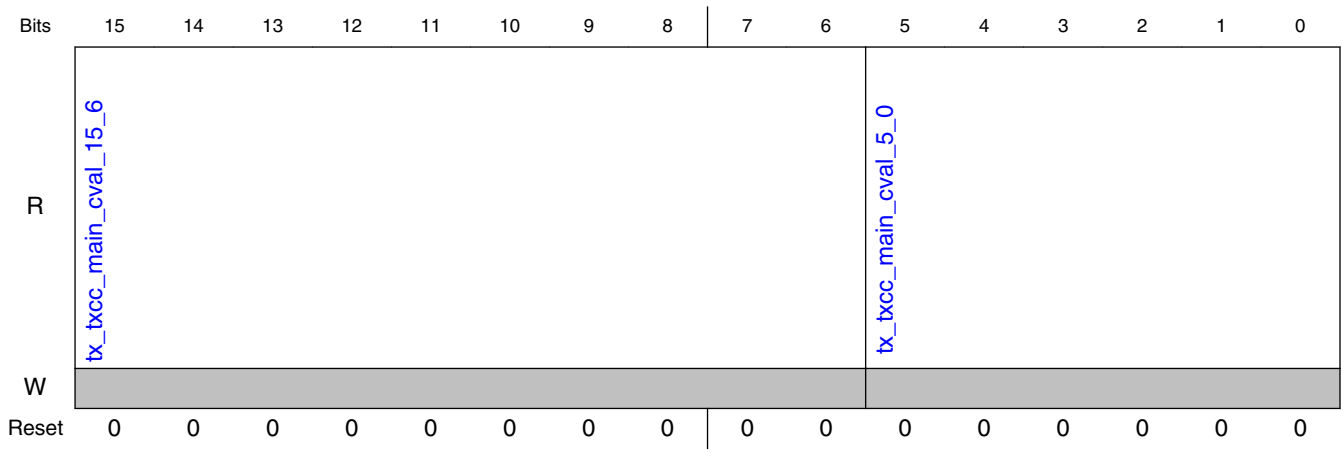
Field	Function
15-6 tx_txcc_pre_cval_15_6	Reserved
5-0 tx_txcc_pre_cval_5_0	Pre-cursor value: The value in this field indicates the current value of the pre-cursor (C-1) coefficient. The value of this field can be any of the following, depending on the current mode of operation.

13.4.10.2.25 TX main-cursor current value register (lane0_tx_txcc_main_cval - lane3_tx_txcc_main_cval)

13.4.10.2.25.1 Offset

Register	Offset
lane0_tx_txcc_main_cval	4045h
lane1_tx_txcc_main_cval	4445h
lane2_tx_txcc_main_cval	4845h
lane3_tx_txcc_main_cval	4C45h

13.4.10.2.25.2 Diagram



13.4.10.2.25.3 Fields

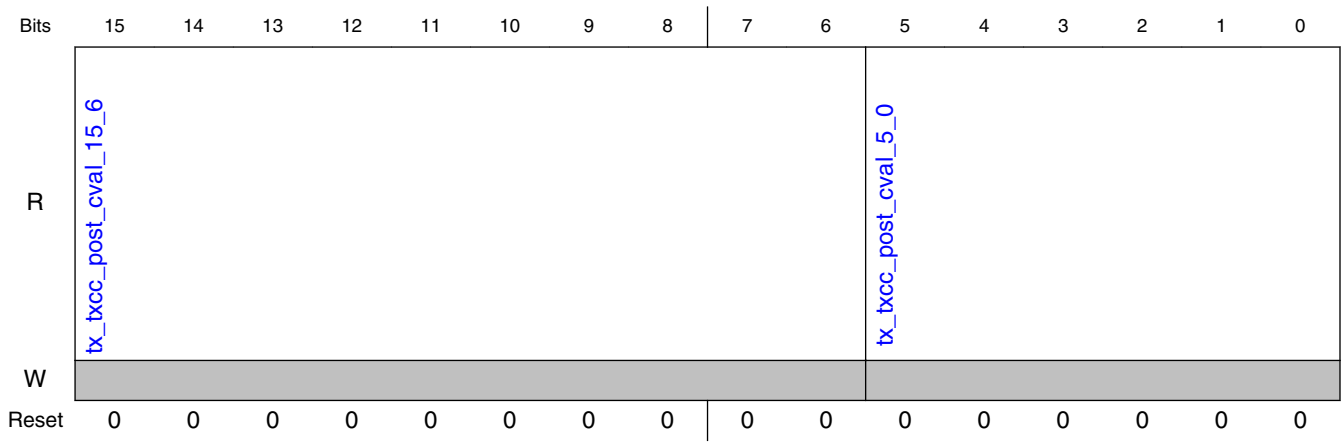
Field	Function
15-6 tx_txcc_main_cval_15_6	Reserved
5-0 tx_txcc_main_cval_5_0	Main-cursor value: The value in this field indicates the current value of the main-cursor (C0) coefficient. The value of this field can be any of the following, depending on the current mode of operation.

13.4.10.2.26 TX post-cursor current value register (lane0_tx_txcc_post_cval - lane3_tx_txcc_post_cval)

13.4.10.2.26.1 Offset

Register	Offset
lane0_tx_txcc_post_cval	4046h
lane1_tx_txcc_post_cval	4446h
lane2_tx_txcc_post_cval	4846h
lane3_tx_txcc_post_cval	4C46h

13.4.10.2.26.2 Diagram



13.4.10.2.26.3 Fields

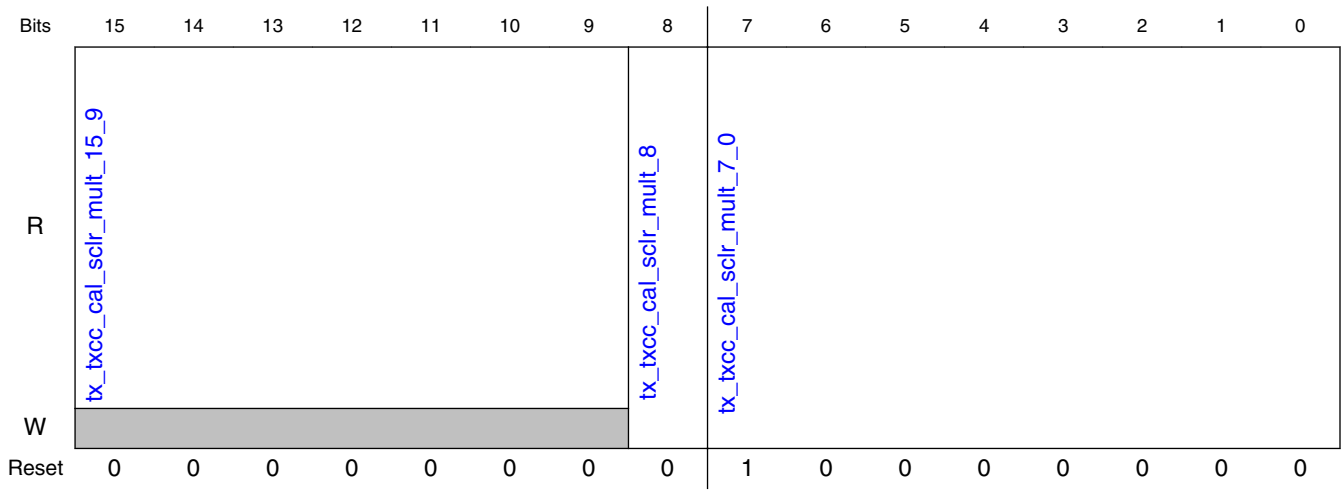
Field	Function
15-6 tx_txcc_post_cval_15_6	Reserved
5-0 tx_txcc_post_cval_5_0	Post-cursor value: The value in this field indicates the current value of the post-cursor (C+1) coefficient. The value of this field can be any of the following, depending on the current mode of operation.

13.4.10.2.27 Resistor calibration code scaler multiplier value register (lane 0_tx_txcc_cal_sclr_mult - lane3_tx_txcc_cal_sclr_mult)

13.4.10.2.27.1 Offset

Register	Offset
lane0_tx_txcc_cal_sclr_mult	4047h
lane1_tx_txcc_cal_sclr_mult	4447h
lane2_tx_txcc_cal_sclr_mult	4847h
lane3_tx_txcc_cal_sclr_mult	4C47h

13.4.10.2.27.2 Diagram



13.4.10.2.27.3 Fields

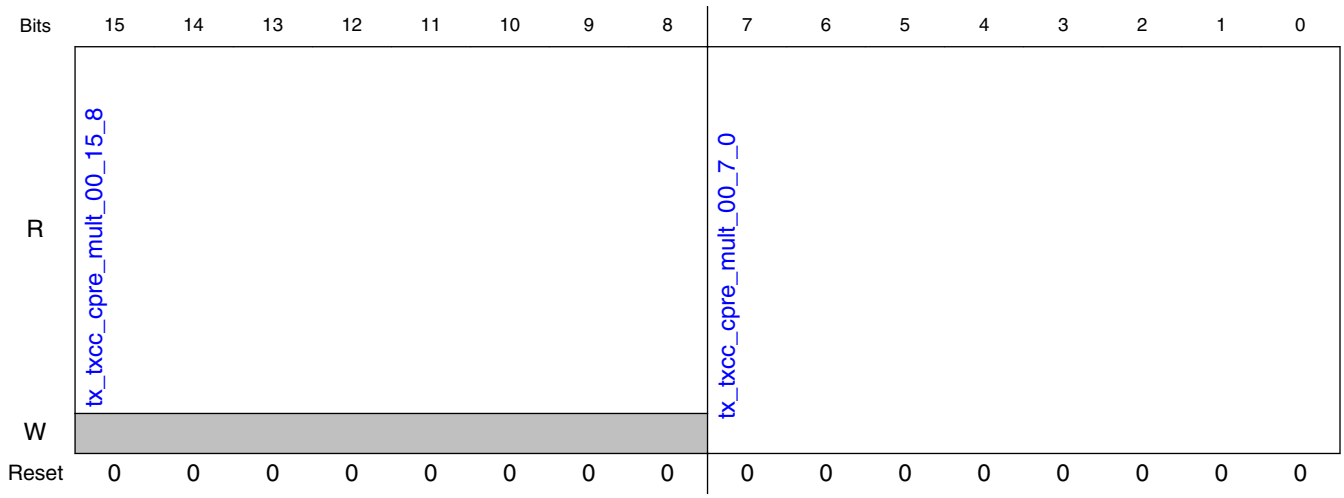
Field	Function
15-9 tx_txcc_cal_sclr_mult_15_9	Reserved
8 tx_txcc_cal_sclr_mult_8	Scaled resistor calibration code add: When this bit is set to
7-0 tx_txcc_cal_sclr_mult_7_0	Resistor calibration multiplier value: The value in this field specifies the multiplier value used to scale the resistor calibration code by. The following describes the multiplier value each bit in this field corresponds to.

13.4.10.2.28 Calculated pre emphasis multiplier value 00 register (lane0_tx_txcc_cpre_mult_00 - lane3_tx_txcc_cpre_mult_00)

13.4.10.2.28.1 Offset

Register	Offset
lane0_tx_txcc_cpre_mult_00	4048h
lane1_tx_txcc_cpre_mult_00	4448h
lane2_tx_txcc_cpre_mult_00	4848h
lane3_tx_txcc_cpre_mult_00	4C48h

13.4.10.2.28.2 Diagram



13.4.10.2.28.3 Fields

Field	Function
15-8 tx_txcc_cpre_mult_00_15_8	Reserved
7-0 tx_txcc_cpre_mult_00_7_0	Calculated pre emphasis multiplier value 00: The value in this field specifies the multiplier value used to generate the calculated pre emphasis value from the FS value when

13.4.10.2.29 Calculated pre emphasis multiplier value 01 register (lane0_tx_txcc_cpre_mult_01 - lane3_tx_txcc_cpre_mult_01)

13.4.10.2.29.1 Offset

Register	Offset
lane0_tx_txcc_cpre_mult_01	4049h
lane1_tx_txcc_cpre_mult_01	4449h
lane2_tx_txcc_cpre_mult_01	4849h

13.4.10.2.153.3 Fields

Field	Function
15-10 rx_sigdet_lh_filt_tmr_15_10	Reserved
9-0 rx_sigdet_lh_filt_tmr_9_0	Signal detect filter low to high filter timer value: This is the value loaded into the filter timer in the signal detect low to high filter circuit. This should be set to 6 less than the number of clocks of desired filter time. This takes into account the synchronizing of the signal to be filtered (4 clocks), the time to load the filter timer (1 clock), and that the timer counts to 0. Therefore, the smallest granularity of filtering available here is 6 clocks. This is more of an issue of latency through the filter circuit as the signal initially rises.

13.4.10.2.154 Receiver signal detect filter low to high delay timer register (lane0_rx_sigdet_lh_dly_tmr - lane3_rx_sigdet_lh_dly_tmr)

8 phy_pma_xcvr_ctrl_8	Drives the tx_differential_invert PMA input for the associated lane.
7-4 phy_pma_xcvr_ctrl_7_4	Reserved
3 phy_pma_xcvr_ctrl_3	Current value of rx_bist_status_ln_{nnn} PMA output for the associated lane.

Table continues on the next page...

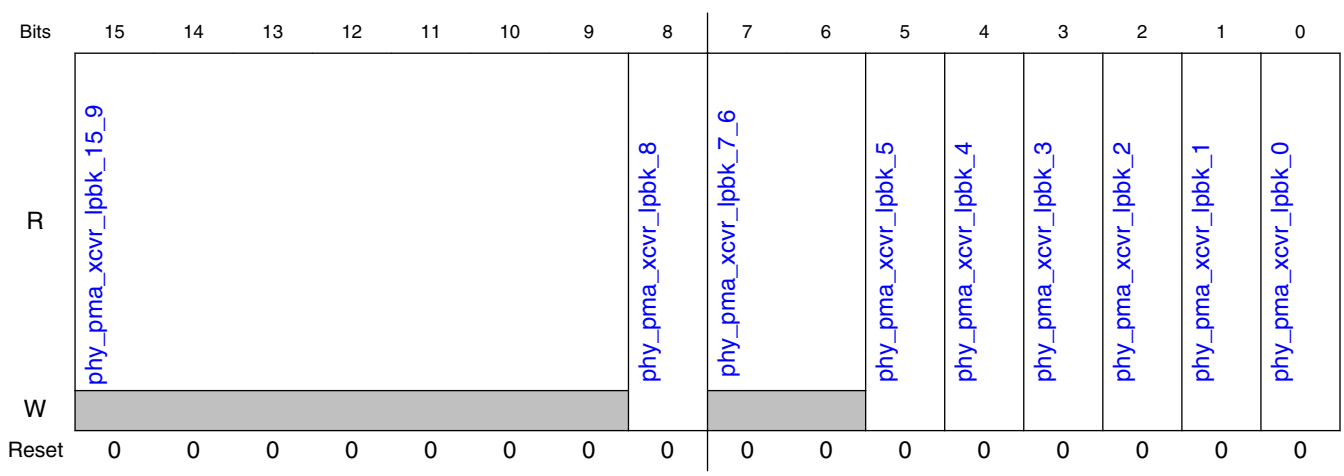
Field	Function
2 phy_pma_xcvr_ctrl_2	Current value of rx_bist_err_toggle_ln_{nnn} PMA output for the associated lane.
1 phy_pma_xcvr_ctrl_1	Current value of rx_bist_sync_ln_{nnn} PMA output for the associated lane.
0 phy_pma_xcvr_ctrl_0	Reserved

13.4.10.2.384 PMA loopback control register (lane0_phy_pma_xcvr_lpbk - lane3_phy_pma_xcvr_lpbk)

13.4.10.2.384.1 Offset

Register	Offset
lane0_phy_pma_xcvr_lpbk	CC01h
lane1_phy_pma_xcvr_lpbk	CC41h
lane2_phy_pma_xcvr_lpbk	CC81h
lane3_phy_pma_xcvr_lpbk	CCC1h

13.4.10.2.384.2 Diagram



13.4.10.2.384.3 Fields

Field	Function
15-9 phy_pma_xcvr_lpbk_15_9	Reserved
8 phy_pma_xcvr_lpbk_8	Drives the tx_bist_hold PMA input for all lanes in the associated link. Synchronized to transmit data rate clock. This signal can be used during test to start each lanes BIST engine on the same clock cycle to test lane to lane transmit skew.
7-6 phy_pma_xcvr_lpbk_7_6	Reserved
5 phy_pma_xcvr_lpbk_5	Drives the txrx_fe_parallel_lpbk_en_ln_{nnn} PMA input for the associated lane.
4 phy_pma_xcvr_lpbk_4	Drives the txrx_ne_parallel_lpbk_en_ln_{nnn} PMA input for the associated lane.
3 phy_pma_xcvr_lpbk_3	Drives the txrx_recovered_clk_lpbk_en_ln_{nnn} PMA input for the associated lane.
2 phy_pma_xcvr_lpbk_2	Drives the txrx_line_lpbk_en_ln_{nnn} PMA input for the associated lane.
1 phy_pma_xcvr_lpbk_1	Drives the txrx_isi_gen_lpbk_en_ln_{nnn} PMA input for the associated lane.
0 phy_pma_xcvr_lpbk_0	Drives the txrx_serial_lpbk_en_ln_{nnn} PMA input for the associated lane.

13.4.10.2.385 PMA PSM current state lower register (lane0_phy_pma_psm_state_lo - lane3_phy_pma_psm_state_lo)

13.4.10.2.385.1 Offset

Register	Offset
lane0_phy_pma_psm_state_lo	CC04h
lane1_phy_pma_psm_state_lo	CC44h
lane2_phy_pma_psm_state_lo	CC84h

Table continues on the next page...

Register	Offset
lane3_phy_pma_psm_state_lo	CCC4h

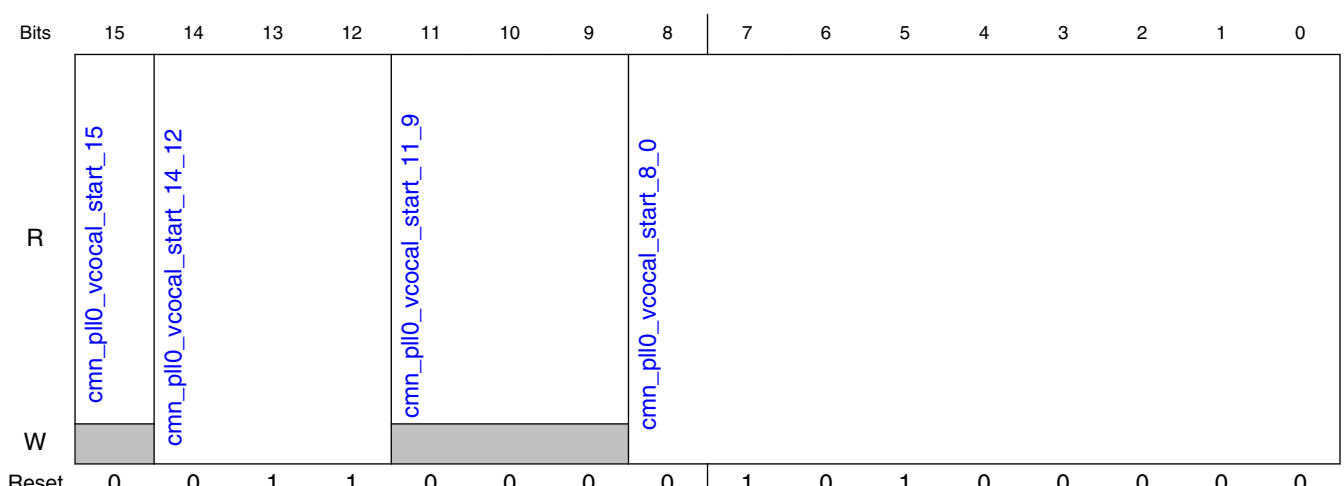
15 cmn_pll0_vcocal_ctrl_15	Start VCO calibration: Activating (1b1) this bit will start a VCO calibration process. This bit must remain active until the VCO calibration process is complete (as indicated by the VCO calibration process done bit in this register). To start another VCO calibration process, the VCO calibration process done bit must have gone inactive from any prior calibration process.
14 cmn_pll0_vcocal_ctrl_14	VCO calibration process done: This bit will be set to 1b1 when the VCO calibration process is complete. It will be cleared by the deactivation of the Start VCO calibration bit in this register.
13-9 cmn_pll0_vcocal_ctrl_13_9	Reserved
8-0 cmn_pll0_vcocal_ctrl_8_0	VCO calibration code: This is the calibration code that was determined by the VCO calibration process. This signal is valid when the VCO calibration process is complete. The values of this field correspond to different frequency bands the VCO will operate in. The frequency bands are controlled by the number of capacitors that are switched in the VCO analog circuit. This field specifies the number of capacitors that are switched in. The following are the values for this code:

13.4.10.2.437 PLL 0 VCO calibration start point register (cmn_pll0_vcocal_start)

13.4.10.2.437.1 Offset

Register	Offset
cmn_pll0_vcocal_start	8_0081h

13.4.10.2.437.2 Diagram



13.4.10.2.437.3 Fields

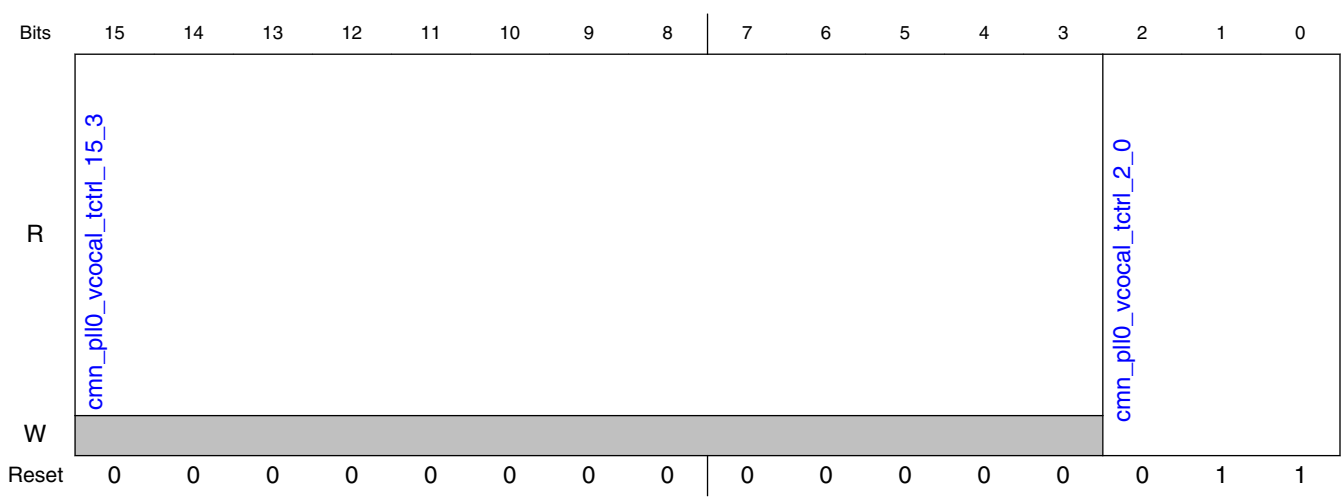
Field	Function
15 cmn_pll0_vcocal_start_15	Reserved
14-12 cmn_pll0_vcocal_start_14_12	VCO calibration initial step size control: This field specifies the initial step size for the VCO calibration state machine. The following are the values that can be used in this field, and the corresponding step sizes.
11-9 cmn_pll0_vcocal_start_11_9	Reserved
8-0 cmn_pll0_vcocal_start_8_0	VCO calibration code starting point value: This field specifies the starting VCO code that is used by the VCO calibration state machine. The purpose of this value is such that the VCO calibration process starts at a point that is, on average, relatively close to the final calibration point. This allows the calibration time to be reduced, on average.

13.4.10.2.438 PLL 0 VCO calibration timer control register (cmn_pll0_vcocal_tctrl)

13.4.10.2.438.1 Offset

Register	Offset
cmn_pll0_vcocal_tctrl	8_0082h

13.4.10.2.438.2 Diagram



13.4.10.2.438.3 Fields

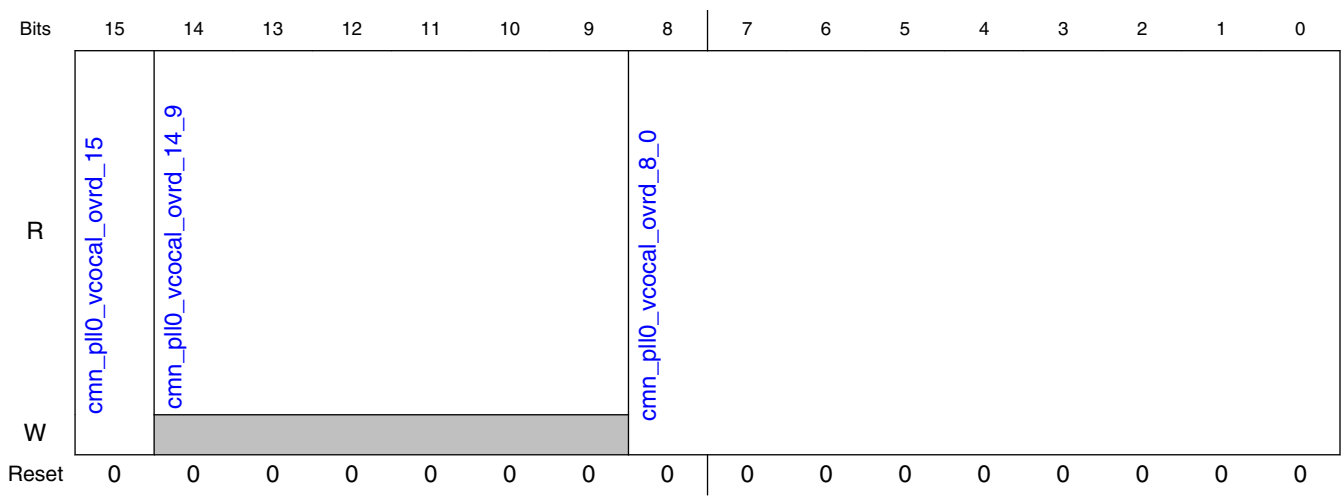
Field	Function
15-3 cmn_pll0_vcocal_tctrl_15_3	Reserved
2-0 cmn_pll0_vcocal_tctrl_2_0	VCO calibration initial time scale control: This field specifies the calibration start time scaling factor applied to the VCO calibration when running the initial step size for the calibration code is not set to 1. Setting this value to a value other than 1 will reduce the calibration measurement time by the amount specified below. Then when the final calibration steps are made the full calibration time will be used to get the appropriate amount of resolution.

13.4.10.2.439 PLL 0 VCO calibration override register (cmn_pll0_vcocal_ovrd)

13.4.10.2.439.1 Offset

Register	Offset
cmn_pll0_vcocal_ovrd	8_0083h

13.4.10.2.439.2 Diagram



13.4.10.2.439.3 Fields

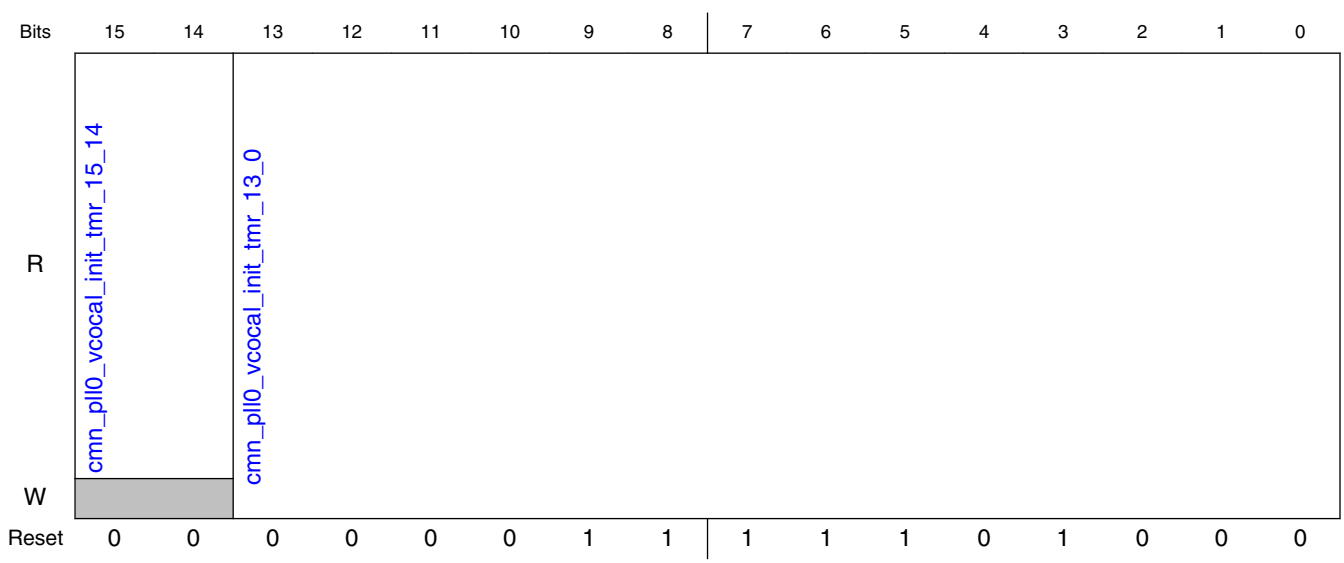
Field	Function
15 cmn_pll0_vcocal_ovrd_15	VCO calibration code override enable: Activating (1b1) this bit allows the VCO code determined during the automatic VCO calibration process to be overridden by the value driven by the VCO calibration code override value field in this register.
14-9 cmn_pll0_vcocal_ovrd_14_9	Reserved
8-0 cmn_pll0_vcocal_ovrd_8_0	VCO calibration code override value: This field is used to override the VCO code determined during the automatic VCO calibration process. The VCO code driven on this field is valid when the VCO calibration code override enable bit in this register is active.

13.4.10.2.440 PLL 0 VCO calibration initialization timer register (cmn_pll0_vcocal_init_tmr)

13.4.10.2.440.1 Offset

Register	Offset
cmn_pll0_vcocal_init_tmr	8_0084h

13.4.10.2.440.2 Diagram



13.4.10.2.440.3 Fields

Field	Function
15-14 cmn_pll0_vcocal_init_tmr_15_14	Reserved
13-0 cmn_pll0_vcocal_init_tmr_13_0	Initialization wait timer value: This is the number of clocks to wait between when the analog VCO calibration circuits are enabled, and when the first calibration code is driven to the analog.

13.4.10.2.441 PLL 0 VCO calibration iteration timer register (cmn_pll0_vcocal_iter_tmr)

13.4.10.2.441.1 Offset

Register	Offset
cmn_pll0_vcocal_iter_tmr	8_0085h

Register	Offset
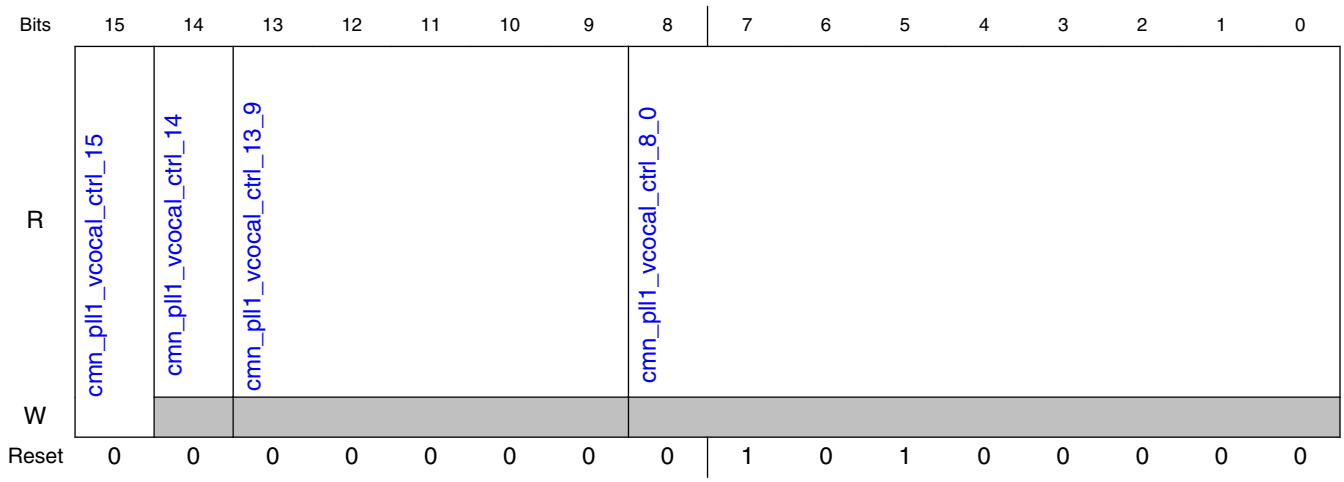
cmn_pll1_vcocal_ctrl	8_00A0h

13.4.10.2.455.2 Diagram



13.4.10.2.455.3 Fields

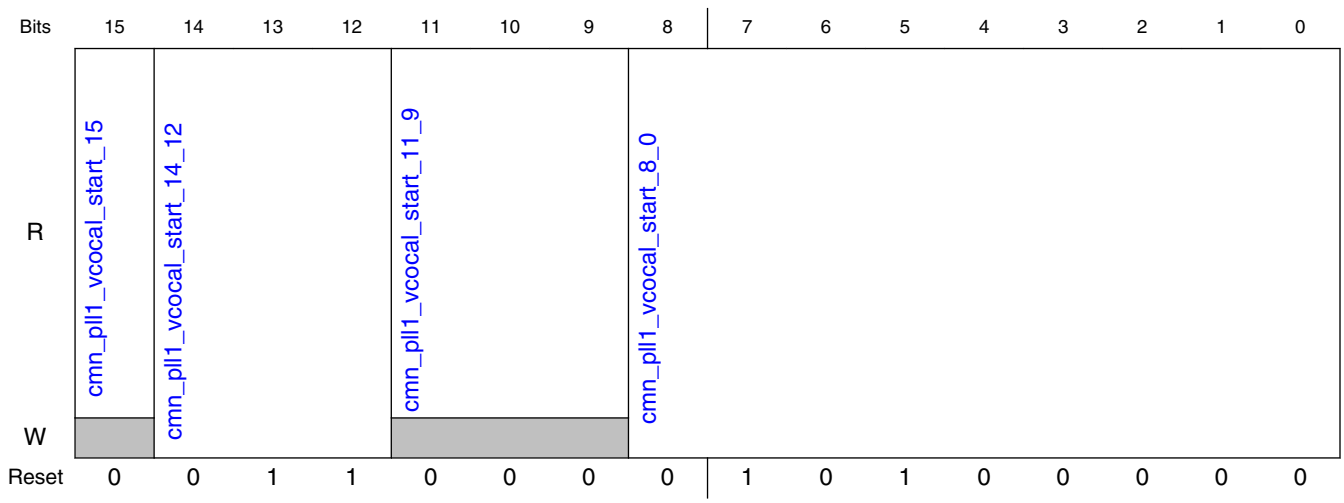
Field	Function
15 cmn_pll1_vcocal_ctrl_15	Start VCO calibration: Activating (1b1) this bit will start a VCO calibration process. This bit must remain active until the VCO calibration process is complete (as indicated by the VCO calibration process done bit in this register). To start another VCO calibration process, the VCO calibration process done bit must have gone inactive from any prior calibration process.
14 cmn_pll1_vcocal_ctrl_14	VCO calibration process done: This bit will be set to 1b1 when the VCO calibration process is complete. It will be cleared by the deactivation of the Start VCO calibration bit in this register.
13-9 cmn_pll1_vcocal_ctrl_13_9	Reserved
8-0 cmn_pll1_vcocal_ctrl_8_0	VCO calibration code: This is the calibration code that was determined by the VCO calibration process. This signal is valid when the VCO calibration process is complete. The values of this field correspond to different frequency bands the VCO will operate in. The frequency bands are controlled by the number of capacitors that are switched in the VCO analog circuit. This field specifies the number of capacitors that are switched in. The following are the values for this code:

13.4.10.2.456 PLL 1 VCO calibration start point register (cmn_pll1_vcocal_start)

13.4.10.2.456.1 Offset

Register	Offset
cmn_pll1_vcocal_start	8_00A1h

13.4.10.2.456.2 Diagram



13.4.10.2.456.3 Fields

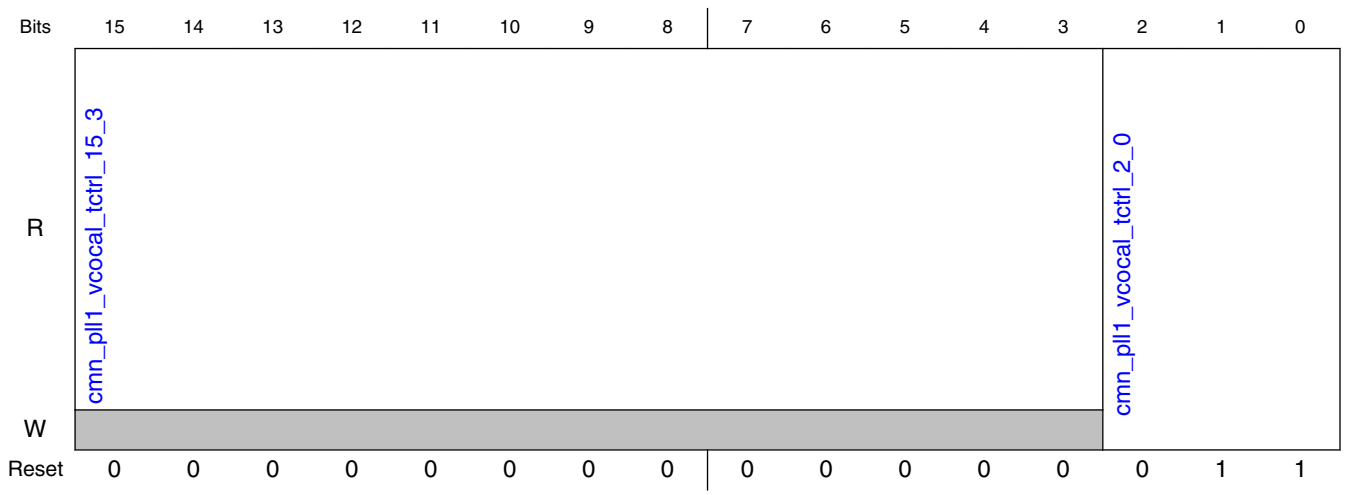
Field	Function
15 cmn_pll1_vcocal_start_15	Reserved
14-12 cmn_pll1_vcocal_start_14_12	VCO calibration initial step size control: This field specifies the initial step size for the VCO calibration state machine. The following are the values that can be used in this field, and the corresponding step sizes.
11-9 cmn_pll1_vcocal_start_11_9	Reserved
8-0 cmn_pll1_vcocal_start_8_0	VCO calibration code starting point value: This field specifies the starting VCO code that is used by the VCO calibration state machine. The purpose of this value is such that the VCO calibration process starts at a point that is, on average, relatively close to the final calibration point. This allows the calibration time to be reduced, on average.

13.4.10.2.457 PLL 1 VCO calibration timer control register (cmn_pll1_vcocal_tctrl)

13.4.10.2.457.1 Offset

Register	Offset
cmn_pll1_vcocal_tctrl	8_00A2h

13.4.10.2.457.2 Diagram



13.4.10.2.457.3 Fields

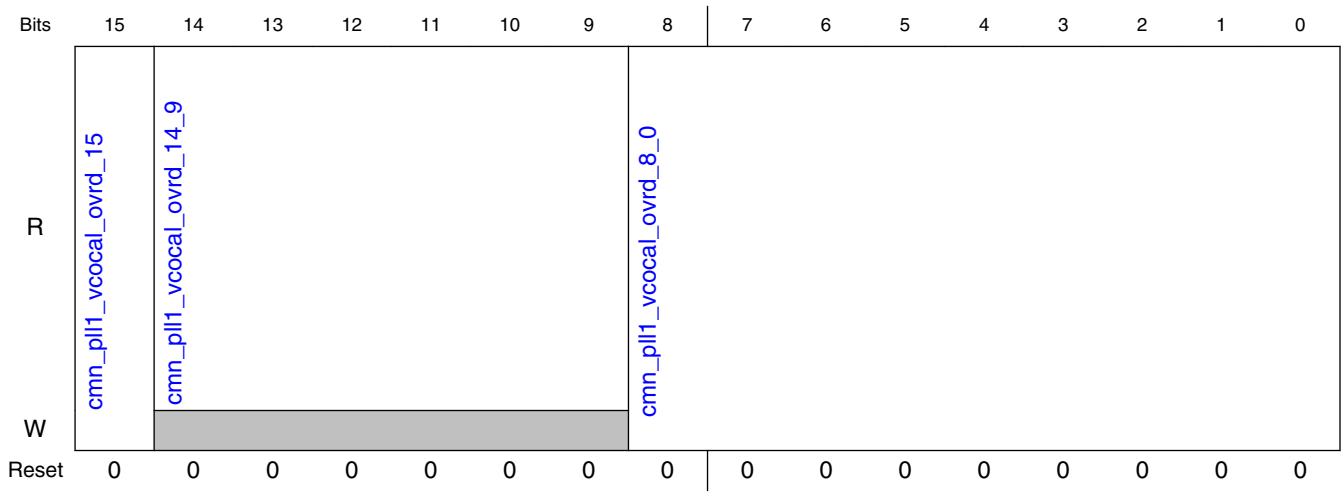
Field	Function
15-3 cmn_pll1_vcocal_tctrl_15_3	Reserved
2-0 cmn_pll1_vcocal_tctrl_2_0	VCO calibration initial time scale control: This field specifies the calibration start time scaling factor applied to the VCO calibration when running the initial step size for the calibration code is not set to 1. Setting this value to a value other than 1 will reduce the calibration measurement time by the amount specified below. Then when the final calibration steps are made the full calibration time will be used to get the appropriate amount of resolution.

13.4.10.2.458 PLL 1 VCO calibration override register (cmn_pll1_vcocal_ovrd)

13.4.10.2.458.1 Offset

Register	Offset
cmn_pll1_vcocal_ovrd	8_00A3h

13.4.10.2.458.2 Diagram



13.4.10.2.458.3 Fields

Field	Function
15 cmn_pll1_vcocal_ovrd_15	VCO calibration code override enable: Activating (1b1) this bit allows the VCO code determined during the automatic VCO calibration process to be overridden by the value driven by the VCO calibration code override value field in this register.
14-9 cmn_pll1_vcocal_ovrd_14_9	Reserved
8-0 cmn_pll1_vcocal_ovrd_8_0	VCO calibration code override value: This field is used to override the VCO code determined during the automatic VCO calibration process. The VCO code driven on this field is valid when the VCO calibration code override enable bit in this register is active.

13.4.10.2.459 PLL 1 VCO calibration initialization timer register (cmn_pll1_vcocal_init_tmr)

14 tx_ana_ctrl_reg_1_14	Controls auxda_se_en
13 tx_ana_ctrl_reg_1_13	Controls txda_cal_latch_en, Enable signal for latch that sample and holds calibration values. Activate this signal for 1 clock cycle to sample new calibration values.
12 tx_ana_ctrl_reg_1_12	Controls auxda_polarity, which selects the polarity of the xcvr
11 tx_ana_ctrl_reg_1_11	Controls txda_drv_power_isolation_en, Power island isolation signal.This signal is currently unused.
10	Controls txda_drv_power_en_ph_2_n, Power island enable signals.This signal is currently unused.

Table continues on the next page...

Field	Function
tx_ana_ctrl_reg_1_10	
9 tx_ana_ctrl_reg_1_9	Comtrols txda_drv_power_en_ph_1_n, Power island enable signals.This signal is currently unused.
8 tx_ana_ctrl_reg_1_8	Controls txda_bgref_en, which enables Bandgap Reference Circuit. Must be asserted after(X=5us) txda_drv_ldo_en, else held to default value
7 tx_ana_ctrl_reg_1_7	Controls txda_drv_ldo_en, which enables the transmitter circuits related to the driver LDO function
6 tx_ana_ctrl_reg_1_6	Controls txda_decap_en_del, delayed version(tX=100ns) of tx_decap_en
5 tx_ana_ctrl_reg_1_5	Controls txda_decap_en, which enables the analog decap circuits.
4 tx_ana_ctrl_reg_1_4	Controls txda_uphy_supply_en_del, delayed version (tX=100ns) of txda_uphy_supply_en
3 tx_ana_ctrl_reg_1_3	Controls txda_uphy_supply_en, which enables the transmitter UPHY components supply
2 tx_ana_ctrl_reg_1_2	Controls txda_low_leakage_en,
1 tx_ana_ctrl_reg_1_1	Controls txda_drv_idle_lowi_en,
0 tx_ana_ctrl_reg_1_0	Controls txda_drv_cmn_mode_en, which enables the analog circuits required, to hold the driver output at a common mode voltage when required.

13.4.10.2.558 DP Aux analog control 2 (tx_ana_ctrl_reg_2)

13.4.10.2.558.3 Fields

Field	Function
15 tx_ana_ctrl_reg_2_15	Controls auxda_debouncing_clk, required in MHL mode, for data reception
14 tx_ana_ctrl_reg_2_14	Controls txda_lpbk_recovered_clk_en,
13 tx_ana_ctrl_reg_2_13	Controls txda_lpbk_isi_gen_en
12 tx_ana_ctrl_reg_2_12	Controls txda_lpbk_serial_en, when enabled (1b1), the serial loopback path from a lanes serializer to its deserializer is activated.
11 tx_ana_ctrl_reg_2_11	Controls txda_lpbk_line_en, when enabled (1b1), the line side loopback path from a lanes serial receiver to its serial transmitter is activated.
10 tx_ana_ctrl_reg_2_10	Controls txda_drv_ldo_redc_sinkiq, when enabled (1'b1) reduces the no-load current from the driver LDO in order to reduce the settling time
9 tx_ana_ctrl_reg_2_9	Controls xcvr_decap_en_del. Delayed verion (tX=100ns) of xcvr_decap_en
8 tx_ana_ctrl_reg_2_8	Controls xcvr_decap_en, which must be enabled when the common module initially powers up, or exits the suspend mode.
7 tx_ana_ctrl_reg_2_7	Controls txda_mphy_enable_hs_nt
6	Controls txda_mphy_sa_mode, which enables the driver LDO small amplitude mode.

Table continues on the next page...

Field	Function
tx_ana_ctrl_reg_2_6	
5 tx_ana_ctrl_reg_2_5	Controls txda_drv_ldo_rbyr_fb_en, TX driver LDO VDD dependent feedback reference enable: Enables VDD dependent feedback reference to LDO.
4 tx_ana_ctrl_reg_2_4	Controls txda_drv_rst_pull_down
3 tx_ana_ctrl_reg_2_3	Controls txda_drv_ldo_bg_fb_en,
2 tx_ana_ctrl_reg_2_2	Controls txda_drv_ldo_bg_ref_en,
1 tx_ana_ctrl_reg_2_1	Controls txda_drv_predrv_en_del, delayed version (tX=100ns) os txda_predrv_en
0 tx_ana_ctrl_reg_2_0	Controls txda_drv_predrv_en,

13.5 HDMI / DisplayPort Transmit PHY (HDMI PHY)

13.5.1 Introduction

13.5.1.1 Overview

The HDMI and DisplayPort Transmit PHY consisting of a multi-protocol PMA, AUX/ ARC channel, and supporting components (APB interface, TAP controller, PHY and PMA isolation and control registers and clock and reset logic). In regards to the top level PHY specification, it is assumed that the reader of this document is familiar with these specifications.

Figure 13-33 illustrates a top-level block diagram for the PHY macro, and how it interfaces with an external MAC. The following are high level points worth noting in this fig- ure.

- The PMA isolation and control logic
  - It contains registers for controlling the PHY/PMA's power state and mode of operation.
- The Async APB Interface Slave module is part of a two module system that allows the internal CDB registers to be written and read by either the external APB interface or the integrated TAP interface. Both interfaces can access the internal CDB, with the TAP having higher priority.

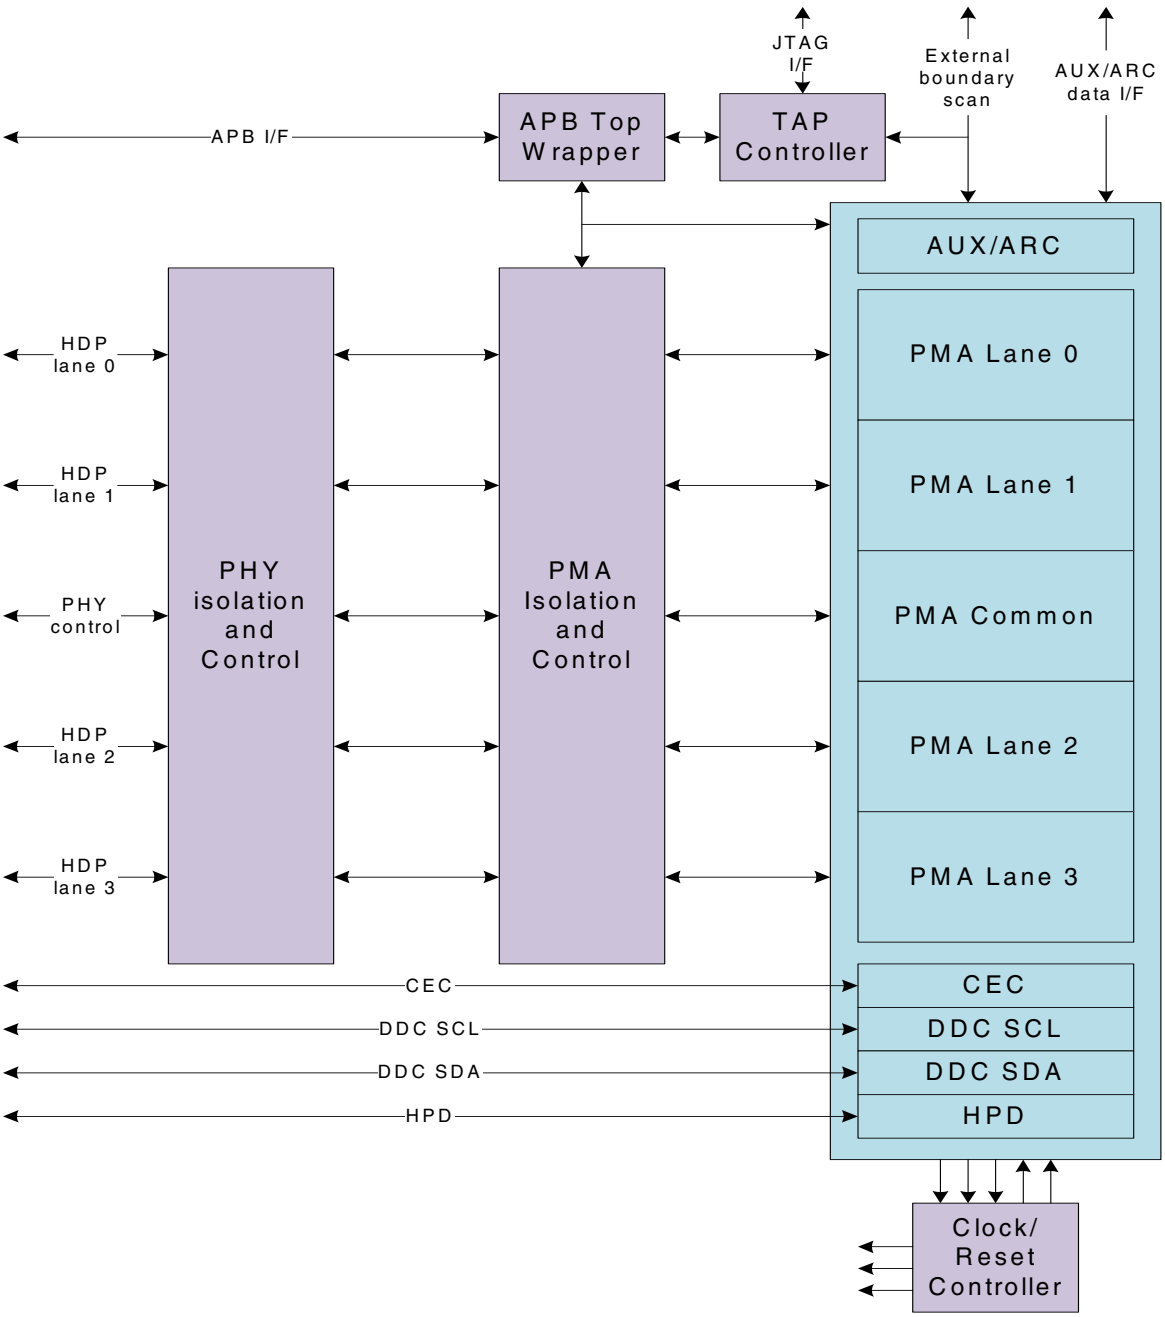

Figure 13-33. HDP PHY block diagram

13.5.1.2 Features

The features of the HDMI and DisplayPort Transmit PHY are listed below:

- Supported standards:
  - HDMI v2.0/1.4
  - DisplayPort 1.3 (RDR, HDR and HDR2 rates)
  - Embedded DisplayPort v1.4

NOTE

DP 1.3 HBR3, 8.1 Gbps, data rate not supported.

- 4 PMA TX lanes
- Supports DisplayPort AUX channel and HDMI ARC channel
- PMA and AUX/ARC
- 20-bit data interface width for both DP and HDMI
- Includes HPD, DDC SDA and SCL and CEC pads

13.5.2 External Signals

The external signals are listed in the table below:

Table 13-19. External signals

Signal Name	Direction	Type	Description
refclk_p refclk_m	input	Analog	PMA external reference clock. Only valid for DP. The HDMI pixel clock cannot be driven on these pins. For DP, supports nominal frequencies of 19.2, 20, 24, 27, 54 and 108 MHz. The following external reference clock sources are supported: • AC coupled differential low swing clock (HCSL levels) • DC single ended clock on refclk_p pin. In this mode refclk_m should be tied to ground. This mode is for test purposes only. For DP, a reference clock must be provided on either these external pins or on the refclock internal SoC-side pin.
tx_p_ln_{3:0} tx_m_ln_{3:0}	output	Diff	PMA transmitter serial data
rext	input	Analog	PMA external calibration resistor
aux_p aux_m	inout	Analog	AUX differential Tx/Rx serial data. For ARC, aux_p pin is used as input only.
hpd	inout	Analog	HDMI Hot Plug Detect
ddc_sda	inout	Analog	HDMI DDC serial data
ddc_scl	inout	Analog	HDMI DDC serial clock
cec	inout	Analog	HDMI CEC

13.5.3 On-Chip Functional Pin List

On-chip functional signals are listed in the table below:

Table 13-20. On-chip functional pin list

Signal Name	Direction	Type	Timing	Description
External APB Interface				
apb_pclk	input	CMOS	n/a	APB bus clock.
apb_preset_n	input	CMOS	async	APB bus reset.
apb_penable	input	CMOS	apb_pclk	APB bus enable.
apb_psel	input	CMOS	apb_pclk	APB bus device select.
apb_pwrite	input	CMOS	apb_pclk	APB bus write.
apb_paddr[15:0]	input	CMOS	apb_pclk	APB bus address.
apb_pwdata[15:0]	input	CMOS	apb_pclk	APB bus write data.
apb_prdata[15:0]	output	CMOS	apb_pclk	APB bus read data.
apb_pready	output	CMOS	apb_pclk	APB bus ready.
HDP Interface				
phy_reset_n	input	CMOS	async	**PHY reset** : Asserting this signal low will reset the PHY, with the exception of the APB registers.
phy_pma_tx_data_clk_in	input	CMOS	n/a	**Tx Data clock**. Transmit data clock. The Tx data is synchronous to this clock.
phy_pma_tx_data_clk_out	output	CMOS	n/a	**PHY data rate clock out** - 20-bit data rate clock out from PHY which provides the clock source for phy_pma_tx_data_clk_in, so that the PHY transmit inter- face is source synchronous.
phy_pma_tx_data_ln_{3:0}[19:0]	input	CMOS	phy_pma_tx_data_clk_in	**Transmit data**. HDMI/ Display Tx display data. Synchro- nous to phy_pma_tx_data_clk_in.
phy_pma_char_clk_out	output	CMOS	n/a	**PHY character clock out** - 10-bit free running clock from PHY. Runs at 2x frequency of phy_pma_tx_data_clk_out. Frequency aligned, but not edge aligned

Table continues on the next page...

Table 13-20. On-chip functional pin list (continued)

Signal Name	Direction	Type	Timing	Description
				(not synchronous) to phy_pma_tx_data_clk_out.
AUX / ARC Interface				
source_aux_arc_oen	input	CMOS	async	**AUX/ARC output enable** : 1 : Receive mode 0 : Transmit mode For ARC, the AUX/ARC block will always be in receive mode. Therefore, this pin shall be tied high for HDMI operation.
source_aux_data_in	input	CMOS	async	**AUX transmit data -** For HDMI Tx, ARC is only used as a receiver and thus there is not ARC transmit data.
source_aux_arc_data_out	output	CMOS	async	**AUX/ARC receive data**
PMA Interface				
refclock	input	CMOS	n/a	**PMA internal reference clock input -** Single-ended alternate reference clock input. For DP, supports nominal frequencies of 19.2, 20, 24, 27, 54 and 108 MHz. For HDMI, the pixel clock must be driven on this pin with a frequency range from 25 to 600 MHz. PHY_PMA_CMN_CTRL1[6:4] is used to select between refclock and refclk_<p/m> as the reference clock source. refclock must be selected as the reference clock source for HDMI.
pma_refclk_rcv_out	output	CMOS	n/a	**PMA common reference clock receiver output -** Clock output from the analog reference clock receiver circuits. Frequency is always the same as the selected reference

Table continues on the next page...

Table 13-20. On-chip functional pin list (continued)

Signal Name	Direction	Type	Timing	Description
				clock input. Once enabled, this clock is free-running and is active in all power states (provided the input reference clock is running). This clock is enabled by setting PHY_PMA_CMN_CTRL1[3]. This clock is provided for use by the SoC, if needed.
HPD Interface				
hpd_in_from_pad	output	CMOS	n/a	**HPD pad data in**
hpd_out_high_to_pad	input	CMOS	n/a	**HPD pad output drive high**
hpd_out_low_to_pad	input	CMOS	n/a	**HPD pad output drive low**
hpd_out_drv_strength[1:0]	input	CMOS	static	**HPD pad output drive strength -** Selects output drive strength for HPD pad.
hpd_out_en_to_pad	input	CMOS	n/a	**HPD pad output enable -** 1 = output mode 0 = input mode
hpd_power_down_to_pad	input	CMOS	n/a	**HPD pad power down -** 1 = power down HPD pad 0 = normal mode
phy_pma_pixel_clk_out	output			PHY Pixel clock out - Pixel clock output from PHY.
DDC SDA Interface				
ddc_sda_in_from_pad	output	CMOS	n/a	**DDC SDA pad in**
ddc_sda_out_high_to_pad	input	CMOS	n/a	**DDC SDA pad output drive high**
ddc_sda_out_low_to_pad	input	CMOS	n/a	**DDC SDA pad output drive low**
ddc_sda_out_drv_strength[1:0]	input	CMOS	n/a	**DDC SDA pad output drive strength -** Selects output drive strength for DDC SDA pad.
ddc_sda_out_en_to_pad	input	CMOS	n/a	**DDC SDA pad output enable -**

Table continues on the next page...

Table 13-20. On-chip functional pin list (continued)

Signal Name	Direction	Type	Timing	Description
				1 = output mode 0 = input mode
ddc_sda_power_down_to_pad	input	CMOS	n/a	**DDC SDA pad power down -** 1 = power down DDC SDA pad 0 = normal mode
DDC SCL Interface				
ddc_scl_in_from_pad	output	CMOS	n/a	**DDC SCL pad in**
ddc_scl_out_high_to_pad	input	CMOS	n/a	**DDC SCL pad output drive high**
ddc_scl_out_low_to_pad	input	CMOS	n/a	**DDC SCL pad output drive low**
ddc_scl_out_drv_strength[1:0]	input	CMOS	n/a	**DDC SCL pad output drive strength -** Selects output drive strength for DDC SDA pad.
ddc_scl_out_en_to_pad	input	CMOS	n/a	**DDC SCL pad output enable -** 1 = output mode 0 = input mode
ddc_scl_power_down_to_pad	input	CMOS	n/a	**DDC SCL pad power down -** 1 = power down DDC SCL pad 0 = normal mode
CEC Interface				
cec_in_from_pad	output	CMOS	n/a	**CEC pad in**
cec_out_high_to_pad	input	CMOS	n/a	**CEC pad output drive high**
cec_out_low_to_pad	input	CMOS	n/a	**CEC pad output drive low**
cec_out_drv_strength[1:0]	input	CMOS	n/a	**CEC pad output drive strength -** Selects output drive strength for DDC SDA pad.
cec_out_en_to_pad	input	CMOS	n/a	**CEC pad output enable -** 1 = output mode 0 = input mode
cec_power_down_to_pad	input	CMOS	n/a	**CEC pad power down -**

13.5.4 PHY Clocking and Reset

This section describes the details of the PHY clocking and reset functions. Note that what is described here is the top level function.

13.5.4.1 Reference and Data Path Clocking

Figure 13-34 illustrates the clocking associated with the reference clock and data path clocks. The following points should be noted about this function.

- The selection of the internal (refclock) or external (refclk_p / refclk_m) clock as the source for the PMA clock, and ulti- mately generates cmn_pllclk_datart0 PMA clock output is controlled by a PMA APB register.
- phy_pma_tx_data_clk_in must be driven from phy_pma_tx_data_clk_out. The DP/HDMI transmit data for all lanes (phy_pma_tx_data_ln_<>[19:0]) is synchronous to phy_pma_tx_data_clk_in.

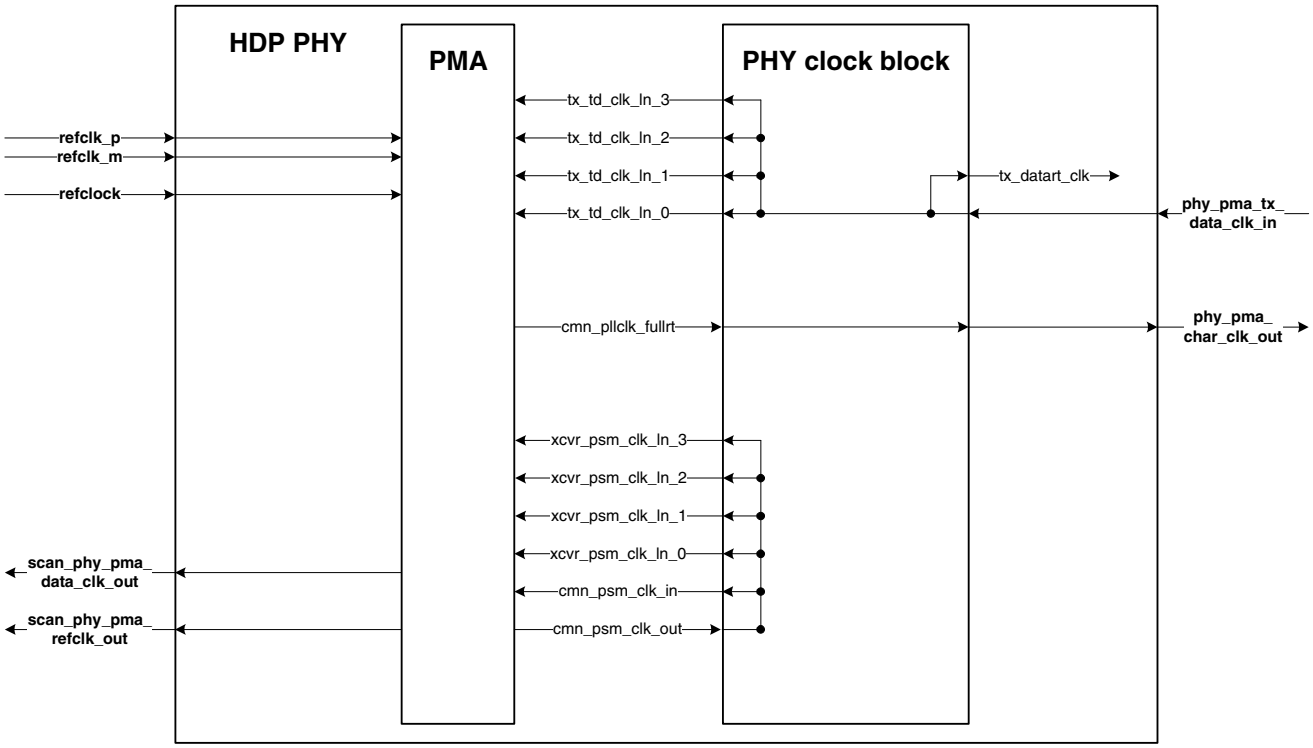

Figure 13-34. PHY clocking block diagram

13.5.4.2 Reset Distribution

All resets are active low, asynchronously activated, and synchronously deactivated (synchronized internally).

phy_reset_n is master reset for entire PHY. Asserting phy_reset_n will drive reset to entire PHY, except for APB and TAP controller registers.

When phy_reset_n is released, a reset sequencer controls the release of the various resets for the entire macro, as follows:

- After phy_reset_n is released, cmn_reset_n going to the PMA is released.
- The PHY reset sequencer waits for cmn_ready from the PMA to go active, indicating common modules are powered up, calibrated, and the PLL has locked.
- At this point, all other resets going to logic in the PHY are synchronously released (1 for each internal PHY clock domain).

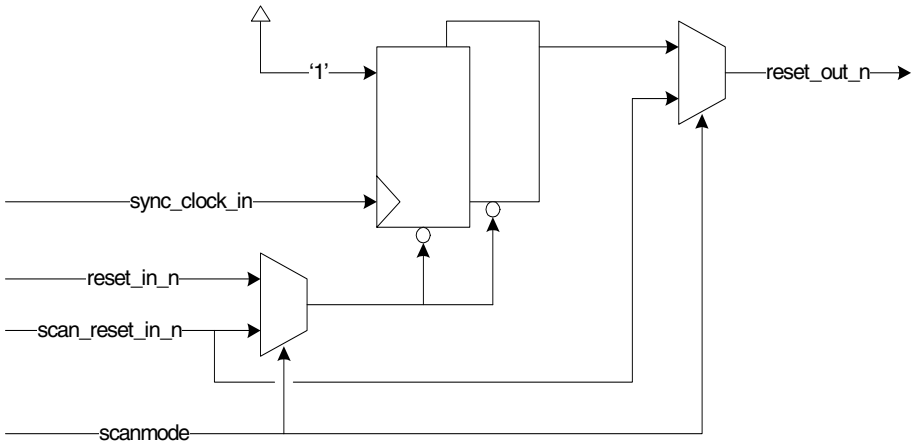

Figure 13-35. Reset synchronizer

13.5.4.3 PHY Clocking

The following table shows the clock names and their associated frequencies in PHY.

Table 13-21. Clock and frequency details

Clock Name	Maximum Frequency (MHz)
refclk_p	600
refclk_m	600
apb_pclk	200
phy_pma_tx_data_clk_in	300
phy_pma_tx_data_clk_out	300
phy_pma_char_clk_out	600
refclock	600
pma_refclk_rcv_out	600
tap_tck	100
scan_phy_pma_refclk_in	200
scan_phy_pma_data_clk_in	300
scan_phy_pma_refclk_out	600
scan_phy_pma_data_clk_out	300
tx_bscan_ext_clockdr	100
tx_bscan_ext_updatedr	100
phy_pma_pixel_clk_out	600

13.5.4.4 Reset Pins

The following table shows the reset names and their polarities.

Table 13-22. Reset pins and their polarities

Reset Name	Polarity
apb_preset_n	Active Low
phy_reset_n	Active Low
tap_trst_n	Active Low

13.5.5 PHY Register Read through TAP

- As required, write PHY macro diagnostic control register with 0x3 to source APB clock from TAP clock.
- Write address of APB register to PHY macro diagnostic APB access address register.
- Write 0x2 to PHY macro diagnostic APB access control register.
- Read PHY macro diagnostic APB access control register. If [0] is set high, continue. Otherwise, read PHY macro diagnostic APB access control register again.
- Read PHY macro diagnostic APB access read data register, which contains the read data.

13.5.6 PHY Register Write through TAP

- As required, write PHY macro diagnostic control register with 0x3 to source APB clock from TAP clock.
- Write address of APB register to PHY macro diagnostic APB access address register.
- Write data to be written to PHY macro diagnostic APB access write data register.
- Write 0x6 to PHY macro diagnostic APB access control register.
- Read PHY macro diagnostic APB access control register. If [0] is set high, the write access is complete. Otherwise, read PHY macro diagnostic APB access control register again.

13.5.7 Functional Description

This section describes PHY functional operation, such as start-up, disable, transmitting data, changing power state and changing the data rate.

13.5.7.1 Start-up Sequence Timing Diagram

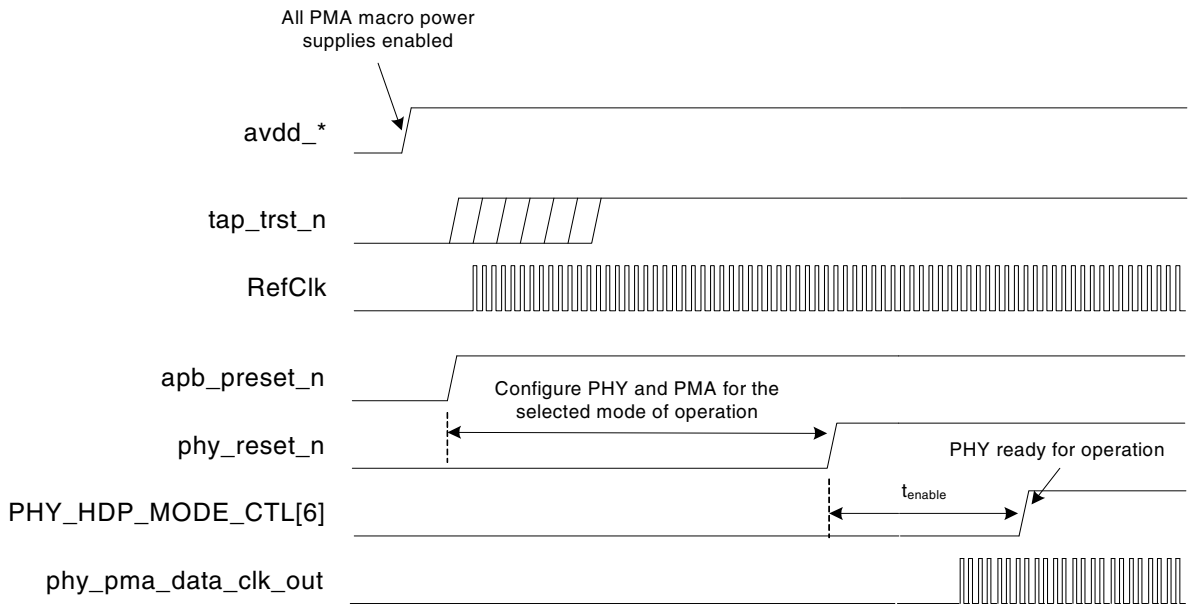

Figure 13-36. Start-up Sequence

Prior to de-assertion of phy_reset_n, write PHY_HDP_MODE_CTL[3:0] with 0x4 (0b0100). Upon start-up, the initial power state for each PMA lane must be A2. The PHY indicates ready for operation upon assertion (high) of the corresponding PHY_HDP_MODE_CTL[6] acknowledgement bit.

13.5.7.2 PHY Disable Description

To disable the PHY, assert apb_preset_n and phy_reset_n low and disable PMA reference clock (refclk_<p/m>/refclock) and apb_pclk. Note: apb_preset_n must be asserted at the same time as or after phy_reset_n is asserted. To re-enable the PHY follow the start-up sequence described above.

13.5.7.3 DP Transmit Data Path Timing Diagram

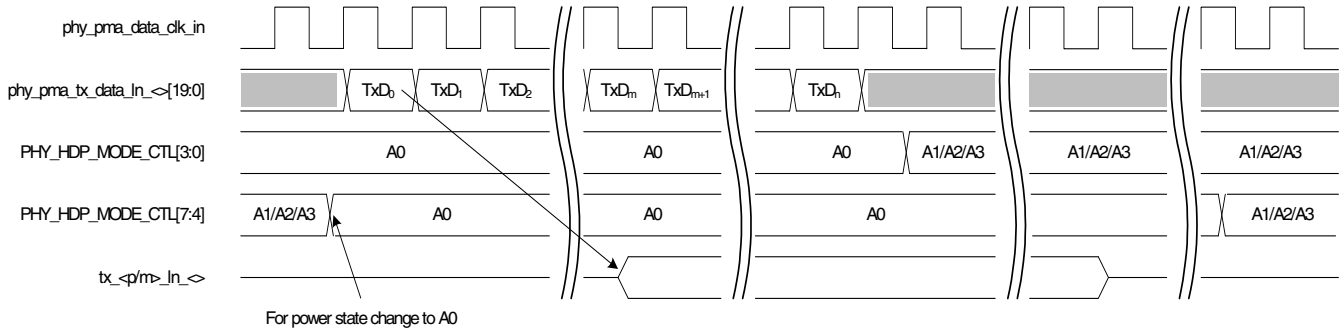

Figure 13-37. DP transmit data path

The HDP PHY must be in the A0 power state in order to transmit data. When in the A0 power state, the data provided on phy_pma_tx_data_ln_* is transmitted on tx_<p/m>_ln_*. When exiting the A0 power state, there is a race condition between the last data provided on phy_pma_tx_data_ln_* traversing the PMA and the PMA changing its power state. This may result in this data not being transmitted. Therefore, it is recommend to send a minimum of 4 dummy words into the PHY after the last valid data word prior to changing the PHY's power state.

13.5.7.3.1 HDMI TMDS Clock Lane

For the HDMI TMDS clock lane, the 20-bit data pattern depends on the HDMI data rate.

- For HDMI 1.4 data rates, a fixed 20-bit data pattern shall be driven on phy_pma_tx_data_ln_<> : 20'b1111_1000_0011_1110_0000 (5 1s, 5 0s, 5 1s, 5 0s).
- For HDMI 2.0 data rates, a repeating pattern that toggles every phy_pma_tx_data_clk_in clock cycle shall be driven on phy_pma_tx_data_ln_<> : toggle between 20'hF_FFFF and 20'h0_0000 (repeating all 1s, then all 0s).

13.5.7.4 Power State Change

The procedure for changing the PHY's power state is:

- Write PHY_HDP_MODE_CTL[3:0] with one-hot encoded value for the new power state (0b0001 = A0, 0b0010 = A1, 0b0100 = A2 and 0b1000 = A3).
- Wait for PHY_HDP_MODE_CTL[7:4] = value for the selected power state.

A0 is the active power state. A1, A2 and A3 are various power down states, with A1 having the fastest recovery to A0 time, but the lowest power savings and A3 having the slowest recovery time, but largest power savings.

13.5.7.5 Data Rate/DP Lane Configuration Change

The procedure for changing the PHY's power state and/or the DisplayPort lane configuration is:

- Write PHY_HDP_MODE_CTL[3:0] with 0b1000. (Place the PHY lanes in the A3 power state.)
- Wait for PHY_HDP_MODE_CTL[7:4] == 0b1000.
- Clear PHY_HDP_CLK_CTL[2]. Gate the PLL clocks from PMA.
- Wait for PHY_HDP_CLK_CTL[3] == 0.
- Clear PHY_HDP_CLK_CTL[0]. Disable the PLL.
- Wait for PHY_HDP_CLK_CTL[1] == 0.
- Re-configure PMA registers for the new data rate (as defined in the PMA specification / programmer's guide) and/or DP lane configuration.
- Set PHY_HDP_CLK_CTL[0]. Enable the PLL.
- Wait for PHY_HDP_CLK_CTL[1] == 1.
- Set PHY_HDP_CLK_CTL[2]. Enable PMA PLL clocks.
- Wait for PHY_HDP_CLK_CTL[3] == 1.
- Write PHY_HDP_MODE_CTL[3:0] with 0b0100 (A2 power state). The PMA must go through the A2 power state upon a data rate change.
- Wait for PHY_HDP_MODE_CTL[7:4] == 0b0100.
- As required, change the PHY power state to A0.

13.5.7.6 Lane Mapping

For the HDP PHY, the PHY lanes have a fixed mapping to the PMA lanes as follows:

- PHY HDP lane 0 → PMA lane 0 (master lane)
- PHY HDP lane 1 → PMA lane 1
- PHY HDP lane 2 → PMA lane 2
- PHY HDP lane 3 → PMA lane 3

13.5.7.7 PMA TX Sync FIFO control

Each PMA lane outputs the following Tx FIFO control signals: tx_sfifo_enq_reset_n_out_ln_<> and tx_sfifo_align_bump_out_ln_<>. Similarly, each PMA lane has a tx_sfifo_enq_reset_n_in_ln_<> and tx_sfifo_align_bump_in_ln_<>. These signals are used to properly align the Tx Sync FIFOs for lanes combined into multi- lane links in order to meet the Tx inter-lane skew requirements. There are 2

aspects to this: (1) the Tx FIFOs for each DP lane must be released from reset on the same clock cycle (through use of a common, re-synchronized tx_sfifo_enq_reset_n_out_ln_<> signal) and (20 the write pointers must be adjusted by the same amount offset from the read pointer by a common tx_sfifo_align_bump_in_<> signal.

To accomplish this, one of the PMA lanes must be selected as the master lanes. The lowest numbered enabled PMA lane (as configured in PHY_DP_MODE_CTL[15:12]) is used as the master lane.

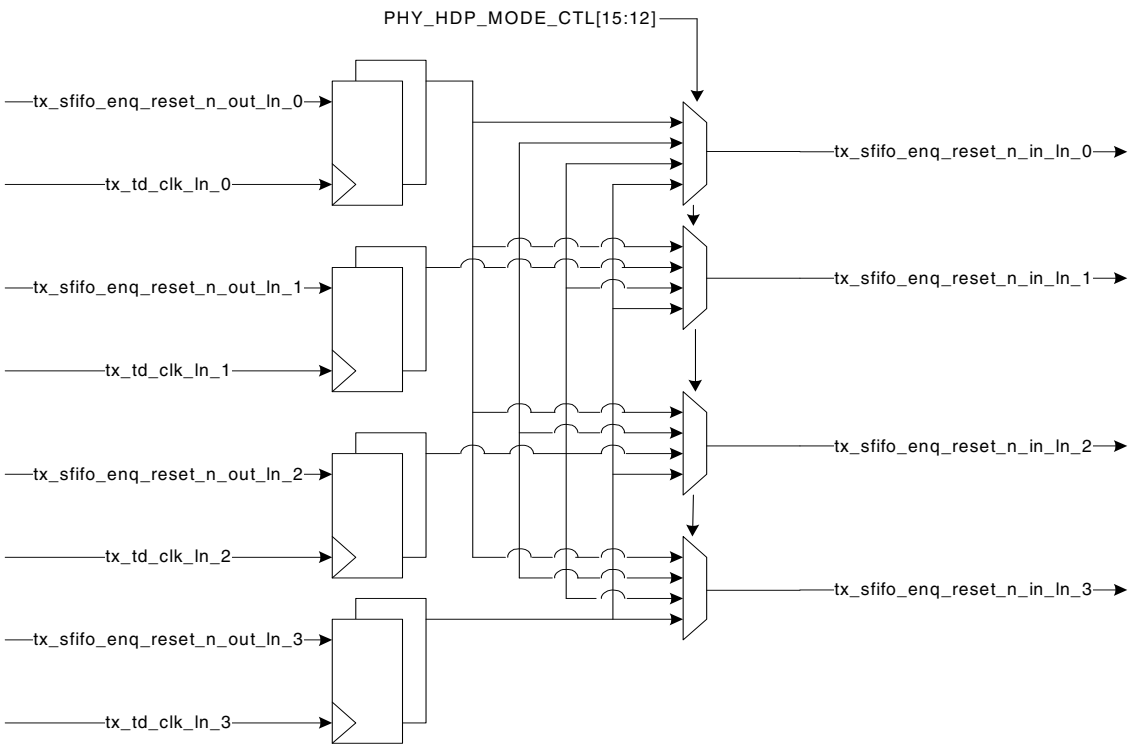

Figure 13-38. tx_sfifo_enq_reset_n_in_ln_<> generation

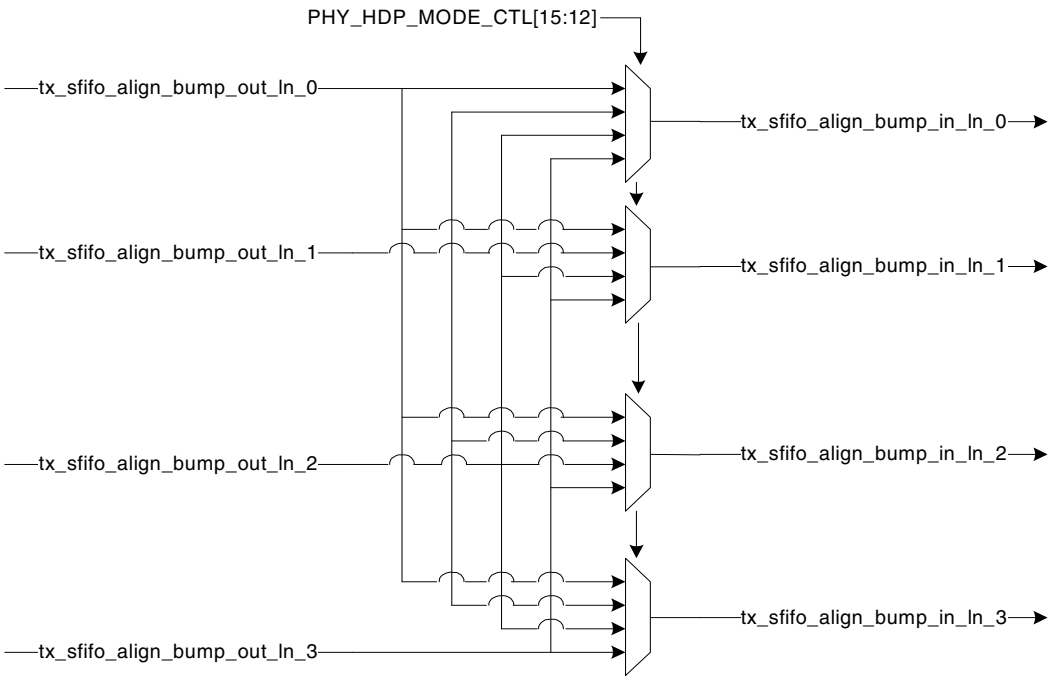

Figure 13-39. tx_sfifo_align_bump_in_ln_<> generation

13.6 MIPI DSI Host Controller (MIPI_DSI)

13.6.1 Overview

The Mobile Industry Processor Interface (MIPI) Display Serial Interface (DSI) controller is a flexible, high-performance, and easy-to-use digital core that implements all protocol functions defined in the MIPI DSI Specification. The MIPI DSI controller provides an interface that allows communication with MIPI DSI-compliant peripherals.

The MIPI DSI D-PHY is a high frequency, low power, low-cost, source-synchronous, physical layer supporting the MIPI Alliance standard for D-PHY.

13.6.2 Features

Key features of the MIPI DSI Controller Core include:

- Implements all three DSI Layers (Pixel to Byte packing, Low Level Protocol, Lane Management)
- Support for Command and Video Modes
- Host Version
- Scalable data lane support, 1 to 4 Data Lanes

    - Optional bidirectional support on lane 0
- Supports High Speed and Low Power operation
- Support for all DSI data types and formats
- Virtual Channel support
- Supports ULPS mode
- Full Low-Level Protocol Error and Contention detection and reporting
- Supports continuous and non-continuous Clock Lane operation
- Supports multiple packets per transmission
- Support for all three Video Mode packet sequences
    - Non-Burst Mode with Sync Pulses
    - Non-Burst Mode with Sync Events
    - Burst mode
- Support for bus turnaround signaling
- Flexible packet based user interface
    - APB interface option (status and control)
    - Display Pixel Interface Core (DPI-2) option
    - Display Bus Interface Core (DBI-2) option
- Supports PHY Protocol Interface (PPI) compatible MIPI D-PHYs
- MIPI Alliance Specification for Display Serial Interface Version 1.1 compliant

The following are the key features of the MIPI DSI D-PHY:

- 1 Clock lane
- 4 data lanes
- Supports MIPI Standard for D-PHY
- Supports both high speed and low power modes
- High Speed Serializers and Deserializers
- Resistance termination calibrator

13.6.3 DSI Host Controller Core

The figure below illustrates the DSI Host Controller Core structure. The DSI Host Controller Core operates on the host (transmit) side of a DSI link.

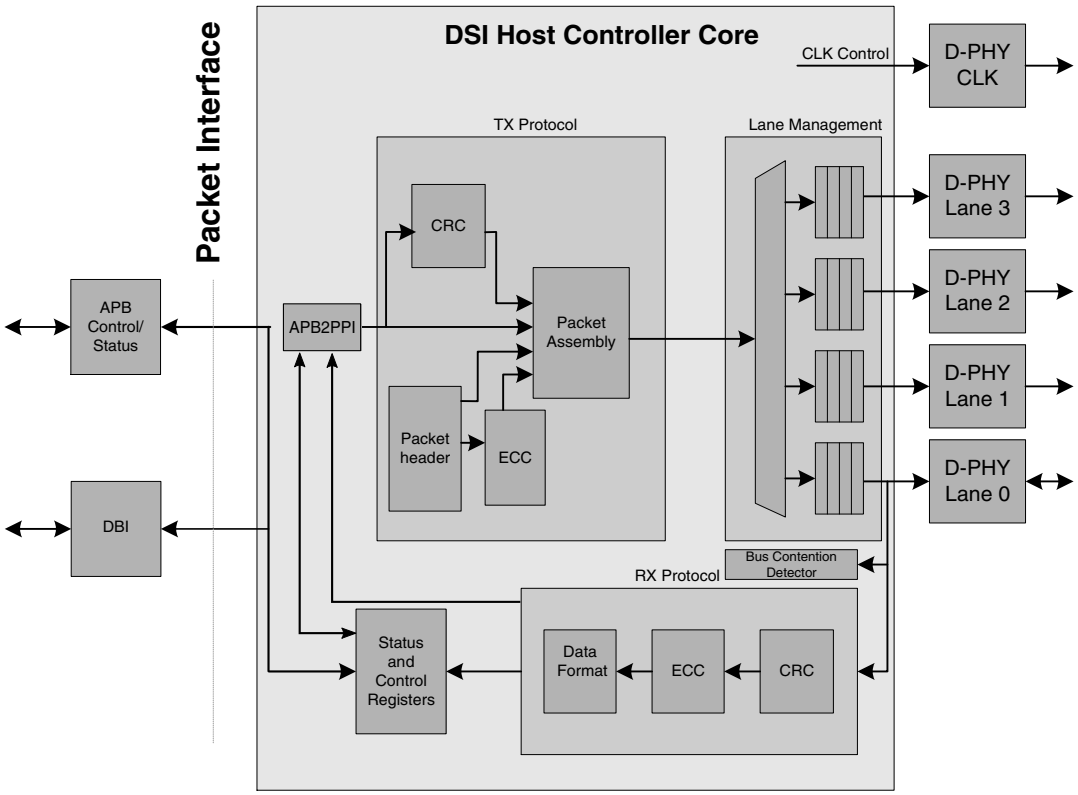

Figure 13-40. DSI Host Controller Core Block Diagram

The DSI Host Controller Core implements all three layers defined by the DSI Specification: Pixel to Byte Packing in the Application layer, Low Level Protocol, and Lane Management. The DSI Host Controller Core sends and receives DSI commands via the Packet Interface. The Packet Interface can be connected to a DBI/DPI translator or to an APB to PPI gasket.

The D-PHY interface of the DSI Host Controller Core supports up to four PHY Protocol Interface (PPI) compatible MIPI D-PHYs.

The Packet Interface is an easy-to-use data interface that accepts commands and data, and sends it over the DSI link. It supports 1 to 4 virtual channels, and the use of 1-4 D-PHY lanes. The DSI Host Controller Core takes care of all packet formatting details and transmission over the MIPI bus.

The DBI/DPI Translator connects to the DSI Host Controller Core via the Packet Interface. DBI/DPI masters may connect directly to the DBI/DPI Translator to send commands across the DSI link.

Sending commands and receiving information through the DSI link is also possible through the APB to PPI gasket. See MIPI DSI Host APB PKT IF Memory Map/Register section for details about the DSI registers which allow the APB to PPI setup and communication.

13.6.3.1 D-PHY Interface

The DSI Host Controller Core D-PHY Interface connects directly to MIPI PPI compliant D-PHYs. The DSI Host Controller Core uses this interface to transmit data, send Escape sequences, receive and transmit triggers, and detect and report D-PHY error conditions.

13.6.3.1.1 High-Speed Transmit Interface

The High-Speed Transmit interface is used to transmit High-Speed data across the MIPI interface. All signals are synchronous to the PPI TX byte clock, TxByteClkHS, and are PPI compliant.

13.6.3.1.2 Escape Mode Transmit Interface

The DSI Host Controller Core uses the Escape Mode Transmit Interface to generate Escape sequences on the MIPI Interface via the D-PHY. Escape sequences are used to change the DPHY transmit mode, go into low-power mode, or initiate a bus turnaround. The Controller generates Escape sequence requests when necessary to implement the DSI protocol. These signals are synchronous to the clk_esc.

13.6.3.1.3 Escape Mode Receive Interface

The DSI Host Controller Core uses the Escape Mode Receive Interface to receive Escape sequences on the MIPI Interface via the D-PHY. The Controller receives Escape sequence requests and Low Power data when necessary to implement the DSI protocol.

The DSI protocol uses Lane 0 in LP mode for returning data from the peripheral to the host. Receive Interface signals are only applicable to the MIPI D-PHY Lane 0. These signals are synchronous to the RxClkEsc_ln0.

13.6.3.2 Packet Interface

The DSI Host Controller Core Packet Interface consists of Transmit, Receive, and Control and Status sections. Through these interfaces, the user application can take complete control of the DSI interface, sending all video timing, sending DSI commands, receiving DSI reads, monitoring the status of the interface and responding to error reporting.

User application may have access to DSI Host Controller Core Packet Interface through DSI_HOST_APB_PKT_IF registers. For details refer to the section MIPI_DSI_HOST_APB_PKT_IF

13.6.3.2.1 Transmit Ports

The Transmit Packet Interface is the mechanism with which the user creates packets to send over the MIPI Interface.

For Long Packets, the user provides the Virtual Channel (VC) number, Data Type (DT), and Word Count (WC) to the controller. The Controller then creates a packet header and pulls the packet data from the Packet Interface and out to the D-PHY to transmit.

For Short Packets, the user provides the Virtual Channel (VC) number, Data Type (DT), and required parameters (if any) to the controller. The Controller then creates the short packet and sends it to the D-PHY to transmit. This interface enables the user application to transmit and receive any type of DSI packet.

The Packet Interface Transmit Interface ports are listed in the table below. Signals are synchronous to the Tx Byte clock.

NOTE

Only a subset of the Packet Interface Signals are accessible by user application through DSI_HOST_APB_PKT_IFx registers or chip-specific registers. For reset_byte_n and reset_esc_n signals, refer to chip-specific MIPI DSI information. For tx_payload, tx_cmd_data_type, tx_cmd_vc, and tx_cmd_byte_count signals, refer to DSI_HOST_APB_PKT_IFx registers.

Table 13-23. DSI Host Controller Core Transmit Packet Interface

PORT	TYPE	DESCRIPTION
clk_byte	Input	Byte clock input. The D-PHY PPI interface, the tx_cmd and tx_payload interfaces are synchronous to clk_byte. This clock can be independent and unrelated to clk_esc.
clk_esc	Input	The low-speed D-PHY Escape Mode clock, which becomes TxClkEsc on the D-PHY interface. This clock can be independent and unrelated to clk_byte.
reset_byte_n	Input	Asynchronous reset, active low. This reset applies to all logic in the clk_byte clock domain.
reset_esc_n	Input	Asynchronous reset, active low. This reset applies to all logic in the clk_esc clock domain.
tx_payload[31:0]	Input	Packet data input.

Table continues on the next page...

Table 13-23. DSI Host Controller Core Transmit Packet Interface (continued)

PORT	TYPE	DESCRIPTION
tx_payload_en	Output	Packet data read enable. This active high signal indicates that the controller requires a valid packet during the next clk_byte period.
tx_payload_en_last	Output	Last packet read enable, active high signals last cycle of tx_payload_en.
tx_cmd_data_type[5:0]	Input	Transmit packet DSI data type. It is written into the command buffer when tx_cmd_ack is asserted high.
tx_cmd_vc[1:0]	Input	Transmit packet command virtual channel. It is written into the command buffer when tx_cmd_ack is asserted high.
tx_cmd_byte_count[15:0]	Input	Transmit packet payload byte count. It is written into the command buffer when tx_cmd_ack is asserted high. For DSI Long packet types, tx_cmd_byte_count defines the number of bytes of packet data to pull from the tx_payload port. For DSI Short packets, the format of tx_cmd_byte_count contains any optional parameters. If the SDI Short packet type does not have any parameters, it is recommended to set tx_cmd_byte_count to all 0s.
tx_cmd_req	Input	Transmit packet command request. This active high signal informs the controller that the packet command is valid. The packet command consists of the ports tx_cmd_data_type, tx_cmd_vc, and tx_cmd_byte_count. The controller will assert tx_cmd_ack when it accepts the command, after which, the user should either update port values for the next transmit packet command or deassert tx_cmd_req.
tx_cmd_ack	Output	Transmit packet command request acknowledge. This active high signal indicates that the controller has accepted the TX packet request and the user logic should either submit a new request or deassert tx_cmd_req on the next rising edge of clk_byte.
trigger_req	Input	Transmit trigger request. This active high signal informs the controller that the trigger number on trigger_send is valid. The controller will assert trigger_ack when it accepts the command, after which, the user should either put update trigger_ack with the values for the next transmit packet or deassert trigger_req.
trigger_ack	Output	Transmit trigger request acknowledge. This active high signal indicates that the controller has accepted the trigger request and the user logic should either submit a new request or deassert trigger_req on the next rising edge of user_clk.
trigger_send[1:0]	Input	Transmit trigger. The trigger number on trigger_send is sampled when trigger_ack is asserted high. The format of trigger_send is as follows: 1’b00 = Trigger 0 (Reset-Trigger) 1’b01 = Trigger 1 ([Reserved]) 1’b10 = Trigger 2 ([Reserved]) 1’b11 = Trigger 3 ([Reserved])

13.6.3.2.2 Receive Ports

The Receive Packet Interface returns data from the Peripheral to the user. The user is provided the Virtual Channel (VC) number, Data Type (DT), Word Count (WC), and Rx Payload Data.

This interface enables the user application to receive any type of DSI packet. These signals are synchronous to the clk_byte clock. The Packet Interface Receive Interface ports are listed in the table below.

NOTE

Only a subset of the Packet Interface signals are accessible by user application through DSI_HOST_APB_PKT_IFx registers and DSI_HOST device registers:

- rx_payload
- rx_cmd_vc
- rx_cmd_data_type
- rx_cmd_byte_count
- ecc_one_bit_error
- ecc_two_bit_error
- ecc_one_bit_error_pos[4:0]
- ecc_err
- ecc_err_pos[2:0]
- crc_err

See DSI_HOST_APB_PKT_IFx and DSI_HOST device sections for details.

Table 13-24. DSI Host Controller Core Receive Packet interface

PORT	TYPE	DESCRIPTION
rx_payload[31:0]	Output	Received packet data output. The Host Receive Packet Interface presents 4 bytes at a time. Bytes are valid in this interface according to the rx_cmd_byte_count signal, beginning with the lowest byte.
rx_payload_valid	Output	Packet data valid. This active high signal indicates that the controller is presenting valid packet during the next clk_byte period.
rx_payload_valid_last	Output	This data is the last of the packet, active high signals last cycle of rx_payload_valid.
rx_cmd_valid	Output	Packet header data is valid on the packet header ports below when this signal is asserted.
rx_cmd_vc[1:0]	Output	Packet virtual channel number, valid when rx_cmd_valid is asserted.
rx_cmd_data_type[5:0]	Output	Packet data type, valid when rx_cmd_valid is asserted. See the MIPI DSI-2 specification for a definition of possible values.

Table continues on the next page...

Table 13-24. DSI Host Controller Core Receive Packet interface (continued)

PORT	TYPE	DESCRIPTION
rx_cmd_byte_count[15:0]	Output	Packet Word Count (byte count). Contains the number of bytes of data in the received packet. Valid when rx_cmd_valid is asserted.
ecc_one_bit_error	Output	Single bit error in the packet header was detected and corrected. Active high. Valid when rx_cmd_valid is high.
ecc_two_bit_error	Output	Two packet header bit errors were detected and not corrected, active high. Valid when rx_cmd_valid is high.
ecc_one_bit_error_pos[4: 0]	Output	Position of the corrected single bit error in the packet header. Valid when ecc_one_bit_error is high.
ecc_err	Output	Error detected in the ECC bits. Active high. Valid when rx_cmd_valid is high.
ecc_err_pos[2:0]	Output	Position of the erroneous bit in the ECC bits, valid when ecc_err is asserted.
crc_err	Output	Asserts high when the CRC calculated on the received data does not reach the end of the packet.

13.6.3.3 Status Interface Ports

The Status Interface Core provides for reading the Status of the DSI Host Controller Core via a simple interface. All signals in the Status Interface are synchronous to the clk_byte clock. The Status Interface ports are listed in the table below.

NOTE

Only a subset of the Packet Interface signals are accessible by user application through DSI_HOST_APB_PKT_IFx registers and DSI_HOST device registers:

- status_out
- hs_tx_timeout
- lp_rx_timeout

Refer to DSI_HOST_APB_PKT_IFx and DSI_HOST device sections for details.

Table 13-25. DSI Host Controller Status Interface Port

PORT	TYPE	DESCRIPTION
status_rd	Input	Initiates a read of the status register. Asserting this input high will result in the contents of the status register being presented on status_out[15:0] along with status_out_valid asserting high to indicate that status_out[15:0] contains a valid value.

Table continues on the next page...

Table 13-25. DSI Host Controller Status Interface Port (continued)

PORT	TYPE	DESCRIPTION
status_addr[3:0]	Input	When status_rd is asserted, indicates which status register is to be returned. Address 0x0 is a valid address while 0x1-0xF are reserved.
status_out[31:0]	Output	Contains the contents of the addressed status register.
status_out_valid	Output	When asserted high, indicates that the data on status_out is valid.
tx_active	Output	tx_active asserts high when the Host Controller is actively transmitting data or when it has accepted a request from the user but has not yet started transmitting.
hs_tx_timeout	Output	Asserts high for one clk_byte period to indicate that a High Speed transmit has timed out.
lp_rx_timeout	Output	Asserts high for one clk_byte period to indicate that a Low Power RX curred.

13.6.3.4 Control and Status Ports

The Control and Status Packet Interface allows the user to control and receive the status of the underlying link between the DSI Host and DSI Peripheral. It works on the same clk_byte clock as the Host Transmit Packet Interface. The Packet Interface Control and Status Interface ports are listed in the table below.

NOTE

Only a subset of the Packet Interface signals may be accessible by user application through DSI_HOST_APB_PKT_IFx registers and DSI_HOST device registers:

- dphy_direction
- tx_hs_mode
- dphy_turnaround

Please refer to DSI_HOST_APB_PKT_IFx and DSI_HOST device sections for details.

Table 13-26. DSI Host Controller Core Control And Status Packet Interface

PORT	TYPE	DESCRIPTION
tx_hs_mode	Input	Switches the DPHY into High Speed Data Transfer mode or Low Power Data Transfer mode. 1'b1 = request HS mode 1'b0 = request LP mode. The Packet interface will not acknowledge packet commands or data while switching modes.

Table continues on the next page...

Table 13-26. DSI Host Controller Core Control And Status Packet Interface (continued)

PORT	TYPE	DESCRIPTION
dphy_turnaround	Input	Requests bus turnaround. 1'b1 = Request reverse direction LP mode, from Host TX to Host RX. 1'b0 = No effect. This signal is ignored if the bus is already in Reverse (Host RX) direction.
dphy_direction	Output	Reports the current bus direction. 1'b1 = Bus is in Reverse direction (Host RX). 1'b0 = Bus is in Forward direction (Host TX).

13.6.3.5 Interface Cores

There are several interface cores for the DSI Host Controller Core. These interface cores provide industry standard interfaces to the DSI Host Controller Core to simplify interfacing and integration the DSI Host Controller Core to your application. When selected, these interface cores provide additional ports to the DSI Host Controller core.

13.6.3.5.1 DPI-2 Interface Host Bridge Core

The DPI-2 Interface Host Bridge Core provides a DPI-2 compliant interface to the DSI Host controller. The DPI-2 Interface Host Bridge Core handles converting the DPI-2 interface into a packet format that is compatible with the DSI Host Controller Core's Packet Interface, and that adheres to the DSI specification. The DPI-2 Interface Core handles all pixel-to-byte packing for all DPI data types.

The DSI Host Controller DPI-2 Interface Core provides the following features:

- Support for Type 2,3, and 4 displays
- Support for 16-, 18- and 24- bit Pixel data and all alignment configurations
- Support for 16, 18, 24, and 18 bit loosely packed DSI data types
- Supports DSI video modes
  - Non-Burst Mode with Sync Pulses
  - Non-Burst Mode with Sync Events
  - Burst Mode
- Supports normal or inverted HSYNC and VSYNC signals
- Handles clock domain crossing from DPI Pixel clock to the Host controller TX Byte clock
- Interfaces directly to the Host Controller's DSI Packet Interface
- Comes already integrated with the DSI Host Controller

A block diagram of the DPI-2 Interface Host Bridge Core is shown below. The DPI-2 Host Bridge Core accepts a MIPI compliant DPI-2 set of signals (vsync, hsync, pixel data), creates DSI packets for the video timing events and video data and transmits those packets via the DSI Host Controller's Packet Interface.

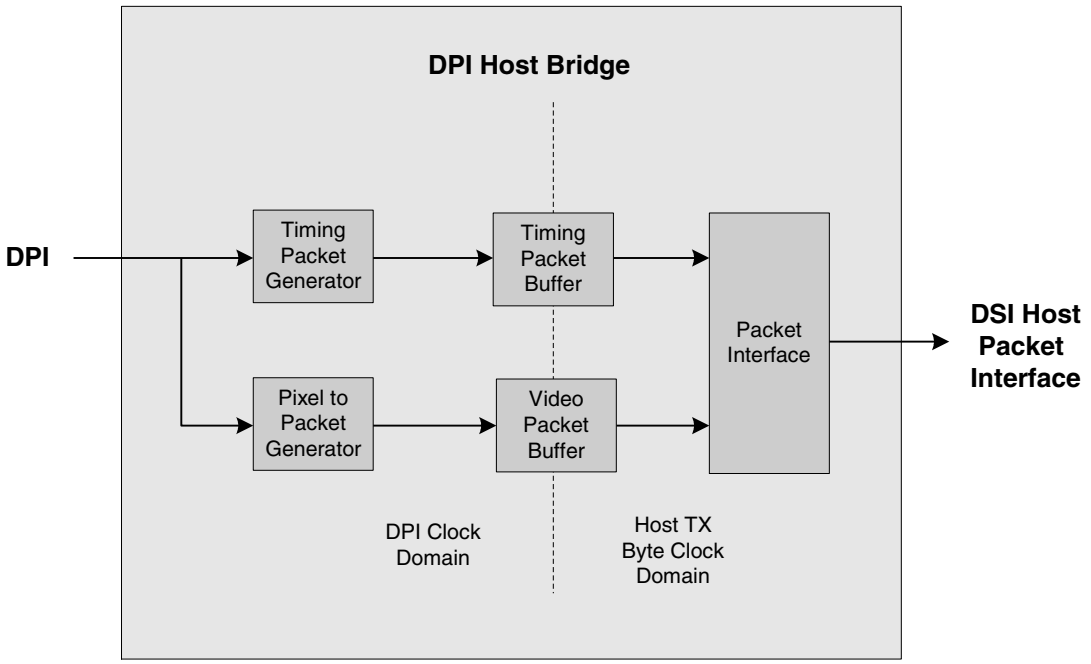

Figure 13-41. DPI-2 Host Bridge Core Block Diagram

13.6.3.5.1.1 DPI-2 Interface Ports

The DPI-2 Interface module provides a MIPI compliant DPI-2 interface to the DSI Host Controller Core. In addition to the standard DPI-2 interface signals (prefixed with a dpi_) there are several configuration and status ports that allow the user to adjust the behavior of the DPI-2 Interface module to better suit a particular application.

NOTE

The DPI configuration signals herein described are accessible to User Application through chip-specific registers (please refer to chip-specific MIPI-DSI information section for details) and DSI_HOST_DPI_INTFC device registers (please refer to MIPI DSI Host Memory Map/Register section for details).

Table 13-27. DSI Host Controller Core Receive Packet interface

PORT	TYPE	DESCRIPTION
dpi_sd	Input	Shut Down – Control to shutdown display (type 4 only) 1'b1= Send shutdown command. 1'b0= No effect

Table continues on the next page...

Table 13-27. DSI Host Controller Core Receive Packet interface (continued)

PORT	TYPE	DESCRIPTION
dpi_cm	Input	Color Mode control. 1'b0== Normal Mode 1'b1== Low-color Mode
cfg_dpi_pixel_payload_size [15:0]	Input	Maximum number of pixels that should send as one DSI packet. Recommended to be evenly divisible by the line size (in pixels).
cfg_dpi_pixel_fifo_send_ level[15:0]	Input	In order to optimize DSI utility, the DPI bridge buffers a certain number of DPI pixels before initiating a DSI packet. This configuration port controls the level at which the DPI Host bridge begins sending pixels.
cfg_dpi_interface_color_ coding[2:0]	Input	Sets the distribution of RGB bits within the 24-bit d bus, as specified by the DPI specification. 0= 16-bit Configuration 1 1= 16-bit Configuration 2 2= 16-bit Configuration 3 3= 18-bit Configuration 1 4= 18-bit Configuration 2 5= 24-bit
cfg_dpi_pixel_format[1:0]	Input	Sets the DSI packet type of the pixels. 0= 16-bit 1= 18-bit 2= 18-bit loosely packed, 3= 24-bit
dpi_host_underrun_err	Output	During DSI Host transmission of DPI data insufficient DPI data was received. This may indicate that DPI_CLK is too slow, or that the cfg_dpi_* parameters are incorrectly set.
cfg_dpi_vsync_polarity	Input	Sets polarity of dpi_vsync input, 0 – active low, 1 active high
cfg_dpi_hsync_polarity	Input	Sets Polarity of dpi_hsync input, 0 – active low, 1 – active high
cfg_host_dpi_video_mode[1:0]	Input	Select DSI video mode that the host DPI module should generate packets for. 2'b00 – Non-Burst mode with Sync Pulses 2'b01 – Non-Burst mode with Sync Events 2'b10 – Burst mode 2'b11 – Reserved, not valid
cfg_host_dpi_hfp[15:0]	Input	Sets the DSI packet payload size, in bytes, of the horizontal front porch blanking packet.
cfg_host_dpi_hbp[15:0]	Input	Sets the DSI packet payload size, in bytes, of the horizontal back porch blanking packet.
cfg_host_dpi_hsa[15:0]	Input	Sets the DSI packet payload size, in bytes, of the horizontal sync g packet.
cfg_enable_mult_packets	Input	Enable Multiple packets per video line. When enabled, cfg_dpi_pixel_payload_size must be set to exactly half the size of the video line. 0 – Video Line is sent in a single packet 1 – Video Line is sent in two packets
cfg_bllp_mode	Input	Optimize bllp periods to Low Power mode when possible 0 – blanking packets are sent during BLLP periods 1 – LP mode is used for BLLP periods

13.6.3.5.1.2 DPI-2 Video Timing Recreation over DSI

The DSI Host DPI-2 module is designed to preserve the receive video timing by properly spacing the DSI packets that carry the DPI video information and by inserting blanking packets into the packet stream. In order to achieve this goal, the DSI Host controller needs to have the cfg_host_dpi_hfp, cfg_host_dpi_hbp, and cfg_host_dpi_hsa ports

properly set. The values of these ports reflect the size of the hfp, hbp, and has in terms of DSI packet bytes, values such that the number of DSI bytes when transmitted takes approximately the same amount of absolute time as the video event took on the DPI interface.

To relate pixel sizes on the DPI interface to DSI packet bytes, use the following relationship:

```
      Time of DPI event - time to transmit x number of bytes on the DSI interface

      dpi_event_size * dpi_pclk_period = number_of_dsi_bytes * 8 * dsi_hs_bit_period /
cfg_num_lanes
```

Solving for number_of_dsi_bytes:

```
      number_of_dsi_bytes = dpi_event_size * dpi_pclk_period * cfg_num_lanes / (8 *
dsi_hs_bit_period)

      number_of_dsi_bytes - value to set the cfg_host_dpi_hfp (hbp, or hsa) port to
      dpi_event_size - size of the video event in pixels (hfp, hbp, hsa)
      dpi_pclk_period - period of dpi_pclk
      dsi_hs_bit_period - bit period of the mipi data lanes in High Speed mode
      cfg_num_lanes - host controller setting for number of active lanes, 0 = 1 lane, 1 = 2
lanes, 2 = 3 lanes, 3 = 4 lanes)
```

13.6.3.5.2 DBI-2 Interface Core

The DBI-2 Interface Core provides a DBI-2 compliant interface that attaches to a Packet Interface Port on the DSI Host controller. The DBI-2 Interface Core handles converting the DBI-2 interface into a packet format that is compatible with the DSI Host Controller Core's Packet Interface and adheres to the DSI specification. The DBI-2 Interface Core handles all pixel-to-byte packing for all DBI data types.

The DSI Host Controller DBI-2 Interface Core provides the following features:

- Support for Type 1, 2, and 3 displays
- Support for DBI-2 Type B and C Interfaces
- Support for 8-, 9- and 16- bit data (Type B)
- Interfaces directly to the Host Controller's Packet Interface
- Comes already integrated with the DSI Host Controller
- Source Code License available (Verilog)
- Provided with expert technical support
- Customization and integration services available

13.6.3.5.2.1 DBI-2 Host Bridge Module Interface Ports

The DBI-2 Interface module provides a MIPI compliant DBI-2 interface to the DSI Host Controller Core. In addition to the standard DBI-2 interface signals (prefixed with a dbi_) there are several configuration and status ports that allow the user to tune adjust the behavior of the DBI-2 Interface module to better suit a particular application.

Table 13-28. DSI Host Controller Core Receive Packet interface

PORT	TYPE	DESCRIPTION
dbi_csx	Input	DBI Chip Select, active low.
dbi_wrx	Input	DBI Write enable. Write data/command is registered at the rising edge of dbi_wrx.
dbi_rdx	Input	DBI Read enable. Read data is read at the rising edge of dbi_rdx.
dbi_d_write[15:0]	Input	8-,9- or 16-bit Input Data for Writes
dbi_d_read[15:0]	Output	8-,9- or 16-bit Output Data for Reads
dbi_dcx	Input	Data/Command indicator. 0 – Command cycle 1 – Data cycle
dbi_resx	Input	Active low DBI Display Module reset
dbi_te	Output	Tearing Effect (optional support)
dbi_host_underrun_err	Output	During DSI Host transmission of DBI data insufficient DBI data was received. This may indicate that the rate of data received on dbi_d_in was insufficient to keep up with the outgoing data rate on the MIPI interface, or that the cfg_dbi_* parameters are incorrectly set.
cfg_dbi_pixel_payload_size[15:0]	Input	Maximum number of pixels that should send as one DSI packet. Recommended to be evenly divisible by the line size (in pixels).
cfg_dbi_pixel_fifo_send_level[15:0]	Input	In order to optimize DSI utility, the DBI bridge buffers a certain number of DBI pixels before initiating a DSI packet. This configuration port controls the level at which the DBI Host bridge begins sending pixels.

13.6.3.5.2.2 DBI-2 Host Bridge Module Write and Read Waveforms

The figure below shows a DBI-2 Write transaction. The command portion of the write is registered with the rising edge of dbi_wrx when dbi_dcx and dbi_csx are low. The write data is registered with the rising edge of dbi_wrx when dbi_dcx is high and dbi_csx is low.

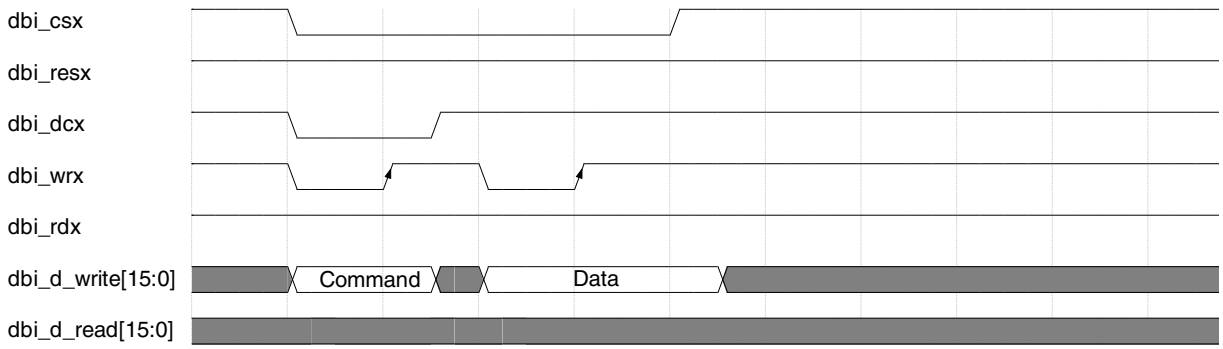

Figure 13-42. DBI-2 Write Waveform

The figure below shows a DBI-2 Read Transaction. The command portion of the read is registered with the rising edge of dbi_wrx when dbi_dcx and dbi_csx are low. The first cycle of read data is invalid with the first rising edge of dbi_rdx while the second cycle of read data is valid with the rising edge of dbi_rdx.

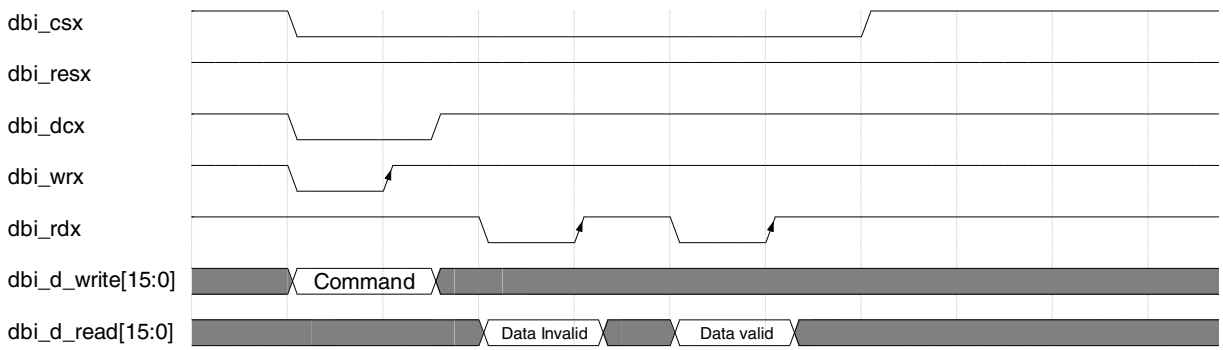

Figure 13-43. DBI-2 Read Waveform

13.6.3.6 RAM Usage

The DSI Host Controller Core requires on-chip RAM arrays. These RAM arrays and their corresponding sizes are listed in the table below.

All RAM arrays used in this core are configured as two-port, having the following attributes:

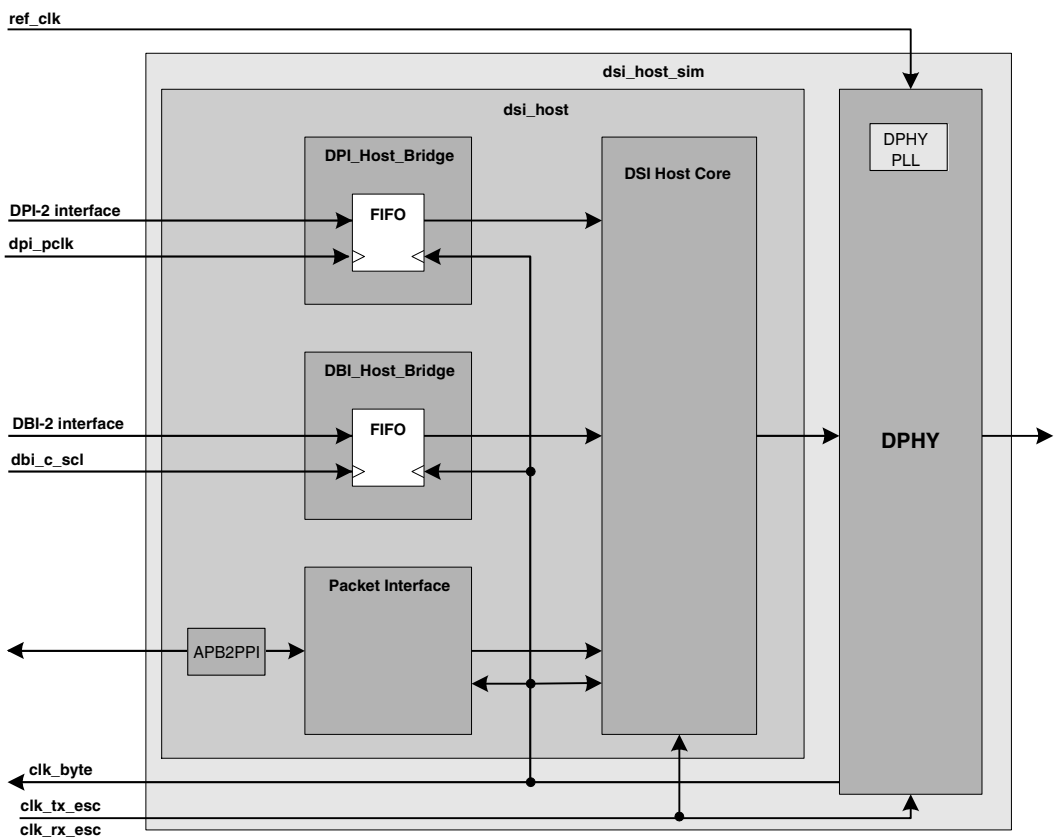
- Two address busses, one for the write port and one for read port
- Two data busses, one for write data on the write port and one for read data on the read port
- Two clock inputs, one for the write port and one for the read port. (Note: In some cases, the core logic will connect the same clock to both the read and write clock inputs of the RAM.)

Ram Purpose	Size (Depth x Width)
DPI Core Pixel Data FIFO	2048 x 32
APB to Packet Interface TX FIFO	64 x 32
APB to Packet Interface RX FIFO	64 x 32

13.6.3.7 DSI Host Clocking

The DSI Host Controller requires the following clocks:

- Reference clock (ref_clk) - used by the DPHY (DPHY PLL generates byte clock)
- Byte clock (clk_byte) - generated by the DPHY, used for packet generation and transfer to the DPHY
- TX escape mode clock (clk_tx_esc) - for internal LPDT state machines and low-power transmissions;
- RX escape mode clock (clk_rx_esc) - used by DPHY for reverse low-power reception.
- Pixel clock (dpi_pclk)
- Serial clock (dbi_c_scl)



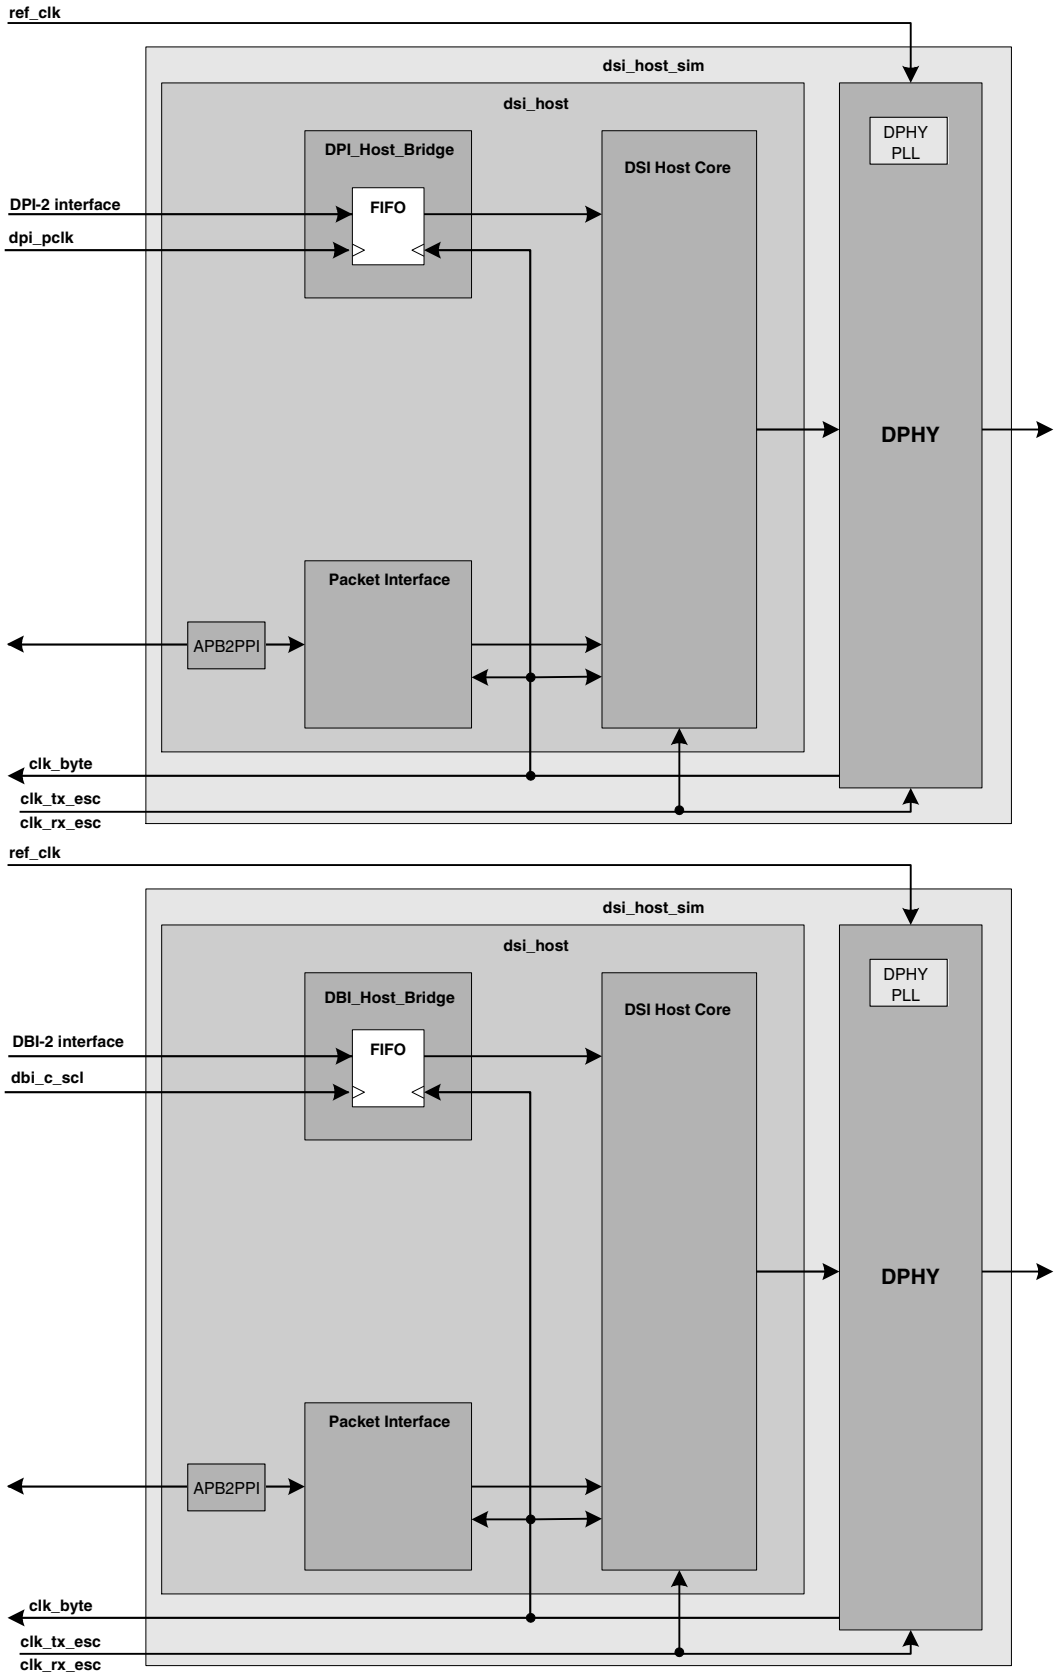


Figure 13-44. DSI Host Controller Clocking Block Diagram

13.6.3.7.1 ref_clk

The reference clock is used by the DPHY (DPHY PLL) to generate the High Speed MIPI clock and High Speed Data Lane signaling. The frequency of the resulting clock generated from DPHY PLL is typically equal to the high speed bit rate of the data lanes. The DPHY will also use this clock to generate the clk_byte clock output used by the Host DSI Controller and user application logic.

The MIPI DPHY PLL must be setup through the MIPI_DSI_HOST_FSL_IP1_DPHY INTFCx registers, prior to starting DSI Host Controller and DPHY operation. For details, please refer to MIPI DSI Host IP1 DPHY INTFC Memory section.

13.6.3.7.2 clk_byte

The clk_byte clock is generated by the DPHY (DPHY PLL) and the frequency is 1/8th the data rate of the DPHY Data Lane High Speed data rate. A DPHY configured to generate High Speed data at 1Gbps/lane would generate a 125MHz clk_byte clock.

The clk_byte clock is used by the DSI Host Controller to interface to the MIPI Tx DPHY High Speed PPI interface. The DSI Host Controller's Packet Interface is synchronous to the clk_byte clock.

13.6.3.7.3 dpi_pclk

The dpi_pclk clock is used on the Host DPI-2 interface. All of the Host DPI-2 signals are synchronous to this clock. The DSI Host Controller's DPI Bridge module handles transferring video data received in the dpi_pclk clock domain over to the clk_byte clock domain.

The dpi_pclk and clk_byte frequencies are related by the following formula:
clk_byte_freq >= dpi_pclk_freq * DPI_pixel_size / (8 * (cfg_num_lanes + 1))

cfg_num_lanes = the configuration port setting that selects the number of active MIPI DPHY data lanes clk_byte_freq = frequency of clk_byte which is 1/8th the High Speed data lane rate. dpi_pclk_freq = frequency of the dpi_pclk clock on the DPI-2 interface. DPI_pixel_size = size of pixels, in bits, on the DPI-2 interface

If the clk_byte frequency does not meet this requirement, the MIPI interface will not be able to keep up with the video stream on the DPI-2 interface resulting in dropped video lines.

13.6.3.7.4 clk_tx_esc

The clk_tx_esc clock is used by the MIPI Tx DPHY for state control and low power data transmission. The DSI Host Controller also uses clk_tx_esc for the portion of controller logic that interfaces to the MIPI Tx DPHY that are synchronous to clk_tx_esc. The frequency of clk_tx_esc is defined by the requirements of the MIPI interface and the MIPI Tx DPHY. For details about the clk_tx_esc source, please refer to the chip-specific MIPI-DSI clocking section.

13.6.3.7.5 clk_rx_esc

The clk_rx_esc clock is used by the MIPI Tx DPHY for reverse low power data reception. The frequency of clk_rx_esc is defined by the Tx DPHY and MIPI DPHY interface timing requirements.

13.6.3.7.6 dbi_c_scl

The dbi_c_scl clock is used by the optional DBI-C interface. The MIPI DBI-2 specification defines the minimum period for dbi_c_scl to be 80ns. The DSI Host Controller DBI-2 bridge module handles the clock domain crossing from dbi_c_scl clock domain to the clk_byte clock domain.

13.6.3.8 Reset and Initialization

Reset and Initialization procedure for the DSI Host Controller is as follows:

1. Assert all resets through the chip-specific registers provided for this purpose:
   - reset_dpi_n
   - reset_byte_n
   - reset_esc_n
2. Setup DSI related clocks through chip-specific registers provided for this purpose (refer to CCM for details).
3. Setup MIPI DSI application by programming all DSI Host Controller and DSI DPHY required parameters (refer to MIPI DSI Host Memory Map/Register for details).
4. Deassert all remaining resets through the Chip-specific registers provided for this purpose:
   - reset_dpi_n
   - reset_byte_n
   - reset_esc_n
5. DSI Host Controller should be ready for use

13.6.4 DSI D-PHY

The figure below shows the block diagram of the MIPI DSI D-PHY. It consists of a clock lane module and four data lane modules. In addition to the data lanes, MIPI DSI D-PHY includes a calibrator module for calibration of termination resistance. Each of these PHY Lane Modules communicates through a differential line to a complementary PHY at the other side of the lane interconnect.

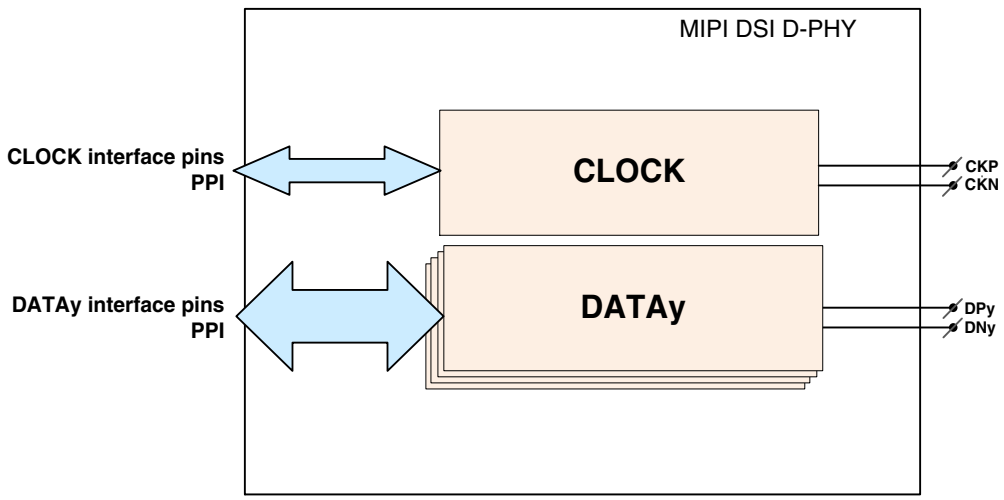

Figure 13-45. MIPI D-PHY Block Diagram

The figure below shows the D-PHY Lane components:

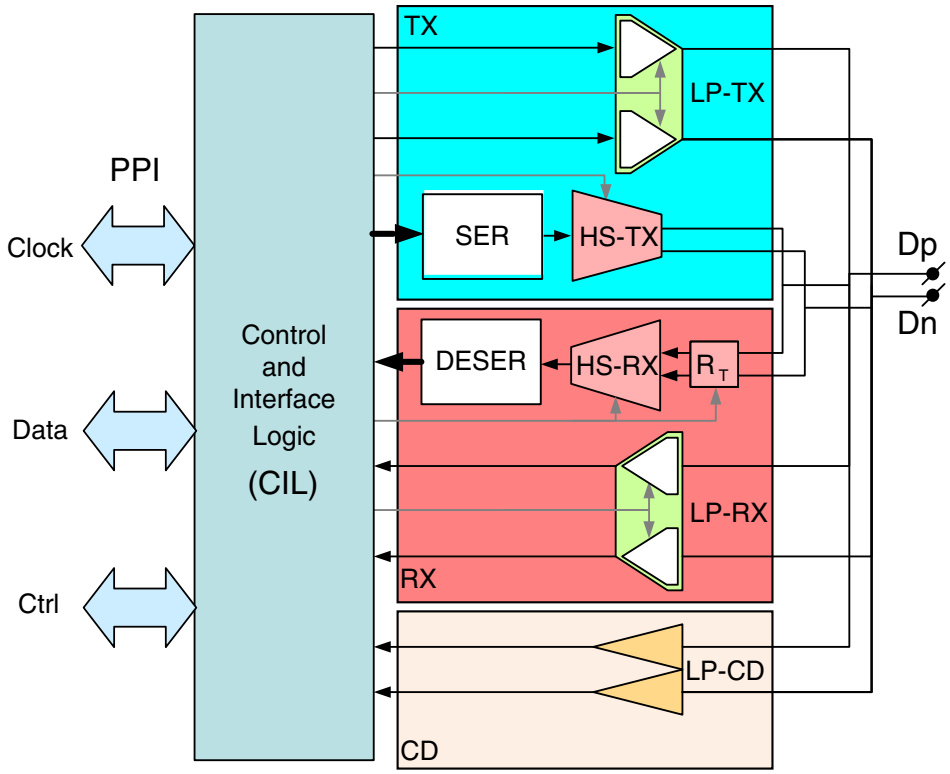

Figure 13-46. D-PHY Lane Diagram

The DATAy are bidirectional lanes and consist of High-Speed Receiver (HS-RX), Low-Power Receiver (LP-RX), High-Speed Transmitter (HS-TX), Low-Power Transmitter (LP-TX), Serializer (SER), De-Serializer (DESER), and Low- Power Contention Detector (LP-CD).

The Clock lane is a bidirectional lane and consists of High-Speed Receiver (HS-RX), Low-Power Receiver (LP-RX), High-Speed Transmitter (HS-TX), and Low-Power Transmitter (LP-TX). The B is optional and is used to calibrate the HS-TX and HS-RX termination, which requires connecting the pin REXT with a precise external resistor.

The Control and Interface Logic (CIL) module interfaces with the Protocol and determines the global operation of the Lane Module. The interface between the D-PHY and the protocol is called the PHY-Protocol Interface (PPI).

During normal operation, a Lane switches between Low-Power and High-Speed mode. Bidirectional Lanes can also switch communication direction. The change of operating mode or direction requires enabling and disabling of certain electrical functions. These enable and disable events do not cause glitches on the Lines that would result in a detection of an incorrect signal level. Therefore, all mode and direction changes are smooth to always ensure a proper detection of the Line signals.

13.6.4.1 High-Speed Transmitter (HS-TX)

The differential output voltage VOD is defined as the difference of the voltages V_{DP} and V_{DN} at the Dp and Dn pins, respectively.

VOD =VDP −VDN

The output voltages V_{DP} and V_{DN} at the Dp and Dn pins will not exceed the high-speed output high voltage V_{OHHS}. The common-mode voltage V_{CMTX} is defined as the arithmetic mean value of the voltages at the Dp and Dn pins:

VCMTX = (VDP + V DN)/2

V_{OD} and V_{CMTX} are graphically shown in Figure 13-47 for ideal HS signals. Figure 13-48 shows single ended HS signals with the possible kinds of distortion of the differential output and common mode voltages. V_{OD} and V_{CMTX} may be slightly different for driving a Differential-1 or a Differential-0 on the pins.

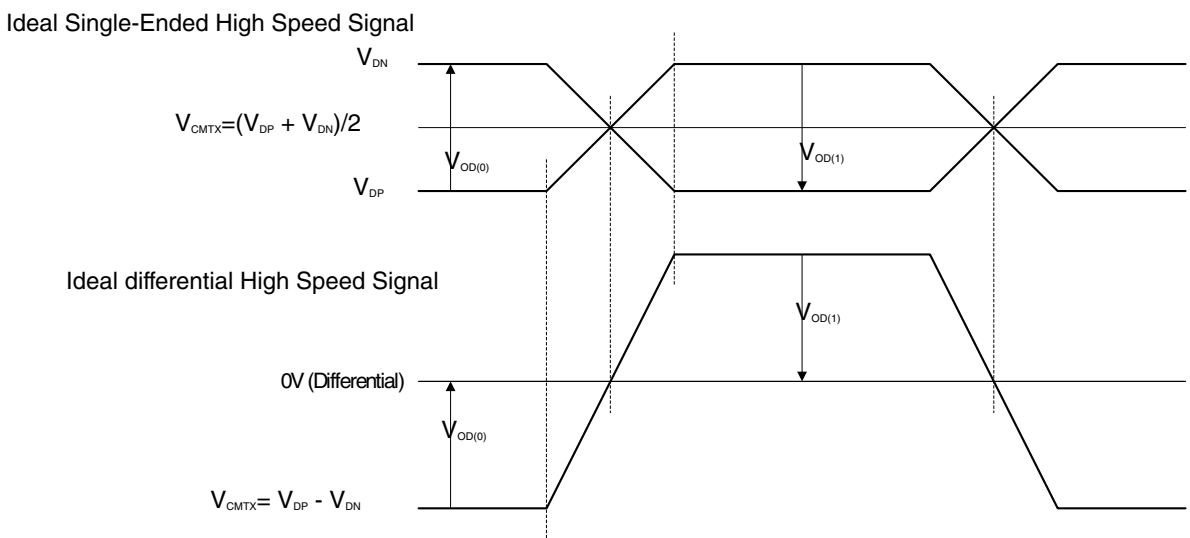

Figure 13-47. Ideal Single-ended and Resulting Differential HS Signals

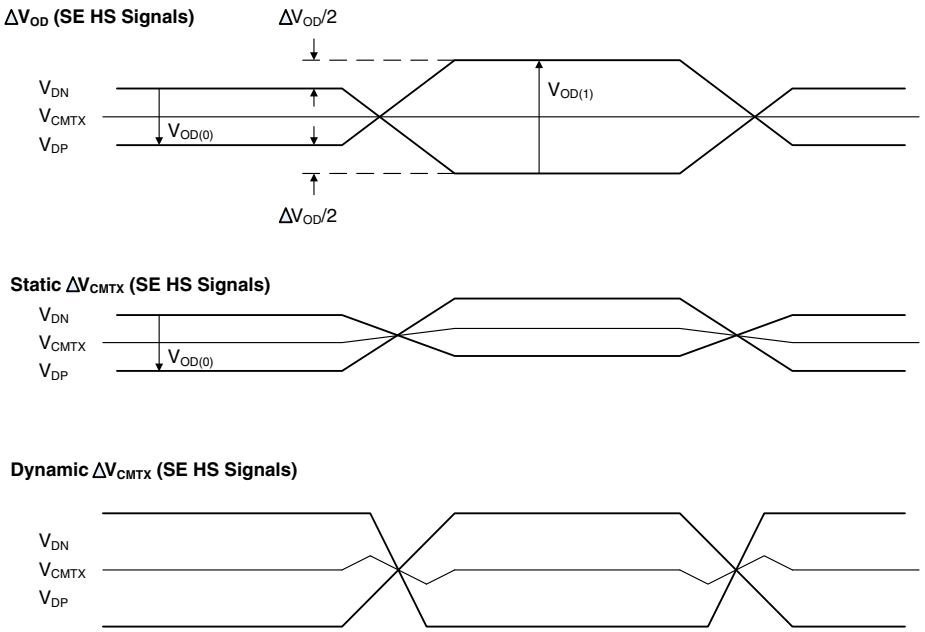

Figure 13-48. Possible ΔVcmtx and ΔVod Distortions of the Single-Ended HS Signals

The output differential voltage mismatch ΔVOD is defined as the difference of the absolute values of the differential output voltage in the Differential-1 state VOD(1) and the differential output voltage in the Differential-0 state VOD(0). This is expressed by:

$$\Delta V = |V_{OD(1)}| - |V_{OD(0)}|$$

If VCMTX(1) and VCMTX(0) are the common-mode voltages for static Differential-1 and Differential- 0 states respectively, then the common-mode reference voltage is defined by:

$$V_{CMTX,\,REF} = (V_{\,CMTX(1)} + V_{\,CMTX(0)})/2$$

The transient common-mode voltage variation is defined by:

$$\Delta V_{CMTX\,(t)} = V_{CMTX\,(t)} - V_{\,CMTX\,,REF(t)}$$

The static common-mode voltage mismatch between the Differential-1 and Differential-0 state is given by:

$$\Delta V_{CMTX\,(1,0\,)} = (V_{CMTX\,(1)} - V\,CMTX\,(0))/2$$

A test circuit for the measurement of VOD and VCMTX is shown:

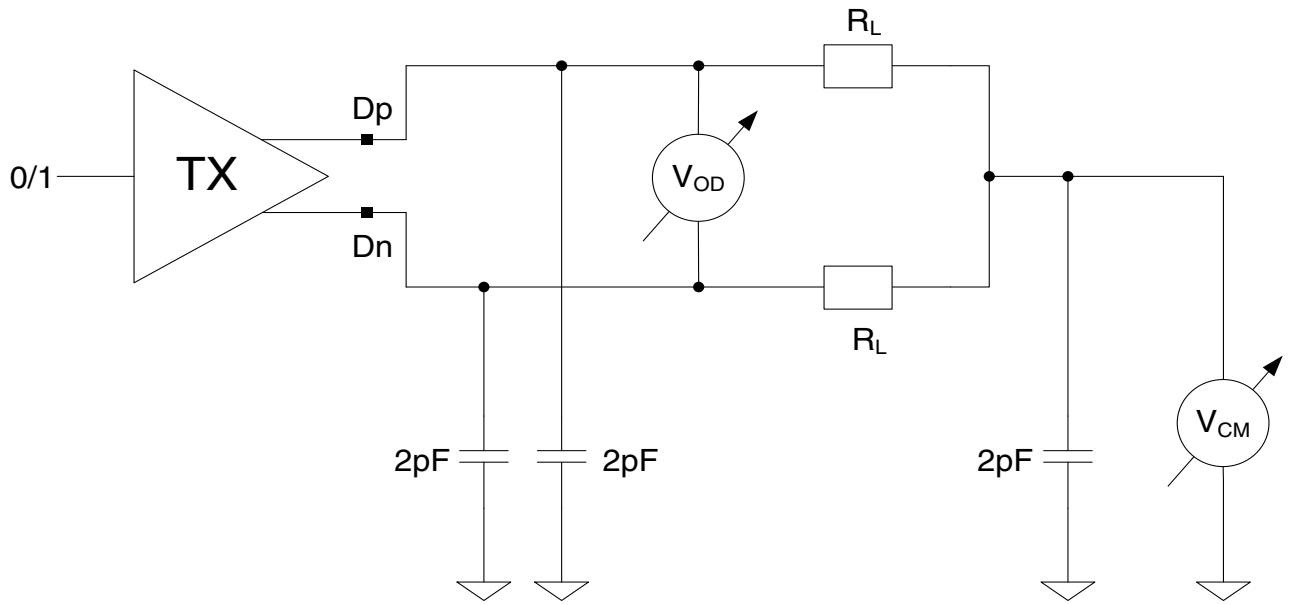

Figure 13-49. Test Circuit for Vcmtx and Vod measurement

The single-ended output impedance of the transmitter at both the Dp and Dn pins is denoted by Z_{OS}. ΔZ_{OS} is the mismatch of the single ended output impedances at the Dp and Dn pins, denoted by ZOSDP and ZOSDN respectively. This mismatch is defined as the ratio of the absolute value of the difference of Z_{OSDP} and Z_{OSDN} and the average of those impedances:

$$\Delta Z_{OS} = (2*|Z_{OSDP} - Z_{OSDN}|)/(Z_{OSDP} + Z_{OSDN})$$

The output impedance ZOS and the output impedance mismatch ΔZOS is compliant with High Speed Transmitter DC Specifications for both the Differential-0 and Differential-1 states for all allowed loading conditions. It is recommended the design keep the output impedance during state transitions as close as possible to the steady state value. The output impedance ZOS can be determined by injecting an AC current into the Dp and Dn pins and measuring the peak-to-peak voltage amplitude. The test circuit for such a measurement is shown in the following figure, where RL are load resistors and VTEST,PP is a test signal applied at the common-mode node via an AC coupling capacitor CAC. The frequency of the test signal is fTEST.

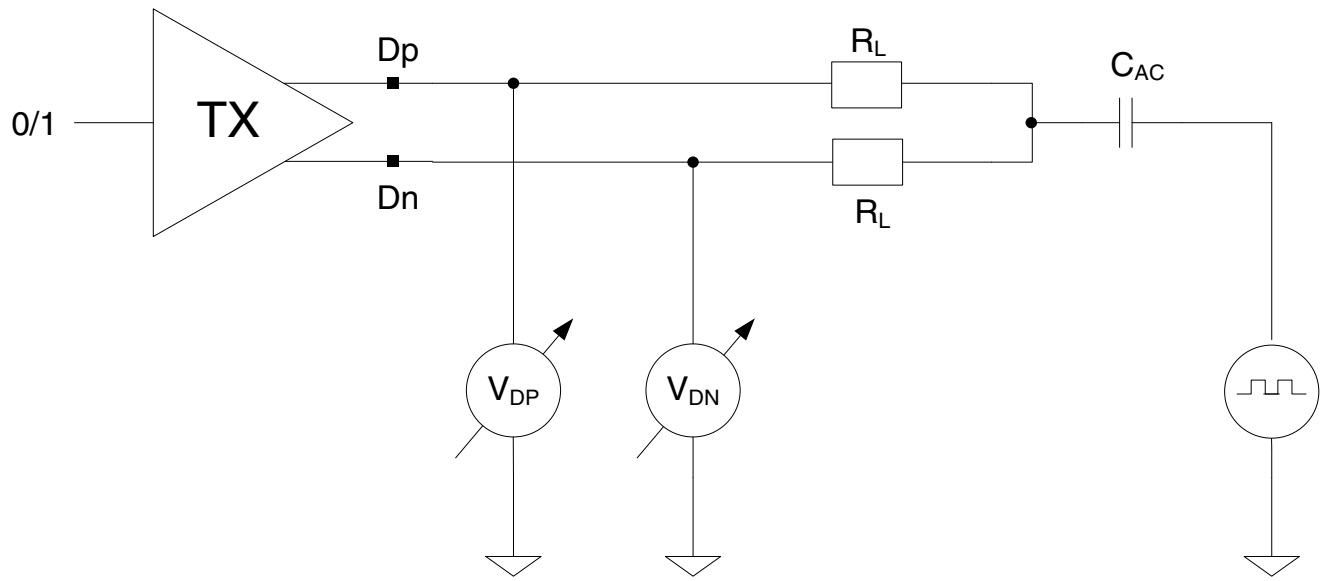

Figure 13-50. Test Circuit for Output Impedance measurements

Assuming negligible effect of the coupling capacitor, the example circuit gives the following relation between peak-to-peak pin voltage VPIN,PP and ZOS. This equation can be used for both Dn and Dp pins individually.

$Z_{OS} = (V_{PIN,PP} * RL)/(V_{TEST,PP} - Z_{PIN,PP})$

Where VPIN,PP is the peak-to-peak voltage at the pin Dp or Dn.

13.6.4.2 High-Speed Receiver (HS-RX)

The HS receiver is a differential line receiver. It contains an on-die switchable parallel input termination, ZID, between the positive input pin Dp and the negative input pin Dn.

The differential input high and low threshold voltages of the HS receiver are denoted by V_{IDTH} and V_{IDTL}, respectively. V_{CMRXDC} is the differential input common mode voltage. The HS receiver is able to detect differential signals at its Dp and Dn input signal pins when both signal voltages, VDP and VDN, are within the common mode voltage range and if the voltage difference of V_{DP} and V_{DN} exceeds either V_{IDTH} or V_{IDTL}.

During operation of the HS receiver, termination impedance is required between the Dx_P and Dx_N pins of the HS receiver. Z_{ID} is disabled when the module is not in the HS receive mode. CCM is the common mode AC termination, which ensures a proper termination of the receiver at higher frequencies.

13.6.4.3 Low-Power Transmitter (LP-TX)

The Low-Power transmitter is a slew-rate controlled push-pull driver. It is used for driving the Lines in all Low-Power operating modes. The LP transmitter has been optimized to minimize static power consumption. The slew-rate of signal transitions is bounded in order to keep EMI low. The LP transmitter will not drive the pad pin potential statically beyond the maximum value of V_{OH}. V_{OH} is the thevenin output, high-level voltage in the high-level state, when the pad pin is not loaded. V_{OL} is the thevenin output, low-level voltage in the LP transmit mode. This is the voltage at an unloaded pad pin in the low-level state.

13.6.4.4 Low-Power Receiver (LP-RX)

The low power receiver is an un-terminated, single-ended receiver circuit. The LP receiver is used to detect the Low-Power state on each pin. For high robustness, the LP receiver filters out noise pulses and RF interference. The LP receiver is optimized for low power operation.

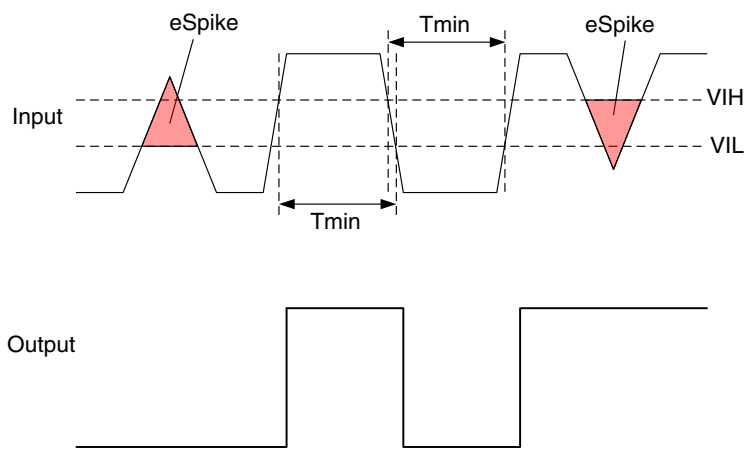

Figure 13-51. Input Glitch Rejection of Low-Power Receiver

The input low-level voltage, VIL, is the voltage at which the receiver is required to detect a low state in the input signal. VIL is larger than the maximum single-ended Line voltage during HS transmission. Therefore, both LP receivers will detect low during HS signaling. The input high-level voltage, VIH, is the voltage at which the receiver is required to detect a high state in the input signal. In order to reduce noise sensitivity on the received signal, the LP receiver incorporates a hysteresis, VHYST.

The LP receiver also rejects any input glitch when the glitch is smaller than eSPIKE. The filter allows pulses wider than TMIN to propagate through the LP receiver. Additionally, the LP receivers are tolerant of super-positioned RF interference on top of the wanted

Line signals. The LP receiver meets all specifications for interference with amplitude VINT and frequency fINT. The interference does not cause glitches or incorrect operation during signal transitions.

13.6.4.5 Low-Power Contention Detector (LP-CD)

Contention can be inferred from any of the following conditions:

- LP high fault is detected when the LP transmitter is driving high and the pin voltage is less than VIL.
- LP low fault is detected when the LP transmitter is driving low and the pad pin voltage is greater than VIHCD. An LP low fault will not be detected when the pin voltage is less than VILCD.

The general operation of a contention detector is similar to that of an LP receiver with lower threshold voltages. Although the DC specifications differ, the AC specifications of the LP-CD are defined to match those of the LP receiver. The LP-CD sufficiently filters the input signal to avoid false triggering on short events

The LP-CD threshold voltages (VILCD, VIHCD) are shown along with the normal signaling voltages:

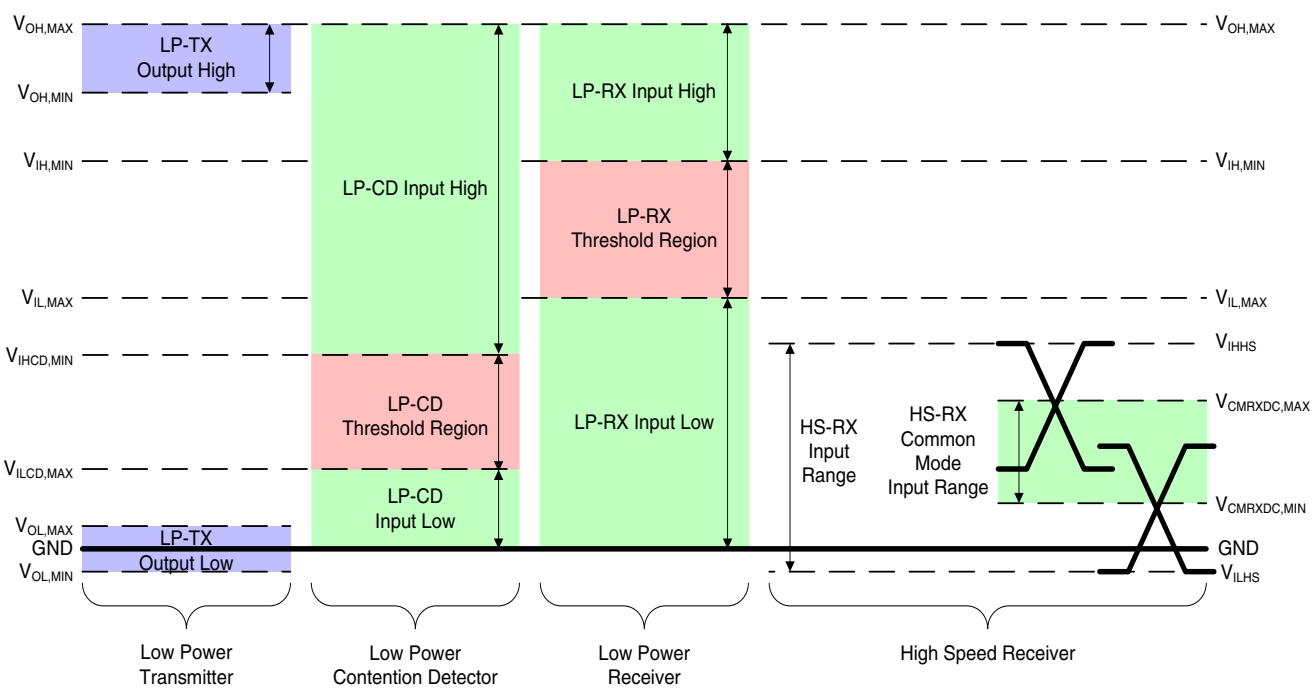

Figure 13-52. Signaling and MIPI Contention Voltage Levels

13.6.4.6 Input Characteristics

No structure within the PHY may be damaged when a DC signal that is within the signal voltage range VPIN is applied to a pad pin for an indefinite period of time. $V_{PIN(absmax)}$ is the maximum transient output voltage at the transmitter pin. The voltage on the transmitter's output pin will not excel $V_{PIN,MAX}$ for a period greater than $T_{VPIN(absmax)}$. When the PHY is in the low-power receive mode the pad pin leakage current will be I_{LEAK} when the pad signal voltage is within the signal voltage range of V_{PIN}. The specification of ILEAK assures interoperability of any PHY in the LP mode by restricting the maximum load current of an LP transmitter. The test circuit for leakage current measurement is shown:

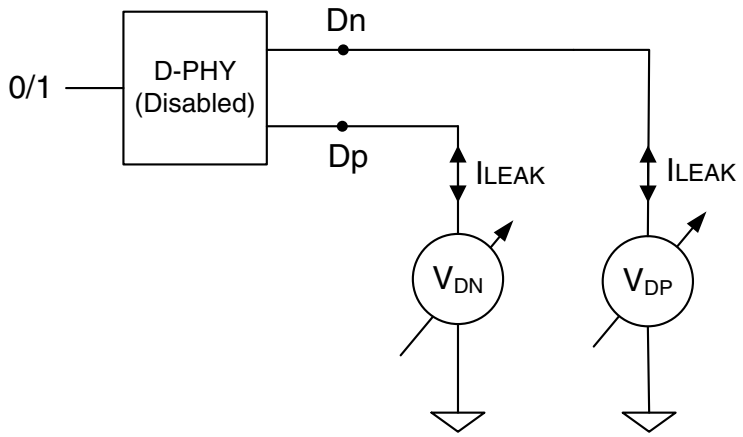

Figure 13-53. Pin-Leakage Measurement DC specification

13.6.4.7 High-Speed Serializer

The HS-Serializer converts 8-bits parallel data into 1 bit data stream to be transmitted by HSTX module. The CIL engine should clock out 8-bits parallel data, HSTX_DATA[7:0], on D0_HS_BYTE_CLKS rising edges. Then the Serializer will capture HSTX_DATA[7:0] on D0_HS_BYTE_CLKS rising edges and the signal connected to HSTX_DATA[0] is transmitted first. There is setup timing constraint and hold timing constraint designated to the rising edge of D0_HS_BYTE_CLKS as constrained in the liberty view provided.

The figure shows the relationship between HS_TXCLKP, HS_TXCLKN, HS_SER_LD, HS_BYTE_CLKS and HSTX_DATA[7:0]. It also shows how the 8-bits of parallel bits are mapped into the serial link:

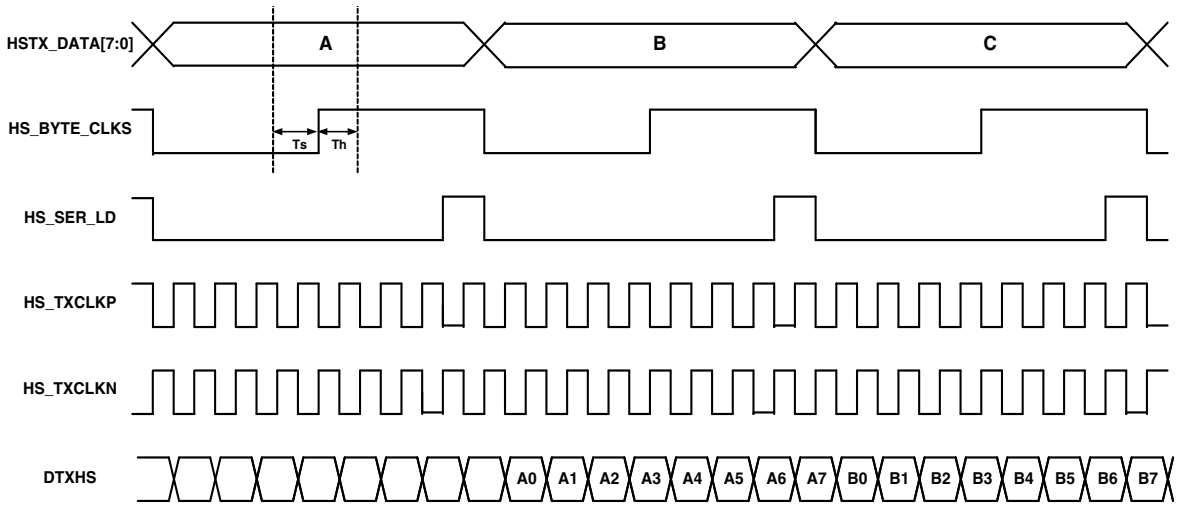

Figure 13-54. Serializer Timing Diagram

13.6.4.8 High-Speed Deserializer

The HS-Deserializer includes a Token Detector to detect SoT leader sequence '011101'. After proper match found (any single bit error allowed) for Sync sequence in HS input data stream, Deserializer then converts 1 bit data stream received by HS-RX module into 8-bits parallel data and HS_BYTE_CLKD becomes active.

The High speed input data stream from HS-RX module, DRXHSP/DRXHSN, is sampled by a differential DDR (half-rate) clock, HS_RXCLKP/HS_RXCLKN. The following bits after the Sync leader sequence are payload bits. The signal connected to HSRX_DATA[0] was received first and HSRX_DATA[7:0] can be captured on rising edges of HS_BYTE_CLKD. The transmitter will ensure that a rising edge of the DDR clock is sent during the first payload bit of a transmission burst such that the first payload bit can be sampled by the receiver on the rising clock edge, the second bit can be sampled on the falling edge, and all following bits can be sampled on alternating rising and falling edges.

HS-Deserializer also provides 3 synchronization condition signals. If sync sequence is properly matched, "SYNC" signal will be asserted. If sync sequence is matched with single bit error, "ERRSYNC" signal will be asserted. If the leader sequence is corrupted in a way that proper synchronization cannot be achieved (more than single-bit error), "NOSYNC" signal will be asserted.

The figures show the relationship between HS_RXCLKP/HS_RXCLKN, DRXHSP/DRXHSN, DRXLPP/DRXLPN, SYNC/ERRSYNC/NOSYNC, HS_BYTE_CLKD and HSRX_DATA[7:0]:

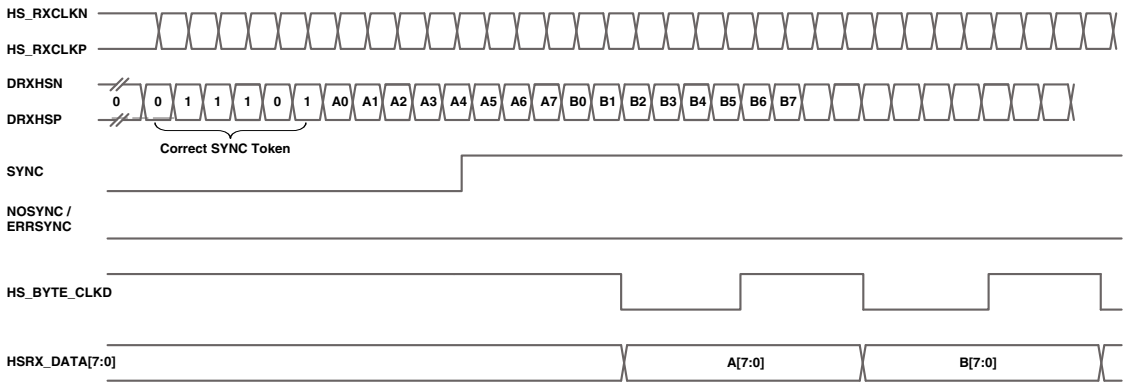

Figure 13-55. Deserializer Timing Diagram with Correct Sync Token

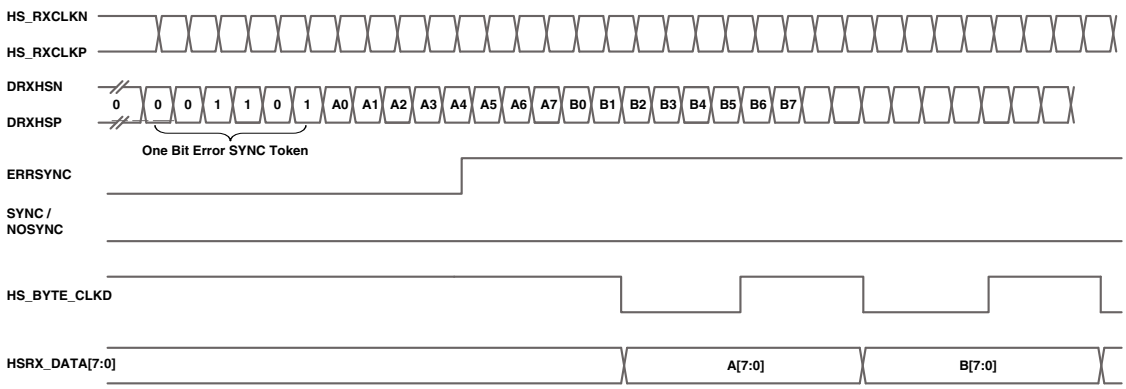

Figure 13-56. Deserializer Timing Diagram with One-Bit-Error Sync Token

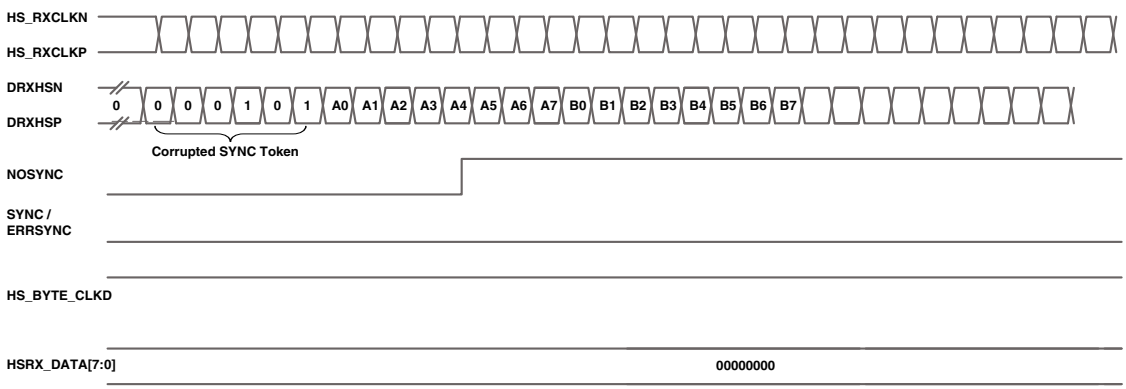

Figure 13-57. Deserializer Timing Diagram with Corrupted Sync Token

13.6.4.9 Termination Calibrator

An optional calibration circuit is implemented inside D-PHY to ensure that the HS-TX and HS-RX meet the required specifications with process corner and temperature variations. A precise external resistor is used to calibrate a scaled replica of the termination resistor, inside the calibrator. The auto calibration procedure is performed every time the D-PHY is powered-up.

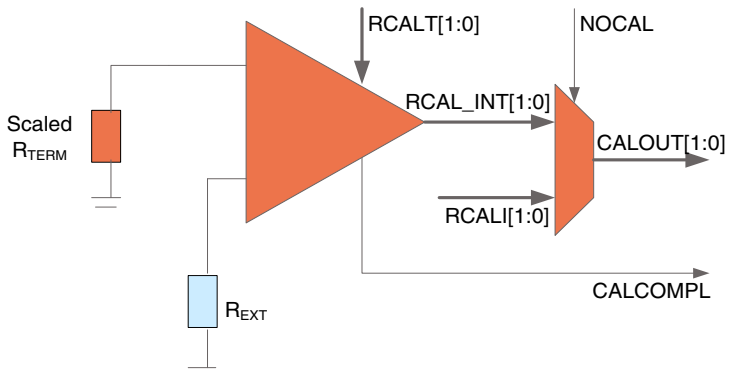

Figure 13-58. Calibrator Block Diagram

The D-PHY supports one of the following receiver termination schemes:

- **Auto Calibration mode:**Termination resistors are automatically configured by calibration circuit with reference resistor connected between REXT and VSSA.
- **User programmable mode:**RCALI[1:0] is programmed by the user through chip registers. In this case, the user has to control NOCAL signal for manual calibration.

13.6.4.10 DSI D-PHY Signals

This section details the interface signals for MIPI DSI D-PHY. For detailed signal spec, please refer to the chip datasheet.

Table 13-29. DSI DPHY PPI Signals

Signal	Type	Description
TxClkEsc	Clock	Escape mode Transmit Clock. This clock is directly used to generate escape sequences. The period of this clock determines the symbol time for low power signals. It is therefore constrained by the normative part of the DPHY specification. **NOTE:** The max frequency of TxClkEsc is 20 MHz **NOTE:** The Min frequency of TxClkEsc is 12 MHz. TxClkEsc is synchronous with RxClkInEsc.

Table continues on the next page...

Table 13-29. DSI DPHY PPI Signals (continued)

Signal	Type	Description
RxClkInEsc_ln0	Clock	Escape mode Clk for RX. Minimum Clk frequency should be 60 MHz in order to correctly detect the LP states, which are minimum 50 ns long but the minimum LP pulse duration could be as low as 20 ns as per D-PHY CTS. RxClkInEsc is synchronous with TxClkEsc
TxByteClkHS	Clock	High-Speed Transmit Byte Clock. This is used to synchronize PPI signals in the High-Speed transmit clock domain. It is recommended that all transmitting Data Lane Modules share on TxByteClkHS signal. The frequency of TxByteClkHS is exactly 1/8 the High-Speed bit rate.

13.6.4.11 Operating Modes

13.6.4.11.1 High-Speed Transmit from the Master Side

The figure shows an example of a High-Speed transmission on the Master side. While TxRequestHS is low, the Lane Module ignores the value of TxDataHS. To begin transmission, the protocol drives TxDataHS with the first byte of data and asserts TxRequestHS. This data byte is accepted by the PHY on the first rising edge of TxByteClkHS with TxReadyHS also asserted. At this point, the protocol logic drives the next data byte onto TxDataHS. After every rising clock cycle with TxReadyHS active, the protocol supplies a new valid data byte or ends the transmission. After the last data byte has been transferred to the Lane Module, TxRequestHS is driven low to cause the Lane Module to stop the transmission and enter Stop state. The minimum number of bytes transmitted could be as small as one.

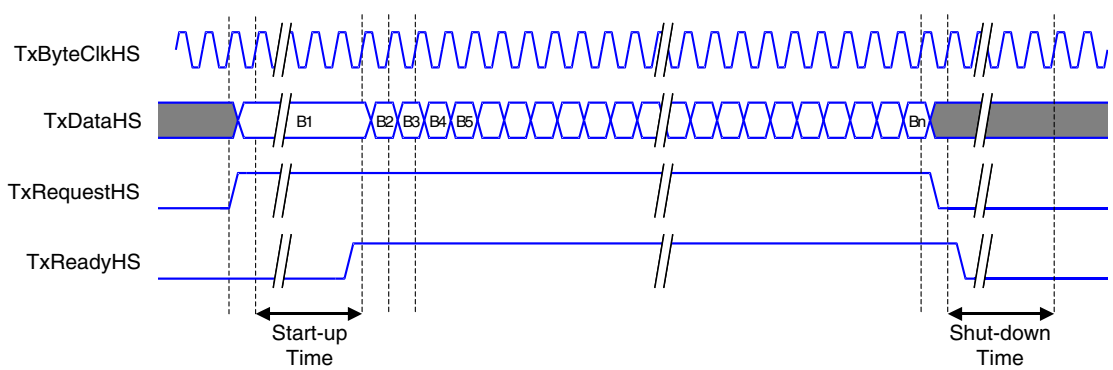

Figure 13-59. High-Speed Transmission from the Master Side

13.6.4.11.2 Low-Power Data Transmission

For Low-Power data transmission the TxClkEsc is used. The Protocol directs the Data Lane to enter Low-Power data transmission Escape mode by asserting TxRequestEsc with TxLpdtEsc high. The Low-Power transmit data is transferred on the TxDataEsc lines when TxValidEsc and TxReadyEsc are both active at a rising edge of TxClkEsc. The byte is transmitted in the time after the TxDataEsc is accepted by the Lane Module (TxValidEsc = TxReadyEsc = high). The Protocol knows the byte transmission is finished when TxReadyEsc is asserted. After the last byte has been transmitted, the protocol de-asserts TxRequestEsc to end the Low-Power data transmission. This causes TxReadyEsc to return low. Whenever TxRequestEsc transitions from high-to-low, it always remains in the low state for a minimum of two TxClkEsc clock cycles. The figure shows an example Low-Power data transmission operation.

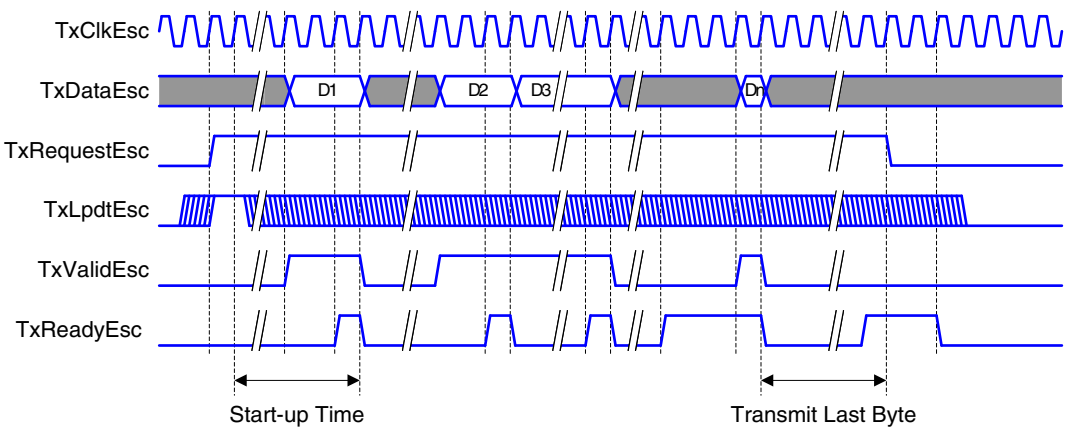

Figure 13-60. Low-Power Data Transmission

13.6.4.11.3 Low-Power Data Reception

The figure shows an example Low-Power data reception. In this example, a Low-Power escape “clock” is generated from the Lane Interconnect by the logical exclusive-OR of the Dp and Dn lines. This “clock” is used within the Lane Module to capture the transmitted data. In this example, the “clock” is also used to generate RxClkEsc. The signal RxLpdtEsc is asserted when the escape entry command is detected and stays high until the Lane returns to Stop state, indicating that the transmission has finished. It is important to note that because of the asynchronous nature of Escape mode transmission, the RxClkEsc signal can stop at anytime in either the high or low state. This is most likely to happen just after a byte has been received, but it could happen at other times as well

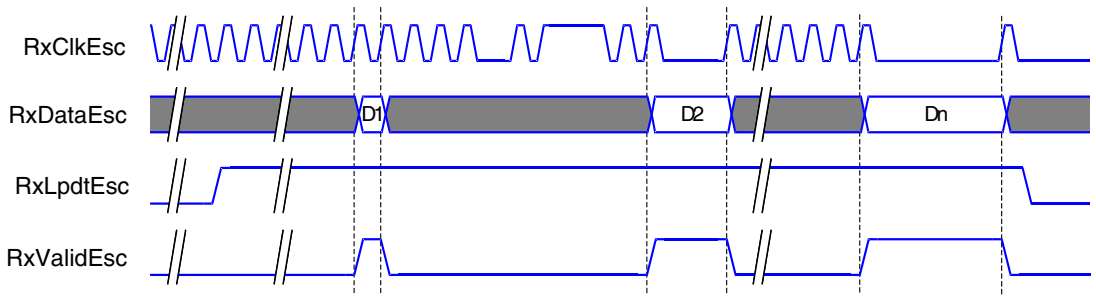

Figure 13-61. Low-Power Data Reception

13.6.4.11.4 Turn-around

If the Master side and Slave side Lane Modules are both bi-directional, it is possible to turn around the Link for Escape mode signaling. Which side is allowed to transmit is determined by passing a “token” back and forth. That is, the side currently transmitting passes the token to the receiving side. If the receiving side acknowledges the turn-around request, as indicated by driving the appropriate line state, the direction is switched. The figure shows an example of two turn-around events. At the beginning, the local side is the transmitter, as shown by Direction=0. When the protocol on this side wishes to turn the Lane around (i.e. give the token to the other side), it asserts TurnRequest for at least one cycle of TxClkEsc. This initiates the turn around procedure. The remote side acknowledges the turn-around request by driving the appropriate states on the Lines. When this happens, the local Direction signal changes from transmit (0) to receive (1). The remote side initiates a turn-around request, passing the token back to the local side. When this happens, the local Direction signal changes back to transmit (0). The transmitter is in control of the Link direction and decides when to turn the Link around, passing control to the receiver. If the remote side does not acknowledge the turnaround request, the Direction signal does not change.

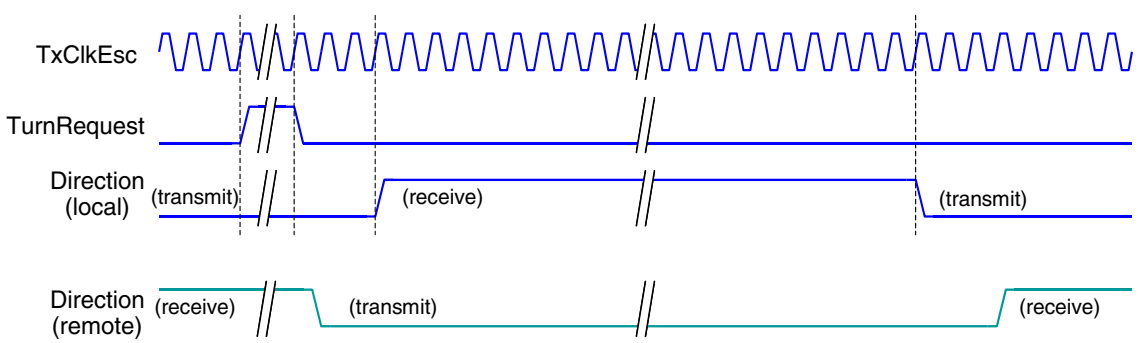

Figure 13-62. Turn-around Actions Transmit-to-Receive and Back to Transmit

13.6.5 DPHY PLL

The MIPI DSI DPHY PLL is a high performance PLL based frequency synthesizer that incorporates a lock detector, independent output divider, and supports power down modes. The PLL block diagram is shown below.

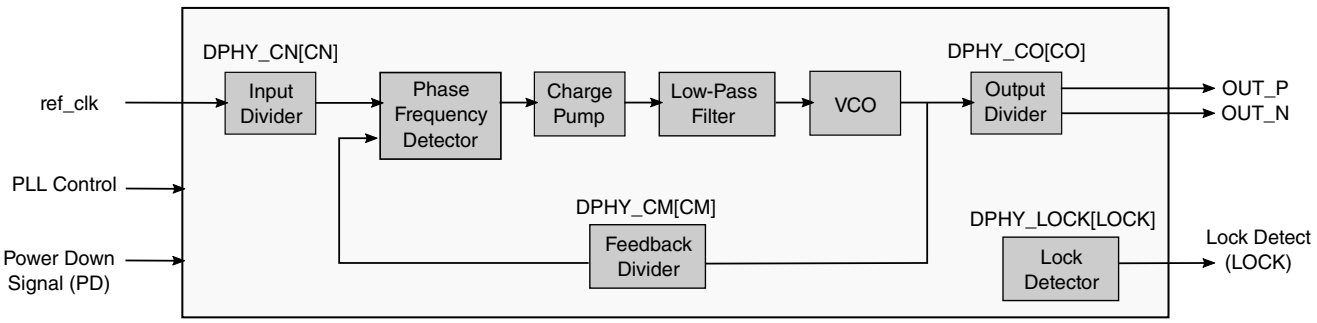

Figure 13-63. MIPI DSI DPHY PLL Block Diagram

The DPHY PLL input clock is ref_clk. The PLL output multiplies the input frequency by `(CM / (CN * CO))`.

NOTE

The input frequency ranges from 24 MHz till 200 MHz. The input divider has to be programmed such that the frequency after the input divider ranges from 24 MHz till 30 MHz.

NOTE

The VCO maximum output frequency is 1.5 GHz.

The power down signal (PD) is active-high and used to power down the PLL. Asserting PD will reset the PLL to it's initial state. To ensure proper PLL functionality, ref_clk needs to be stable before PLL power up. The expected power-on sequence for the DSI DPHY PLL is illustrated below.

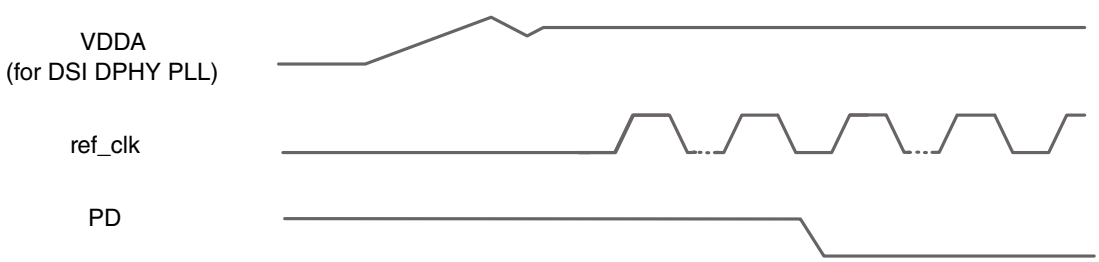

Figure 13-64. MIPI DSI DPHY PLL Power-on Sequence

13.6.6 DPHY Programming

The following sections detail the programming of the MIPI DSI DPHY high-speed timers.

13.6.6.1 High-Speed Prepare Timer ($T_{HS-PREPARE}$)

Calculate the value for clock lane high-speed prepare timer (mc_PRG_HS_PREPARE) using the formula below:

Assuming TxClkEsc = 20 MHz (T_{per} = 50 ns)
When mc_PRG_HS_PREPARE = 0, $T_{CLK-PREPARE}$= 1 * TxClkEsc Period = 50 ns
When mc_PRG_HS_PREPARE = 1, $T_{CLK-PREPARE}$ = 1.5 * TxClkEsc Period = 75 ns

Calculate the value for data lane high-speed prepare timer (m_PRG_HS_PREPARE) using the formula below:

Assuming TxClkEsc (TLPX) = 20 MHz (T_{per} = 50 ns)
When m_PRG_HS_PREPARE = 00, $T_{HS-PREPARE}$ = 1 * TxClkEsc Period = 50 ns
When m_PRG_HS_PREPARE = 01, $T_{HS-PREPARE}$ = 1.5 * TxClkEsc Period = 75 ns
When m_PRG_HS_PREPARE = 10, $T_{HS-PREPARE}$ = 2 * TxClkEsc Period = 100 ns
When m_PRG_HS_PREPARE = 11, $T_{HS-PREPARE}$ = 2.5 * TxClkEsc Period = 125 ns

13.6.6.2 High-Speed Zero Timer($T_{HS-ZERO}$)

Calculate the value for clock lane high-speed zero timer (mc_PRG_HS_ZERO) using the formula below:

$T_{CLK-ZERO}$= (mc_PRG_HS_ZERO + 3)*(TxByteClkHS Period)
TxByteClkHS = 1/8 Data Rate
When mc_PRG_HS_ZERO = 000110 @ 250 Mb/s, $T_{CLK-ZERO}$ = (6+3) * 32 ns = 288 ns
When mc_PRG_HS_ZERO = 100000 @ 1 Gb/s, $T_{CLK-ZERO}$ = (32+3) * 8 ns = 280 ns

Calculate the value for data lane high-speed zero timer (m_PRG_HS_ZERO) using the formula below:

$T_{HS-ZERO}$ = (m_PRG_HS_ZERO + 6)*(TxByteClkHS Period)
TxByteClkHS = 1/8 Data Rate
When m_PRG_HS_ZERO = 00001 @ 250 Mb/s, $T_{HS-ZERO}$ = (1+6) * 32 ns = 224 ns
When m_PRG_HS_ZERO = 01001 @ 1 Gb/s, $T_{HS-ZERO}$ = (9+6) * 8 ns = 120 ns

13.6.6.3 High-Speed Trail Timer ($T_{HS-TRAIL}$)

Calculate the value for the high-speed trail timer (PRG_HS_TRAIL) using the formula below:

$T_{HS-TRAIL}$= (PRG_HS_TRAIL)*(TxByteClkHS Period)
TxByteClkHS = 1/8 Data Rate
When PRG_HS_TRAIL = 0100 @ 250 Mb/s, >$T_{HS-TRAIL}$ = 4 * 32 ns = 128 ns
When PRG_HS_TRAIL = 1100 @ 1 Gb/s, >$T_{HS-TRAIL}$ = 12 * 8 ns = 96 ns

13.6.7 Packet Data and Pixel Formats

The DSI Host Controller Core and the external DSI Peripheral explicitly handle and exchanges 32-bit words encapsulated as packet data. The mapping between pixel formats and pixel data must be done on both sides by user application on both sides of the DSI link. The DSI spec gives many examples of common pixel formats. The DSI Host Controller Core and external DSI Peripheral have no preference or limitation on which pixel formats it will handle. The IP which provides video source packet data through DPI-2 interface (e.g. LCDIF) onto DSI should also be configured by the user application to match the pixel formats expected by the DSI Host Controller.

The DPI-2/DBI-2 interface core handles pixel to byte packing and byte to pixel unpacking according to the MIPI DSI specification.

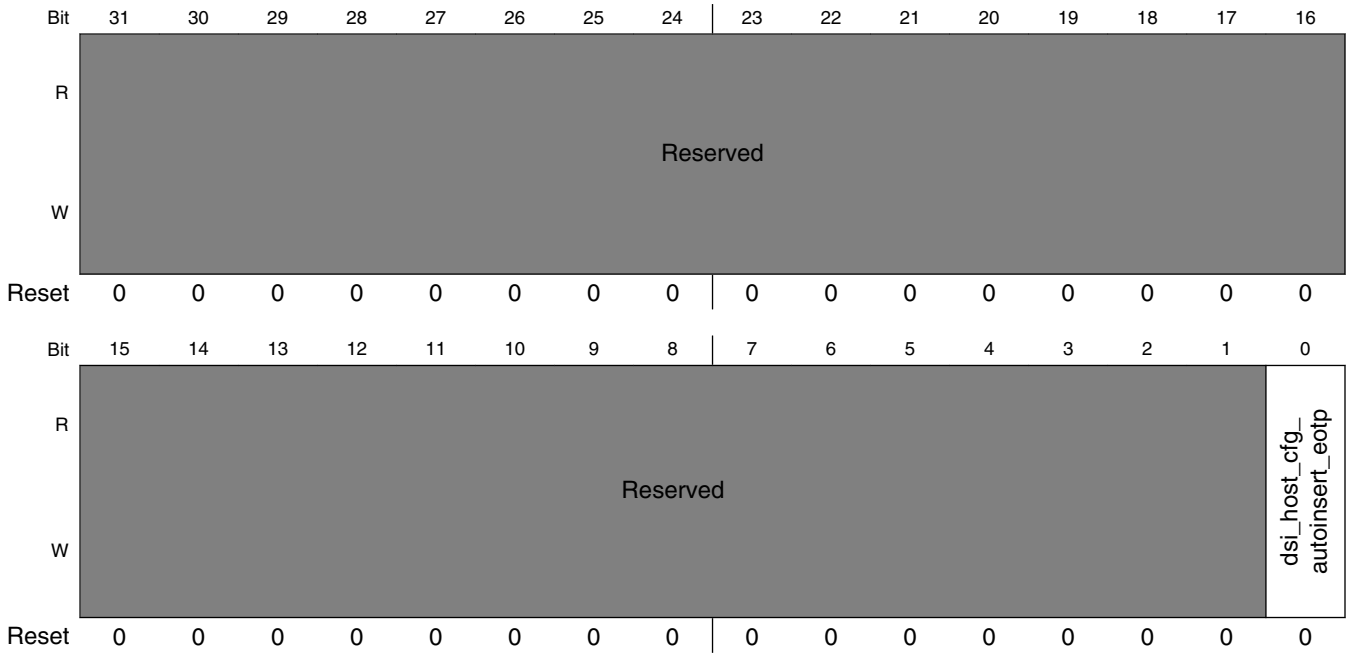
MIPI_DSI_HOST_DSI_HOST_CFG_TX_GAP field descriptions

Field	Description
31–7 -	This field is reserved.
dsi_host_cfg_tx_gap	Sets the number of byte clock periods ('clk_byte' input) that the controller will wait after the clock lane has been put into LP mode before enabling the clock lane for HS mode again. This setting represents the THS-EXIT parameter. The minimum value for this port is 1.

13.6.8.6 MIPI_DSI_HOST_DSI_HOST_CFG_AUTOINSERT_EOTP

Address: 30A0_0000h base + 14h offset = 30A0_0014h

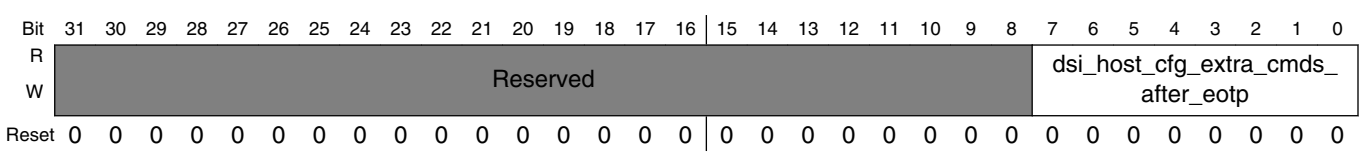


MIPI_DSI_HOST_DSI_HOST_CFG_AUTOINSERT_EOTP field descriptions

Field	Description
31–1 -	This field is reserved.
0 dsi_host_cfg_autoinsert_eotp	Enables the Host Controller to automatically insert an EoTp short packet when switching from HS to LP mode. • 1'b0 - EoTp is not automatically inserted • 1'b1 - EoTp is automatically inserted

13.6.8.7 MIPI_DSI_HOST_DSI_HOST_CFG_EXTRA_CMDS_AFTER_EOTP

Address: 30A0_0000h base + 18h offset = 30A0_0018h



MIPI_DSI_HOST_DSI_HOST_CFG_EXTRA_CMDS_AFTER_EOTP field descriptions

Field	Description
31–8 -	This field is reserved.
dsi_host_cfg_ extra_cmds_ after_eotp	Configures the DSI Host Controller to send extra End Of Transmission Packets after the end of a packet. The value is the number of extra EOTP packets sent.

13.6.8.8 MIPI_DSI_HOST_DSI_HOST_CFG_HTX_TO_COUNT

Address: 30A0_0000h base + 1Ch offset = 30A0_001Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved								dsi_host_cfg_htx_to_count																								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MIPI_DSI_HOST_DSI_HOST_CFG_HTX_TO_COUNT field descriptions

Field	Description
31–24 -	This field is reserved.
dsi_host_cfg_ htx_to_count	Sets the value of the DSI Host High Speed TX timeout count in clk_byte clock periods that once reached will initiate a timeout error and follow the recovery procedure documented in the DSI specification. This timeout parameter should be configured to represent the time taken to transmit the biggest HS data payload. If this timeout is reached the DSI byte count is cleared and the HS transmission is aborted. This timer can be also disabled, when set to 0.

13.6.8.9 MIPI_DSI_HOST_DSI_HOST_CFG_LRX_H_TO_COUNT

Address: 30A0_0000h base + 20h offset = 30A0_0020h

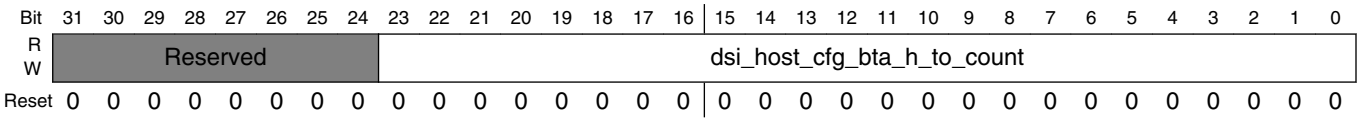
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved								dsi_host_cfg_lrx_h_to_count																								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MIPI_DSI_HOST_DSI_HOST_CFG_LRX_H_TO_COUNT field descriptions

Field	Description
31–24 -	This field is reserved.
dsi_host_cfg_lrx_ h_to_count	Sets the value of the DSI Host low power RX timeout count in clk_byte clock periods that once reached will initiate a timeout error and follow the recovery procedure documented in the DSI specification. This timeout parameter should be configured to represent the time taken to receive the biggest LP (Escape mode) data payload. If this timeout is reached, the DSI byte count is cleared and the LP reception is aborted. This timer can be also disabled, when set to 0

13.6.8.10 MIPI_DSI_HOST_DSI_HOST_CFG_BTA_H_TO_COUNT

Address: 30A0_0000h base + 24h offset = 30A0_0024h

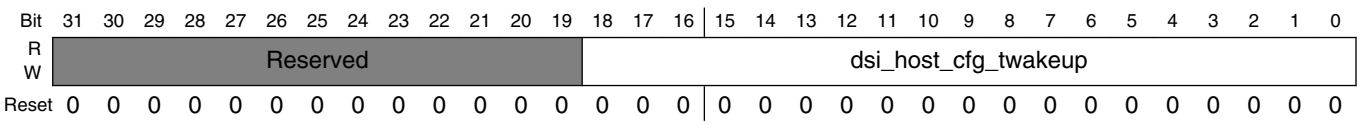


MIPI_DSI_HOST_DSI_HOST_CFG_BTA_H_TO_COUNT field descriptions

Field	Description
31–24 -	This field is reserved.
dsi_host_cfg_ bta_h_to_count	Sets the value of the DSI Host Bus Turn Around (BTA) timeout in clk_byte clock periods that once reached will initiate a timeout error.

13.6.8.11 MIPI_DSI_HOST_DSI_HOST_CFG_TWAKEUP

Address: 30A0_0000h base + 28h offset = 30A0_0028h

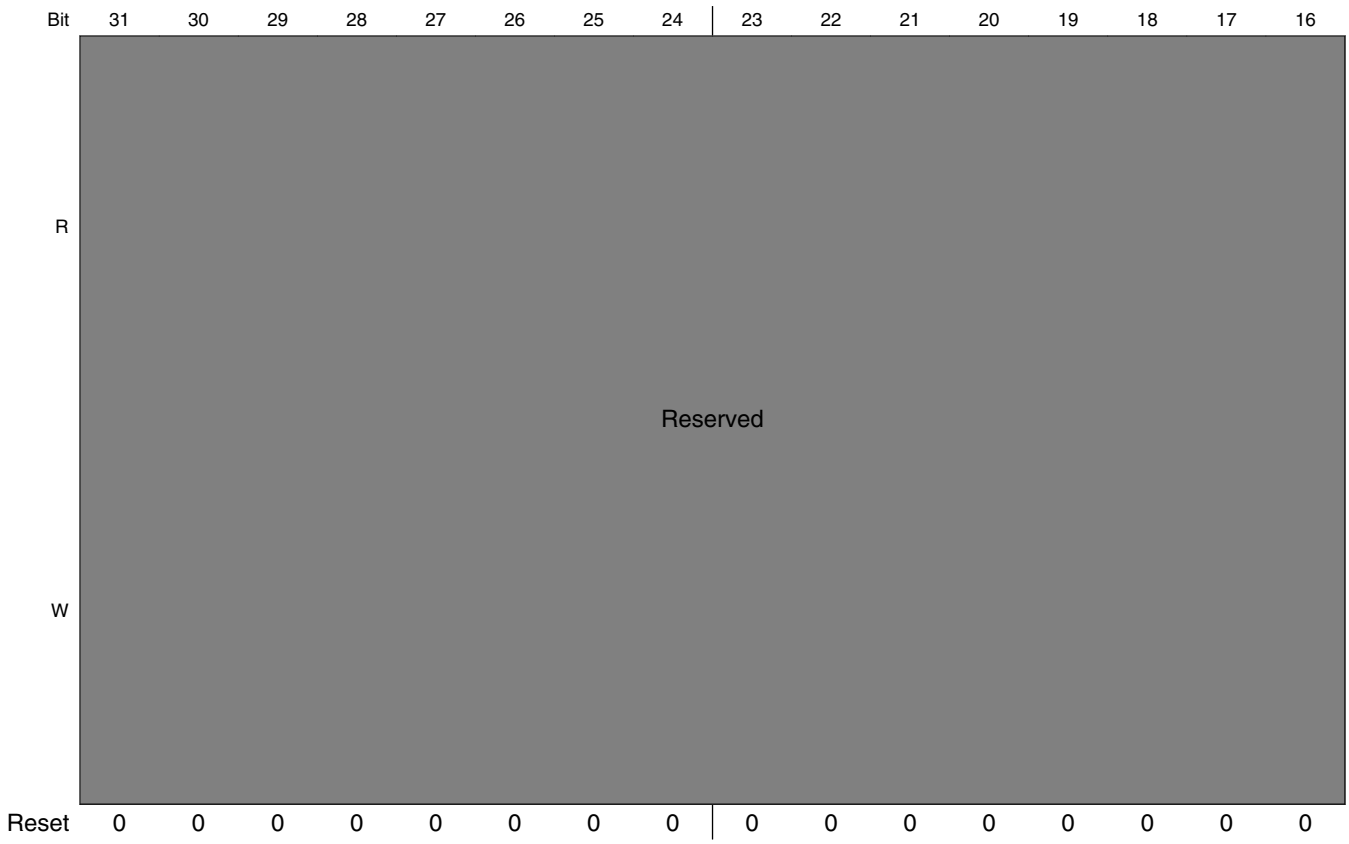


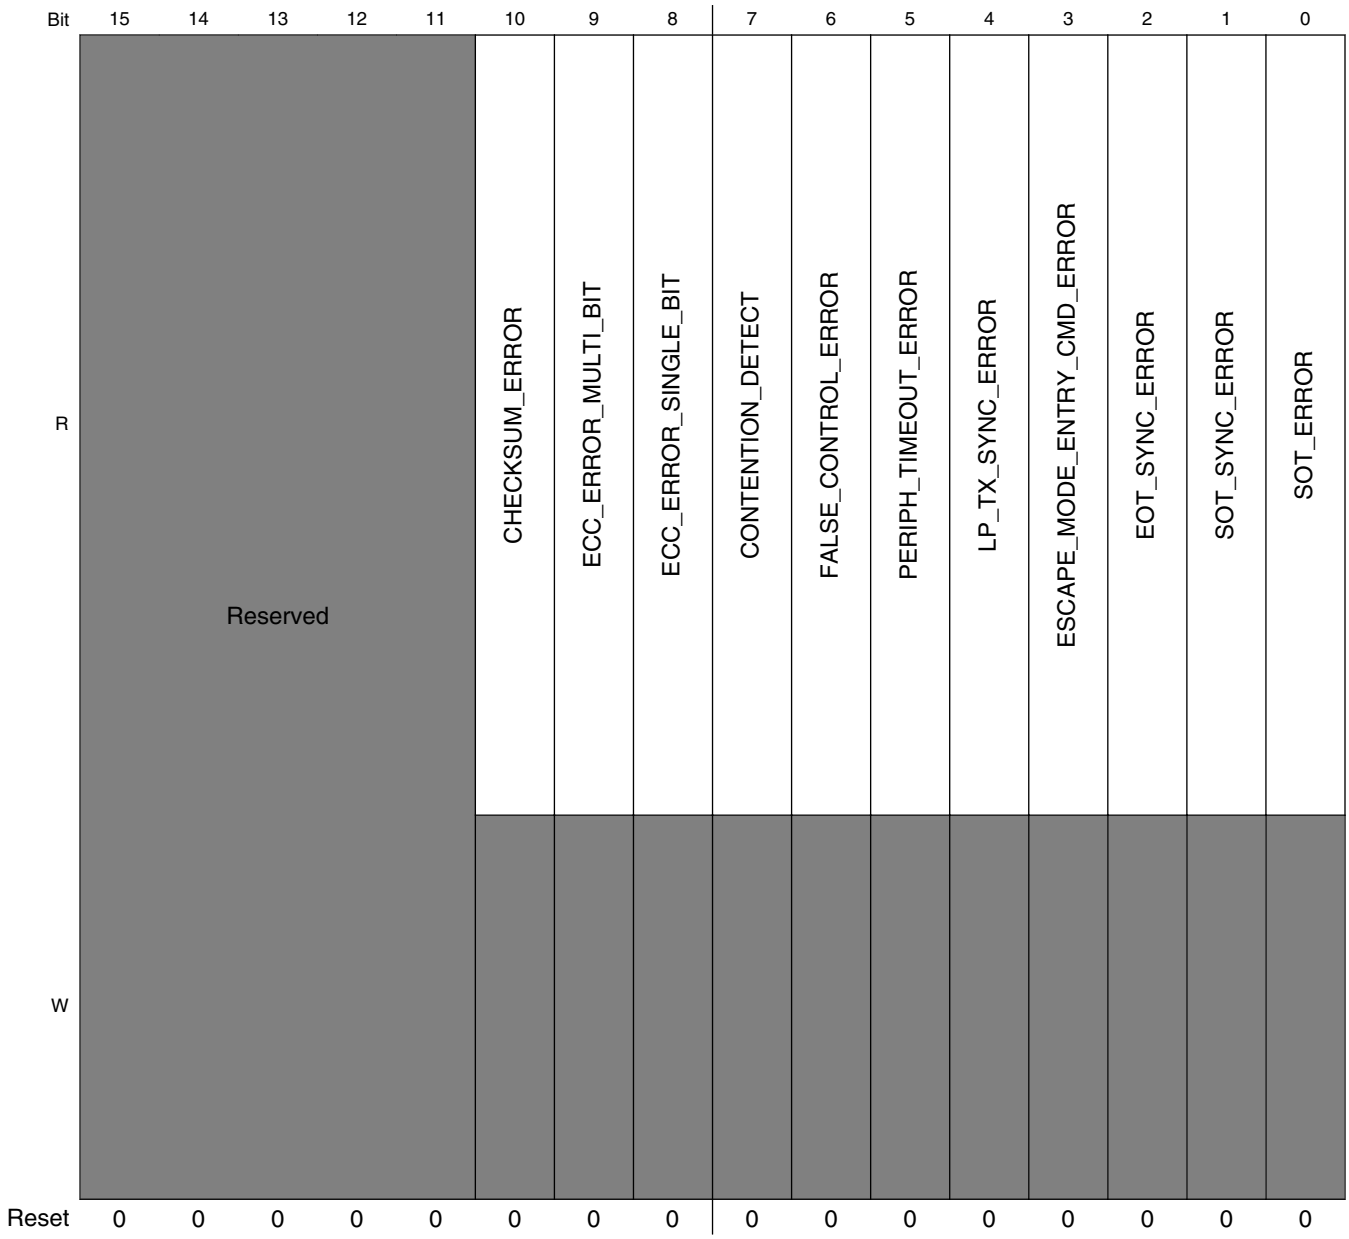
MIPI_DSI_HOST_DSI_HOST_CFG_TWAKEUP field descriptions

Field	Description
31–19 -	This field is reserved.
dsi_host_cfg_ twakeup	DPHY Twakeup timing parameter. Sets the number of clk_esc clock periods to keep a clock or data lane in Mark-1 state after exiting ULPS. The MIPI DPHY spec requires a minimum of 1ms in Mark-1 state after leaving ULPS.

13.6.8.12 MIPI_DSI_HOST_DSI_HOST_CFG_STATUS_OUT

Address: 30A0_0000h base + 2Ch offset = 30A0_002Ch





MIPI_DSI_HOST_DSI_HOST_CFG_STATUS_OUT field descriptions

Field	Description
31–11 -	This field is reserved. Reserved
10 CHECKSUM_ ERROR	Checksum Error (long packet only) – Checksum error from peripheral error report, cleared upon read
9 ECC_ERROR_ MULTI_BIT	ECC Error, multi-bit (detected, not corrected) – ECC multi-bit error from peripheral error report, cleared upon read

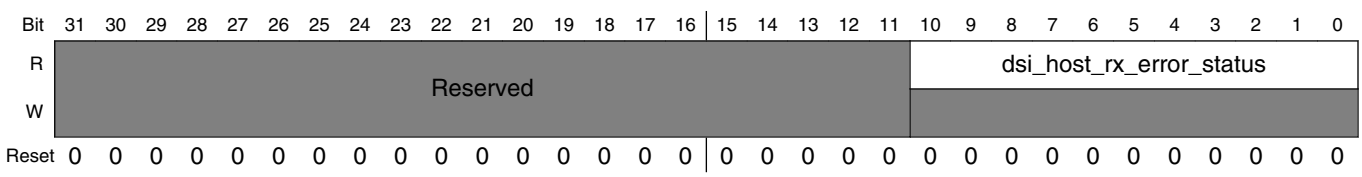
Table continues on the next page...

MIPI_DSI_HOST_DSI_HOST_CFG_STATUS_OUT field descriptions (continued)

Field	Description
8 ECC_ERROR_ SINGLE_BIT	ECC single bit error from peripheral error report, cleared upon read.
7 CONTENTION_ DETECT	Contention Detected – Contention Detection from peripheral error report, cleared upon read
6 FALSE_ CONTROL_ ERROR	False Control Error – False Control Error from peripheral error report, cleared upon read
5 PERIPH_ TIMEOUT_ ERROR	Peripheral Timeout Error – Peripheral Timeout error from peripheral error report, cleared upon read
4 LP_TX_SYNC_ ERROR	Low-Power Transmit Sync Error – Low Power Transmit Sync error from peripheral error report, cleared upon read.
3 ESCAPE_ MODE_ENTRY_ CMD_ERROR	Escape Mode Entry Command Error – Escape Mode Entry Command Error from peripheral error report, cleared upon read
2 EOT_SYNC_ ERROR	EoT Sync Error – End of Transmission (EoT) Sync Error from peripheral error report, cleared upon read
1 SOT_SYNC_ ERROR	SoT Sync Error – Start of Transmission (SoT) Sync Error from peripheral error report, cleared upon read
0 SOT_ERROR	SoT Error – Start of Transmission (SoT) Error from peripheral error report, cleared upon read.

13.6.8.13 MIPI_DSI_HOST_DSI_HOST_RX_ERROR_STATUS

Address: 30A0_0000h base + 30h offset = 30A0_0030h



MIPI_DSI_HOST_DSI_HOST_RX_ERROR_STATUS field descriptions

Field	Description
31–11 -	This field is reserved.
dsi_host_rx_ error_status	Status Register for Host receive error detection, ECC errors, CRC errors and for timeout indicators

Table continues on the next page...

MIPI_DSI_HOST_DSI_HOST_RX_ERROR_STATUS field descriptions (continued)

Field	Description
	• [0] ECC single bit error detected • [1] ECC multi bit error detected • [6:2] Errored bit position for single bit ECC error • [7] CRC error detected • [8] High Speed forward TX timeout detected • [9] Reverse Low power data receive timeout detected • [10] BTA timeout detected

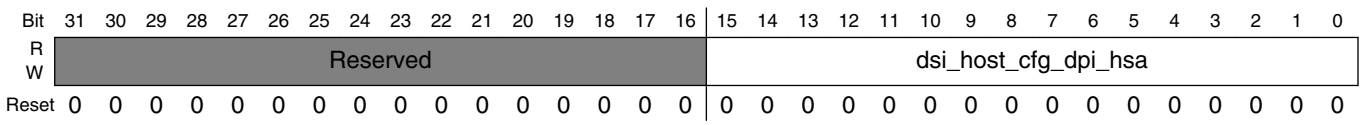
MIPI_DSI_HOST_DPI_INTFC_DSI_HOST_CFG_DPI_HBP field descriptions

Field	Description
31–16 -	This field is reserved.
dsi_host_cfg_ dpi_hbp	Sets the DSI packet payload size, in bytes, of the horizontal back porch blanking packet.

13.6.9.10 MIPI_DSI_HOST_DPI_INTFC_DSI_HOST_CFG_DPI_HSA

Address: 30A0_0000h base + 224h offset = 30A0_0224h

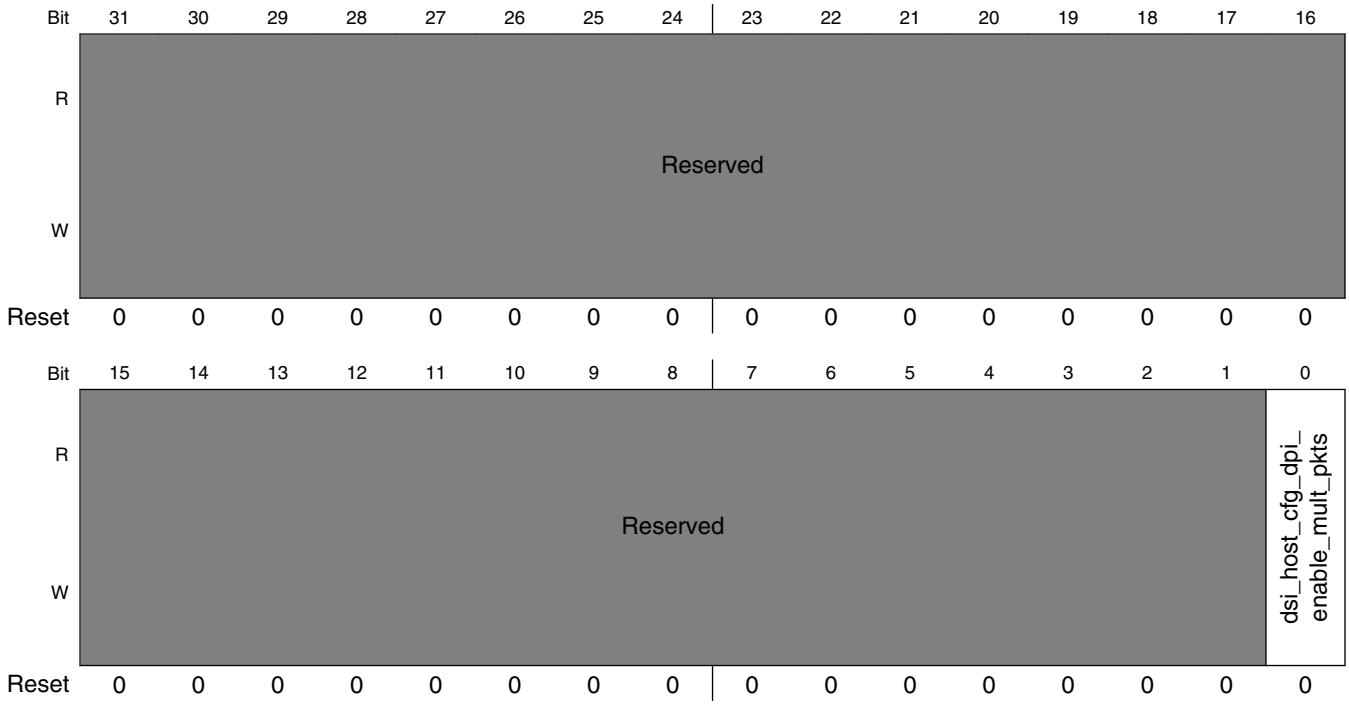


MIPI_DSI_HOST_DPI_INTFC_DSI_HOST_CFG_DPI_HSA field descriptions

Field	Description
31–16 -	This field is reserved.
dsi_host_cfg_ dpi_hsa	Sets the DSI packet payload size, in bytes, of the horizontal sync width filler blanking packet.

13.6.9.11 MIPI_DSI_HOST_DPI_INTFC_DSI_HOST_CFG_DPI_ENABLE_MULT_

Address: 30A0_0000h base + 228h offset = 30A0_0228h

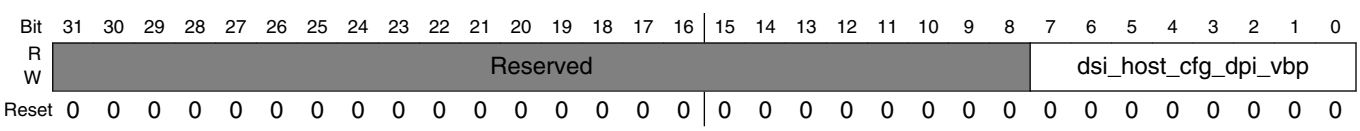


MIPI_DSI_HOST_DPI_INTFC_DSI_HOST_CFG_DPI_ENABLE_MULT_PKTS field descriptions

Field	Description
31–1 -	This field is reserved.
0 dsi_host_cfg_dpi_enable_mult_pkts	Enable Multiple packets per video line. When enabled, cfg_dpi_pixel_payload_size must be set to exactly half the size of the video line. 0 - Video Line is sent in a single packet 1 - Video Line is sent in two packets

13.6.9.12 MIPI_DSI_HOST_DPI_INTFC_DSI_HOST_CFG_DPI_VBP

Address: 30A0_0000h base + 22Ch offset = 30A0_022Ch

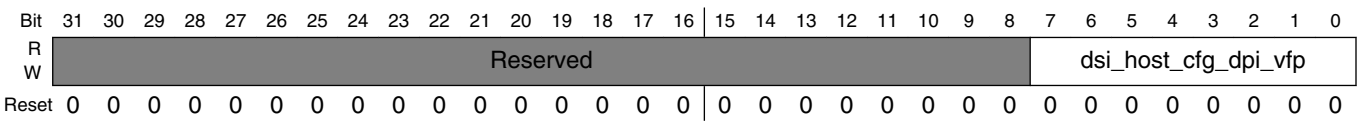


MIPI_DSI_HOST_DPI_INTFC_DSI_HOST_CFG_DPI_VBP field descriptions

Field	Description
31–8 -	This field is reserved.
dsi_host_cfg_ dpi_vbp	Sets the number of lines in the vertical back porch.

13.6.9.13 MIPI_DSI_HOST_DPI_INTFC_DSI_HOST_CFG_DPI_VFP

Address: 30A0_0000h base + 230h offset = 30A0_0230h

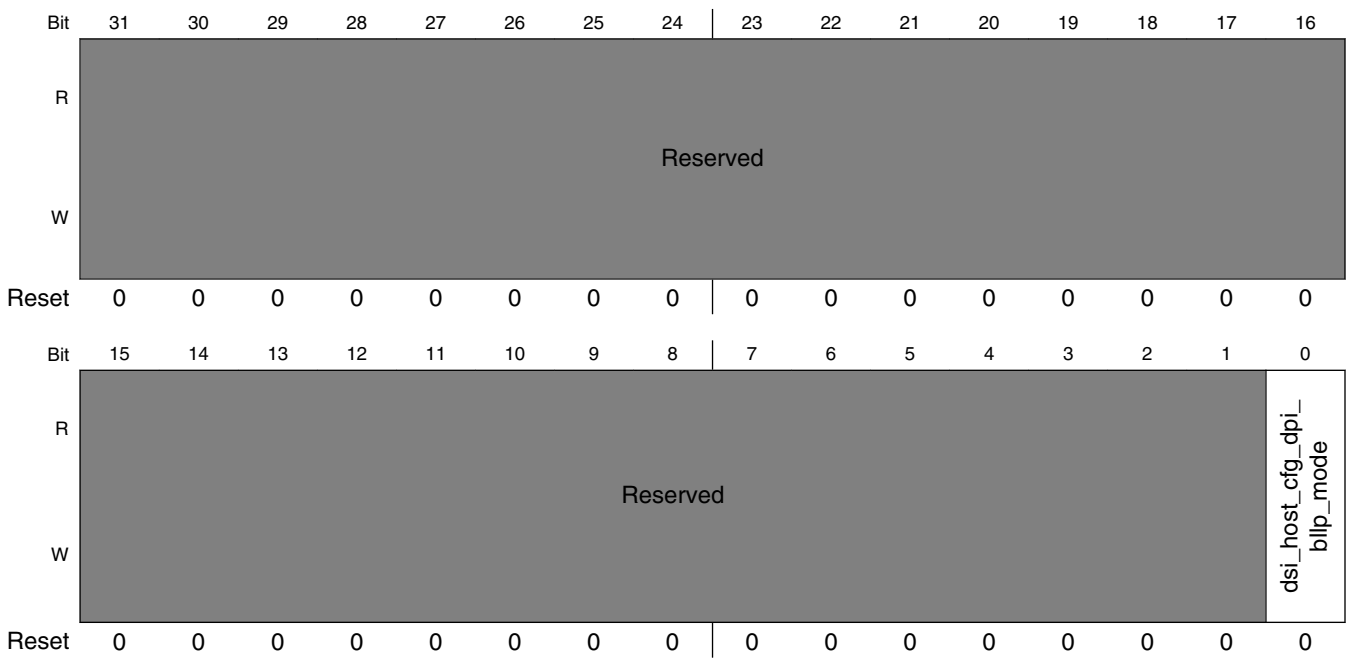


MIPI_DSI_HOST_DPI_INTFC_DSI_HOST_CFG_DPI_VFP field descriptions

Field	Description
31–8 -	This field is reserved.
dsi_host_cfg_ dpi_vfp	Sets the number of lines in the vertical front porch.

13.6.9.14 MIPI_DSI_HOST_DPI_INTFC_DSI_HOST_CFG_DPI_BLLP_MODE

Address: 30A0_0000h base + 234h offset = 30A0_0234h

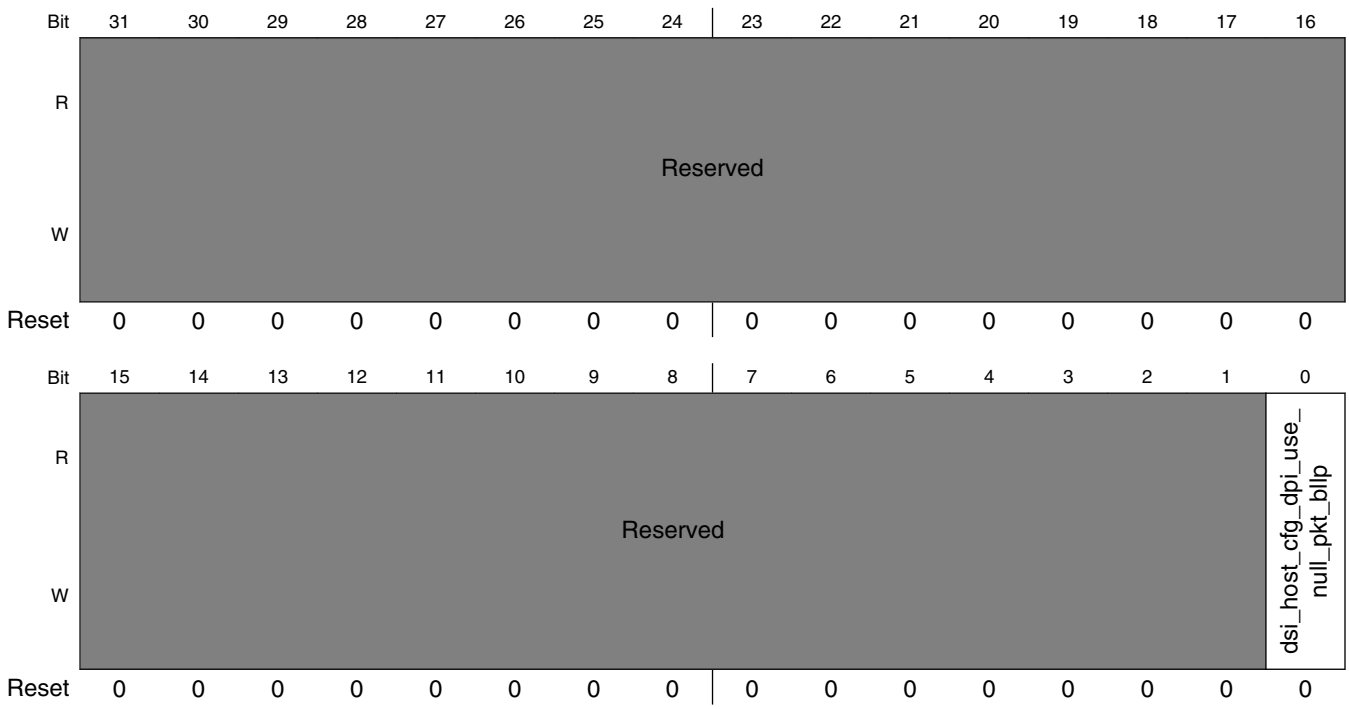


MIPI_DSI_HOST_DPI_INTFC_DSI_HOST_CFG_DPI_BLLP_MODE field descriptions

Field	Description
31–1 -	This field is reserved.
0 dsi_host_cfg_ dpi_bllp_mode	Optimize bllp periods to Low Power mode when possible 0 - blanking packets are sent during BLLP periods 1 - LP mode is used for BLLP periods

13.6.9.15 MIPI_DSI_HOST_DPI_INTFC_DSI_HOST_CFG_DPI_USE_NULL_PKT

Address: 30A0_0000h base + 238h offset = 30A0_0238h



MIPI_DSI_HOST_DPI_INTFC_DSI_HOST_CFG_DPI_USE_NULL_PKT_BLLP field descriptions

Field	Description
31–1 -	This field is reserved.
0 dsi_host_cfg_ dpi_use_null_ pkt_bllp	Selects type of blanking packet to be sent during bllp region 0 - Blanking packet used in bllp region 1 - Null packet used in bllp region

13.6.9.16 MIPI_DSI_HOST_DPI_INTFC_DSI_HOST_CFG_DPI_VACTIVE

Address: 30A0_0000h base + 23Ch offset = 30A0_023Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

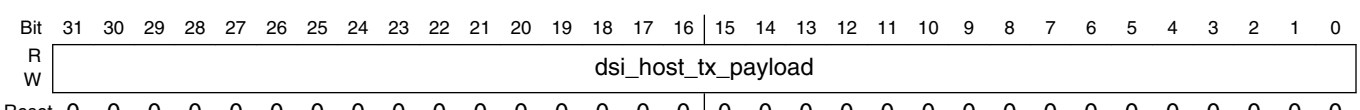
13.6.10.1 MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_TX_PAYLOAD

Address: 30A0_0000h base + 280h offset = 30A0_0280h

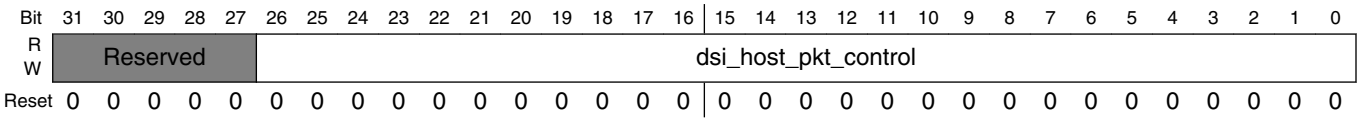


MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_TX_PAYLOAD field descriptions

Field	Description
dsi_host_tx_payload	Tx Payload data write register. Writes to this registers load the payload fifo with 32 bit values.

13.6.10.2 MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_PKT_CONTROL

Address: 30A0_0000h base + 284h offset = 30A0_0284h

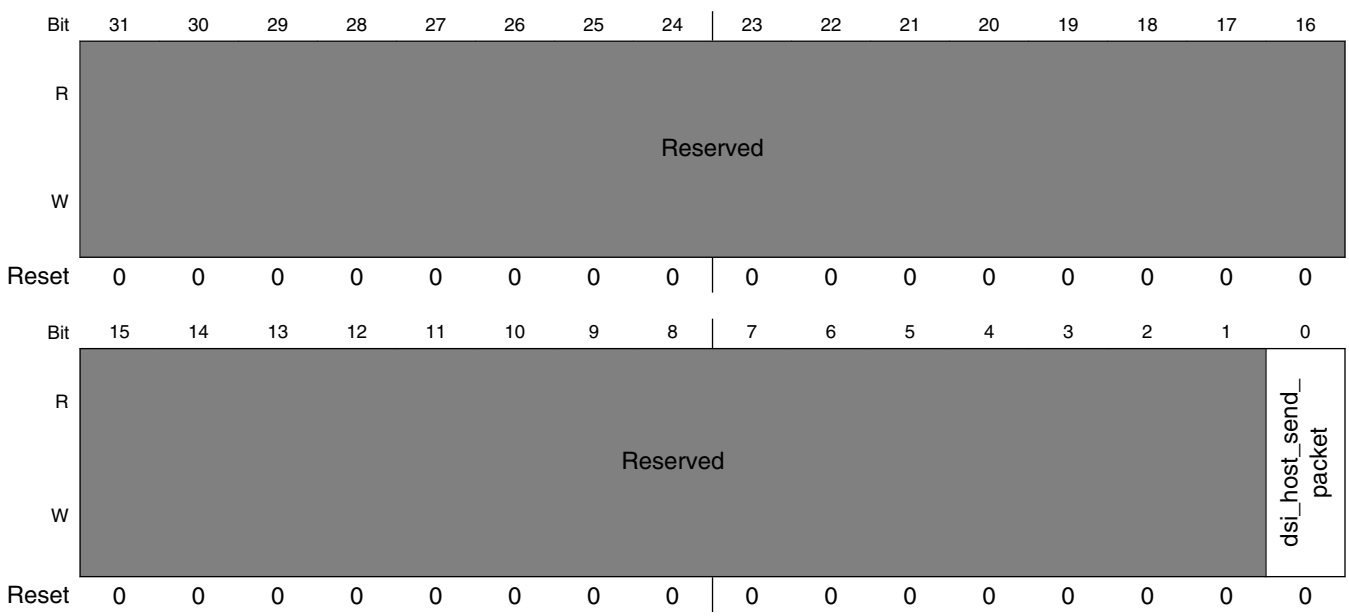


MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_PKT_CONTROL field descriptions

Field	Description
31–27 -	This field is reserved.
dsi_host_pkt_ control	Tx packet control register. • [15:0] - Packet word count • [17:16] - Packet Virtual Channel • [23:18] - Packet Header DSI Data Type • [24] - Lp or HS select. 0 - LP mode, 1 - HS mode • [25] - perform BTA after packet is sent • [26] - perform BTA only, no packet tx

13.6.10.3 MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_SEND_PACKET

Address: 30A0_0000h base + 288h offset = 30A0_0288h

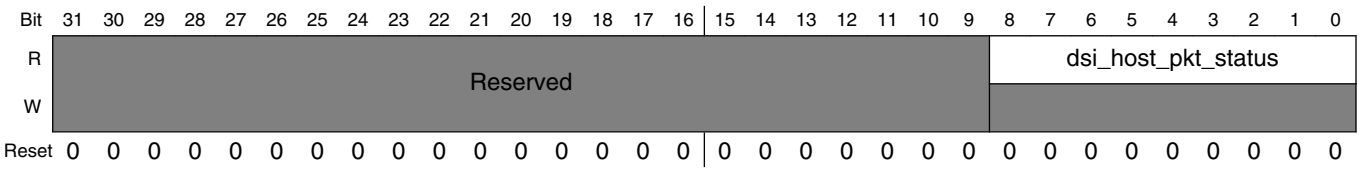


MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_SEND_PACKET field descriptions

Field	Description
31–1 -	This field is reserved.
0 dsi_host_send_packet	Tx send packet. Writing to this register causes the packet described in dsi_host_pkt_control to be sent.

13.6.10.4 MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_PKT_STATUS

Address: 30A0_0000h base + 28Ch offset = 30A0_028Ch

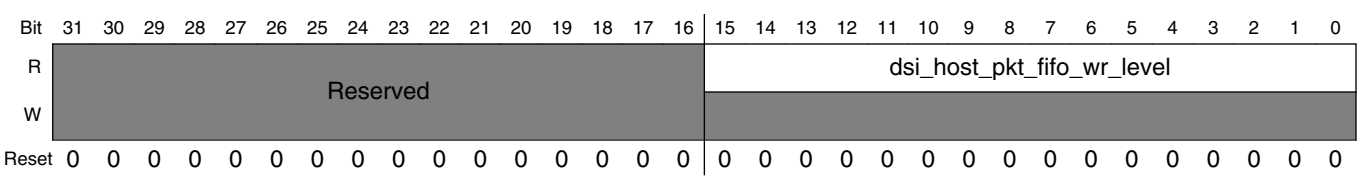


MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_PKT_STATUS field descriptions

Field	Description
31–9 -	This field is reserved.
dsi_host_pkt_status	Status of APB to packet interface • [0] - state machine not idle • [1] - Tx packet done • [2] - dphy direction 0 - tx had control, 1 - rx has control • [3] - tx fifo overflow • [4] - tx fifo underflow • [5] - rx fifo overflow • [6] - rx fifo underflow • [7] - rx packet header has been received • [8] - all rx packet payload data has been receive d

13.6.10.5 MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_PKT_FIFO_WR_LEVEL

Address: 30A0_0000h base + 290h offset = 30A0_0290h

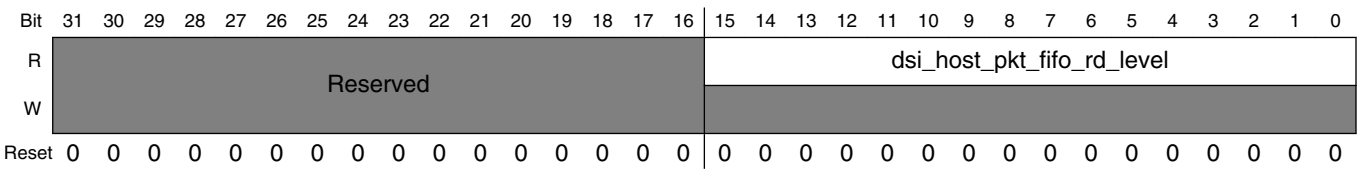


MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_PKT_FIFO_WR_LEVEL field descriptions

Field	Description
31–16 -	This field is reserved.
dsi_host_pkt_ fifo_wr_level	Write level of APB to pkt interface fifo

13.6.10.6 MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_PKT_FIFO_RD_LEVEL

Address: 30A0_0000h base + 294h offset = 30A0_0294h

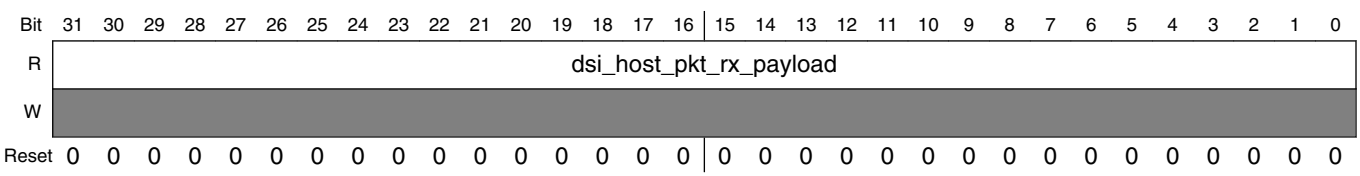


MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_PKT_FIFO_RD_LEVEL field descriptions

Field	Description
31–16 -	This field is reserved.
dsi_host_pkt_ fifo_rd_level	Read level of APB to pkt interface fifo

13.6.10.7 MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_PKT_RX_PAYLOAD

Address: 30A0_0000h base + 298h offset = 30A0_0298h

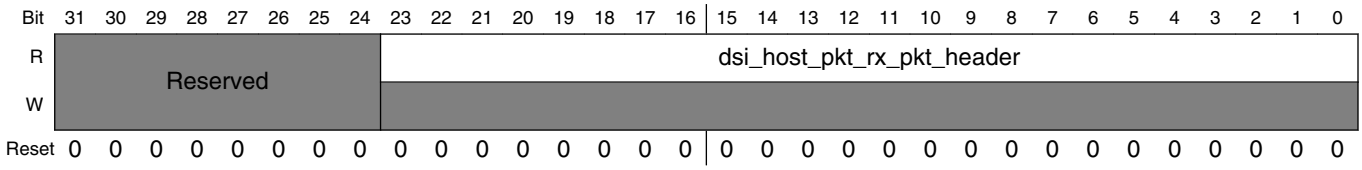


MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_PKT_RX_PAYLOAD field descriptions

Field	Description
dsi_host_pkt_rx_ payload	APB to pkt interface rx payload read

13.6.10.8 MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_PKT_RX_PKT_HEADER

Address: 30A0_0000h base + 29Ch offset = 30A0_029Ch

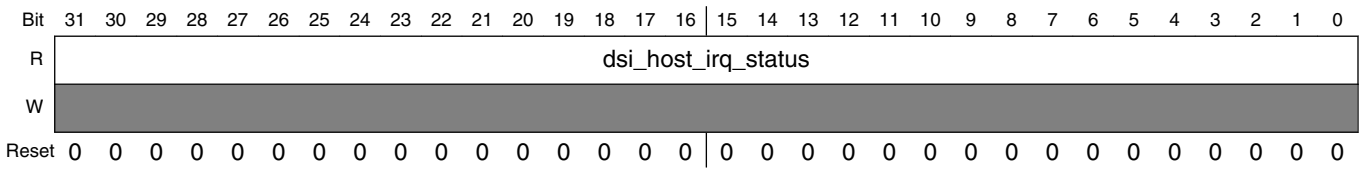


MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_PKT_RX_PKT_HEADER field descriptions

Field	Description
31–24 -	This field is reserved.
dsi_host_pkt_rx_ pkt_header	APB to pkt interface rx packet header • [15:0] word count • [21:16] data type • [23:22] Virtual Channel

13.6.10.9 MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_IRQ_STATUS

Address: 30A0_0000h base + 2A0h offset = 30A0_02A0h

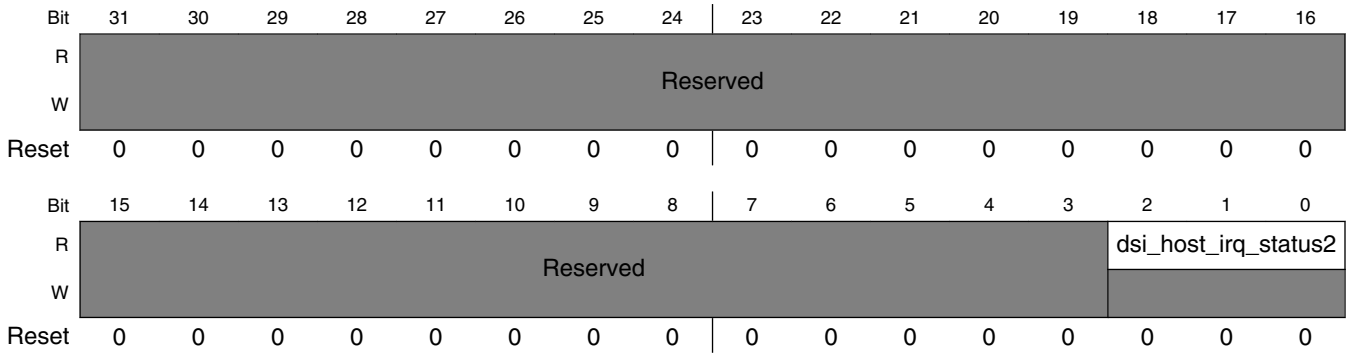


MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_IRQ_STATUS field descriptions

Field	Description
dsi_host_irq_ status	Status of APB to packet interface • [0] - state machine not idle • [1] - Tx packet done • [2] - dphy direction 0 - tx had control, 1 - rx has control • [3] - tx fifo overflow • [4] - tx fifo underflow • [5] - rx fifo overflow • [6] - rx fifo underflow • [7] - rx packet header has been received • [8] - all rx packet payload data has been received • [28:9] - map directory to dsi host controller status_out port bit descriptions • [29] - host bta timeout, host controller host_bta_timeout port • [30] - low power rx timeout, host controller lp_rx_timeout port • [31] - high speed tx timeout, host controller hs_tx_timeout port

13.6.10.10 MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_IRQ_STATUS2

Address: 30A0_0000h base + 2A4h offset = 30A0_02A4h

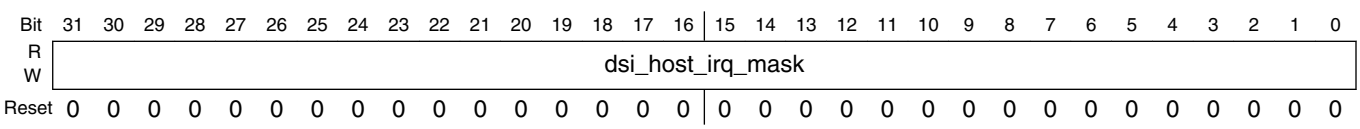


MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_IRQ_STATUS2 field descriptions

Field	Description
31–3 -	This field is reserved.
dsi_host_irq_ status2	Status of APB to packet interface part 2. Read part 2 first then dsi_host_irq_status. Reading dsi_host_irq_status will clear both status and status 2. • [0] - single bit ecc error • [1] - multi bit ecc error • [2] - crc error

13.6.10.11 MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_IRQ_MASK

Address: 30A0_0000h base + 2A8h offset = 30A0_02A8h



MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_IRQ_MASK field descriptions

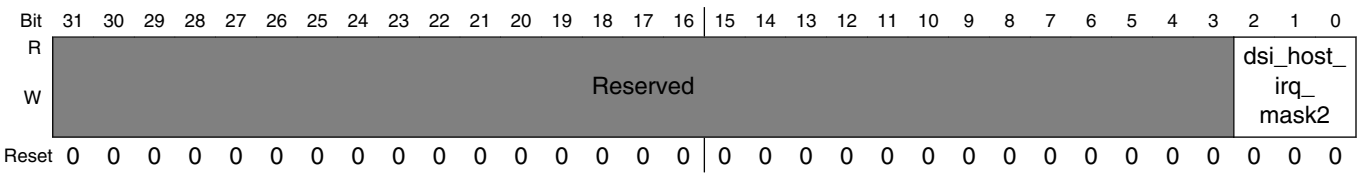
Field	Description
dsi_host_irq_ mask	irq mask • [0] - state machine not idle • [1] - Tx packet done • [2] - dphy direction 0 - tx had control, 1 - rx has control • [3] - tx fifo overflow • [4] - tx fifo underflow • [5] - rx fifo overflow • [6] - rx fifo underflow • [7] - rx packet header has been received • [8] - all rx packet payload data has been received • [28:9] - map directory to dsi host controller status_out port bit descriptions

MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_IRQ_MASK field descriptions (continued)

Field	Description
	• [29] - host bta timeout, host controller host_bta_timeout port • [30] - low power rx timeout, host controller lp_rx_timeout port • [31] - high speed tx timeout, host controller hs_tx_timeout port

13.6.10.12 MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_IRQ_MASK2

Address: 30A0_0000h base + 2ACh offset = 30A0_02ACh



MIPI_DSI_HOST_APB_PKT_IF_DSI_HOST_IRQ_MASK2 field descriptions

Field	Description
31–3 -	This field is reserved.
dsi_host_irq_mask2	irq mask 2 • [0] - single bit ecc error • [1] - multi bit ecc error • [2] - crc error

13.7 CSI Bridge (CSI)

13.7.1 Overview

This chapter presents the CMOS Sensor Interface (CSI) architecture, operation principles, and programming model.

The CSI enables the chip to connect directly to external CMOS image sensors. CMOS image sensors are separated into two classes, dumb and smart. Dumb sensors are those that support only traditional sensor timing (Vertical SYNC and Horizontal SYNC) and output only Bayer and statistics data, while smart sensors support CCIR656 video decoder formats and perform additional processing of the image (for example, image compression, image pre-filtering, and various data output formats).

The capabilities of the CSI include:

- Configurable interface logic to support most commonly available CMOS sensors.
- Support for CCIR656 video interface as well as traditional sensor interface.
- 8-bit / 16-bit / 24-bit data port for YCbCr, YUV, or RGB data input.
- 8-bit / 10-bit / 16-bit data port for Bayer data input.
- Full control of 8-bit/pixel, 10-bit/pixel or 16-bit / pixel data format to 64-bit receive FIFO packing.
- 256 x 64 FIFO to store received image pixel data.
- Reveive FIFO overrun protection mechanism.
- Embedded DMA controllers to transfer data from receive FIFO or statistic FIFO through AHB bus.
- Support 2D DMA transfer from the receive FIFO to the frame buffers in the external memory.
- Support double bufferring two frames in the external memory.
- Single interrupt source to interrupt controller from maskable interrupt sources: Start of Frame, End of Frame, Change of Field, FIFO full, FIFO overrun, DMA transfer done, CCIR error and AHB bus response error.
- Configurable master clock frequency output to sensor.
- Statistic data generation for Auto Exposure (AE) and Auto White Balance (AWB) control of the camera (only for Bayer data and 8-bit/pixel format).
- Supports simple deinterlacing of interlaced input.

13.7.2 Clocks

The following table describes the clock sources for CSI.

Table 13-30. CSI Clocks

Clock name	Clock Root	Description
csi_hclk		Module clock
ipg_clk		Peripheral clock
ipg_clk_s		Peripheral access clock
ipg_clk_s_raw		Peripheral raw data clock

13.7.3 Principles of Operation

The information found here describes the modes of operation of the sensor interface.

The CSI is designed to support generic sensor interface timing as well as CCIR656 video interface timing. Traditional CMOS sensors typically use VSYNC (SOF), HSYNC (BLANK), and PIXCLK signals to output Bayer or YUV data. Smart CMOS sensors, that come with on-chip imaging processing, usually support video mode transfer. They use an embedded timing codec to replace the VSYNC and HSYNC signal. The timing codec is defined by the CCIR656 standard.

The CSI can support connection with the sensor as follows.

- To connect with one 8-bit sensor, the sensor data interface should connect to CSI_DATA[9:2].
- To connect with one 10-bit sensor, the sensor data interface should connect to CSI_DATA[9:0].
- To connect with one 16-bit sensor, the sensor data interface should connect to CSI_DATA[15:0].

13.7.3.1 Data Transfer with the Embedded DMA Controllers

The CSI has two embedded DMA controllers, one for the receive FIFO and the other for the statistic FIFO. It supports 2D DMA transfer from the receive FIFO to the frame buffers in the external memory and linear DMA transfer from the statistic FIFO.

To transfer data from the RxFIFO to the external memory, the user should set the start address in the frame buffer where the transferred data is stored, the parameters of the frame buffers, and the parameters of the image coming from the sensor. The user can have two frame buffers in the external memory. Each one will store a frame of image coming from the sensor. The embedded DMA controller will first write the frame buffer1 and then frame buffer2. These two frame buffers will be written by turns. The start address should be aligned in double words and set in the CSIDMASA-FB1 and CSIDMASA-FB2 registers. In the CSIFBUF_PARA register, the user should set the stride of the frame buffer to show how many double words to skip before starting to write the next row of the image. In the CSIIMAG_PARA register, the user should set the width and height of the image coming from the sensor. The RxFF_LEVEL and DMA_REQ_EN_RFF bits in CSICR3 registers also need to be set before the data transfer starts. When the number of the data in the RxFIFO reaches the trigger level, a DMA request will be sent to the embedded DMA controller and the data will be read out from the RxFIFO and written through AHB bus into the external frame buffers. The burst type of transfer can be INCR4, INCR8 and INCR16 by setting DMA_BURST_TYPE_RFF bits in CSICR2 register. After all data in an image frame are transferred, the DMA_TSF_DONE_FB1 or DMA_TSF_DONE_FB2 bit will be set in CSISR register and the interrupt can be triggered if the corresponding enable bit is set in CSICR1 register. The DMA_REFLASH_RFF bit in CSICR3 can be used to activate or restart the embedded DMA controller.

The RxFIFO has the overrun protection mechanism in case the RxFIFO is overrun during data transfer. If the RxFIFO is full and more data needs to be received during the data transfer, the RxFIFO will be overwritten continuously and all 128 words of data in the RxFIFO before overrun occurred will be discarded; the corresponding 128 words memory space in the frame buffer will keep the previous values.

To transfer data from the statistic FIFO to the external memory, the user should set the start address of the externl memory where the transferred data is stored and the total transfer sizes. The start address and the transfer sizes are all aligned in double words and should be set in the CSIDMASA-STATFIFO and CSIDMATS-STATFIFO registers. The STATFF_LEVEL and DMA_REQ_EN_SFF bits in CSICR3 registers should also be set before the data transfer starts. When the number of the data in the STATFIFO reaches the trigger level, a dma request will be sent to the embedded DMA controller and the data will be read out from the STATFIFO and written through AHB bus into the external

memory. The burst type of transfer can be INCR4, INCR8 and INCR16 by setting DMA_BURST_TYPE_SFF bits in CSICR2 register. After all expected data (defined by the total transfer sizes) are transferred, the DMA_TSF_DONE_SFF bit will be set in CSISR register and an interrupt can be triggered if the SFF_DMA_DONE_INTEN is enabled in CSICR1 register. The DMA_REFLASH_SFF bit in CSICR3 can be used to activate or re-start the embedded DMA controller.

13.7.3.2 Gated Clock Mode

VSYNC, HSYNC, and PIXCLK signals are used in gated clock mode.

A frame starts with an active edge on VSYNC, then HSYNC asserts and holds for the entire line. The Pixel clock is valid as long as HSYNC is asserted. Data is latched at the active edge of the valid pixel clocks. HSYNC deasserts at the end of line. Pixel clocks then become invalid and CSI stops receiving data from the stream. For the next line the HSYNC timing repeats. For the next frame the VSYNC timing repeats.

13.7.3.3 Non-Gated Clock Mode

In non-gated clock mode, only the VSYNC and PIXCLK signals are used; the HSYNC signal is ignored.

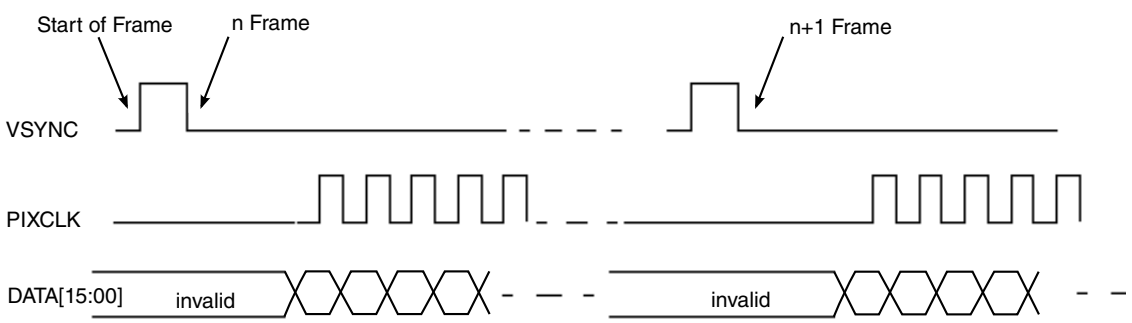

Figure 13-65. Non-Gated Clock Mode Timing Diagram

The overall timing of non-gated mode is the same as the gated-clock mode, except for the HSYNC signal. HSYNC signal is ignored by the CSI. All incoming pixel clocks are valid and cause data to be latched into RxFIFO. The PIXCLK signal is inactive (states low) until valid data is ready to be transmitted over the bus.

Figure 13-65 shows the timing of a typical sensor. Other sensors may have the slightly different timing from that shown. The CSI can be programed to support rising/falling-edge triggered VSYNC, active-high/low HSYNC, and rising/falling-edge triggered PIXCLK.

13.7.3.4 CCIR656 Interlace Mode

In CCIR656 interlace mode, only the PIXCLK and CSI_DATA[9:2] signals are used. The start of frame and blank signals are replaced by a timing codec which is embedded in the data stream. Each active line starts with an Start of Active Video (SAV) code and ends with an End of Active Video (EAV) code. In some cases, digital blanking is inserted in between EAV and SAV code. The CSI decodes and filters out the timing-coding from the data stream, recovering VSYNC and HSYNC signals for internal use, such as statistical block control. Data is forwarded to the data receive and packing block in a sequential manner without reordering-that is, field 1 followed by field 2. The fields must be reordered in software to get back the original image.

Change of Field (COF) interrupt is triggered upon every field change. The interrupt service routine reads the status register to check for the current field.

According to the CCIR656 specification, the image must be in 625/50 PAL or 525/60 NTSC format. In addition, the image is interlaced into odd and even fields with vertical and horizontal blank data being filled into certain lines. Data must be in YCbCr422 format, each pixel contains 2 bytes, either Y + Cr or Y + Cb. These requirements are set for TV systems. The CSI module supports PAL and NTSC format only.

The following figure describes the frame structure in PAL system, showing vertical and horizontal blanking.

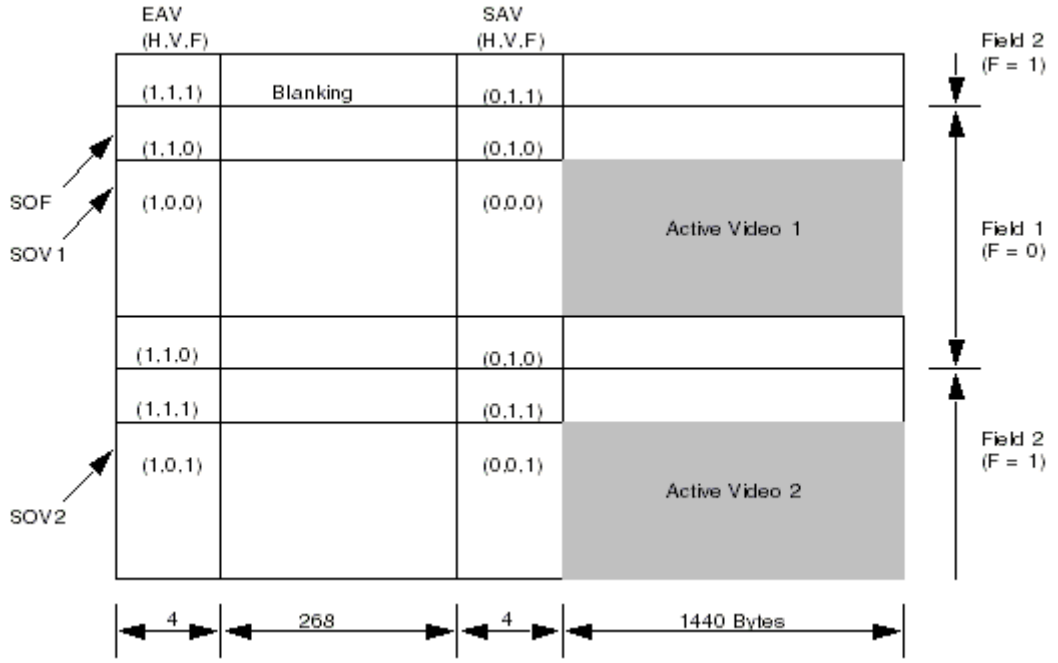

Figure 13-66. CCIR656 Interlace Mode (PAL)

The following figure describes the general timing for a single line, showing SAV and EAV.

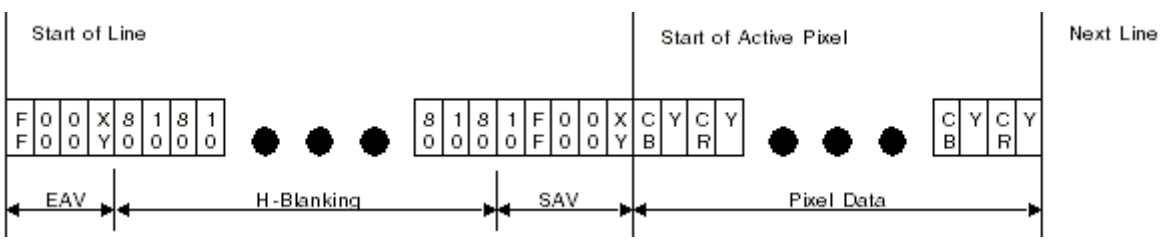

Figure 13-67. CCIR656 General Line Timing

The coding tables recommended by the CCIR656 specification are shown below. It is used in the CCIR656 mode to decode the video stream. An interrupt is generated for SOF, which is decoded from the embedded timing codec.

Table 13-32. Coding for SAV and EAV

Data Bit Number	1st Byte 0xFF	2nd Byte 0x00	3rd Byte 0x00	4th Byte 0xXY
7 (MSB)	1	0	0	1

Table 13-34. Representations by F-Bit

F-Bit	Representations
0	ODD FIELD (FIELD 1)
1	EVEN FIELD (FIELD 2)

13.7.3.5 CCIR656 Progressive Mode

For a CMOS camera system of VGA or CIF resolution, strict adherence to the interlace requirements stated in the CIR standard is not required.

The image is considered to have only 1 active field which is scanned in a progressive manner. This active field is regarded as field 1 and the F-bit in the timing codec is ignored by the decoder. Most sensors support CCIR timing in this mode (progressive) by default.

The following figure shows the typical flow of progressive mode.

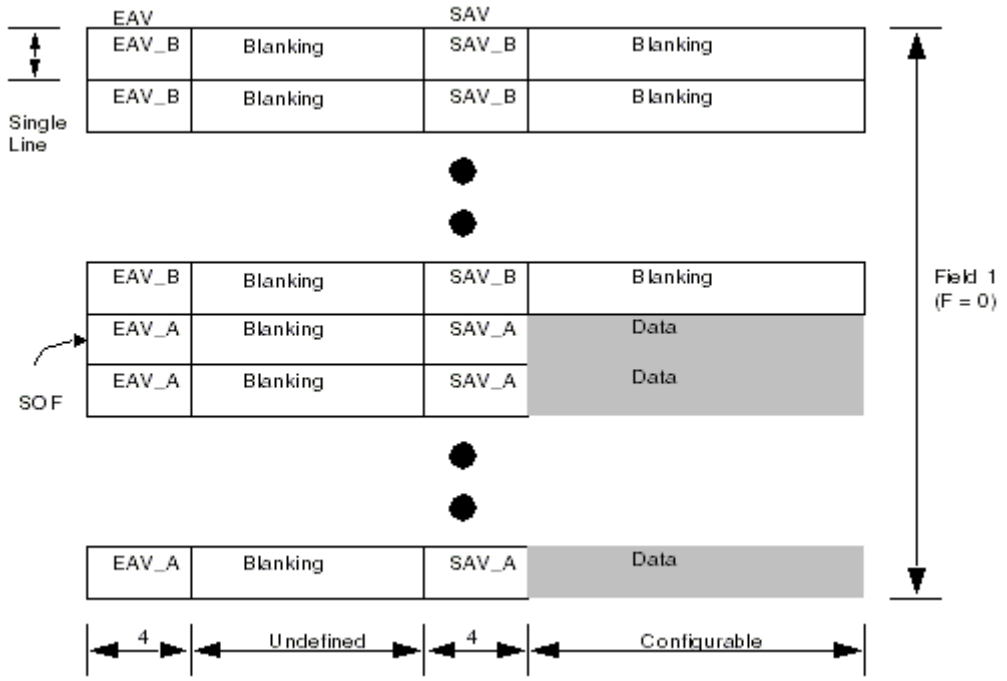

Figure 13-68. CCIR656 Progressive Mode (General Case)

An interrupt is generated for SOF but not for COF. In the general case, when SOF information is retrieved from the embedded coding, it is known as internal VSYNC mode. In other cases, when the VSYNC signal is provided by the sensor, it is known as external VSYNC mode. The CSI can be operated in internal or external VSYNC mode.

13.7.3.6 Error Correction for CCIR656 Coding

According to the algorithm for CCIR coding, protection bits in the SAV and EAV are encoded in the way that allows a 1-bit error to be corrected, or a 2-bit error to be detected by the decoder. This feature is supported by the interlace mode CCIR decoder in CSI.

For the 1-bit error case, users can select the error to be corrected automatically, or simply shown as a status flag instead. For the 2-bit error case, because the decoder is unable to make a correction, the error would be shown as a status flag only.

An interrupt can be generated upon the detection of an error. This signal can be enabled or disabled without affecting the operation of the status bit.

13.7.3.7 Deinterlacer

Deinterlacing is the process of converting interlaced video, such as CCIR656 input, into a non-interlaced form.

The CSI uses the weaving method to do deinterlacing. Weaving is done by adding consecutive fields together. CSI uses top-field detection function. No matter input is NTSC or PAL mode, the combined frame will always put the top-field first and then bottom-field.

13.7.4 Interrupt Generation

The information found here describes CSI events that generate interrupts.

13.7.4.1 Start Of Frame Interrupt (SOF_INT)

The source of an SOF interrupt is dependent on the mode of operation.

In traditional mode, VSYNC signal is taken from sensor and SOF_INT is generated at the rising or falling edge (programmable) of VSYNC.

In CCIR interlace mode, the SOF interrupt information is retrieved from the embedded coding and SOF_INT is generated.

In CCIR progressive mode, there are two sources of an SOF interrupt:

- In *internal* VSYNC mode, SOF is retrieved from the embedded coding.
- In *external* VSYNC mode, VSYNC is taken from the sensor and SOF is generated at the rising edge of VSYNC.

13.7.4.2 End Of Frame Interrupt (EOF_INT)

An EOF interrupt is generated when the frame ends and the complete frame data in RXFIFO is read.

The EOF event triggering works with the RX count register (CSIRXCNT). Software sets the RX count register to the frame size (in words). The CSI RX logic then counts the number of pixel data being received and compares it with the RX count. If the preset value is reached, an EOF interrupt is generated and the data in the RXFIFO are read. If a SOF event is detected before this happens, the EOF interrupt is not generated.

13.7.4.3 Change Of Field Interrupt (COF_INT)

The Change of Field interrupt is only valid in CCIR Interlace mode. The COF interrupt is generated when the field toggles, either from field 1 to field 2, or field 2 to field 1.

Software should first check COF_INT bit in the CSI Status Register (CSISTAT) before checking that F1_INT or F2_INT is turned on.

In PAL systems, the field changes at the beginning of the frame and coincides with SOF. For the first field, a COF interrupt is not generated, only an SOF. The COF interrupt is generated for the second field.

13.7.4.4 CCIR Error Interrupt (ECC_INT)

The CCIR Error Interrupt is only valid for CCIR Interlace mode. An ECC interrupt is generated when an error is found on the SAV or EAV codes in the incoming stream. When this happens, the ECC_INT status bit is set.

13.7.4.5 RxFIFO Full Interrupt (RxFF_INT)

A RxFIFO full interrupt is generated when the number of data in RXFIFO reaches the water mark defined by RxFF_LEVEL in CSICR3.

13.7.4.6 Statistic FIFO Full Interrupt (STATFF_INT)

A StatFIFO full interrupt is generated when the number of data in STATFIFO reaches the water mark defined by STATFF_LEVEL in CSICR3.

13.7.4.7 RxFIFO Overrun Interrupt (RFF_OR_INT)

A RxFIFO Overrun interrupt is generated when the RxFIFO has 128 words data and more data is being written in.

13.7.4.8 Statistic FIFO Overrun Interrupt (SFF_OR_INT)

A StatFIFO Overrun interrupt is generated when the STATFIFO has 64 words data and more data is being written in.

13.7.4.9 Frame Buffer1 DMA Transfer Done Interrupt (DMA_TSF_DONE_FB1)

A DMA transfer done interrupt of frame buffer1 is generated when one frame of data are transferred from RxFIFO to the frame buffer1 in the external memory.

13.7.4.10 Frame Buffer2 DMA Transfer Done Interrupt (DMA_TSF_DONE_FB2)

A DMA transfer done interrupt of frame buffer2 is generated when one frame of data are transferred from RxFIFO to the frame buffer2 in the external memory.

13.7.4.11 Statistic FIFO DMA Transfer Done Interrupt (DMA_TSF_DONE_SFF)

A StatFIFO DMA transfer done interrupt is generated when all the data are transferred from StatFIFO to the external memory. The transfer size is defined in the STATFIFO DMA Transfer Size Register.

13.7.4.12 AHB Bus Response Error Interrupt (HRESP_ERR_INT)

An AHB Bus response error interrupt is generated when a bus error is detected.

13.7.5 Data Packing Style

Careful attention to endianess is needed given the different port sizes at different stages of the image capture path.

To enable flexible packing of image data before storage in the FIFOs, the CSI module can swap data fields by use of the PACK_DIR and the SWAP16_EN bit in CSI Control Register 1 (CSICR1).

The CSI module accepts 8-bit, 10-bit or 16-bit data from the sensor by configuring PIXEL_BIT bit in CSI Control Register 1 (CSICR1) and TWO_8BIT_SENSOR bit in CSI Control Register3 (CSICR3). The input data is packed according to the setting of PACK_DIR bit. The packed data is stored in the RX FIFO according to the setting of the SWAP16_EN bit.

For 10-bit per pixel data format, each pixel is expanded to 16 bits by appending 6 zeros bits to the most significant bit.

13.7.5.1 RX FIFO Path

13.7.5.1.1 Bayer Data

Bayer data is a type of raw data from the image sensor. This byte-wide data must be converted to the RGB space or YUV space by software. The data path for Bayer data is from the CSI to memory. If the system is in little endian, then the PACK_DIR bit should be set to 0. 8-bit data format from a sensor is packed to 64 bits as P7.P6.P5.P4.P3.P2.P1.P0, where P0 is the pixel coming in time slot 0 (first data) and P3 is the pixel coming in time slot 3 (the last data in the 64-bit word). When the data is addressed as bytes by software, P0 is transferred first, P1 is transferred next, and so on. 10-bit data format is packed to 64 bits as 000000.P3.000000.P2.000000.P1.000000.P0, where P0 is the 10-bit data coming in time slot 0 (first pixel) and P3 is the 10-bit data coming in time slot 3 (fourth pixel). 16-bit data is packed to 64 bits as P7.P6.P5.P4.P3.P2.P1.P0.

13.7.5.1.2 RGB565 Data

RGB565 data is processed data from the image sensor, which can be put directly into the display buffer. The data is 16 bits wide. The data path is from CSI to memory to the display controller. On the sensor side, data must be transmitted as P0 first, followed by P1, and so on. For each pixel, whether the MSB or LSB is sent first depends on the endianness of the sensor. Data is 16 bits wide with the MSB labeled RG, and the LSB labeled GB. P0 is represented as RG0 and GB0.

CSI receives data in one of the following sequence:

- RG0, GB0, RG1, GB1, while RG0 comes out at time slot 0 (first data), and GB1 comes out at time slot 3 (last data)
- GB0, RG0, GB1, RG1

Using the first sequence as an example, and assuming the system is running in little endian, the data is presented as:

- 8-bit data from sensor: RG0, GB0, RG1, GB1, …
- 64-bit data before storage in the CSI RX FIFO (PACK_DIR bit = 1): RG0GB0RG1GB1RG2GB2RG3GB3
- 64-bitdata in CSI RX FIFO (SWAP16_EN bit enabled): RG3GB3RG2GB2RG1GB1RG0GB0
- 64-bit transfer to system memory: RG3GB3RG2GB2RG1GB1RG0GB0
- 16-bit read by display controller: RG0GB0, RG1GB1

13.7.5.1.3 RGB888 Data

This is another kind of processed data from image sensor, which can be used for further image processing directly. Each of the data consist of 8-bit Red, 8-bit Green, and 8-bit Blue data. An example of timing scheme is shown in the following figure.

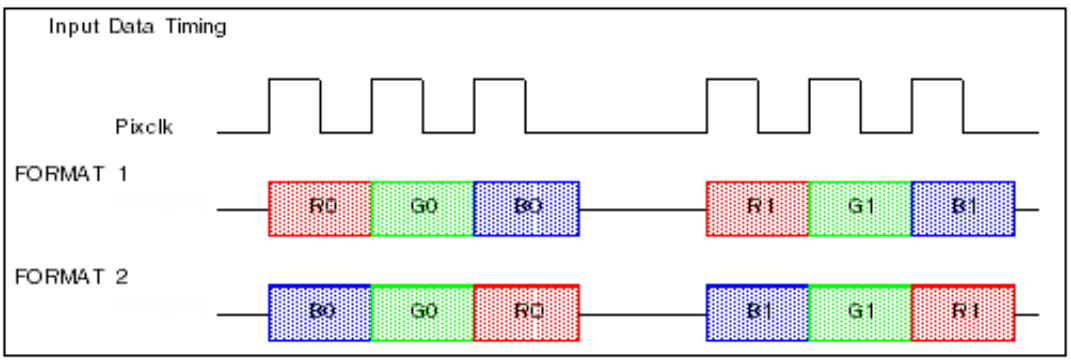

Figure 13-69. Sample Timing Diagram for RGB888 8 bits/cycle Data

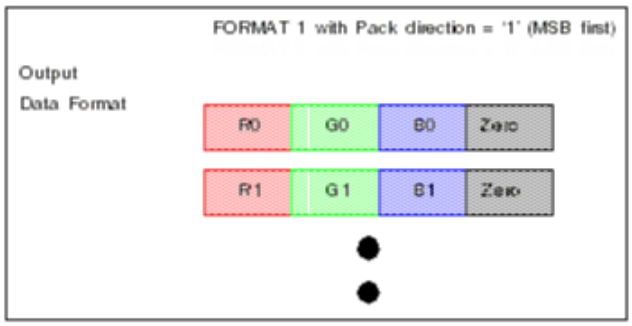
An optional scheme to pack a dummy byte is provided. For every group of 3 bytes data, a dummy zero is packed to form a 32-bit word as shown in the following figure. The dummy zero can be packed at the LSB position or MSB position. Using RGB888A_FORMAT_SEL in CSI_CSICR18[18] to determine to put the dummy bytes packed at LSB or MSB position.



FORMAT 1 with Pack direction = '1' (MSB first)
Output
Data Format
R0
G0
B0

R1
G1
B1
Zero

13.7.5.2 STAT FIFO Path

Statistics only works for Bayer data in 8-bit per pixel format. It generates 16-bit statistical output from the 8-bit Bayer input (CSI_DATA[13:6]). The outputs are Sum of Green (G), Sum of Red (R), Sum of Blue (B), and Auto Focus (F). Each output is 16-bits wide.

The settings of PACK_DIR and SWAP16_EN bits in the CSICR1 register have no effect on the input path. The PACK_DIR only controls how the 16-bit stat output is packed into the 32-bit STAT FIFO.

When the PACK_DIR bit = 1, the stat data is packed as:

First 32-bit: RG

Second 32-bit: BF

…

When the PACK_DIR bit = 0, the stat data is packed as:

First 32-bit GR

Second 32-bit: FB

...

13.7.6 CSI Memory Map/Register Definition

All the 32-bit registers of the CSI module are summarized in the Memory Map below:

CSI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	CSI Control Register 1 (CSI_CSICR1)	32	R/W	4000_0800h	13.7.6.1/ 4962
4	CSI Control Register 2 (CSI_CSICR2)	32	R/W	0000_0000h	13.7.6.2/ 4966
8	CSI Control Register 3 (CSI_CSICR3)	32	R/W	0000_0000h	13.7.6.3/ 4968
C	CSI Statistic FIFO Register (CSI_CSISTATFIFO)	32	R	0000_0000h	13.7.6.4/ 4970

Table continues on the next page...

CSI memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
10	CSI RX FIFO Register (CSI_CSIRFIFO)	32	R	0000_0000h	13.7.6.5/ 4970
14	CSI RX Count Register (CSI_CSIRXCNT)	32	R/W	0000_9600h	13.7.6.6/ 4971
18	CSI Status Register (CSI_CSISR)	32	R/W	0000_4000h	13.7.6.7/ 4972
20	CSI DMA Start Address Register - for STATFIFO (CSI_CSIDMASA_STATFIFO)	32	R/W	0000_0000h	13.7.6.8/ 4975
24	CSI DMA Transfer Size Register - for STATFIFO (CSI_CSIDMATS_STATFIFO)	32	R/W	0000_0000h	13.7.6.9/ 4975
28	CSI DMA Start Address Register - for Frame Buffer1 (CSI_CSIDMASA_FB1)	32	R/W	0000_0000h	13.7.6.10/ 4976
2C	CSI DMA Transfer Size Register - for Frame Buffer2 (CSI_CSIDMASA_FB2)	32	R/W	0000_0000h	13.7.6.11/ 4977
30	CSI Frame Buffer Parameter Register (CSI_CSIFBUF_PARA)	32	R/W	0000_0000h	13.7.6.12/ 4977
34	CSI Image Parameter Register (CSI_CSIIMAG_PARA)	32	R/W	0000_0000h	13.7.6.13/ 4978
48	CSI Control Register 18 (CSI_CSICR18)	32	R/W	0002_D000h	13.7.6.14/ 4979

13.7.6.1 CSI Control Register 1 (CSI_CSICR1)

This register controls the sensor interface timing and interrupt generation. The interrupt enable bits in this register control the interrupt signals and the status bits. That means status bits will only function when the corresponding interrupt bits are enabled.

Address: 0h base + 0h offset = 0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CSI_CSICR1 field descriptions

Field	Description
31 SWAP16_EN	SWAP 16-Bit Enable. This bit enables the swapping of 16-bit data. Data is packed from 8-bit or 10-bit to 32-bit first (according to the setting of PACK_DIR) and then swapped as 16-bit words before being put into the RX FIFO. The action of the bit only affects the RX FIFO and has no affect on the STAT FIFO. **NOTE:** Example of swapping enabled: Data input to FIFO = 0x11223344 Data in RX FIFO = 0x 33441122 **NOTE:** Example of swapping disabled: Data input to FIFO = 0x11223344 Data in RX FIFO = 0x11223344

Table continues on the next page...

CSI_CSICR1 field descriptions (continued)

Field	Description
	0 Disable swapping 1 Enable swapping
30 EXT_VSYNC	External VSYNC Enable. This bit controls the operational VSYNC mode. **NOTE:** This only works when the CSI is in CCIR progressive mode. 0 Internal VSYNC mode 1 External VSYNC mode
29 EOF_INT_EN	End-of-Frame Interrupt Enable. This bit enables and disables the EOF interrupt. 0 EOF interrupt is disabled. 1 EOF interrupt is generated when RX count value is reached.
28 PrP_IF_EN	CSI-PrP Interface Enable. This bit controls the CSI to PrP bus. When enabled the RxFIFO is detached from the AHB bus and connected to PrP. All CPU reads or DMA accesses to the RxFIFO register are ignored. All CSI interrupts are also masked. 0 CSI to PrP bus is disabled 1 CSI to PrP bus is enabled
27 VIDEO_MODE	Video mode select. This bit controls the video mode in CCIR mode. 0 Progressive mode is selected 1 Interlace mode is selected
26 COF_INT_EN	Change Of Image Field (COF) Interrupt Enable. This bit enables the COF interrupt. This bit works only in CCIR interlace mode which is when CCIR_EN = 1 and CCIR_MODE = 1. 0 COF interrupt is disabled 1 COF interrupt is enabled
25 SF_OR_INTEN	STAT FIFO Overrun Interrupt Enable. This bit enables the STATFIFO overrun interrupt. 0 STATFIFO overrun interrupt is disabled 1 STATFIFO overrun interrupt is enabled
24 RF_OR_INTEN	RxFIFO Overrun Interrupt Enable. This bit enables the RX FIFO overrun interrupt. 0 RxFIFO overrun interrupt is disabled 1 RxFIFO overrun interrupt is enabled
23 -	This field is reserved. Reserved. This bit is reserved and should read 0.
22 SFF_DMA_ DONE_INTEN	STATFIFO DMA Transfer Done Interrupt Enable. This bit enables the interrupt of STATFIFO DMA transfer done. 0 STATFIFO DMA Transfer Done interrupt disable 1 STATFIFO DMA Transfer Done interrupt enable
21 STATFF_INTEN	STATFIFO Full Interrupt Enable. This bit enables the STAT FIFO interrupt. 0 STATFIFO full interrupt disable 1 STATFIFO full interrupt enable
20 FB2_DMA_ DONE_INTEN	Frame Buffer2 DMA Transfer Done Interrupt Enable. This bit enables the interrupt of Frame Buffer2 DMA transfer done.

Table continues on the next page...

CSI_CSICR1 field descriptions (continued)

Field	Description
	0 Frame Buffer2 DMA Transfer Done interrupt disable 1 Frame Buffer2 DMA Transfer Done interrupt enable
19 FB1_DMA_DONE_INTEN	Frame Buffer1 DMA Transfer Done Interrupt Enable. This bit enables the interrupt of Frame Buffer1 DMA transfer done. 0 Frame Buffer1 DMA Transfer Done interrupt disable 1 Frame Buffer1 DMA Transfer Done interrupt enable
18 RXFF_INTEN	RxFIFO Full Interrupt Enable. This bit enables the RxFIFO full interrupt. 0 RxFIFO full interrupt disable 1 RxFIFO full interrupt enable
17 SOF_POL	SOF Interrupt Polarity. This bit controls the condition that generates an SOF interrupt. 0 SOF interrupt is generated on SOF falling edge 1 SOF interrupt is generated on SOF rising edge
16 SOF_INTEN	Start Of Frame (SOF) Interrupt Enable. This bit enables the SOF interrupt. 0 SOF interrupt disable 1 SOF interrupt enable
15–12 Reserved	This field is reserved. Reserved. This field is reserved.
11 HSYNC_POL	HSYNC Polarity Select. This bit controls the polarity of HSYNC. This bit only works in gated-clock-that is, GCLK_MODE = 1 and CCIR_EN = 0. 0 HSYNC is active low 1 HSYNC is active high
10 CCIR_EN	CCIR656 Interface Enable. This bit selects the type of interface used. When the CCIR656 timing decoder is enabled, it replaces the function of timing interface logic. 0 Traditional interface is selected. Timing interface logic is used to latch data. 1 CCIR656 interface is selected.
9 Reserved	This field is reserved. This field is reserved.
8 FCC	FIFO Clear Control. This bit determines how the RXFIFO and STATFIFO are cleared. When Synchronous FIFO clear is selected the RXFIFO and STATFIFO are cleared, and STAT block is reset, on every SOF. FIFOs and STAT block restarts immediately after reset. For information on the operation when Asynchronous FIFO clear is selected, refer to the descriptions for the CLR_RXFIFO and CLR_STATFIFO bits. 0 Asynchronous FIFO clear is selected. 1 Synchronous FIFO clear is selected.
7 PACK_DIR	Data Packing Direction. This bit Controls how 8-bit/10-bit image data is packed into 32-bit RX FIFO, and how 16-bit statistical data is packed into 32-bit STAT FIFO. 0 Pack from LSB first. For image data, 0x11, 0x22, 0x33, 0x44, it will appear as 0x44332211 in RX FIFO. For stat data, 0xAAAA, 0xBBBB, it will appear as 0xBBBBAAAA in STAT FIFO. 1 Pack from MSB first. For image data, 0x11, 0x22, 0x33, 0x44, it will appear as 0x11223344 in RX FIFO. For stat data, 0xAAAA, 0xBBBB, it will appear as 0xAAAABBBB in STAT FIFO.

Table continues on the next page...

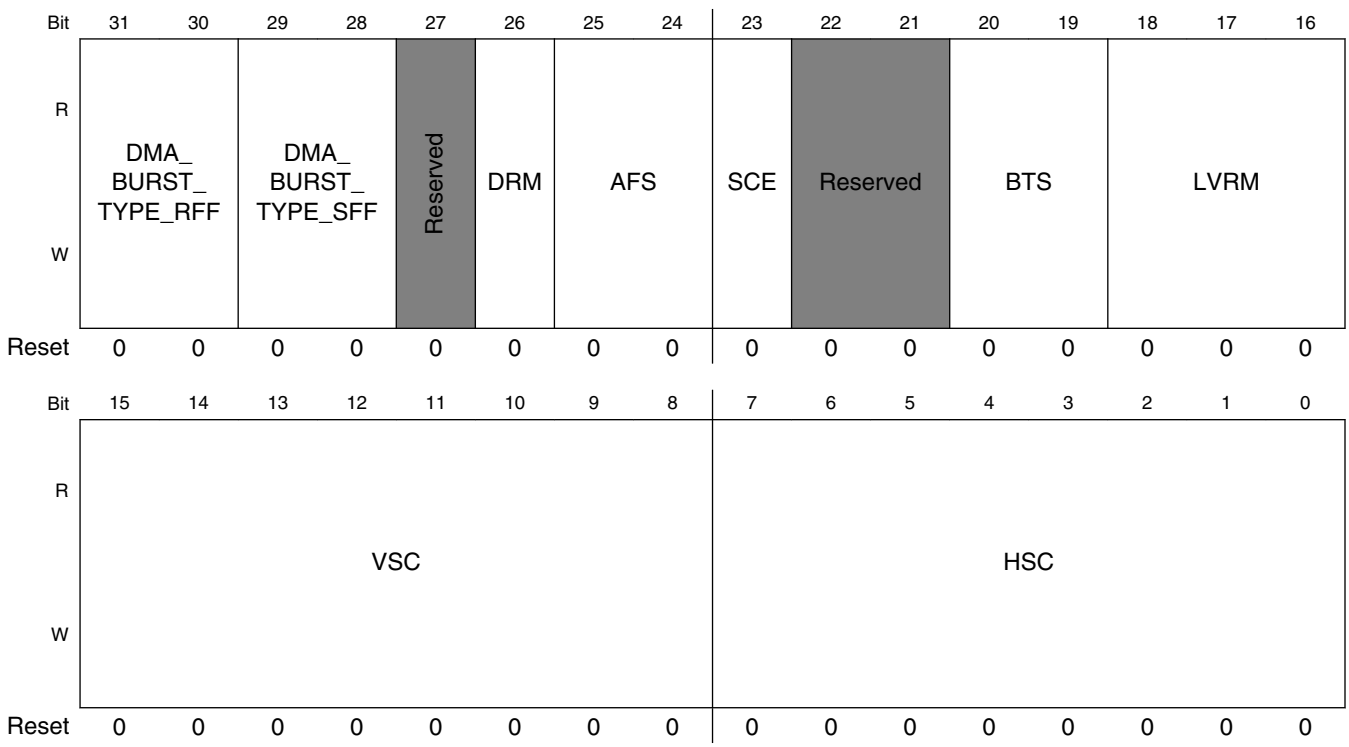
CSI_CSICR1 field descriptions (continued)

Field	Description
6 CLR_STATFIFO	Asynchronous STATFIFO Clear. This bit clears the STATFIFO and Reset STAT block. This bit works only in async FIFO clear mode-that is, FCC = 0. Otherwise this bit is ignored. Writing 1 will clear STATFIFO and reset STAT block immediately, STATFIFO and STAT block then wait and restart after the arrival of next SOF. The bit is restored to 0 automatically after finish. Normally reads 0.
5 CLR_RXFIFO	Asynchronous RXFIFO Clear. This bit clears the RXFIFO. This bit works only in async FIFO clear mode-that is, FCC = 0. Otherwise this bit is ignored. Writing 1 clears the RXFIFO immediately, RXFIFO restarts immediately after that. The bit is restored to 0 automatically after finish. Normally reads 0.
4 GCLK_MODE	Gated Clock Mode Enable. Controls if CSI is working in gated or non-gated mode. This bit works only in traditional mode-that is, CCIR_EN = 0. Otherwise this bit is ignored. 0 Non-gated clock mode. All incoming pixel clocks are valid. HSYNC is ignored. 1 Gated clock mode. Pixel clock signal is valid only when HSYNC is active.
3 INV_DATA	Invert Data Input. This bit enables or disables internal inverters on the data lines. 0 CSI_D[7:0] data lines are directly applied to internal circuitry 1 CSI_D[7:0] data lines are inverted before applied to internal circuitry
2 INV_PCLK	Invert Pixel Clock Input. This bit determines if the Pixel Clock (CSI_PIXCLK) is inverted before it is applied to the CSI module. 0 CSI_PIXCLK is directly applied to internal circuitry 1 CSI_PIXCLK is inverted before applied to internal circuitry
1 REDGE	Valid Pixel Clock Edge Select. Selects which edge of the CSI_PIXCLK is used to latch the pixel data. 0 Pixel data is latched at the falling edge of CSI_PIXCLK 1 Pixel data is latched at the rising edge of CSI_PIXCLK
0 PIXEL_BIT	Pixel Bit. This bit indicates the bayer data width for each pixel. This bit should be configured before activating or re-starting the embedded DMA controller. 0 8-bit data for each pixel 1 10-bit data for each pixel

13.7.6.2 CSI Control Register 2 (CSI_CSICR2)

This register provides the statistic block with data about which live view resolution is being used, and the starting sensor pixel of the Bayer pattern. It also contains the horizontal and vertical count used to determine the number of pixels to skip between the 64 x 64 blocks of statistics when generating statistics on live view image that are greater than 512 x 384.

Address: 0h base + 4h offset = 4h



CSI_CSICR2 field descriptions

Field	Description
31–30 DMA_BURST_ TYPE_RFF	Burst Type of DMA Transfer from RxFIFO. Selects the burst type of DMA transfer from RxFIFO. X0 INCR8 01 INCR4 11 INCR16
29–28 DMA_BURST_ TYPE_SFF	Burst Type of DMA Transfer from STATFIFO. Selects the burst type of DMA transfer from STATFIFO. X0 INCR8 01 INCR4 11 INCR16

Table continues on the next page...

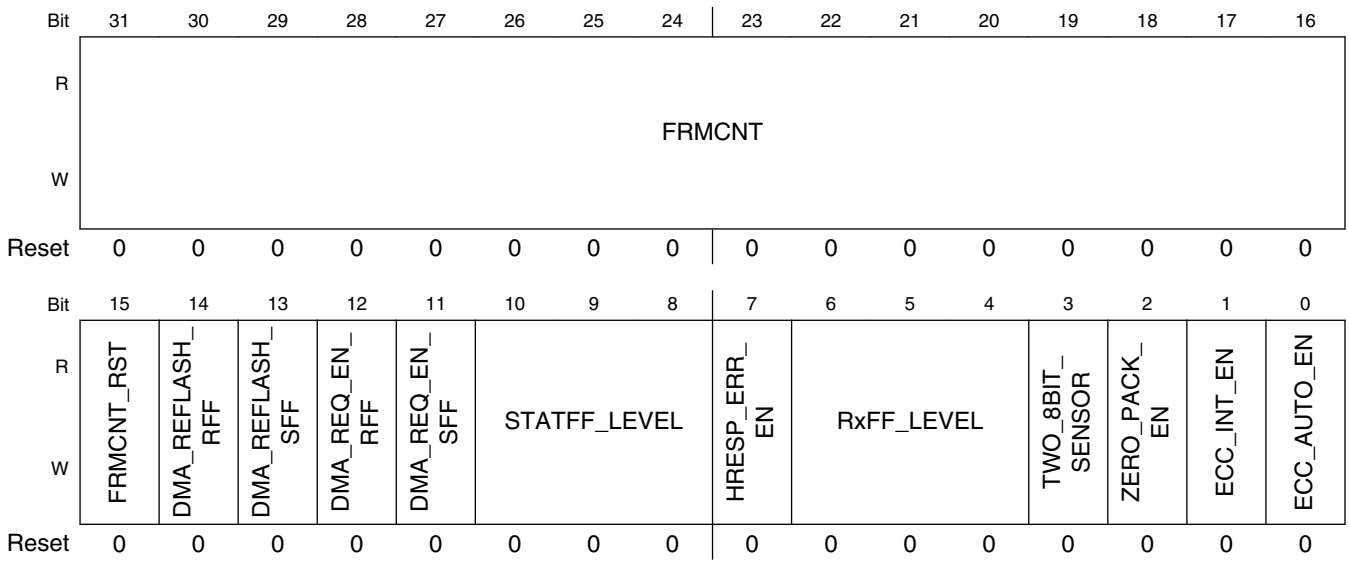
Field	Description
27 -	This field is reserved. Reserved. These bit is reserved and should read 0.
26 DRM	Double Resolution Mode. Controls size of statistics grid. 0 Stats grid of 8 x 6 1 Stats grid of 8 x 12
25–24 AFS	Auto Focus Spread. Selects which green pixels are used for auto-focus. 00 Abs Diff on consecutive green pixels 01 Abs Diff on every third green pixels 1x Abs Diff on every four green pixels
23 SCE	Skip Count Enable. Enables or disables the skip count feature. 0 Skip count disable 1 Skip count enable
22–21 -	This field is reserved. Reserved. These bits are reserved and should read 0.
20–19 BTS	Bayer Tile Start. Controls the Bayer pattern starting point. 00 GR 01 RG 10 BG 11 GB
18–16 LVRM	Live View Resolution Mode. Selects the grid size used for live view resolution. 0 512 x 384 1 448 x 336 2 384 x 288 3 384 x 256 4 320 x 240 5 288 x 216 6 400 x 300
15–8 VSC	Vertical Skip Count. Contains the number of rows to skip. SCE must be 1, otherwise VSC is ignored. 0-255 Number of rows to skip minus 1
HSC	Horizontal Skip Count. Contains the number of pixels to skip. SCE must be 1, otherwise HSC is ignored. 0-255 Number of pixels to skip minus 1

13.7.6.3 CSI Control Register 3 (CSI_CSICR3)

This read/write register acts as an extension of the functionality of the CSI Control register 1, adding additional control and features.

Address: 0h base + 8h offset = 8h



CSI_CSICR3 field descriptions

Field	Description
31–16 FRMCNT	Frame Counter. This is a 16-bit Frame Counter (Wraps around automatically after reaching the maximum)
15 FRMCNT_RST	Frame Count Reset. Resets the Frame Counter. (Cleared automatically after reset is done) 0 Do not reset 1 Reset frame counter immediately
14 DMA_REFLASH_RFF	Reflash DMA Controller for RxFIFO. This bit reflash the embedded DMA controller for RxFIFO. It should be reflashed before the embedded DMA controller starts to work. (Cleared automatically after reflashing is done) 0 No reflashing 1 Reflash the embedded DMA controller
13 DMA_REFLASH_SFF	Reflash DMA Controller for STATFIFO. This bit reflash the embedded DMA controller for STATFIFO. It should be reflashed before the embedded DMA controller starts to work. (Cleared automatically after reflashing is done) 0 No reflashing 1 Reflash the embedded DMA controller

Table continues on the next page...

CSI_CSICR3 field descriptions (continued)

Field	Description
12 DMA_REQ_EN_RFF	DMA Request Enable for RxFIFO. This bit enables the dma request from RxFIFO to the embedded DMA controller. 0 Disable the dma request 1 Enable the dma request
11 DMA_REQ_EN_SFF	DMA Request Enable for STATFIFO. This bit enables the dma request from STATFIFO to the embedded DMA controller. 0 Disable the dma request 1 Enable the dma request
10–8 STATFF_LEVEL	STATFIFO Full Level. When the number of data in STATFIFO reach this level, STATFIFO full interrupt is generated, or STATFIFO DMA request is sent. 000 4 Double words 001 8 Double words 010 12 Double words 011 16 Double words 100 24 Double words 101 32 Double words 110 48 Double words 111 64 Double words
7 HRESP_ERR_EN	Hresponse Error Enable. This bit enables the hresponse error interrupt. 0 Disable hresponse error interrupt 1 Enable hresponse error interrupt
6–4 RxFF_LEVEL	**RxFIFO Full Level**. When the number of data in RxFIFO reaches this level, a RxFIFO full interrupt is generated, or an RXFIFO DMA request is sent. 000 4 Double words 001 8 Double words 010 16 Double words 011 24 Double words 100 32 Double words 101 48 Double words 110 64 Double words 111 96 Double words
3 TWO_8BIT_SENSOR	16-bit Sensor Mode. This bit indicates one 16-bit sensor connected to the 16-bit data ports. This bit should be set if there is one 16-bit sensor connected. This bit should be configured before activating or restarting the embedded DMA controller. 0 Only one 8-bit sensor is connected. 1 One 16-bit sensor is connected.
2 ZERO_PACK_EN	Dummy Zero Packing Enable. This bit causes a dummy zero to be packed with every 3 incoming bytes, forming a 32-bit word. The dummy zero is always packed to the LSB position. This packing function is only available in 8-bit/pixel mode. 0 Zero packing disabled 1 Zero packing enabled

Table continues on the next page...

CSI_CSICR3 field descriptions (continued)

Field	Description
1 ECC_INT_EN	Error Detection Interrupt Enable. This bit enables and disables the error detection interrupt. This feature only works in CCIR interlace mode. 0 No interrupt is generated when error is detected. Only the status bit ECC_INT is set. 1 Interrupt is generated when error is detected.
0 ECC_AUTO_EN	Automatic Error Correction Enable. This bit enables and disables the automatic error correction. If an error occurs and error correction is disabled only the ECC_INT status bit is set. This feature only works in CCIR interlace mode. 0 Auto Error correction is disabled. 1 Auto Error correction is enabled.

13.7.6.4 CSI Statistic FIFO Register (CSI_CSISTATFIFO)

The StatFIFO is a read-only register containing statistic data from the sensor. Writing to this register has no effect.

Address: 0h base + Ch offset = Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

CSI_CSIRFIFO field descriptions

Field	Description
IMAGE	Received image data

13.7.6.6 CSI RX Count Register (CSI_CSIRXCNT)

This register works for EOF interrupt generation. It should be set to the number of words to receive that would generate an EOF interrupt.

There is an internal counter that counts the number of words read from the RX FIFO. Whenever the RX FIFO is being read, by either the CPU or the embedded DMA controller, the counter value is updated and compared with this register. If the values match, then an EOF interrupt is triggered.

Address: 0h base + 14h offset = 14h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved										RXCNT																					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1	0	1	1	0	0	0	0	0	0	0	0	0

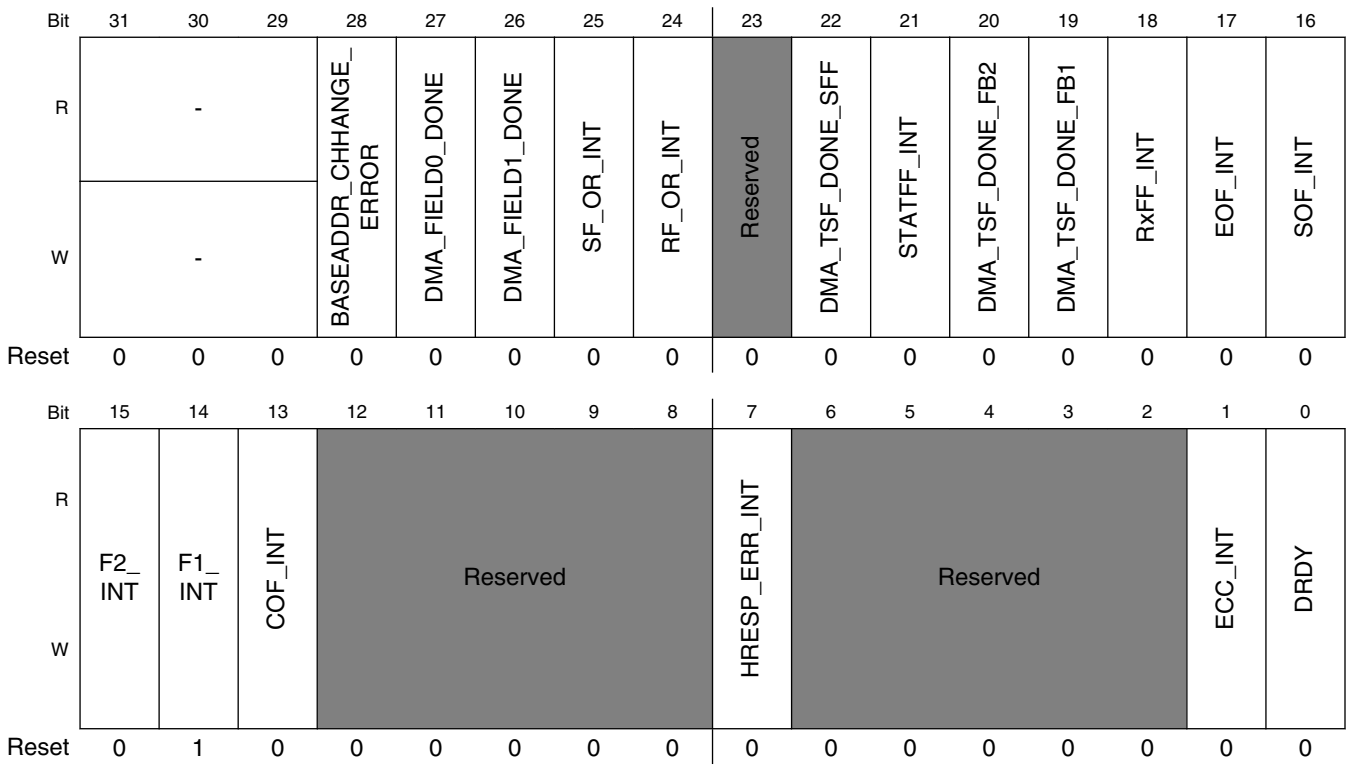
CSI_CSIRXCNT field descriptions

Field	Description
31–22 -	This field is reserved. Reserved. These bits are reserved and should read 0.
RXCNT	RxFIFO Count. This 22-bit counter for RXFIFO is updated each time the RXFIFO is read by CPU or DMA.This counter should be set to the expected number of words to receive that would generate an EOF interrupt.

13.7.6.7 CSI Status Register (CSI_CSISR)

This read/write register shows sensor interface status, and which kind of interrupt is being generated. The corresponding interrupt bits must be set for the status bit to function. Status bits should function normally even if the corresponding interrupt enable bits are not enabled.

Address: 0h base + 18h offset = 18h



CSI_CSISR field descriptions

Field	Description
31–29 -	Reserved. These bits are reserved and should read 0.
28 BASEADDR_CHHANGE_ERROR	When using base address switching enable, this bit will be 1 when switching occur before DMA complete. This bit will be clear by writing 1. When this interrupt happens, follow the steps listed below. 1. Unassert the CSI enable, CSIx_CSICR18 bit31, 2. Reflash the DMA, assert the CSIX_CSICR3 bit 14, 3. Assert the CSI enable, CSIx_CSICR18 bit31.
27 DMA_FIELD0_DONE	When DMA field 0 is complete, this bit will be set to 1(clear by writing 1).

Table continues on the next page...

CSI_CSISR field descriptions (continued)

Field	Description
26 DMA_FIELD1_ DONE	When DMA field 0 is complete, this bit will be set to 1(clear by writing 1).
25 SF_OR_INT	STATFIFO Overrun Interrupt Status. Indicates the overflow status of the STATFIFO register. (Cleared by writing 1) 0 STATFIFO has not overflowed. 1 STATFIFO has overflowed.
24 RF_OR_INT	RxFIFO Overrun Interrupt Status. Indicates the overflow status of the RxFIFO register. (Cleared by writing 1) 0 RXFIFO has not overflowed. 1 RXFIFO has overflowed.
23 -	This field is reserved. Reserved. This bit is reserved and should read 0.
22 DMA_TSF_ DONE_SFF	DMA Transfer Done from StatFIFO. Indicates that the dma transfer from StatFIFO is completed. It can trigger an interrupt if the corresponding enable bit is set in CSICR1. This bit can be cleared by writting 1 or reflashing the StatFIFO dma controller in CSICR3.(Cleared by writing 1) 0 DMA transfer is not completed. 1 DMA transfer is completed.
21 STATFF_INT	STATFIFO Full Interrupt Status. Indicates the number of data in the STATFIFO reaches the trigger level. (this bit is cleared automatically by reading the STATFIFO) 0 STATFIFO is not full. 1 STATFIFO is full.
20 DMA_TSF_ DONE_FB2	DMA Transfer Done in Frame Buffer2. Indicates that the DMA transfer from RxFIFO to Frame Buffer2 is completed. It can trigger an interrupt if the corresponding enable bit is set in CSICR1. This bit can be cleared by by writting 1 or reflashing the RxFIFO dma controller in CSICR3. (Cleared by writing 1) 0 DMA transfer is not completed. 1 DMA transfer is completed.
19 DMA_TSF_ DONE_FB1	DMA Transfer Done in Frame Buffer1. Indicates that the DMA transfer from RxFIFO to Frame Buffer1 is completed. It can trigger an interrupt if the corresponding enable bit is set in CSICR1. This bit can be cleared by by writting 1 or reflashing the RxFIFO dma controller in CSICR3. (Cleared by writing 1) 0 DMA transfer is not completed. 1 DMA transfer is completed.
18 RxFF_INT	RXFIFO Full Interrupt Status. Indicates the number of data in the RxFIFO reaches the trigger level. (this bit is cleared automatically by reading the RxFIFO) 0 RxFIFO is not full. 1 RxFIFO is full.
17 EOF_INT	End of Frame (EOF) Interrupt Status. Indicates when EOF is detected. (Cleared by writing 1) 0 EOF is not detected. 1 EOF is detected.
16 SOF_INT	Start of Frame Interrupt Status. Indicates when SOF is detected. (Cleared by writing 1)

Table continues on the next page...

CSI_CSISR field descriptions (continued)

Field	Description
	0 SOF is not detected. 1 SOF is detected.
15 F2_INT	CCIR Field 2 Interrupt Status. Indicates the presence of field 2 of video in CCIR mode. (Cleared automatically when current field does not match) **NOTE:** Only works in CCIR Interlace mode. 0 Field 2 of video is not detected 1 Field 2 of video is about to start
14 F1_INT	CCIR Field 1 Interrupt Status. Indicates the presence of field 1 of video in CCIR mode. (Cleared automatically when current field does not match) **NOTE:** Only works in CCIR Interlace mode. 0 Field 1 of video is not detected. 1 Field 1 of video is about to start.
13 COF_INT	Change Of Field Interrupt Status. Indicates that a change of the video field has been detected. Only works in CCIR Interlace mode. Software should read this bit first and then dispatch the new field from F1_INT and F2_INT. (Cleared by writing 1) 0 Video field has no change. 1 Change of video field is detected.
12–8 -	This field is reserved. Reserved. These bits are reserved and should read 0.
7 HRESP_ERR_INT	Hresponse Error Interrupt Status. Indicates that a hresponse error has been detected. (Cleared by writing 1) 0 No hresponse error. 1 Hresponse error is detected.
6–2 -	This field is reserved. Reserved. These bits are reserved and should read 0.
1 ECC_INT	CCIR Error Interrupt. This bit indicates an error has occurred. This only works in CCIR Interlace mode. (Cleared by writing 1) 0 No error detected 1 Error is detected in CCIR coding
0 DRDY	RXFIFO Data Ready. Indicates the presence of data that is ready for transfer in the RxFIFO. (Cleared automatically by reading FIFO) 0 No data (word) is ready 1 At least 1 datum (word) is ready in RXFIFO.

13.7.6.8 CSI DMA Start Address Register - for STATFIFO (CSI_CSIDMASA_STATFIFO)

This register provides the start address for the embedded DMA controller of STATFIFO. The embedded DMA controller will read data from STATFIFO and write it to the external memory from the start address. This register should be configured before activating or restarting the embedded DMA controller.

Address: 0h base + 20h offset = 20h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	DMA_START_ADDR_SFF															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DMA_START_ADDR_SFF														Reserved	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSI_CSIDMASA_STATFIFO field descriptions

Field	Description
31–2 DMA_START_ ADDR_SFF	DMA Start Address for STATFIFO. Indicates the start address to write data. The embedded DMA controller will read data from STATFIFO and write it from this address through AHB bus. The address should be double words aligned.
-	This field is reserved. Reserved. These bits are reserved and should read 0.

13.7.6.9 CSI DMA Transfer Size Register - for STATFIFO (CSI_CSIDMATS_STATFIFO)

This register provides the total transfer size for the embedded DMA controller of STATFIFO. This register should be configured before activating or restarting the embedded DMA controller.

Address: 0h base + 24h offset = 24h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DMA_TSF_SIZE_SFF																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSI_CSIDMATS_STATFIFO field descriptions

Field	Description
DMA_TSF_SIZE_SFF	DMA Transfer Size for STATFIFO. Indicates how many words to be transfered by the embedded DMA controller. The size should be double words aligned.

13.7.6.10 CSI DMA Start Address Register - for Frame Buffer1 (CSI_CSIDMASA_FB1)

This register provides the start address in the frame buffer1 for the embedded DMA controller of RxFIFO. The embedded DMA controller will read data from RxFIFO and write it to the frame buffer1 from the start address. This register should be configured before activating or restarting the embedded DMA controller.

Address: 0h base + 28h offset = 28h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	DMA_START_ADDR_FB1

R W	DMA_START_ADDR_FB1														Reserved	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSI_CSIDMASA_FB1 field descriptions

Field	Description
31–2 DMA_START_ADDR_FB1	DMA Start Address in Frame Buffer1. Indicates the start address to write data. The embedded DMA controller will read data from RxFIFO and write it from this address through AHB bus. The address should be double words aligned.
-	This field is reserved. Reserved. These bits are reserved and should read 0.

13.7.6.11 CSI DMA Transfer Size Register - for Frame Buffer2 (CSI_CSIDMASA_FB2)

This register provides the start address in the frame buffer2 for the embedded DMA controller of RxFIFO. The embedded DMA controller will read data from RxFIFO and write it to the frame buffer2 from the start address. This register should be configured before activating or restarting the embedded DMA controller.

Address: 0h base + 2Ch offset = 2Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	DMA_START_ADDR_FB2														Reserved	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSI_CSIDMASA_FB2 field descriptions

Field	Description
31–2 DMA_START_ ADDR_FB2	DMA Start Address in Frame Buffer2. Indicates the start address to write data. The embedded DMA controller will read data from RxFIFO and write it from this address through AHB bus. The address should be double words aligned.
-	This field is reserved. Reserved. These bits are reserved and should read 0.

13.7.6.12 CSI Frame Buffer Parameter Register (CSI_CSIFBUF_PARA)

This register provides the stride of the frame buffer to show how many words to skip before starting to write the next row of the image. The width of the frame buffer minus the width of the image is the stride. This register should be configured before activating or restarting the embedded DMA controller.

Address: 0h base + 30h offset = 30h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DEINTERLACE_STRIDE																FBUF_STRIDE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSI_CSIFBUF_PARA field descriptions

Field	Description
31–16 DEINTERLACE_ STRIDE	DEINTERLACE_STRIDE is only used in the deinterlace mode. If line stride feature is supported in deinterlace mode, FBUF_STRIDE and DEINTERLACE_STRIDE need to be configured at the same time. DEINTERLACE_STRIDE is configured the same as line width. In normal line stride feature, only FBUF_STRIDE needs to be configured. FBUF_STRIDE	Frame Buffer Parameter. Indicates the stride of the frame buffer. The width of the frame buffer(in double words) minus the width of the image(in double words) is the stride. The stride should be double words aligned. The embedded DMA controller will skip the stride before starting to write the next row of the image.

13.7.6.13 CSI Image Parameter Register (CSI_CSIIMAG_PARA)

This register provides the width and the height of the image from the sensor. The width and height should be aligned in pixel. The width of the image multiplied by the height is the total pixel size that will be transfered in a frame by the embedded DMA controller. This register should be configured before activating or restarting the embedded DMA controller.

Address: 0h base + 34h offset = 34h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	IMAGE_WIDTH																IMAGE_HEIGHT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

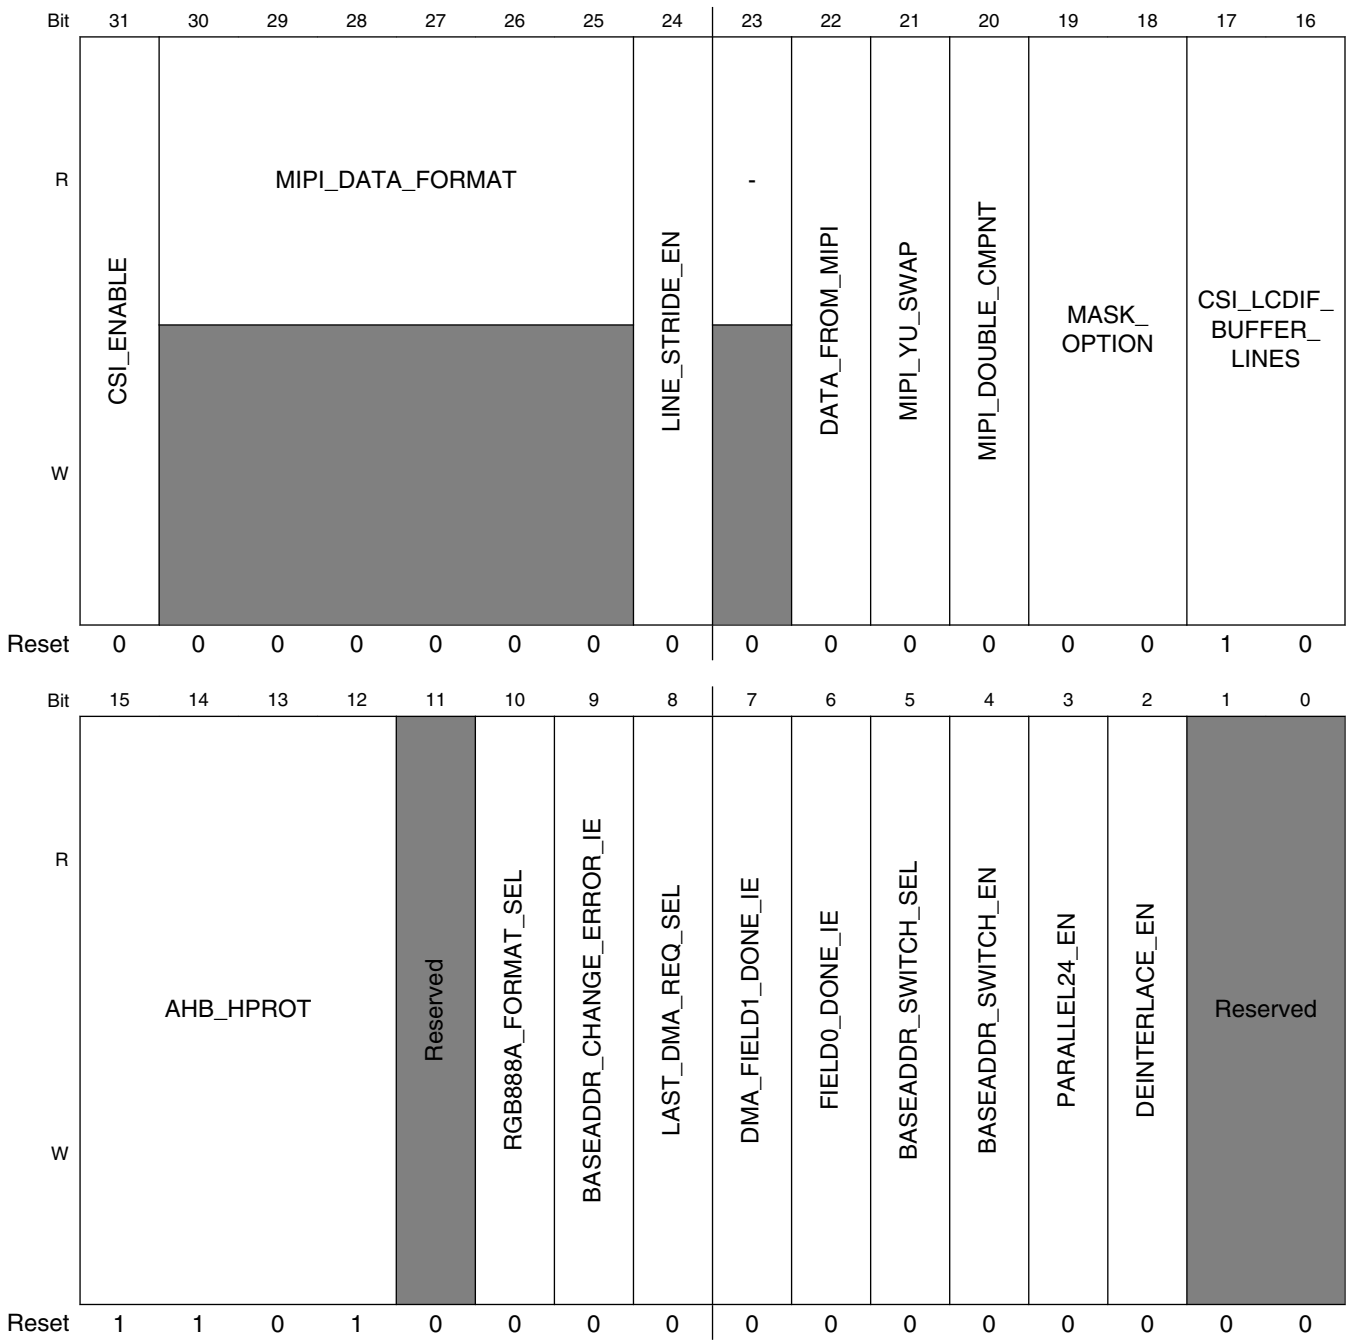
CSI_CSIIMAG_PARA field descriptions

Field	Description
31–16 IMAGE_WIDTH	Image Width. Indicates how many pixels in a line of the image from the sensor. If the input data from the sensor is 8-bit/pixel format, the IMAGE_WIDTH should be a multiple of 8 pixels. If the input data from the sensor is 10-bit/pixel or 16-bit/pixel format, the IMAGE_WIDTH should be a multiple of 4 pixels.
IMAGE_HEIGHT	Image Height. Indicates how many pixels in a column of the image from the sensor.

13.7.6.14 CSI Control Register 18 (CSI_CSICR18)

This read/write register acts as an extension of the functionality of the CSI Control register 1

Address: 0h base + 48h offset = 48h



CSI_CSICR18 field descriptions

Field	Description
31 CSI_ENABLE	CSI global enable signal. Only when this bit is 1, CSI can start to receive the data and store to memory.
30–25 MIPI_DATA_FORMAT	Image Data Format Generic Short Packet: 0x08 ~ 0x0F Embedded 8-bit non Image: 0x12 YUV420 (8-bit) 0x18 YUV420 (10-bit) 0x19 YUV420 (8-bit legacy) 0x1A YUV420 (8-bit CSPS) 0x1C YUV420 (10-bit CSPS) 0x1D YUV422 (8-bit) 0x1E YUV422 (10-bit) 0x1F RGB444 0x20 (Not support) RGB555 0x21 (Not support) RGB565 0x22 RGB666 0x23 RGB888 0x24 RAW6 0x28 RAW7 0x29 RAW8 0x2A RAW10 0x2B RAW12 0x2C RAW14 0x2D User defined 1 0x30 User defined 2 0x31 User defined 3 0x32 User defined 4 0x33 User defined 5 0x34 User defined 6 0x35 User defined 7 0x36 User defined 8 0x37
24 LINE_STRIDE_EN	When the line width are not the multiple of the burst length, assert this bit.
23 -	Reserved
22 DATA_FROM_MIPI	0 Data from parallel sensor 1 Data from MIPI
21 MIPI_YU_SWAP	It only works in MIPI CSI YUV422 double component mode.
20 MIPI_DOUBLE_CMPNT	Double component per clock cycle in YUV422 formats. 0 Single component per clock cycle

Table continues on the next page...

CSI_CSICR18 field descriptions (continued)

Field	Description
	(half pixel per clock cycle) 1 Double component per clock cycle (a pixel per clock cycle)
19–18 MASK_OPTION	These bits used to choose the method to mask the CSI input. 00 Writing to memory from first completely frame, when using this option, the CSI_ENABLE should be 1. 01 Writing to memory when CSI_ENABLE is 1. 02 Writing to memory from second completely frame, when using this option, the CSI_ENABLE should be 1. 03 Writing to memory when data comes in, not matter the CSI_ENABLE is 1 or 0.
17–16 CSI_LCDIF_ BUFFER_LINES	The number of lines are used in handshake mode with LCDIF. 00 4 lines 01 8 lines 02 16 lines 03 16 lines
15–12 AHB_HPROT	Hprot value in AHB bus protocol.
11 -	This field is reserved.
10 RGB888A_ FORMAT_SEL	Output is 32-bit format. 0 {8'h0, data[23:0]} 1 {data[23:0], 8'h0}
9 BASEADDR_ CHANGE_ ERROR_IE	Base address change error interrupt enable signal.
8 LAST_DMA_ REQ_SEL	Choosing the last DMA request condition. 0 fifo_full_level 1 hburst_length
7 DMA_FIELD1_ DONE_IE	When in interlace mode, field 1 done interrupt enable. 0 Interrupt disabled 1 Interrupt enabled
6 FIELD0_DONE_ IE	In interlace mode, fileld 0 means interrupt enabled. 0 Interrupt disabled 1 Interrupt enabled
5 BASEADDR_ SWITCH_SEL	CSI 2 base addresses switching method. When using this bit, BASEADDR_SWITCH_EN is 1. 0 Switching base address at the edge of the vsync 1 Switching base address at the edge of the first data of each frame
4 BASEADDR_ SWITCH_EN	When this bit is enabled, CSI DMA will switch the base address according to BASEADDR_SWITCH_SEL rather than atomically by DMA completed.

Table continues on the next page...

CSI_CSICR18 field descriptions (continued)

Field	Description
3 PARALLEL24_ EN	When input is parallel rgb888/yuv444 24bit, this bit can be enabled.
2 DEINTERLACE_ EN	This bit is used to select the output method When input is standard CCIR656 video. 0 Deinterlace disabled 1 Deinterlace enabled
-	This field is reserved. Reserved.

13.8 MIPI CSI Host Controller (MIPI_CSI)

13.8.1 Overview

This section introduces the MIPI CSI-2 RX subsystem with the CSI-2 RX PHY and host controller. This subsystem handles the sensor/image input and process for all the input imaging devices.

13.8.1.1 Features

The MIPI-CSI2 Controller has the following key features:

- Implements all three CSI-2 MIPI layers (Pixel to byte packing, low level protocol, Lane management)
- Supports unidirectional Master operation
- Transmitter and receiver versions
- Scalable data lane support, 1 to 4 Data Lanes
- Supports high speed mode(80Mbps - 1.5Gbps) per lane, providing 4K@30fps capability for the 4 lanes
- Supports 10Mbps data rate in low power mode
- Includes high speed deserializers
- Loopback testability support
- Support for all CSI-2 data types
- Support for DPHY Ultra Low Power State (ULPS)
- Error collection support (Rx Only)
- Flexible pixel-based user interface
    - Supports user generated packets
    - Supports single interface

- Supports PHY Protocol Interface (PPI) compatible MIPI D-PHYs
  - Delivered fully integrate and verified with target MIPI D-PHY
- RX Video Interface
- APB Control and Status Register (CSR) interface with IRQ support
- Easy configuration and control via core ports

13.8.2 Reset

Reset and Initialization procedure for the CSI-2 Rx Controller is as follows:

1. Assert all resets.
2. Wait until clocks to the Rx Controller are stable and ensure DPHY interface is idle (Stop State on all lanes)
3. De-assert reset to CSR, pclk_reset_n, if CSR is included with the controller. If no CSR go to step 4.
4. Program CSR registers if CSR is present. If CSR is not present, set values to all configuration ports (cfg_* inputs) to appropriate values.
5. De-assert all remaining resets.
6. CSI-2 Rx Controller is ready for use by the next rising edge of clk_ui.

13.8.3 Functional description

The CSI-2 Rx Controller Core implements all three layers defined by the CSI-2 Specification: Pixel to Byte Packing, Low Level Protocol, and Lane Management. The D-PHY interface of the CSI-2 Rx Controller Core supports PHY Protocol Interface (PPI) compatible MIPI D-PHYs. The Local Interface is an easy to use pixel based interface that supports all data types. The Local interface runs at the User Interface clock rate for all implementations. The CSI-2 Rx Controller Core takes care of all packet formatting details and transmission over the MIPI bus. The CSI-2 Rx Controller Core also includes an Rx Video Interface. This interface watches the local interface of the controller and generates a simplified video output interface. Image packet types which are supported by the Pixel Format block are assembled into a Video output bus which carries the pixel data which is received by the controller. Valid video output data is indicated using the data enable output(s). Horizontal and vertical sync outputs are also provided.

13.8.3.1 CSI-2 RX Block diagram

The block diagram for the MIPI CSI-2 RX block is given below:

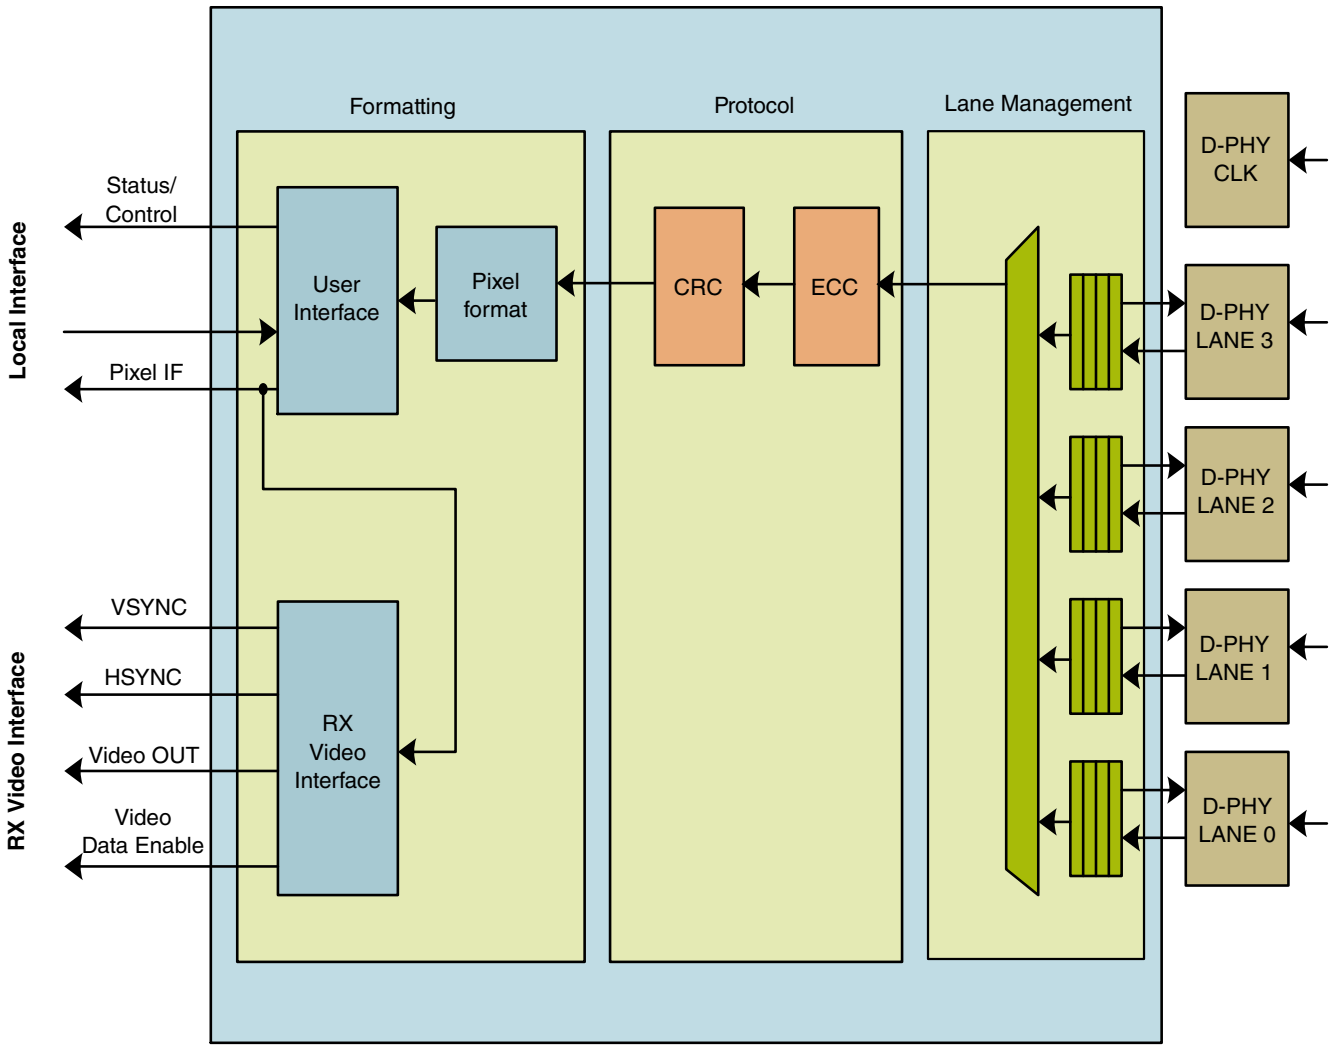


Figure 13-71. MIPI CSI-2 RX Block Diagram

13.8.3.2 Rx Controller Core Configuration Port Descriptions

The CSI-2 Rx Controller Core has configuration ports that can control the configuration of the core in real time. The ports are listed and described in the table below. When the CSR module is included with the CSI-2 RX Controller, the cfg_* ports are removed from the top level and connected to ports on the CSR module, making them accessible through the APB interface.

Table 13-35. Rx Controller Core Configuration Port Descriptions

Port	Type	Description
cfg_num_lanes[1:0]	Input	Sets the number of active lanes that are to be used for receiving MIPI data.

Table continues on the next page...

Table 13-35. Rx Controller Core Configuration Port Descriptions (continued)

		2'b00 –1 Lane 2'b01 – 2 Lanes 2'b10 – 3 Lanes 2'b11 – 4 Lanes
cfg_disable_payload[48:0]	Input	Disables payload data for the selected data type. When a bit is set that represents a supported data type, only the packet header will be presented at the user interface, along with the sop and eop indication where the payload data would have appeared if enabled. [0] – NULL [1] –BLANK [2] –EMBEDDED [9:3] –Reserved [10] – Legacy YUV420 8 bit [13:11] – Reserved [14] – YUV422 8 bit [15] – YUV422 10 bit [16] – RGB444 [17] – RGB555 [18] – RGB565 [19] – RGB666 [20] – RGB888 [23:21] – Reserved [24] –RAW6 [25] –RAW7 [26] –RAW8 [27] –RAW10 [28] –RAW12 [29] –RAW14 [31:30] – Reserved [32] – User defined type 0x30 [33] – User defined type 0x31 [34] – User defined type 0x32 [35] – User defined type 0x33 [36] – User defined type 0x34 [37] – User defined type 0x35 [38] – User defined type 0x36 [39] – User defined type 0x37 [47:40] – Reserved [48] – Unsupported data types
cfg_disable_data_lanes	[3:0]	Setting bits to a'1' value causes the DPHY Enable signal to deassert. [0] – data lane 0 [1] – data lane 1 [2] – data lane 2 [3] – data lane 3

13.8.3.3 CSI-2 RX Controller Core Local Interface

The CSI-2 Rx Controller Core Local Interface consists of a Receive Interface.

Packets are received from the MIPI Interface via the Receive Local Interface. The Receive Interface is designed to easily interface to a FIFO on the user side that holds the pixels that are received until the user application can process them.

13.8.3.3.1 RX Local Interface Description

The Receive Local Interface is the mechanism with which the user receives packets from the MIPI Interface.

The Receive Local Interface first announces that a packet is being or has been received by asserting the pkt_hdr_valid signal with the other packet information output ports containing details about the packet. Next, the sop_out signal will assert indicating that data is about to arrive at the Receive Local Interface. Dav_out will assert with every cycle of pixel data on the data_out port. The last cycle of receive data is signaled by the assertion of eop_out.

With a single pixel interface, data_out contains a single pixel every clock that dav_out (data valid) is asserted. The single pixel interface must run at a frequency that is equal to number of MIPI lanes times the byte lane frequency.

Table 13-36. Receive Local Interface

Port	Type	Description
clk	Input	RX Controller Core Clock input. This clock must be exactly equal to or faster than the receive byteclock, RxByteClkHS_ln0, from the RX DPHY.
clk_ui	Input	User interface clock. The frequency of clk_ui must be such that the data received on the data_out output is greater than or equal to the total bandwidth of the physical MIPI interface. Clk_ui has no relationship requirement with regards to ‘clk’ other than the bandwidth requirement mentioned previously.
clk_esc	Input	Rx Escape Clock. This must be the same escape clock that the RX DPHY receives.
reset_n	Input	Aysnc reset, active low. This reset applies to all logic in the Controller Core that is in the ‘clk’ clock domain.

Table continues on the next page...

Table 13-36. Receive Local Interface (continued)

clk_ui_reset_n	Input	Async reset, active low. This reset applies to all logic in the Controller Core that is in the 'clk_ui' clock domain.
clk_esc_reset_n	Input	Async reset, active low. This reset applies to all logic in the Controller Core that is in the clk_esc domain.
byte_clk_reset_n	Input	Asnyc reset, active low. This reset applies to all logic in the Controller Core that is in the byte clock (RxByteClkHS_lnx clock inputs) that is received from the RX DPHY.
data_out[n-1:0]	Output	Pixel Data output. The Rx Controller can present pixel data in single pixels or in pairs. The width of the data_out port is dependent on the largest pixel size possible and whether the controller is configured for single, double, or quad pixel mode. Pixel data types narrower than 'n' bits are justified down into the least significant bits (ie, bits [7:0] in a 12 bit field [11:0]). When in double pixel mode, the first pixel resides at [n-1:0] while the second pixel received is at [n*2-1:n]. When in quad pixel mode, the first pixel resides at [n-1:0], second pixel received is at [n*2-1:n], the third pixel is at [n*3-1:n*2] and the fourth is at [n*4-1:n*3] where 'n' is the maximum pixel width supported.
dav_out	Output	Data Valid Out. When asserted high, data_out, sop_out, and eop_out outputs are valid.
sop_out	Output	Start of packet signal. This active high signal indicates the first cycle of data on dataout. Valid when dav_out asserts high
eop_out[3:0]	Output	Last pixel indicator. Asserts to indicate the last pixel in a transmission. When in single pixel mode, eop_out[0] is used. When in double pixel mode two bits are used, [1:0]. 2'b01 indicates the last pixel is on the lower pixel path. 2'b10 indicates the last pixel is on the upper pixel path. When in quad pixel mode, all four bits are utilized. A value of 4'b0001 indicates the last pixel is on the lowest pixel path portion of data_out. 4'b0010 indicates the last pixel is on the second pixel path of data_out. 4'b0100 indicates the last pixel is on the third pixel path of data_out. 4'b1000 indicates the last pixel is on the fourth and highest pixel path of data_out. Valid when dav_out asserts high.

Table continues on the next page...

Table 13-36. Receive Local Interface (continued)

pkt_hdr_valid	Output	Packet header data is valid on the packet header ports below when this signal is asserted.
pkt_hdr_data_type[4:0]	Output	Packet data type, valid when pkt_hdr_valid is asserted. See the CSI-2 specification for a definition of possible values.
pkt_hdr_wc[15:0]	Output	Packet Word Count. Number of bytes of pixel data in the received payload for long packet data types. See the MIPI CSI-2 specification for meaning for short packet. The value on pkt_hdr_wc is the Word count field from the received packet header. The RX controller does not modify the value in any way. Valid when pkt_hdr_valid is asserted.
pixel_cnt_out[15:0]	Output	Number of pixels in receive packet. The pixel_cnt_out value is updated one clock after eop_out asserts and represents the packet of pixels there were in the just received packet. The pixel_cnt_out value is only valid for long packets.
ecc_one_bit_error	Output	Single bit error in the packet header was detected and corrected. Active high and is valid when pkt_hdr_valid is high.
ecc_two_bit_error	Output	Two packet header bit errors were detected and not corrected, active high and is valid when pkt_hdr_is high..
ecc_one_bit_error_pos[4:0]	Output	Position of the corrected single bit error in the packet header. Valid when pkt_hdr_valid is asserted high.
ecc_err	Output	Error detected in the ECC bits. This signal is no longer supported.
ecc_err_pos[2:0]	Output	Position of the bit in the ECC bits, valid when ecc_err is asserted. This signal is no longer supported.
crc_err	Output	Asserts high when the CRC calculated on the received data does not match the CRC the transmitter sent at the end of the packet. Valid when the eop_out output asserts.
ulps_active[4:0]	Output	Receive UltraLow Power State active. Bits assert high when corresponding clock or data lane is in ULPS mode. Bit [0] – Clock Lane Bit [1] – Data Lane 0 Bit [2] – Data Lane 1 Bit [3] – Data Lane 2 Bit [4] – Data Lane 3

Table continues on the next page...

Table 13-36. Receive Local Interface (continued)

ulps_mark_active[4:0]	Output	Receive UltraLow Power State Mark status. Bits assert high when corresponding clock or data lane has exited ULPS and entered Mark-1 state. Lanes will remain in Mark-1 state for a minimum of 1ms as per the MIPI DPHY specification. While in Mark-1 state, no other active, like High Speed data transmission, is allowed. Bit [0] – Clock Lane Bit [1] – Data Lane 0 Bit [2] – Data Lane 1 Bit [3] – Data Lane 2 Bit [4] – Data Lane 3
rx_enable	Input	Receive Enable, active high. When deasserted, the RX controller will pause data reception at the next packet boundary. Since the CSI-2 protocol does not allow the Receiver to pause data, when rx_enable is deasserted the RX Controller still receives data from the RX DPHY but it does not forward the receive packets to the user interface but instead discards the received data. When rx_enable is asserted, the RX controller will wait for the start of the next packet before allowing data to be sent out over the user interface.

13.8.3.3.2 Receive Interface Example Transaction

High Speed receive packets appear immediately on the Receive local interface as they are received.

13.8.3.3.2.1 Long packet receive with RAW 8 data and one DPHY

Initially, pkt_hdr_valid asserts along with the packet header information. The packet header ports, pkt_hdr_data_type, pkt_hdr_wc, and pkt_hdr_vc indicate that the packet contains RAW8 data, has 4 btes total and a Virtual Channel of zero. Several clocks later sop_out asserts with dav_out indicating the first cycle of receive data. Dav_out asserts for 4 clocks, framing the 4 bytes (pixels) of RAW8 pixel data on data_out[7:0]. During the last cycle of dav_out eop_out[0] asserts indicating the last cycle of received RAW8 data. When the pixel data has a width less than the 24 bit width of the data_out port the data is

justified down into the lower bits. In the example previously described, the RAW8 data will appear on data_out[7:0]. If the data had been RAW10 pixels, the RAW10 data would be contained on data_out[9:0].

The figure below shows a waveform of the received packet on the local interface.

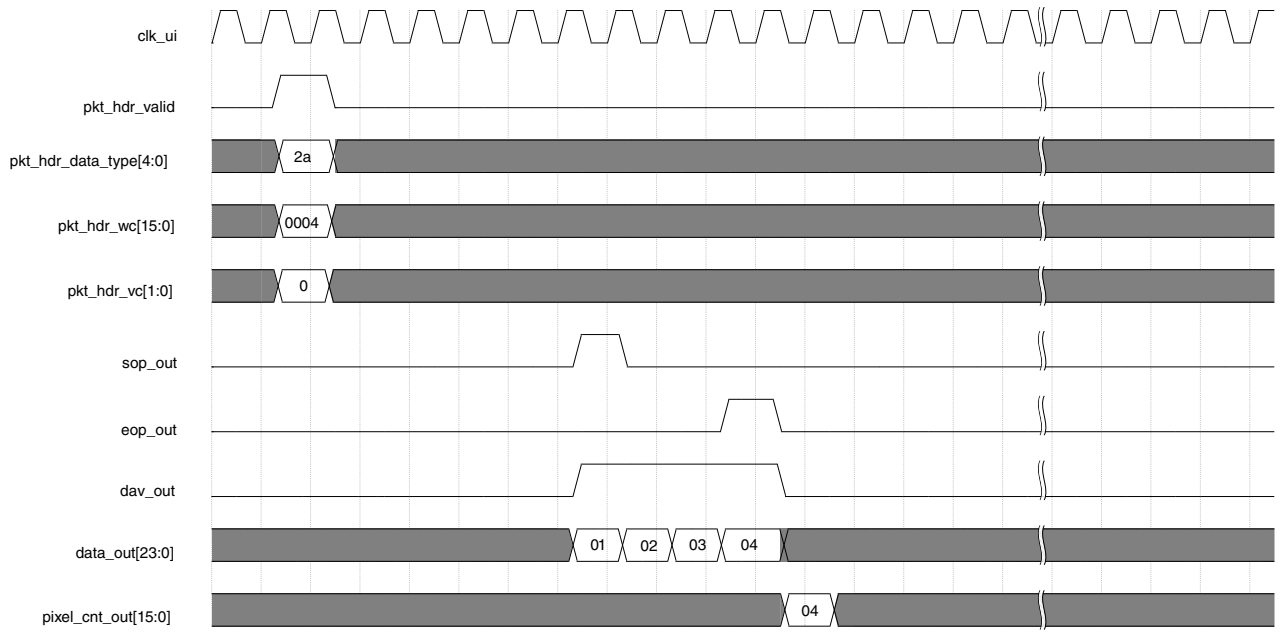

Figure 13-72. Receive Packet with a payload of 8 RAW8 pixels, single DPHY lane, and Virtual Channel = 0 single pixel configuration

13.8.3.3.2.2 Two back to back long packet request with RAW8 data and two DPHY lanes

The figure shows two packet requests that occur back to back. L_tx_pkt_cmd_req is asserted along with the packet parameters on l_tx_pkt_cmd. The request is acknowledged by the controller during the next clock period when l_tx_pkt_cmd_ack is asserted. The second request is immediate submitted by keeping l_tx_pkt_cmd_req asserted and changing the value on l_tx_pkt_cmd, indicating that the next packet will contain 4 bytes rather than the 3 that the previous packet contained. Note that it is not necessary to change l_tx_pkt_cmd in order to request another packet immediately following the first packet.

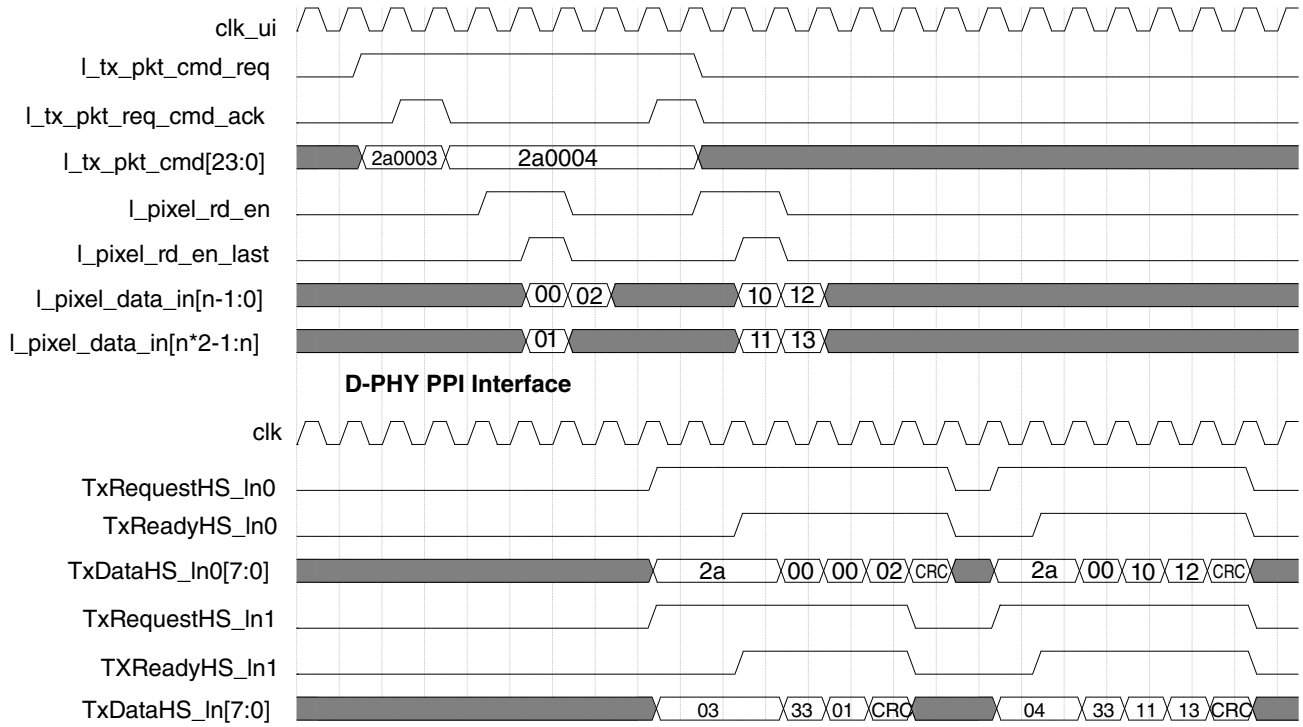

Figure 13-73. Two Transmit Packets, payloads of 3 and 4 pixels, two DPHY lanes, Virtual Channel=0, Double Pixel Mode

NOTE

The relationship of l_tx_pkt_cmd_req, l_tx_pkt_cmd_ack to TxRequestHS , TxReadyHS and l_pixel_data_in to TxDataHS is not defined. Furthermore, the relationship shown in the above figure is compressed for formatting considerations.

13.8.3.3.2.3 Short Packet Receive

The short packets do not contain any data. All the information in a short packet is contained in the 32 bit header. Pkt_hdr_valid asserts indicating that the packet header information contained on pkt_hdr_data_type, pkt_hdr_wc, and pkt_hdr_vc is valid. Short packets are defined as having a pkt_hdr_data_type value that is less than 0x10. With a short packet the CSI-2 Rx Controller Core does not assert sop_out, eop_out, nor dav_out.

The figure below shows the reception of a CSI-2 Short Packet type.

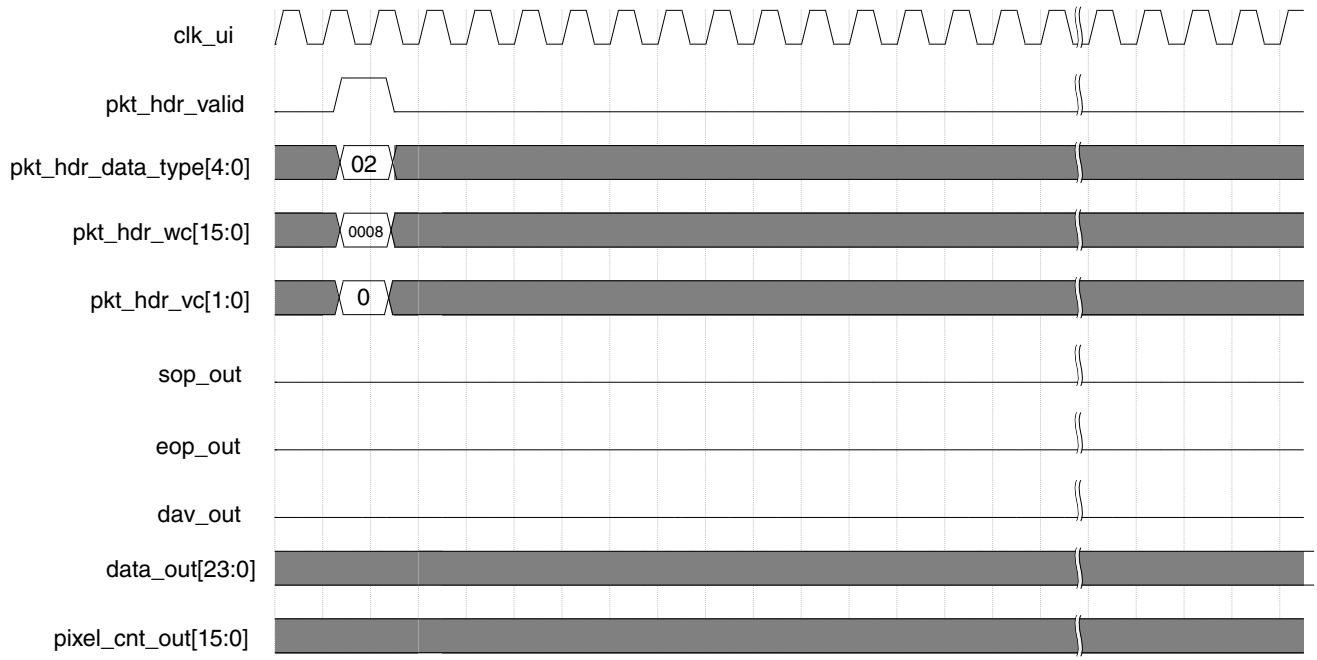

Figure 13-74. Short Packet receive with a data type of Line Start, Line Number of 8 , and Virtual Channel = 0 single pixel configuration

In this example, the data type ix 0x30, a user defined byte data type. Initially, pkt_hdr_valid asserts along with the packet header information. The packet header ports, pkt_hdr_data_type, pkt_hdr_wc, and pkt_hdr_vc indicate that the packet is a user defined data type with a payload of 4 bytes. For unsupported types, the Rx Controller outputs the entire packet minus the two byte CRC value at the end of the packet. The first four bytes are the packet header followed immediately by the 4 bytes of payload data.

The figure below shows a waveform diagram of a received packet on the local interface for an unsupported data type.

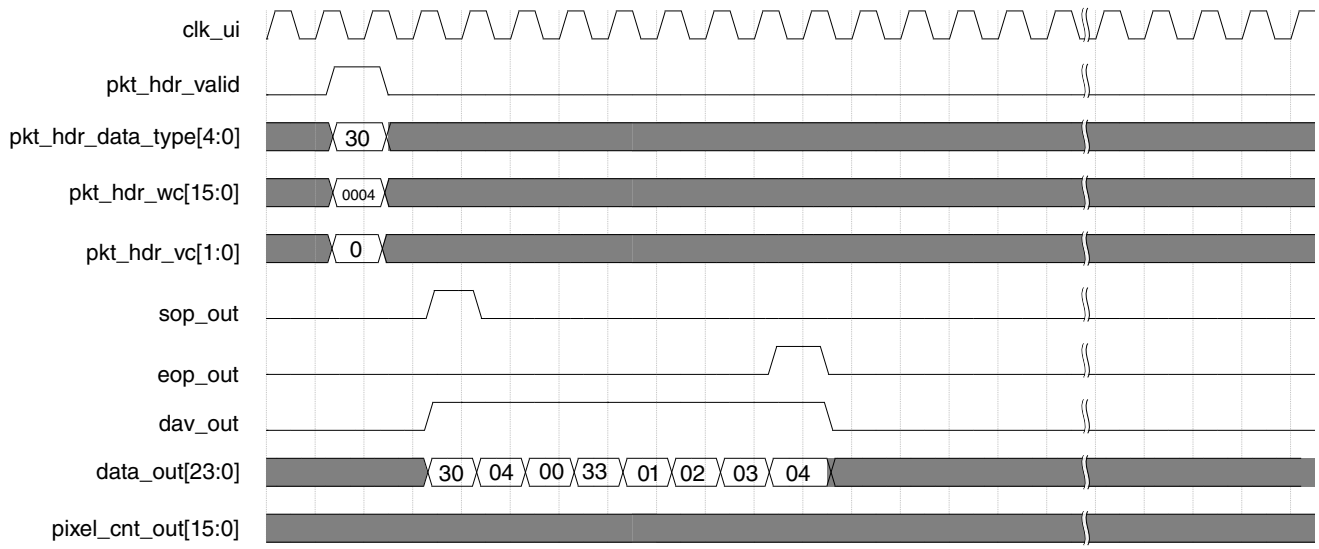

Figure 13-75. Received packet of an unsupported data type, 0x30, user defined data, single pixel configuration

13.8.3.4 CSI-2 Rx Controller Core Clocking

The RX controller core requires two clocks for proper operation clk_ui and clk. The clk_ui clock is the clock that the user interface is synchronous to, with all inputs and outputs referenced to the rising edge of clk_ui. The clk input is the clock that the CSI-2 Rx Controller Core uses to process data received from the D-PHY. Clk_ui must be of a sufficient frequency to keep up with the incoming data from the CSI-2 MIPI interface.

The data from the D-PHY is clocked into shallow FIFOs (one per DPHY lane) using a receive clock that the D-PHY generates. There is no direct timing requirements between the D-PHY generated receive clock and the CSI-2 Rx Controller Core's clk or clk_ui input. The frequency of the clock used for the RX controller's clk input must be of a sufficient frequency that the RX controller can keep up with the data from DPHY. The Rx Controller processes the Rx D-PHY data in a 32 bit wide data sufficient frequency that the Rx Controller can keep up with the receive data from the D-PHY. The Rx Controller processes the Rx D-PHY data in a 32 bit wide data path regardless of whether the CSI-2 MIPI receive data is coming across one, two, three, or four lanes. The frequency of clk must be exactly equal to or greater than the RX byte clock coming from the RX DPHY.

The CSI-2 Rx Controller Core can supply pixel data to the User application either one, two or four pixels per clock.

When in single Pixel Mode, the minimum frequency for clk_ui must be high enough to keep up with the incoming data rate of the CSI-2 MIPI interface. It is important to realize that the user interface is pixel based and therefore may be wider than the incoming byte data from the MIPI RX DPHY. As an example, if RGB888 data is being received, the user interface data width will be 24 bits wide (1 pixel per clk_ui rising edge and each pixel is 24 bits). As an example, let the MIPI interface run at 1000Mbps with a single lane. The data rate into the CSI-2 RX controller will be 125MBps so clk must run at 125MHz or higher. Since the user interface is 3 bytes wide, clk_ui must run at 125MHz/3 or higher to keep up with the incoming data.

the figure below shows one possible clocking methodology. In this example, the user Clk_Gen module generates the edge aligned clk_ui and clk clocks. It also generates a reference clock that the D-PHY might require. The Reference clock has no relationship to any of the CSI-2 Rx Controller Core's clocks.

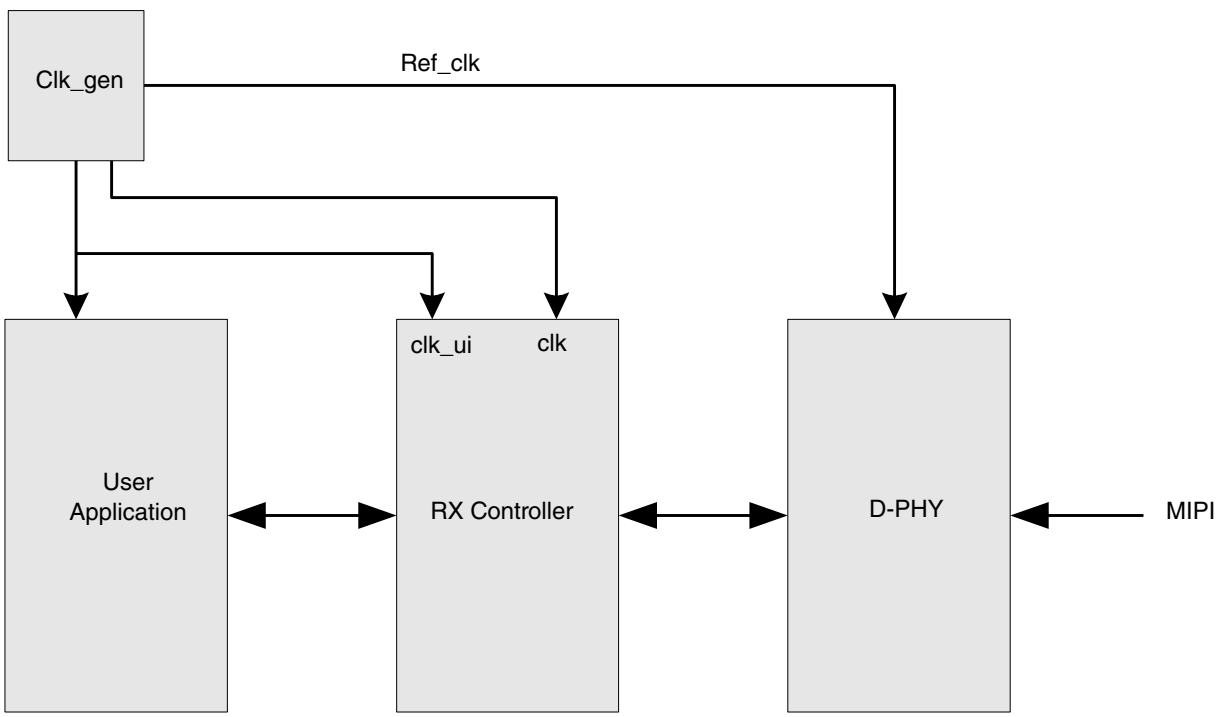

Figure 13-76. CSI-2 Rx Controller Core clocking example

13.8.3.5 CSI-2 Controller Core Configurations

The CSI-2 RX Controller Core User Interface supports either a single, double, or quad pixel wide data path. The double and quad wide pixel modes can help reduce the frequency the user interface must run at while the single pixel wide mode can be easier to interface to for some applications.

This chip supports the following:

- Single Pixel Configuration

13.8.3.5.1 Single Pixel Configuration

The CSI-2 Rx Controller Core User Interface supports a configuration where a single pixel of received data is processed every clock period.

The CSI-2 Rx Controller Core contains minimal pixel buffering (16 pixels or less) so the frequency of that the user interface runs at must be at least high enough to receive the data from the controller at a rate that is equal to or greater than the highest transmission data rate on the MIPI interface for all lanes combined. For example, if the total bandwidth of the physical MIPI interface will be 800Mbps with a data type of 8RAW then the user interface must be clocked at a minimum of 100MHz.

13.8.3.6 CSI-2 Rx Controller Core Data Types Formatting

The CSI-2 Rx Controller Core supports the various CSI-2 Data Types via the data_out port. The following subsections describe how the controller presents the various received data types on the data_out output port.

The CSI2 Controller supports the Single Pixel Configuration.

13.8.3.6.1 RAW6 (Data Type = 0x28)

With RAW6 data type (0x28) and the Rx Controller configured for single pixel mode, RAW6 data is contained on data_out[5:0].

13.8.3.6.2 RAW7 (Data Type = 0x29)

With RAW7 data type (0x29) and the Rx Controller configured for single pixel mode, RAW7 data is contained on data_out[6:0].

13.8.3.6.3 RAW8 (Data Type = 0x2A)

With RAW8 data type (0x2A) and the Rx Controller configured for single pixel mode, RAW8 data is contained on data_out[7:0].

13.8.3.6.4 RAW10 (Data Type = 0x2B)

With RAW10 data type (0x2B) and the Rx Controller configured for single pixel mode, the received RAW10 data is contained on data_out[9:0].

13.8.3.6.5 RAW12 (Data Type = 0x2C)

With RAW12 data type (0x2C) and the Rx Controller configured for single pixel mode, the received RAW12 data is contained on data_out[11:0].

13.8.3.6.6 RAW14 (Data Type = 0x2D)

With RAW14 data type (0x2D) and the Rx Controller configured for single pixel mode, the received RAW14 data is contained on data_out[13:0].

13.8.3.6.7 RGB444 (Data Type = 0x20)

With RGB444 data type (0x20) and the Rx Controller configured for single pixel mode, the blue data is on data_out[3:0], green on data_out[7:4], and red on data_out[11:8].

13.8.3.6.8 RGB555 (Data Type = 0x21)

With RGB555 data type (0x21) and the Rx Controller configured for single pixel mode the blue data is on data_out[4:0], green on data_out[9:5], and red on data_out[14:10].

13.8.3.6.9 RGB565 (Data Type = 0x22)

With RGB565 data type (0x22) and the Rx Controller configured for single pixel mode the blue data is on data_out[4:0], green on data_out[10:5], and red on data_out[15:11].

13.8.3.6.10 RGB666 (Data Type = 0x23)

With RGB666 data type (0x23) and the Rx Controller configured for single pixel mode, the blue data is on data_out[5:0], green on data_out[11:6], and red on data_out[17:12].

13.8.3.6.11 RGB888 (Data Type = 0x24)

With RGB888 data type (0x24) and the Rx Controller configured for single pixel mode, the blue data is on data_out[7:0], green on data_out[15:8], and red on data_out[23:16].

13.8.3.6.12 Legacy YUV420 8 bit (Data Type = 0x1A)

With Legacy YUV420 8 bit and the Rx Controller configured for single pixel mode the video data is received in UYY…/VYY sequences in odd/even lines. The U component is received with YY in a UYY group on odd lines while the V component is received with the same YY pairs in VYY groups on the even lines. See the MIPI CSI-2 Specification for a more complete description. When receiving an odd line data_out[7:0] contains the U component, data_out[15:8] Y1 and data_out[23:16] Y2. On even lines data_out[7:0] contains the V component, data_out[15:8] Y1 and data_out[23:16] Y2.

13.8.3.6.13 YUV420 8 bit (Data Type = 0x18,1C)

With YUV420 8 bit and YUV420 8 bit chroma shifted is received as YYYY (odd lines) UYVY (even lines) sequence. With the Rx controller configured for single pixel mode and receiving even numbered lines, data_out[7:0] contains the U1 component, bits [15:8] Y1. On the next data valid cycle bits [7:0] V1, bits [15:8] Y2. When receiving odd lines, data_out[7:0] contains the Y1 component, bits [15:8] Y2. On the next data valid cycle bits [7:0] Y3, bits [15:8] Y4.

13.8.3.6.14 YUV420 10 bit (Data Type = 0x19, 0x1D)

With YUV420 10 bit and YUV420 10 bit chroma shifted is received as YYYY (odd numbered lines) and UYVY (even numbered lines) sequence with each component represented by 10 bits. With the Rx controller configured for single pixel mode and receiving even numbered lines, data_out[9:0] contains the U1 component, bits [19:10] Y1. On the next data valid cycle bits [9:0] V1, bits [19:10] Y2. When receiving odd lines, data_out[9:0] contains the Y1 component, bits [19:10] Y2. On the next data valid cycle bits [9:0] Y3, bits [19:10] Y4.

13.8.3.6.15 YUV422 8 bit (Data Type = 0x1E)

With YUV422 8 bit is received as UYVY sequence. With the Rx controller configured for single pixel mode, data_out[7:0] contains the U1 component, bits [15:8] Y1. On the next data valid cycle bits [7:0] V1, bits [15:8] Y2.

13.8.3.6.16 YUV422 10 bit (Data Type = 0x1F)

With YUV422 10 bit is received as a UYVY sequence with each component represented by 10 bits. With the Rx controller configured for single pixel mode, data_out[9:0] contains the U1 component, bits [19:10] Y1. On the next RX data valid cycle, bits [9:0] V1, bits [19:10] Y2.

13.8.3.6.17 User Defined Data Types, (Data Type = 0x30,0x31,0x32,0x33,0x34,0x35,0x36,0x37)

With User Defined Data Types and the Rx Controller configured for single pixel mode, User Defined data is contained on data_out[7:0].

13.8.3.6.18 Null Data Type, (Data Type = 0x10)

With User Null Data Type and the Rx Controller configured for single pixel mode, Null data is contained on data_out[7:0].

13.8.3.6.19 Blanking Data Type, (Data Type = 0x11)

With Blanking Data Type and the Rx Controller configured for single pixel mode, Blanking data is contained on data_out[7:0].

13.8.3.6.20 Embedded Data Type, (Data Type = 0x12)

With User Null Data Type and the Rx Controller configured for single pixel mode, Embedded data is contained on data_out[7:0].

When the Rx Controller is configured for double pixel mode, the Embedded data that is received is contained on data_out[7:0] and data_out[MAX_PIXEL_WIDTH +7:MAX_PIXEL_WIDTH] with data_out[7:0] having been received first.

When the Rx Controller is configured for quad pixel mode, the first Embedded data that is received is contained on data_out[7:0], the second on data_out[MAX_PIXEL_WIDTH +7:MAX_PIXEL_WIDTH], the third on data_out[MAX_PIXEL_WIDTH*2+7:MAX_PIXEL_WIDTH*2],

13.8.3.6.21 Unsupported Data Types

With unsupported data types and the Rx Controller configured for single pixel mode, the raw packet data (including the header but minus the CRC) is contained on data_out[7:0].

13.8.3.7 RX Video Interface

The CSI-2 Rx Video Interface is connected internally to the local interface outputs of the CSI-2 Rx Controller Core. This interface provides both the packet header information and the pixel data (after processing by the Pixel Format block). CSI-2 Rx Controller Cores may be built with any number of Pixel Formats supported. The CSI-2 Rx Video Interface only recognizes video formats for which the CSI-2 Rx Controller Core has been configured to support.

The general timing of the video interface is determined by the timing of the packets received by the CSI-2 RX controller which are used to determine when to generate a Vertical Sync and when to output a line of video data.

The CSI-2 Rx Video Interface may receive several different types of packet data types as shown in the table below.

Packet Type	Data ID	Function
Frame Start Code (FS)	0x00	Indicates start of frame
Frame End Code (FE)	0x01	Indicates end of frame
Line Start Code (LS)	0x02	Indicates start of line
Line End Code (LS)	0x02	Indicates end of line
Image Data Codes (IMG)	various	Image data packets carry the sample data. The CSI-2 Rx Video Interface will respond to those Data types which are enabled in the CSI-2 Rx Controller Core. See CSI-2 Rx Controller Core Data Types Formatting

13.8.3.7.1 Video Interface Output Raster Timing

The output timing of the raster is formed by the packets sent to the CSI-2 Rx Controller Core and is determined by the relative timing of these packets. This timing is controlled by the transmitter and is not determined by the CSI-2 Rx Controller Core. As shown in Figure 4.8 below, the basic sequence of packets sent by the transmitter (often a sensor or camera) consists of a Frame Start packet (short packet), followed by some number of Image Data packets (long packets) with one Image data packet per video line and the followed by a Frame End packet (short packet). The Frame End packet is followed by pause which determines the Blanking Lines interval. The length of the Image Data packets is determined by the horizontal resolution of the sensor and each line's samples are carried by a single Image Data packet.

NOTE

Note that each Image Data packet may optionally be preceded by a Line Start packet and followed by an optional Line End packet. The Line Start and Line End packets are ignored by the CSI-2 Rx Video Interface.

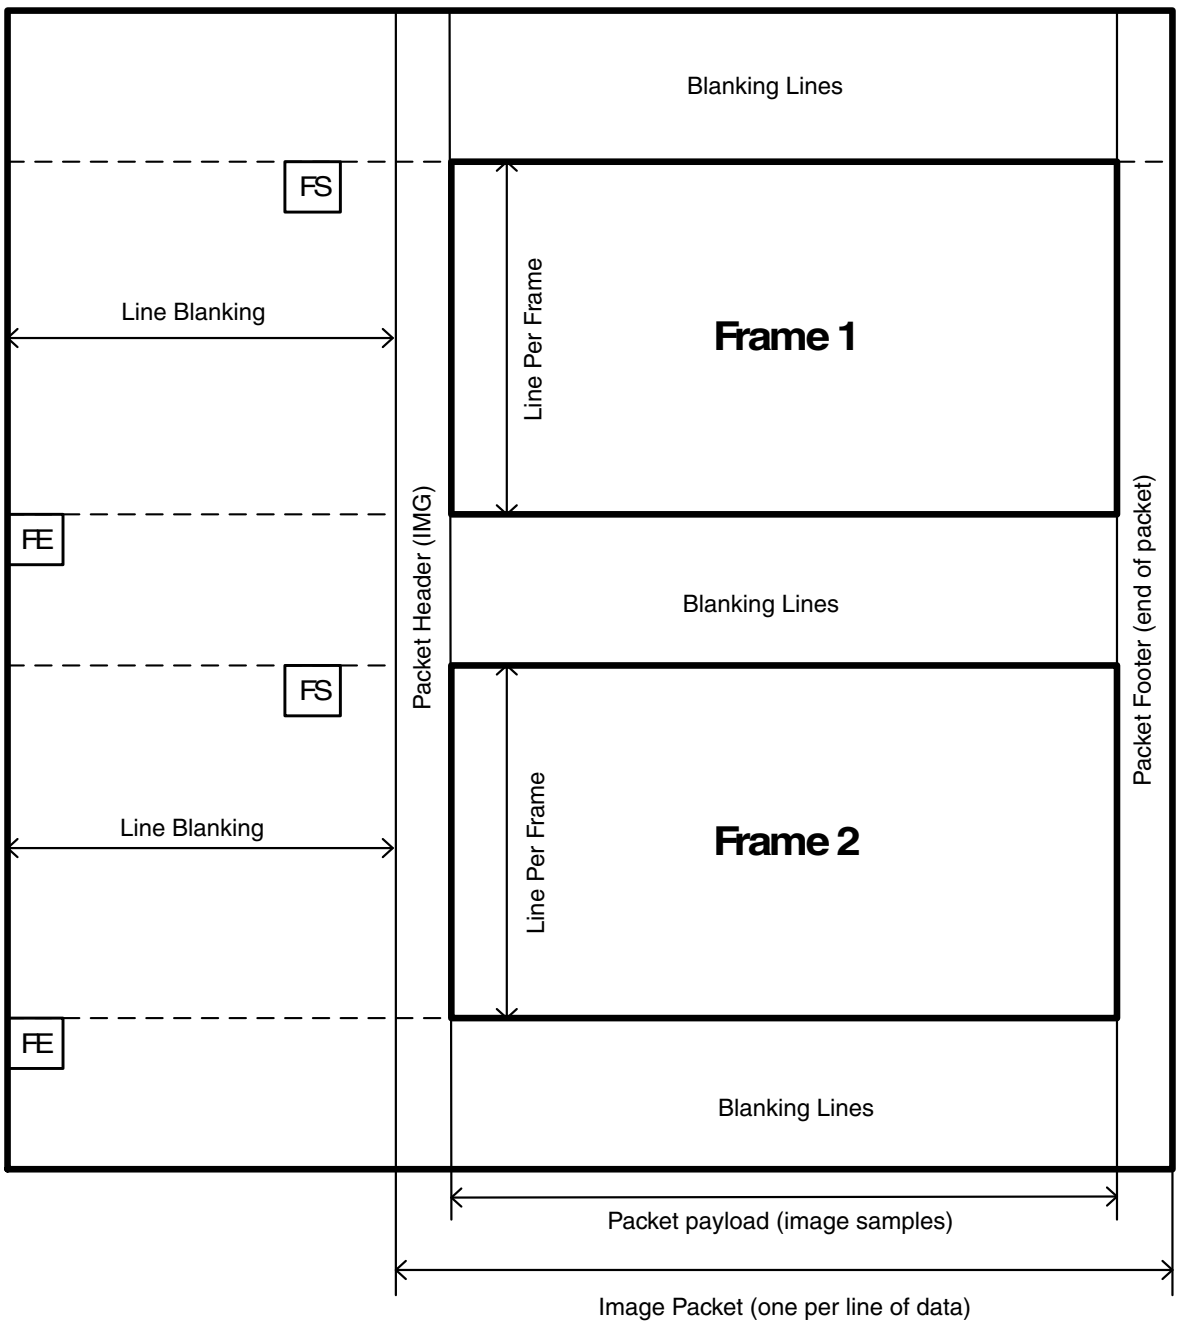

Figure 13-77. Rx Video Interface Raster Timing

NOTE

- FS- Frame Start Packet

- FE- Frame End Packet
- IMG- Image Data Packet

Note that the interface does not generate Horizontal sync pulses during the Blanking Lines.

The CSI-2 Rx Video controller generates a Vertical sync pulse upon the occurrence of every Frame Start packet. Each line of video sample data is preceded by a Horizontal sync pulse.

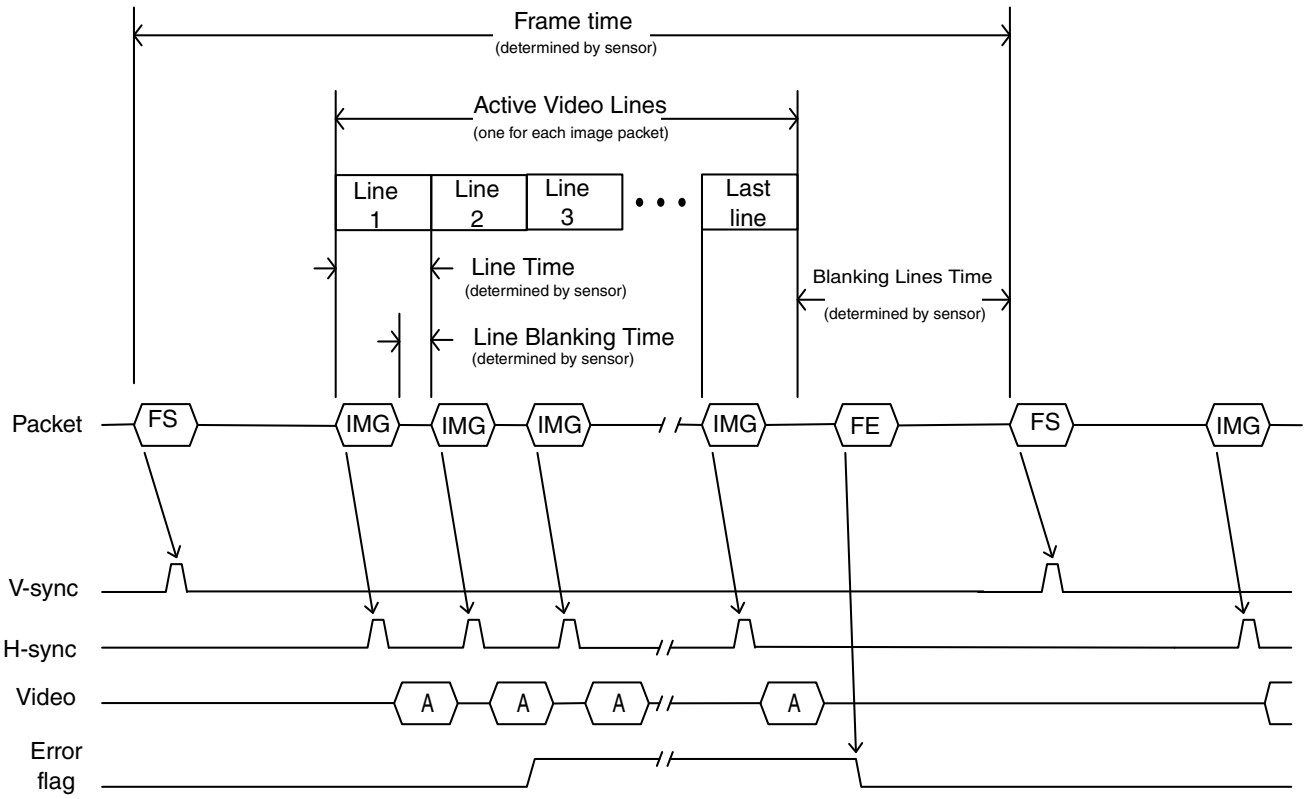

Figure 13-78. Relationship of Packet Stream to Video Interface

NOTE

- FS - Frame start Packet (causes V-sync)
- IMG - Image Data Packet(causes H-sync and Video after FIFO reaches send level)
- FE - Frame End Packet (causes any pending Error Flags which were set in the previous frame)
- A - Time period when video samples are valid (follows H-sync)

The video sample output bus (vid_out) is logically divided up into pixel lanes. The number of pixel lanes is determined by the pixel width of the CSI-2 Controller Core. This width may be one, two or four pixels wide (single, double or quad pixel interface). The bit width of each pixel lane is determined the widest pixel width supported by the core controller's Pixel Format block. When transferring image data whose pixels are narrower than the maximum required width unused more significant bits in each pixel lane will be output as zero.

To determine the validity of the data presented on each pixel lane the CSI-2 Rx Video Interface supplies a data enable output (vid_de) whose width is equal to the number of pixel lanes in the interface. When a data enable bit is high its pixel lane is valid.

Thus as a design example:

1. Controller supports a double pixel interface and data types RAW8, RAW10 and RAW12. In this case the maximum pixel width is 12 bits.
2. For this interface the total width of the video output bus is 24 bits (2 * 12) This bus is logically divided into two pixel lanes each supplying 12 bits. That sample which arrived earlier is delivered on the low half (bits[11:0]) of this bus while the following sample is delivered on the high half (bits[23:12]).
3. The vid_de bus would be 2 bits with the least significant bit enabling the low pixel lane and the most significant bit enabling the high pixel lane

The situation is similar for a single pixel controller interface. In this case there is only a single pixel lane in the video output bus and a single video enable bit. For a four pixel controller interface there would be four pixel lanes and a four bit vid_de bus.

The only time at which all vid_de bits will not be asserted is on the final transfer of video pixels in a scan line. At this time only some of the lower order bits in the vid_de bus will be asserted only if the number of samples per line is not evenly divisible by the number of pixel lanes.

Thus as a design example:

1. Assume a double pixel interface which results in a two video data lanes. Image data packets are 1023 samples long.
2. This would result in 511 transfers of video out with both bits of vid_de set (1022 samples). The last transfer would only have the least significant vid_de bits set to transfer the final sample to achieve the 1023 samples in the scan line.

13.8.3.7.2 Video Interface Video Port Descriptions

The Video output interface outputs all the signals associated with video port. All output signals in the interface are synchronous to clk_vid.

PORT	TYPE	DESCRIPTION
clk_vid	Input	Clock for all signals associated with the video port
clk_vid_reset_n	Input	Asynchronous active low reset for all logic clocked by clk_vid
vid_intfc_enb	Input	Active high enable for the video interface.
vid_h_sync	Output	Video H Sync pulse
vid_v_sync	Output	Video V Sync pulse
vid_out [VID_PIXEL_WIDTH*RX_PIXELS_PER_CLK-1:0]	Output	Video data bus. Contains 1, 2 or 4 pixel lanes as set by the CSI-2 Rx Controller port configuration (single, double or quad pixel interface). The width of each pixel lane is set by the widest pixel with of all the data types enabled in the controller. See CSI-2 Rx Controller Core Data Types Formatting SinglePixelInterface: Pixel lane 0= vid_out[VID_PIXEL_WIDTH-1:0] Dual Pixel Interface: Pixel lane 0= vid_out[VID_PIXEL_WIDTH-1:0] Pixel lane 1= vid_out[(2*VID_PIXEL_WIDTH)-1:VID_PIXEL_WIDTH] Quad Pixel Interface: Pixel lane 0= vid_out[VID_PIXEL_WIDTH-1:0] Pixel lane 1= vid_out[(2*VID_PIXEL_WIDTH)-1:VID_PIXEL_WIDTH] Pixel lane 2 = vid_out[(3*VID_PIXEL_WIDTH)-1:2*VID_PIXEL_WIDTH] Pixel lane 3 = vid_out[(4*VID_PIXEL_WIDTH)-1:3*VID_PIXEL_WIDTH]
vid_de [0]	Output	Video data pixel lane valid. One bit per Pixel lane. Logic 1 indicates a valid pixel value. SinglePixelInterface: Bit 0: Pixel lane 0 Dual Pixel Interface: Bit 0 : Pixel lane 0 Bit 1: Pixel lane 1 Dual Pixel Interface: Bit 0 : Pixel lane 0 Bit 1: Pixel lane 1 Bit 2: Pixel lane 2 Bit 3: Pixel lane 3

13.8.3.7.3 Video Output Port Waveforms

The vid_de port is used to enable capture of valid video pixels from the vid_out bus. The vid_de will have a single bit for each pixel lane in the vid_out bus. Thus for a single pixel interface (one pixel lane) this bus will be a single signal.

The vid_de port will assert all its signals high for all transfers except possibly the last transfer. This last transfer may only assert some number of lower order bits to one and the remaining higher order bits to zero. The number of valid pixel lanes in the last transfer is determined by the number of pixels transferred by the image packet which generated the video line.

The ending value may be predicted by taking number of pixels transferred in an image packet modulo number of pixel lanes. Any non-zero remainder indicates some number of vid_de bits will be zero on the last transfer.

The following table shows the last vid_de value as a function of number of pixel lanes and packet size:

MODULO	
	Single Pixel Interface
0	1
1	NA
2	NA
3	NA

NOTE

MODULO = Number_of_pixels_in_image_packet MOD number_of_pixel_lanes

13.8.3.7.4 Video Interface Error Port Descriptions

The video interface outputs three error flags which can assist in hardware debugging or be used to notify software of problems. Whenever one of these error conditions occurs the video interface stops responding to input packets until such time a Frame End packet is detected. At this time the error flags are reset and the interface tries again on the next frame. Assertion of these error conditions can mean a misconfigured interface or bad input packets.

All these flags are synchronous to the controller clk_ui. The interface must be enabled (vid_intfc_enb = 1) for these errors to be detected.

Table 13-37. CSI-2 Rx Video Interface Error Port Descriptions

Port	Type	Description
vid_err_send_level	Output	This flag indicates the video interface pixel fifo did not accumulate enough sample to trigger its send level setting before the end of an image data packet was detected. This flag would generally mean that the cfg_vid_p_fifo_send_level is set to high.
vid_err_fifo_wr_ovfl	Output	This flag indicates the video interface pixel fifo overflowed on a pixel write. This means the output video port is not removing pixels quickly enough to keep up with the input data rate. This flag would generally mean the clk_vid rate is too low.

The figure below shows the error flag interface waveforms:

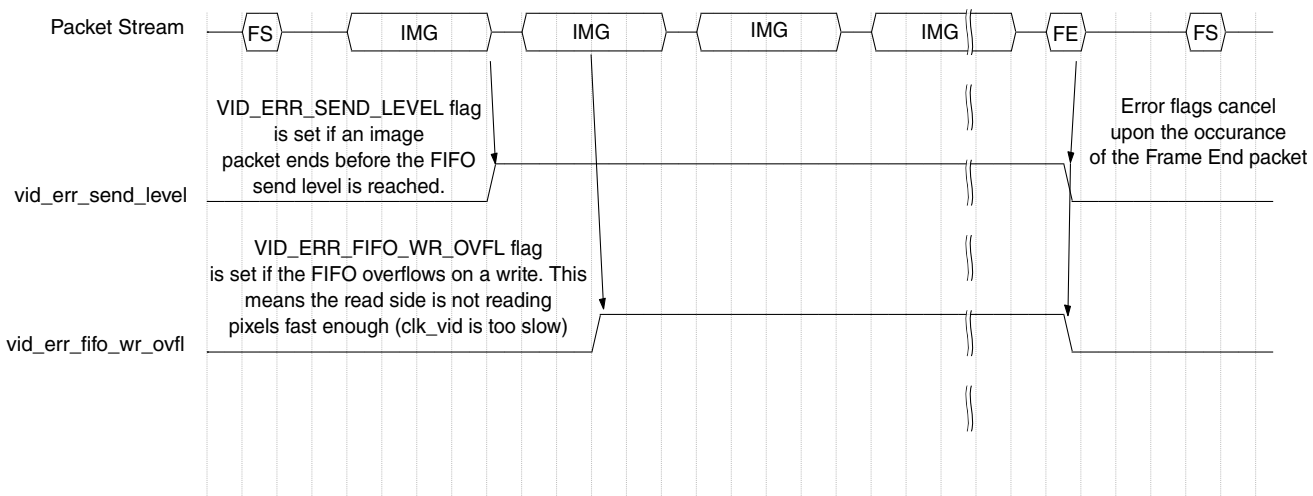

Figure 13-79. Error Flag Interface Waveforms

13.8.3.8 Rx Control and Status Register (CSR) APB Interface

The CSR provides an APB compatible interface that enables control of the controller's configuration inputs via registers accessible via the APB interface.

13.8.4 Memory Map and register definition

This section includes the memory map and detailed descriptions of all registers.

13.8.4.1 register descriptions

13.8.4.1.1 CSI2RX memory map

13.9 Sony/Philips Digital Interface (SPDIF)

13.9.1 Overview

The Sony/Philips Digital Interface (SPDIF) audio block is a stereo transceiver that allows the processor to receive and transmit digital audio.

The SPDIF transceiver allows the handling of both SPDIF channel status (CS) and User (U) data and includes a frequency measurement block that allows the precise measurement of an incoming sampling frequency.

A recovered clock is provided to drive both internal components in the system, such as SAI ports, and external components, such as A/Ds or D/As, with clocking control provided via related registers.

As the SPDIF internal data width is 24-bit, the eight most-significant bits of all registers return zeros.

The figure below shows a block diagram of the SPDIF transceiver data paths (receiver and transmitter) and its interface.

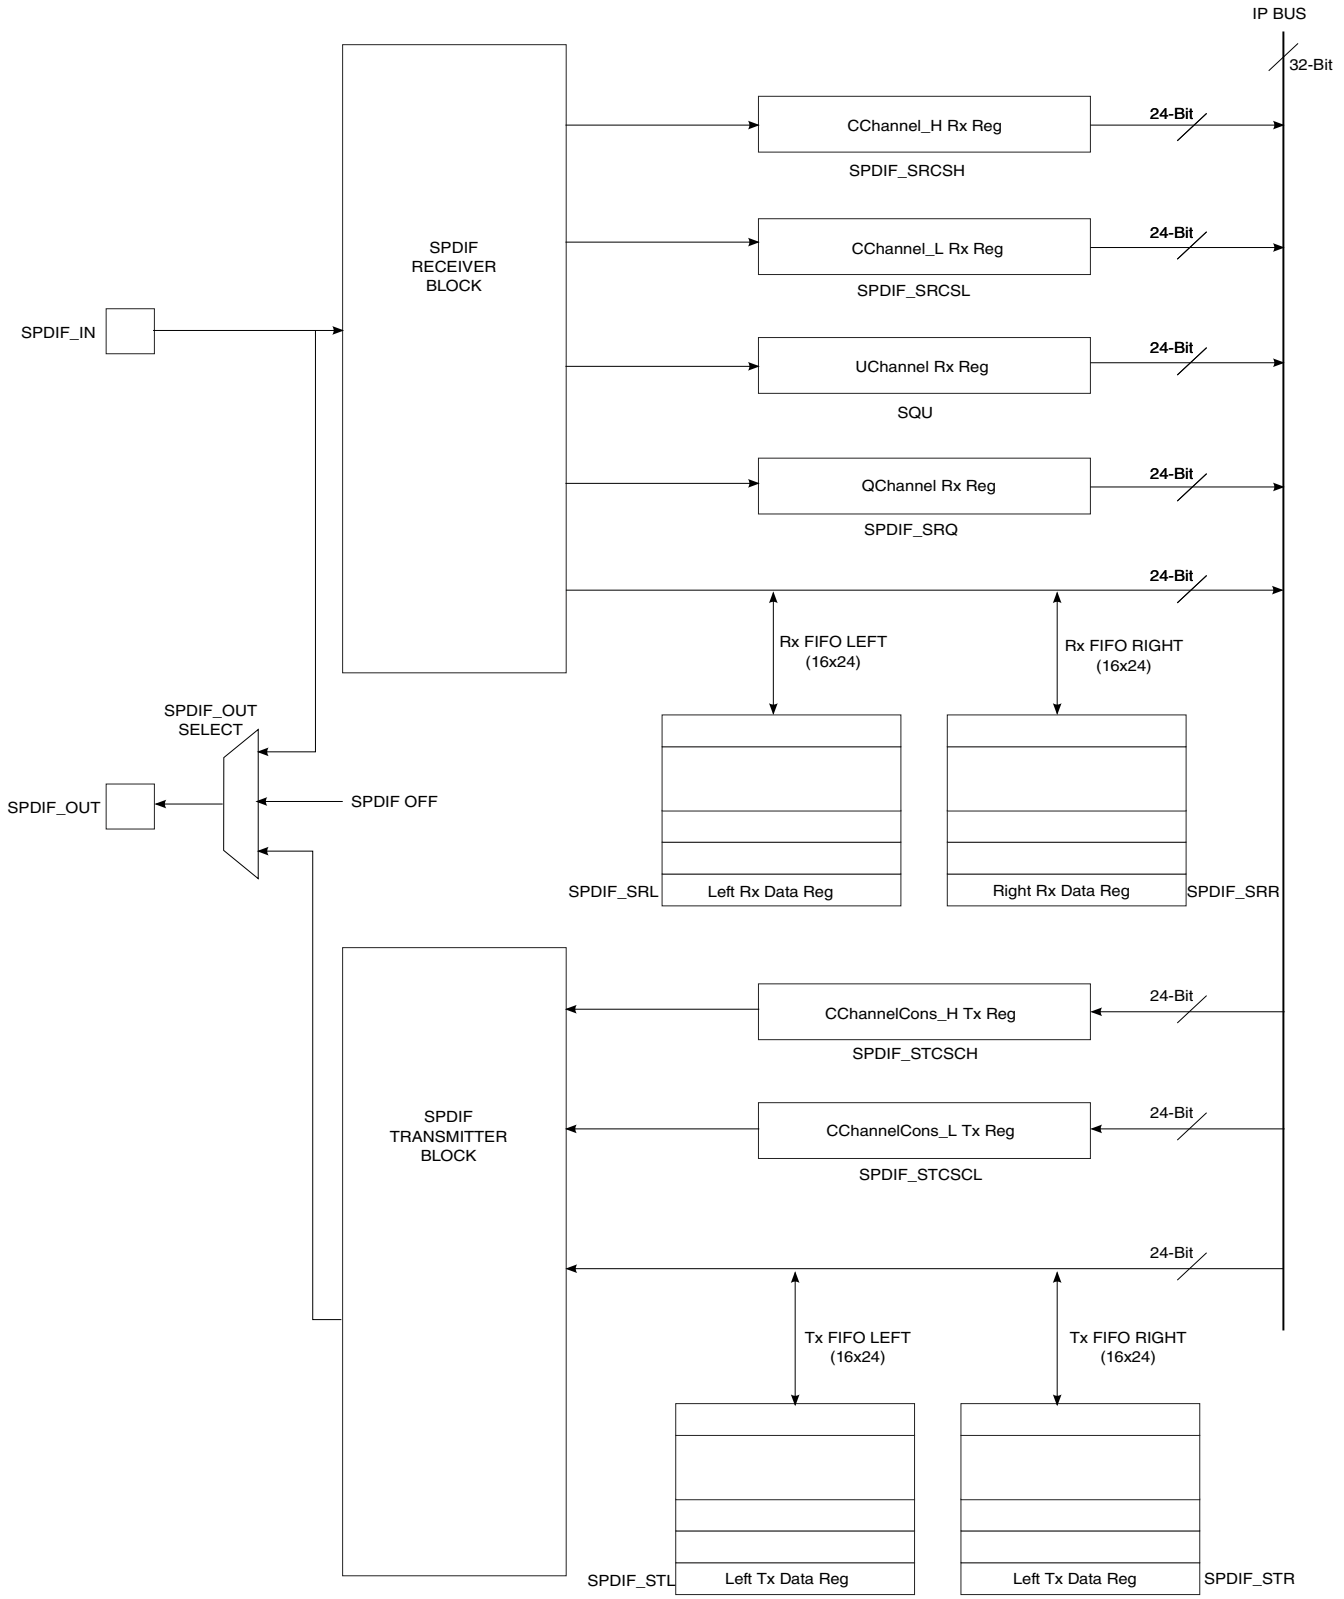

Figure 13-80. SPDIF Transceiver Data Interface Block Diagram

13.9.2 Clocks

The table found here describes the clock sources for SPDIF.

Please see clock control block for clock setting, configuration and gating information.

Table 13-38. SPDIF Clocks

Clock name	Clock Root	Description
gclkw_t0	ipg_clk_root	Global clock
ipg_clk_s	ipg_clk_root	Peripheral access clock
tx_clk	spdif0_clk_root	Module Tx clock

13.9.3 Functional Description

The SPDIF is composed of two parts: SPDIF Receiver and SPDIF Transmitter.

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in the SPDIF Rx left and right FIFOs. The Channel Status and User Bits are also extracted from each frame and placed in the corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

For the SPDIF transmitter, the audio data is provided by the processor via the SPDIFTxLeft and SPDIFTxRight registers. The Channel Status bits are also provided via the corresponding registers. The SPDIF transmitter generates a SPDIF output bitstream in the biphase mark format (IEC60958), which consists of audio data, channel status and user bits.

In the SPDIF transmitter, the IEC60958 biphase bit stream is generated on both edges of the SPDIF Transmit clock. The SPDIF Transmit clock is generated by the SPDIF internal clock generate block and the sources are from outside of the SPDIF block. For the SPDIF receiver, it can recover the SPDIF Rx clock. Figure 1 shows the clock structure of the SPDIF transceiver.

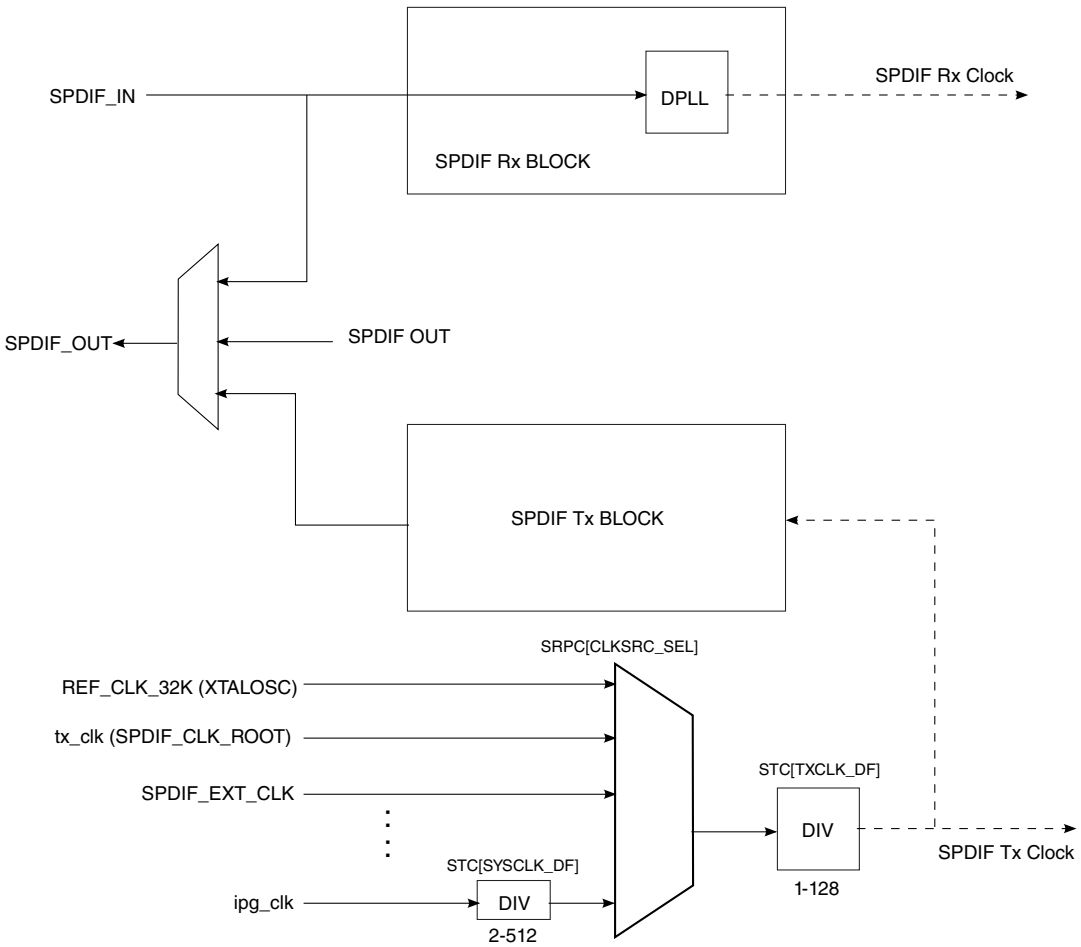

Figure 13-81. SPDIF Transceiver Clock Diagram

13.9.3.1 SPDIF Receiver

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in Rx left and right FIFOs.

The Tx left and right FIFOs are 16-deep and 24-bit-wide (equal to the audio data width). The Channel Status and User Bits are also extracted from each frame and placed in corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

The SPDIF receiver handles the main data audio stream and recovers the bit clock from the SPDIF input signal. The sample rate can be determined from the frequency measuring block. Additionally, the receiver supports the SPDIF C and U channels. The SPDIF C and U channel data is interfaced directly to memory-mapped registers.

All the data registers are controlled by the Interrupt Control Block and transferred to the memory-mapped IP bus.

The following functions are performed by the SPDIF receiver:

- Audio Data Reception see Audio Data Reception
- Channel Status bits Reception see Channel Status Reception
- U Channel bits Reception see User Bit Reception
- Validity Flag Reception see Validity Flag Reception
- SPDIF Receiver Exception support see SPDIF Receiver
- SPDIF Lock Detection

13.9.3.1.1 Audio Data Reception

The SPDIF Receiver block extracts the audio data from the IEC60958 stream, and outputs this via Rx left and right FIFOs to the memory-mapped registers SPDIFRxLeft and SPDIFRxRight.

Data from the SPDIF receiver is buffered in receive FIFO, and can be read by the processor from the memory-mapped registers.

- **SPDIF receiver data registers - Behavior on overrun, underrun**

The SPDIF Data Receive registers (SPDIFRxLeft and SPDIFRxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFOs. To prevent this from happening, hardware has been added to the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If a SPDIF Data Rx FIFO overrun occurs on e.g. the right half of the FIFO, the sample that caused the overrun is not written to the right half (due to overrun). Special hardware will make sure the next sample is not written to the left half of the FIFO. If the overrun occurs on the left half of the FIFO, the next sample is not written to the right half of the FIFO.

- **SPDIF receiver data registers - Automatic resynchronization of FIFOs**

An automatic FIFO resynchronization feature is available. It can be enabled and disabled separately for every FIFO. If it is enabled, the hardware will check to see if the left and right FIFOs are in sync. If that is not the case, it will set the filling pointer of the right FIFO to be equal to the filling pointer of the left FIFO.

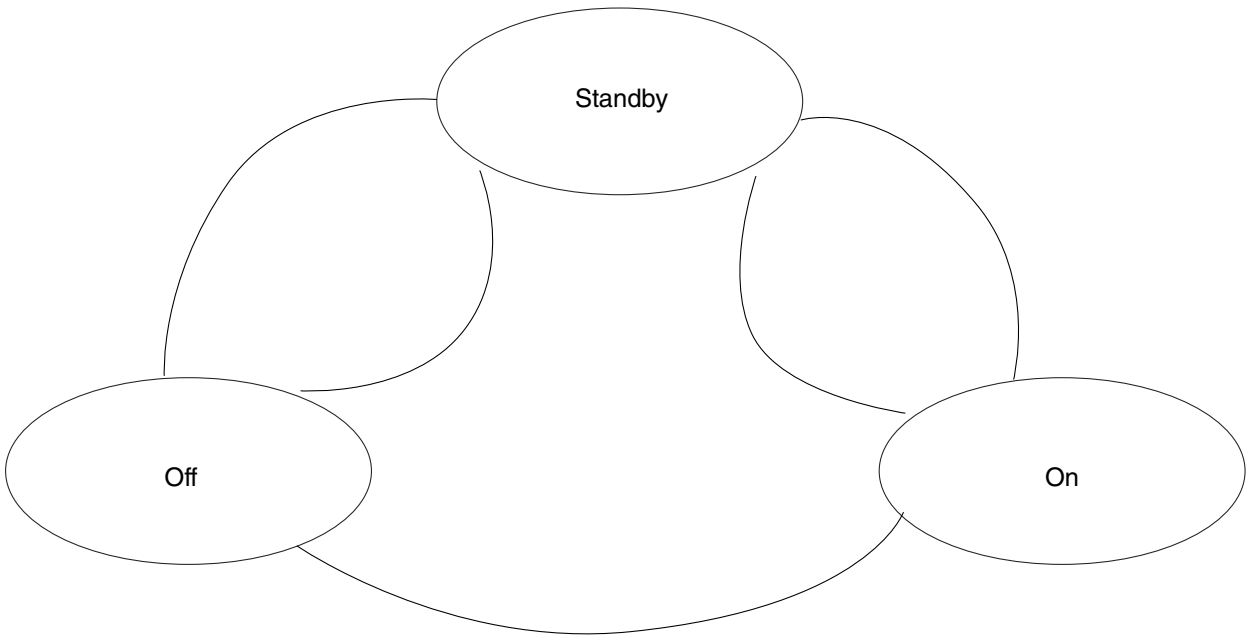

Figure 13-82. FIFO Auto-resync Controller State Machine

The operation is explained from the state diagram shown above. Every FIFO auto-resync controller has a state machine with 3 states: Off, StandBy and On. In the On state, the filling of the left FIFO is compared with the filling of right, and if they are not equal, right is made equal to left, and an interrupt is generated.

The controller will stay in Off state when the feature is disabled. When not disabled, the state machine will go to Off state on any processor read or write to the FIFO. It will go from On or Off to Standby on any left sample read from SPDIF Tx FIFOs, or on any left sample write to SPDIF Rx FIFOs. The controller will go from Standby to On on any right sample read from SPDIF Tx FIFO, or on any right sample write to SPDIF Rx FIFO. There is a control bit in the SPDIFConfig register to enable/disable the feature for the SPDIF Rx FIFO and SPDIF Tx FIFO.

13.9.3.1.1.1 Application Note

The automatic FIFO resynchronization can be switched on, and will avoid all mismatches between left and right FIFOs, if the software obeys the following rules: 1. When the left data is read or written to the left FIFO, in the same place of the program, data must be read or written to the right FIFO. Maximum time difference between left and right is 1/2 sample clock. (E.g. if sample frequency is 44 Khz, approximately 10 micro-seconds. For 88 Khz, approximately 5 micro-seconds.) 2. Write/read data to FIFO s at least 2 samples

at the time. If there is a mismatch Left-Right, the resync logic may go on only 1 sample clock after last data is read/written to the FIFO. Also acceptable is polling the FIFO, if at least part of the time 2 samples will be read/written to it.

- **SPDIF receiver - Additional features**

There are three exceptions associated with the SPDIF Receivers FIFOs

- full
- under/overrun
- resync

When the "full" condition is set for processor data input registers, the processor should read data from the FIFO, before overrun occurs. When "full" is set, and the FIFO contains e.g. 6 samples, it is acceptable for the software to read first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 6 samples from the RIGHT address, followed by 6 samples from the LEFT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. There is no order specified.

The implementation for SPDIF Rx is a double FIFO, one for left and one for right. "full" is set when both FIFOs are full. "underrun, overrun" are set when one of the FIFOs do underrun or do overrun. The resync interrupt means hardware took special action to resynchronize left and right FIFOs.

The FIFO level at which the "full" interrupt is generated, is programmable via the Full Select field in the SPDIFConfigReg register.

Rx FIFO on and Rx FIFO reset.

Two additional control fields of the SPDIF Rx FIFO are the on/off select and FIFO reset fields.

If on/off select is set to off, all-zero will be read from the FIFO, irrespective of the data received over the SPDIF interface.

If FIFO reset is set, the FIFO is blocked at "1 sample in FIFO". In this, the full interrupt will be on if FullSelect is set to "00". If FullSelect is set to any other value, interrupt will be off. The other interrupts are always off.

13.9.3.1.2 Channel Status Reception

A total of 48 channel status bits are received in two registers. No interpretation is performed by the SPDIF receiver block.

Channel Status Bits are ordered first bit left. CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFRxCChannel_h. CS-channel bit "23" is considered the LSB bit 0 in the register. C-channel bit 24 to 47 is seen as [23:0] bits of register SPDIFRxCChannel_l.

13.9.3.1.2.1 Channel Status Interrupt

When the value of a new SPDIF "CS" channel status frame is loaded in the register, an interrupt is generated. The interrupt is cleared when the processor writes the corresponding bit in the InterruptStat register.

13.9.3.1.3 User Bit Reception

There are two modes for U Channel reception, CD and non-CD. As is decided by USyncMode (bit 1 of CDText_Control register).

- **Behavior of U Channel receive interface on incoming CD U Channel Sub-code in SPDIF receiver**.

This mode is selected if UsyncMode, bit 1 in register CD Text control is set "1".

The CD sub-code stream embedded into the SPDIF U channel consists of a sequence of packets. Every packet is made up 98 "symbols". The first two symbols of every packet are "sync symbols", the other 96 symbols are "data symbols".

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

Data symbols are coming in MSB first. The MSB is the leading one.

When a "long pause" is seen between 2 subsequent "data symbols", the SPDIF receiver will assume the reception of one or more "sync symbols". Table below gives details.

Table 13-39. Sync Control Bits

Number of U Channel zero bits	Corresponding number of sync symbols
0-1	Unpredictable, not allowed
2-10	0
11-22	1
23-34	2
35-46	3
>45	Unpredictable, not allowed

The recognition of the number of sync symbols derives from the fact that the U channel transmitter in the CD channel decoder will transmit one symbol on average every 12 SPDIF channel bits. On this average rate, there is a maximum tolerance of 5%.

The SPDIF receiver is tolerant of symbol errors. Due to the physical nature of the transmission of the data over the CD disc, not more than 1 out of any 5 consecutive user channel symbols may be in error. The error may cause a change in data value, which is not detected by this interface, or it may cause a data symbol to be seen as a sync symbol, or a sync symbol to be seen as a data symbol. However, not more than 1 out of any 5 consecutive user channel symbols should be affected in this way.

The SPDIF U channel circuitry recognizes the 98-symbol packet structure, and sends the 96 symbol payload to the processor application. The 96 symbol payload is transmitted to the processor via 2 registers:

- The SPDIFRxUChannel register. In this register, data is presented 3 symbols at the time to the processor. Every time 3 new valid symbols, received on the SPDIF U Channel are present, the UChannelRxFull interrupt is asserted. For one 98-symbol packet, 96 symbols are carried across SPDIFRxUChannel. To transfer all this data, 32 UChannelRxFull interrupts are generated.
- The QChannelReceive register. In this register, only the Q bit of the packet is accumulated.Operation is similar to UChannelReceive. Because only Q-bit is transferred, only 96 Q-bits are transferred for any 98-symbol packet. To transfer this data, 4 QChannelRxFull interrupts are generated. When QChannelRxFull occurs, it is coincident with UChannelRxFull. There is only one QChannelRxFull for every 8 UChannelRxFull. The convention is that most significant data is transmitted first, and is left-aligned in the registers.
- Timing regarding packet boundary is extracted by hardware. The last UChannelRxFull corresponding to a given packet should be coincident with the last QChannelRxFull. In this last U, Q channel interrupt, symbols 95-98 are received, Q channel bits 67-98. The interrupts are coincident with UQSyncFound, flagging last symbols of the current frame.
- When the start of the new packet is found before the current packet is complete (less than 98 symbols in the packet), the UQFrameError interrupt is set. The application software should read out UChannelReceive and QchannelReceive registers, discard the value, and assume the start of a new packet.
- As already said, packet sync extraction is tolerant for single-symbol errors. Packet sync detection is based on the recognition of the sequence data-sync-sync-data in the symbol stream, because this is the only syncing sequence that is not affected by single errors. If the sync symbols are not found 98 symbols after the previous

occurrence, it is assumed to be destroyed by channel error, and a new sync symbols is interpolated.
- Normally, only data bytes are passed to the application software. Every databyte will have its most significant bit set. If sync symbols are passed to the application software, they are seen as all-zero symbols. Sync symbols can only end up in the data stream due to channel error.

- **Behavior of U Channel receive interface on incoming non-CD data**.

This mode is selected if UsyncMode, bit 1 in register CD Text control is set'0'.

In non-CD mode, the SPDIF U channel stream is recognized as a sequence of "data symbols". No packet recognition is done.

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

3 consecutive data symbols seen in the SPDIF U Channel stream are grouped together into the SPDIFRxUChannel register. First symbol is left, last symbol is right aligned. When SPDIFRxUChannel contains 3 new data symbols, UChannelRxFull is asserted.

In this mode, the operation of QchannelRx and associated interrupt QchannelRxFull is reserved, undefined. And the operation of UQFrameError and UQSyncFound is also reserved, undefined.

The U channel is extracted, and output by the SPDIF Rx on SPDIFRxUChannel-Stream.

When incoming SPDIF data parity error or bit error is detected, and if the next SPDIF word for that channel is error-free, the SPDIF word in error is replaced with the average of the previous word and next word. When incoming SPDIF data parity error or bit error is detected, and the next SPDIF word is in error, the previous SPDIF word is repeated.

13.9.3.1.4 Validity Flag Reception

An interrupt is associated with the Validity flag. (interrupt 16 - SPDIFValNoGood). This interrupt is set every time a frame is seen on the SPDIF interface with the validity bit set to "invalid".

13.9.3.1.5 SPDIF Receiver Interrupt Exception Definition

Several SPDIF exceptions can trigger an interrupt.

They are:

- Control Status channel change. Set when SPDIFRxCChannel_1 register is updated. The register is updated for every new C-Channel received. The exception is reset on write to InterruptClear register.
- SPDIF Illegal Symbol. Set on reception of illegal symbol during SPDIF receive. Reset by writing register InterruptClear.[1]
- SPDIF bit error. Set on reception of bit error. (Parity bit does not match). Reset on write to InterruptClear register.
- Receive data FIFO full. Set when SPDIF receive data FIFO is full.
- Receive data FIFO underrun/overrun. Set when there is a underrun/overrun on the SPDIF receive data FIFO.
- Receive data FIFO resynchronization. Set when a resynchronization event occurs on the SPDIF receive data FIFO.
- Receive U Channel buffer full. Set when next 24 bits of U channel code are available.
- Receive Q Channel buffer overrun. Set when Q channel buffer overrun.
- Receive U Channel buffer overrun. Set on U channel buffer overrun.
- Receive Q Channel buffer full. Set when next 24 bits of Q channel code are available.
- Receive UQ sync found. Set when UQ channel sync found.
- Receive UQ frame error. Set when UQ frame error found.

13.9.3.1.6 Standards Compliance

The SPDIF interface is compatible with the Tech 3250-E standard of the European Broadcasting Union, except clause 6.3.3 and the IEC60958-3 Ed2 for relevant topics.

Supported input frequency range is 12 Khz up to 96 Khz. (fully compliant) and 96 Khz up to 176 Khz (Can interface with compliant SPDIF transmitter within same cabinet, making reasonable assumptions on jitter added due to interconnecting wire.)

Tolerated jitter on SPDIF input signals are 0.25 bit peak-peak for high frequencies. There is no jitter limit for low frequencies. The user channel extraction in CD mode is capable of coping with single-symbol errors, and still retrieve U channel frames on correct boundaries. This capability is required for reliable reception of CD-Text from some Philips CD channel decoders. This capability was deemed more important than compliance with the IEC60958 annex A.3 standard, and for this reason user channel

1. The SPDIF input is a biphase/mark modulated signal. The time between any two successive transitions of the SPDIF signal is always 1, 2 or 3 SPDIF symbol periods long. The SPDIF receiver will parse the stream, and split it in so-called symbols. It recognizes s1, s2 and s3 symbols, depending on the length of the symbols. Not all sequences of these symbols are allowed. To give an example, a sequence s2-s1-s1-s1-s2 cannot occur in a no-error SPDIF signal. If the receiver finds such an illegal sequence, the illegal symbol interrupt is set. No corrective action is undertaken. When the interrupt occurs, this means that(a) The SPDIF signal is destroyed by noise (b) The SPDIF frequency changed.

reception is not compliant with IEC60958 annex A.3. However, the interface is capable to receive U channel inserted by a typical CD channel decoder. Also, in this case, it is more robust and tolerant for channel error than what is required by IEC60958 annex A.3.

13.9.3.1.7 SPDIF PLOCK Detection and Rxclk Output

Using the high speed system clock, the internal DPLL can extract the bit clock (advanced pulse) from the input bitstream. When this internal DPLL is locked, the LOCK bit of PhaseConfig Register will be set, and the SPDIF Lock output pin SPDIF_LOCK will be asserted.

After DPLL has locked, the pulses are generated, and the average pulse rate is 128 x the sampling frequency.(For a 44.1 Khz input sampling frequency, the average pulse rate = 128 x 44.1 Khz.) The pulse signal is used in the FreqMeas circuit to generate the frequency measurement result.

13.9.3.1.8 Measuring Frequency of SPDIF_RxClk

The internal DPLL can extract the bit clock (advanced plus) from the input bitstream. To do that, it is necessary to measure the frequency of the incoming signal in relationship with the system clock (BUS_CLK).

Associated with it are two registers, PhaseConfig and FreqMeas. The circuit will measure the frequency of the incoming clock as a function of the BUS_CLK. The circuit is a second-order filter. The output is a value represented by an unsigned number stored in the 24-bit FreqMeas register, giving the frequency of the source as a function of the BUS_CLK.

FreqMeas[23:0] = FreqMeas_CLK / BUS_CLK * 2^{10} * GAIN.

For example, if the GAIN is selected as 8*(2**10) (PhaseConfig[5:3] = 3'b011), the actual result

FreqMeas_CLK / BUS_CLK is equal to FreqMeas[23:0] / 2^{23}.

13.9.3.2 SPDIF Transmitter

Audio data for the SPDIF transmitter is provided by processor via the SPDIFTxLeft and SPDIFTxRight registers.

Clocking for SPDIF transmitter is selected through a multiplexer from several clock sources (see TxClk_Source for clock source inputs). The SPDIF transmitter clock source can be divided down as needed using Txclk_DF. The SPDIF transmitter output can be chosen from either the SPDIF transmitter block, directly from the SPDIF receiver (via the output multiplexer), or disabled.

The SPDIF transmitter generates a SPDIF output bitstream in IEC60958 biphase mark format, consisting of audio data, channel status.

13.9.3.2.1 Audio Data Transmission

Audio data for the SPDIF transmitter is provided by the processor via SPDIFTxLeft and SPDIFTxRight registers. They send audio data to Tx left and right FIFOs. The Tx left and right FIFOs are also 16-deep and 24-width (equal to the audio data width).

- **SPDIF transmitter data registers - Behavior on overrun, underrun**

The SPDIF Data Transmit registers (SPDIFTxLeft and SPDIFTxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFO. To prevent this from happening, hardware has been added on the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If SPDIF Tx FIFO underruns on the right half of the FIFO, no sample leaves that FIFO (because it was already empty). Special hardware will make sure that the next sample read from the left FIFO will not leave the FIFO (no read strobe is generated). If the underrun occurs on the left half of the FIFO, next read strobe to the right FIFO is blocked.

- **SPDIF transmitter data registers - Automatic resynchronization of FIFOs**

See Audio Data Reception.

- **SPDIFTxLeft, SPDIFTxRight details**

With SPDIF Tx FIFOs three exceptions are associated.

- empty
- under/overrun
- resync

When the empty condition is set for processor data output registers, the processor should write data to the FIFO, before underrun occurs. When empty is set and, for instance, 6 samples need to be written, it is acceptable for the software to write first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 1 sample LEFT,

followed by 1 sample RIGHT repeated 6 times. Left should be written before right. The implementation of all data out FIFOs is a double FIFO, one for left and one for right. Empty is set when both FIFOs are empty. Underrun, overrun are set when one of the FIFOs do underrun or do overrun. Resync is set when the hardware resynchronizes left and right FIFOs.

On receiving underrun, overrun interrupt, synchronization between Left and Right words in the FIFOs may be lost. Synchronization will not be lost when the underrun or overrun comes from the IEC60958 side of the FIFO. If the processor reads or writes more data from, for example, left than from right, synchronization will be lost. If automatic resynchronization is enabled, and if the software obeys the rules to let this work, resynchronization will be automatic.

13.9.3.2.2 Channel Status Transmission

A total of 48 Consumer channel status bits are transmitted from two registers. Channel Status Bits are ordered first bit left.

CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFTxCChannelCons_h. CS-channel bit "23" is considered bit 0 in the register. C-channel bits 24-47 are seen as MSB-LSB bits of register SPDIFTxCChannelCons_l.

13.9.3.2.3 Validity Flag Transmission

The validity bit setting is performed via bit 5 of the SPDIF_SCR register.

13.9.4 SPDIF Memory Map/Register Definition

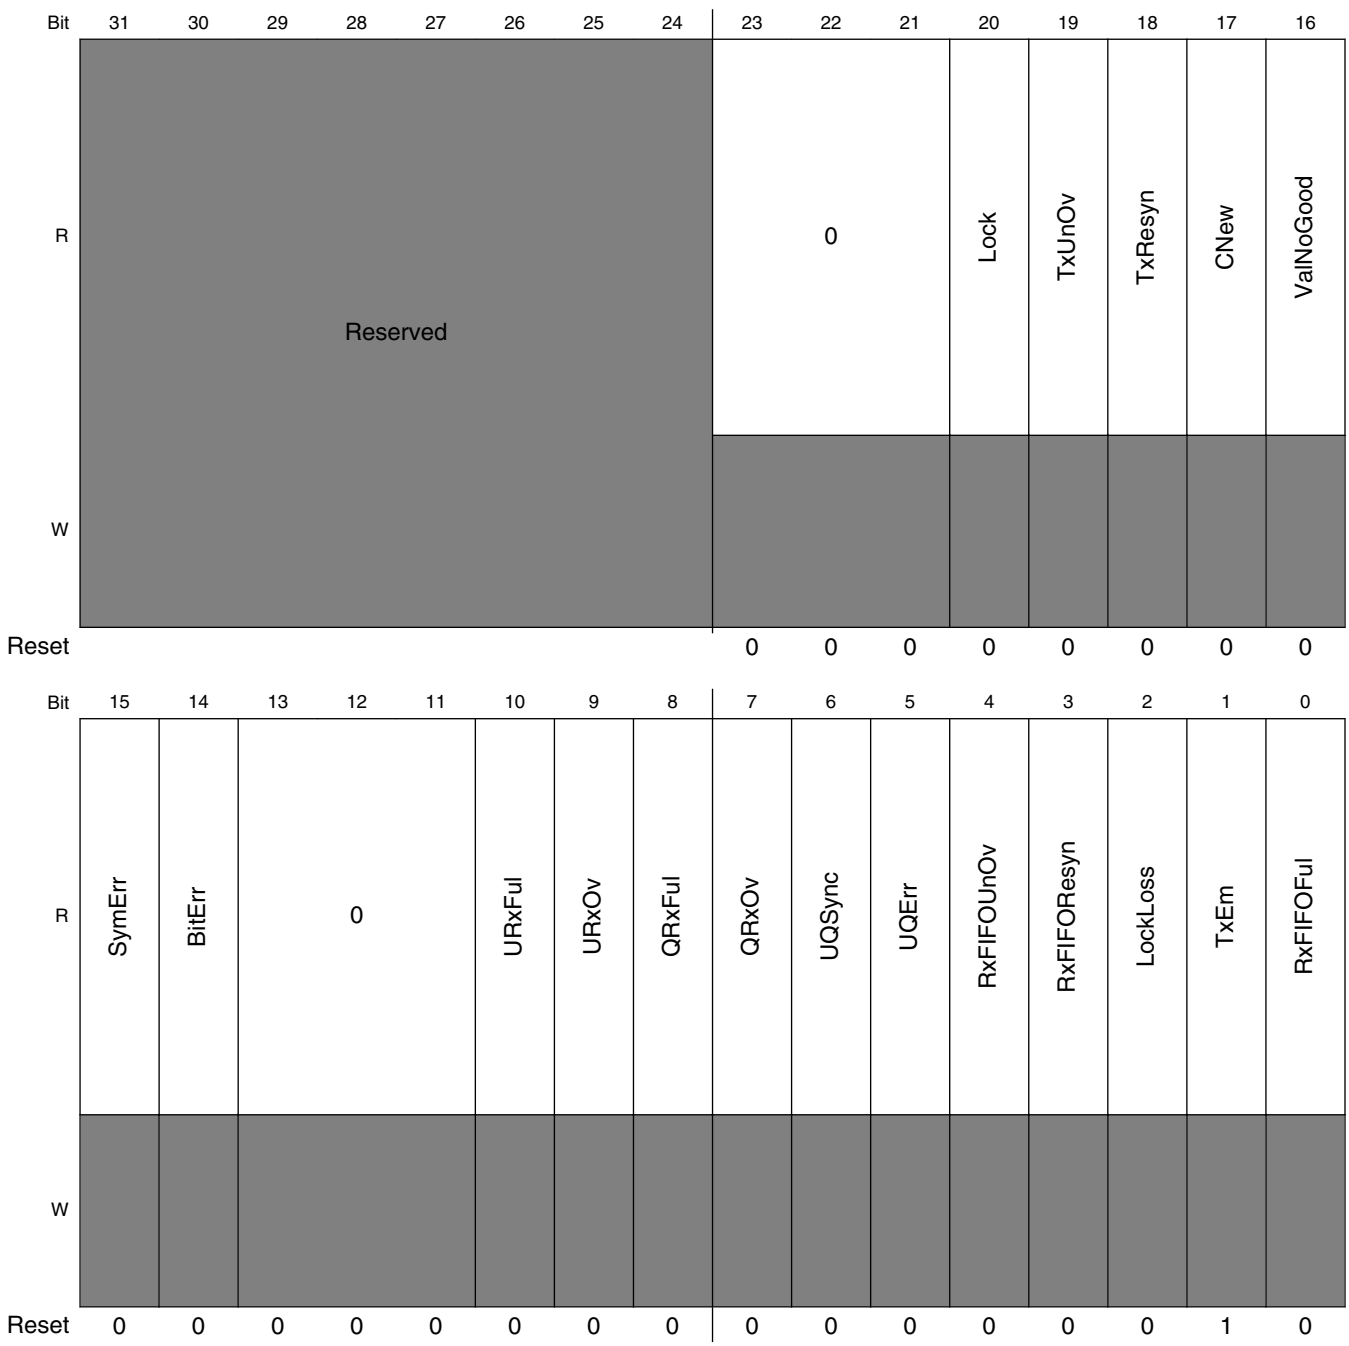
SPDIFx_SIE field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23 Reserved	This read-only field is reserved and always has the value 0.
22–21 -	This field is reserved. Reserved. set to zero.
20 Lock	SPDIF receiver's DPLL is locked
19 TxUnOv	SPDIF Tx FIFO under/overrun
18 TxResyn	SPDIF Tx FIFO resync
17 CNew	SPDIF receive change in value of control channel
16 ValNoGood	SPDIF validity flag no good
15 SymErr	SPDIF receiver found illegal symbol
14 BitErr	SPDIF receiver found parity bit error
13–11 -	This field is reserved. Reserved. set to zero.
10 URxFul	U Channel receive register full, can't be cleared with reg. IntClear. To clear it, read from U Rx reg.
9 URxOv	U Channel receive register overrun
8 QRxFul	Q Channel receive register full, can't be cleared with reg. IntClear. To clear it, read from Q Rx reg.
7 QRxOv	Q Channel receive register overrun
6 UQSync	U/Q Channel sync found
5 UQErr	U/Q Channel framing error
4 RxFIFOUnOv	Rx FIFO underrun/overrun
3 RxFIFOResyn	Rx FIFO resync
2 LockLoss	SPDIF receiver loss of lock
1 TxEm	SPDIF Tx FIFO empty, can't be cleared with reg. IntClear. To clear it, write toTx FIFO.
0 RxFIFOFul	SPDIF Rx FIFO full, can't be cleared with reg. IntClear. To clear it, read from Rx FIFO.

13.9.4.5 InterruptStat Register (SPDIFx_SIS)

The InterruptStat (SPDIF_SIS) register is a read only register that provides the status on interrupt operations.

Address: Base address + 10h offset



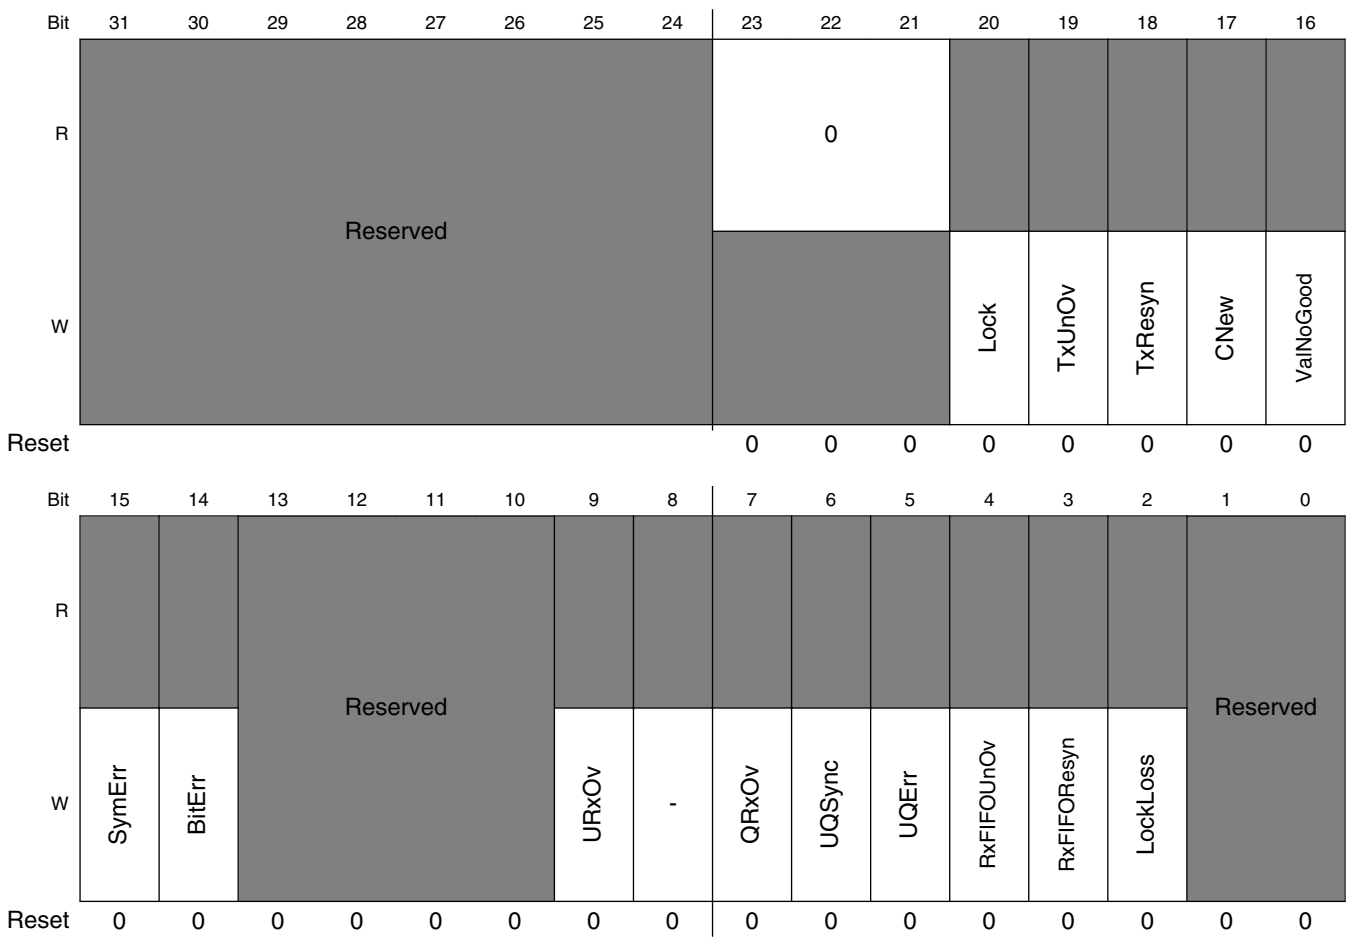
SPDIFx_SIS field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–21 Reserved	This read-only field is reserved and always has the value 0.
20 Lock	SPDIF receiver's DPLL is locked
19 TxUnOv	SPDIF Tx FIFO under/overrun
18 TxResyn	SPDIF Tx FIFO resync
17 CNew	SPDIF receive change in value of control channel
16 ValNoGood	SPDIF validity flag no good
15 SymErr	SPDIF receiver found illegal symbol
14 BitErr	SPDIF receiver found parity bit error
13–11 Reserved	This read-only field is reserved and always has the value 0.
10 URxFul	U Channel receive register full, can't be cleared with reg. IntClear. To clear it, read from U Rx reg.
9 URxOv	U Channel receive register overrun
8 QRxFul	Q Channel receive register full, can't be cleared with reg. IntClear. To clear it, read from Q Rx reg.
7 QRxOv	Q Channel receive register overrun
6 UQSync	U/Q Channel sync found
5 UQErr	U/Q Channel framing error
4 RxFIFOUnOv	Rx FIFO underrun/overrun
3 RxFIFOResyn	Rx FIFO resync
2 LockLoss	SPDIF receiver loss of lock
1 TxEm	SPDIF Tx FIFO empty, can't be cleared with reg. IntClear. To clear it, write toTx FIFO.
0 RxFIFOFul	SPDIF Rx FIFO full, can't be cleared with reg. IntClear. To clear it, read from Rx FIFO.

13.9.4.6 InterruptClear Register (SPDIFx_SIC)

The InterruptClear (SPDIF_SIC) register is a write only register and is used to clear interrupts.

Address: Base address + 10h offset



SPDIFx_SIC field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–21 Reserved	This read-only field is reserved and always has the value 0.
20 Lock	SPDIF receiver's DPLL is locked
19 TxUnOv	SPDIF Tx FIFO under/overrun

Table continues on the next page...

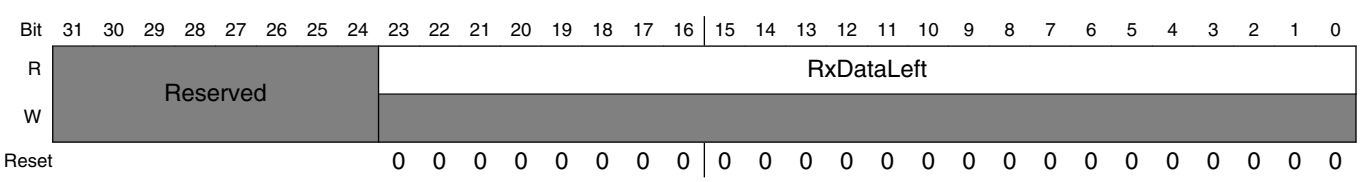
SPDIFx_SIC field descriptions (continued)

Field	Description
18 TxResyn	SPDIF Tx FIFO resync
17 CNew	SPDIF receive change in value of control channel
16 ValNoGood	SPDIF validity flag no good
15 SymErr	SPDIF receiver found illegal symbol
14 BitErr	SPDIF receiver found parity bit error
13–10 -	This field is reserved. Reserved.
9 URxOv	U Channel receive register overrun
8 -	Reserved
7 QRxOv	Q Channel receive register overrun
6 UQSync	U/Q Channel sync found
5 UQErr	U/Q Channel framing error
4 RxFIFOUnOv	Rx FIFO underrun/overrun
3 RxFIFOResyn	Rx FIFO resync
2 LockLoss	SPDIF receiver loss of lock
-	This field is reserved. Reserved.

13.9.4.7 SPDIFRxLeft Register (SPDIFx_SRL)

SPDIFRxLeft register is an audio data reception register.

Address: Base address + 14h offset



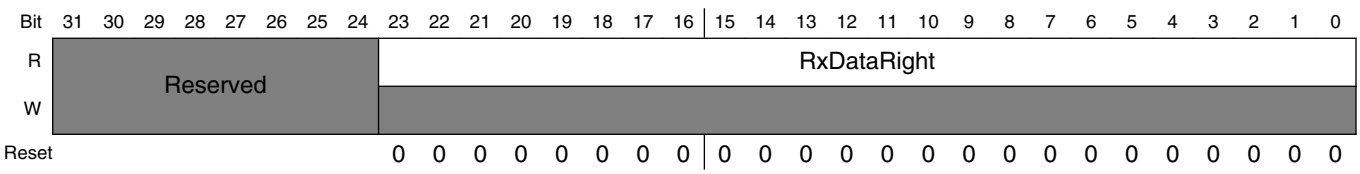
SPDIFx_SRL field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxDataLeft	Processor receive SPDIF data left

13.9.4.8 SPDIFRxRight Register (SPDIFx_SRR)

SPDIFRxRight register is an audio data reception register.

Address: Base address + 18h offset



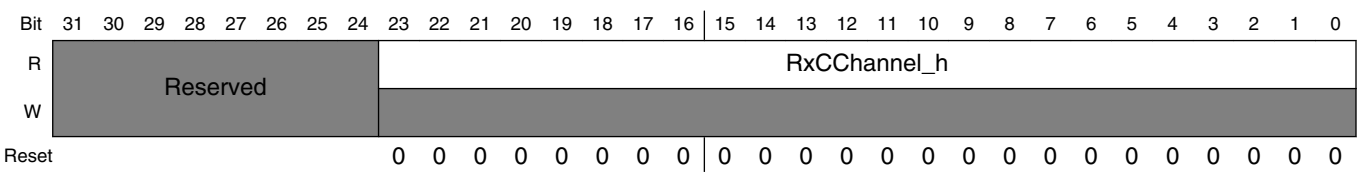
SPDIFx_SRR field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxDataRight	Processor receive SPDIF data right

13.9.4.9 SPDIFRxCChannel_h Register (SPDIFx_SRCSH)

SPDIFRxCChannel_h register is a channel status reception register.

Address: Base address + 1Ch offset



SPDIFx_SRCSH field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.

Table continues on the next page...

SPDIFx_SRCSH field descriptions (continued)

Field	Description
	This field is reserved.
RxCChannel_h	SPDIF receive C channel register, contains first 24 bits of C channel without interpretation

13.9.4.10 SPDIFRxCChannel_l Register (SPDIFx_SRCSL)

SPDIFRxCChannel_l register is a channel status reception register.

Address: Base address + 20h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
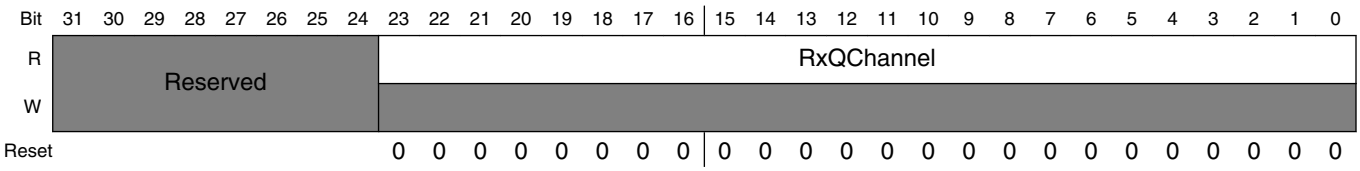
31–24 [unimplemented]	This field is reserved. This is a 24-bit register the upper byte is unimplemented.
RxUChannel	SPDIF receive U channel register, contains next 3 U channel bytes

13.9.4.12 QchannelRx Register (SPDIFx_SRQ)

QChannelRx register is a user bits reception register.

Address: Base address + 28h offset



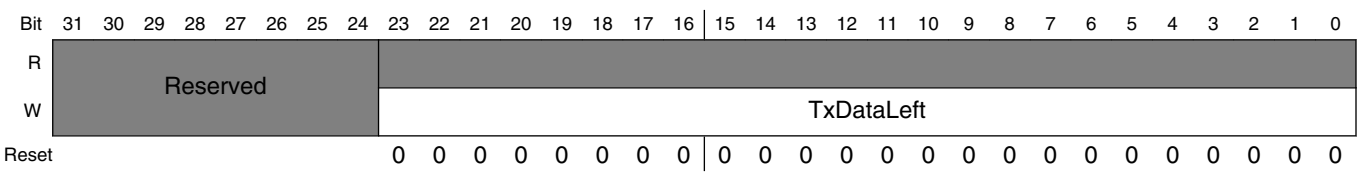
SPDIFx_SRQ field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxQChannel	SPDIF receive Q channel register, contains next 3 Q channel bytes

13.9.4.13 SPDIFTxLeft Register (SPDIFx_STL)

SPDIFTxLeft register is an audio data transmission register.

Address: Base address + 2Ch offset



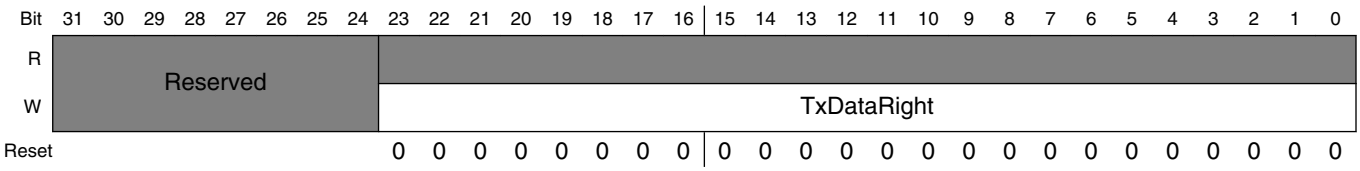
SPDIFx_STL field descriptions

Field	Description
31–24 [unimplemented]	This field is reserved. This is a 24-bit register the upper byte is unimplemented.
TxDataLeft	SPDIF transmit left channel data. It is write-only, and always returns zeros when read

13.9.4.14 SPDIFTxRight Register (SPDIFx_STR)

SPDIFTxRight register is an audio data transmission register.

Address: Base address + 30h offset



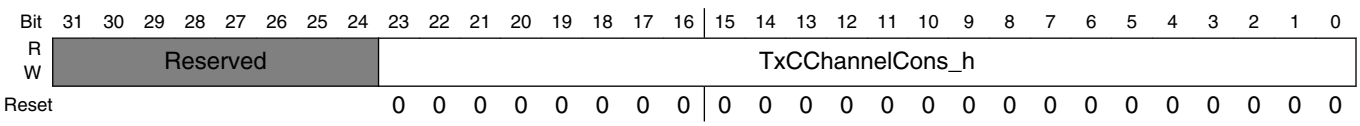
SPDIFx_STR field descriptions

Field	Description
31–24 [unimplemented]	This field is reserved. This is a 24-bit register the upper byte is unimplemented.
TxDataRight	SPDIF transmit right channel data. It is write-only, and always returns zeros when read

13.9.4.15 SPDIFTxCChannelCons_h Register (SPDIFx_STCSCH)

SPDIFTxCChannelCons_h register is a channel status transmission register.

Address: Base address + 34h offset



SPDIFx_STCSCH field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
TxCChannelCons_h	SPDIF transmit Cons. C channel data, contains first 24 bits without interpretation. When read, it returns the latest data written by the processor

13.9.4.16 SPDIFTxCChannelCons_l Register (SPDIFx_STCSCL)

SPDIFTxCChannelCons_l register is a channel status transmission register.

Address: Base address + 38h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

13.10 Synchronous Audio Interface (SAI)

13.10.1 Introduction

The I^2S (or I2S) module provides a synchronous audio interface (SAI) that supports full-duplex serial interfaces with frame synchronization such as I^2S, AC97, TDM, and codec/DSP interfaces.

13.10.1.1 Features

Note that some of the features are not supported across all SAI instances; see the chip-specific information in the first section of this chapter.

- Transmitter with independent bit clock and frame sync supporting 8 data lines
- Receiver with independent bit clock and frame sync supporting 8 data lines
- Each data line can support a maximum Frame size of 32 words
- Word size of between 8-bits and 32-bits
- Word size configured separately for first word and remaining words in frame
- Asynchronous 128 x 32-bit FIFO for each transmit and receive data line
- Supports graceful restart after FIFO error
- Supports automatic restart after FIFO error without software intervention
- Supports packing of 8-bit and 16-bit data into each 32-bit FIFO word
- Supports combining multiple data line FIFOs into single data line FIFO

13.10.1.2 Block diagram

The following block diagram also shows the module clocks.

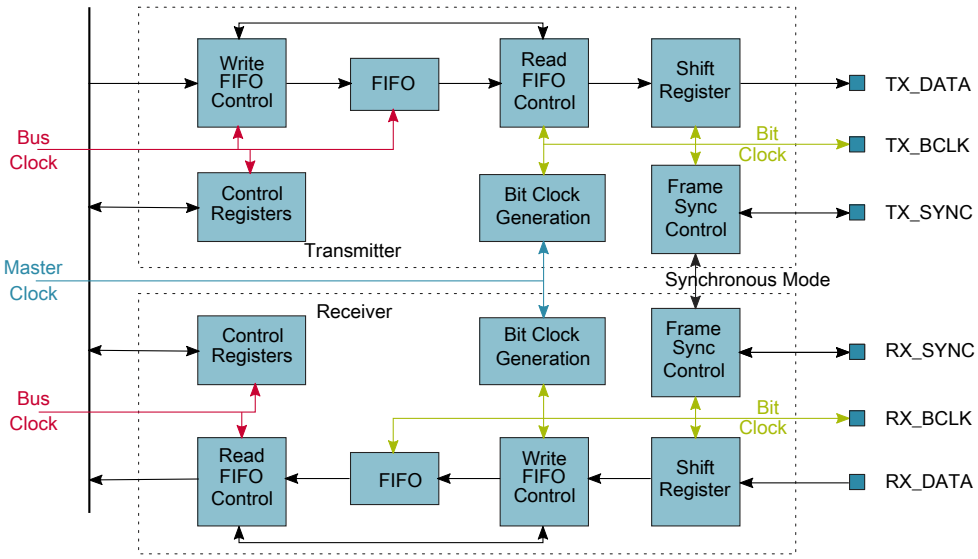

Figure 13-83. I²S/SAI block diagram

13.10.1.3 Modes of operation

Module power modes include Run mode, and Debug mode.

13.10.1.3.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

13.10.1.3.2 Debug mode

In Debug mode, the SAI transmitter and/or receiver can continue operating provided the Debug Enable bit is set. When TCSR[DBGE] or RCSR[DBGE] bit is clear and Debug mode is entered, the SAI is disabled after completing the current transmit or receive frame. The transmitter and receiver bit clocks are not affected by Debug mode.

13.10.2 External signals

Name	Function	I/O
TX_BCLK	Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O

Table continues on the next page...

Name	Function	I/O
TX_SYNC	Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
TX_DATA[7:0]	Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word.	O
RX_BCLK	Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
RX_SYNC	Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
RX_DATA[7:0]	Receive Data. The receive data is sampled synchronously by the bit clock.	I

13.10.3 Functional description

This section provides a complete functional description of the block.

13.10.3.1 SAI clocking

The SAI clocks include:

- The audio master clock
- The bit clock
- The bus clock

13.10.3.1.1 Audio master clock

The audio master clock is used to generate the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

The audio master clock generation and selection is chip-specific. Refer to chip-specific clocking information about how the audio master clocks are generated.

13.10.3.1.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter or between multiple SAI peripherals.

- If both transmitter and receiver are configured for asynchronous operation, then the transmitter and receiver will each use *their own* bit clock and frame sync.
- If the *transmitter* is configured for asynchronous mode and the receiver is configured for synchronous mode, then both transmitter and receiver will use the *transmitter* bit clock and frame sync.
- If the *receiver* is configured for asynchronous mode and the transmitter is configured for synchronous mode, then both transmitter and receiver will use the *receiver* bit clock and frame sync.

Note that the software configures synchronous or asynchronous mode, and that choice selects the bit clock/frame sync used.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames

If the SAI transmitter or receiver is using an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously.

13.10.3.1.3 Bus clock

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

NOTE

Although there is no specific minimum bus clock frequency specified, the bus clock frequency must be fast enough (relative to the bit clock frequency) to ensure that the FIFOs can be serviced, without generating either a transmitter FIFO underrun or receiver FIFO overflow condition.

13.10.3.2 SAI resets

The SAI is asynchronously reset on system reset. The SAI has a software reset and a FIFO reset.

13.10.3.2.1 Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

13.10.3.2.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the same value as the FIFO read pointer. This empties the FIFO contents and is to be used after TCSR[FEF] is set, and before the FIFO is re-initialized and TCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI transmitter can also reset the FIFO of individual data channels by setting the appropriate TCR3[CFR] bit. This should only be done when the corresponding TCR3[TCE] bit is clear.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the same value as the FIFO write pointer. This empties the FIFO contents and is to be used after the RCSR[FEF] is set and any remaining data has been read from the FIFO, and before the RCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI receiver can also reset the FIFO of individual data channels by setting the appropriate RCR3[CFR] bit. This should only be done when the corresponding RCR3[RCE] bit is clear.

13.10.3.3 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other.

13.10.3.3.1 Synchronous mode

The SAI transmitter and receiver can be configured to operate with synchronous bit clock and frame sync.

If the transmitter bit clock and frame sync are to be used by both the transmitter and receiver:

- The transmitter must be configured for asynchronous operation and the receiver for synchronous operation.
- In synchronous mode, the receiver is enabled only when both the transmitter and receiver are enabled.
- It is recommended that the transmitter is the last enabled and the first disabled.

If the receiver bit clock and frame sync are to be used by both the transmitter and receiver:

- The receiver must be configured for asynchronous operation and the transmitter for synchronous operation.
- In synchronous mode, the transmitter is enabled only when both the receiver and transmitter are both enabled.
- It is recommended that the receiver is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The transmitter and receiver otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

13.10.3.4 Frame sync configuration

When enabled, the SAI continuously transmits and/or receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, any given word can be masked causing the receiver to ignore that word and the transmitter to tri-state for the duration of that word.

The frame sync signal is used to indicate the start of each frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected and the transmitter or receiver cannot be busy with a previous frame. A valid frame sync is also ignored (slave mode) or not generated (master mode) for the first four bit clock cycles after enabling the transmitter or receiver.

The transmitter and receiver frame sync can be configured independently with any of the following options:

- Externally generated or internally generated
- Active high or active low
- Assert with the first bit in frame or asserts one bit early
- Assert for a duration between 1 bit clock and the first word length
- Frame length from 1 to 32 words per frame

- Word length to support 8 to 32 bits per word
  - First word length and remaining word lengths can be configured separately
- Words can be configured to transmit/receive MSB first or LSB first

These configuration options cannot be changed after the SAI transmitter or receiver is enabled.

13.10.3.5 Data FIFO

Each transmit and receive channel includes a FIFO of size 128 x 32-bit. The FIFO data is accessed using the SAI Transmit/Receive Data Registers.

13.10.3.5.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit wide register through the use of the First Bit Shifted configuration field, which selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are illustrated in Figure 13-84 for LSB First configurations and Figure 13-85 for MSB First configurations.

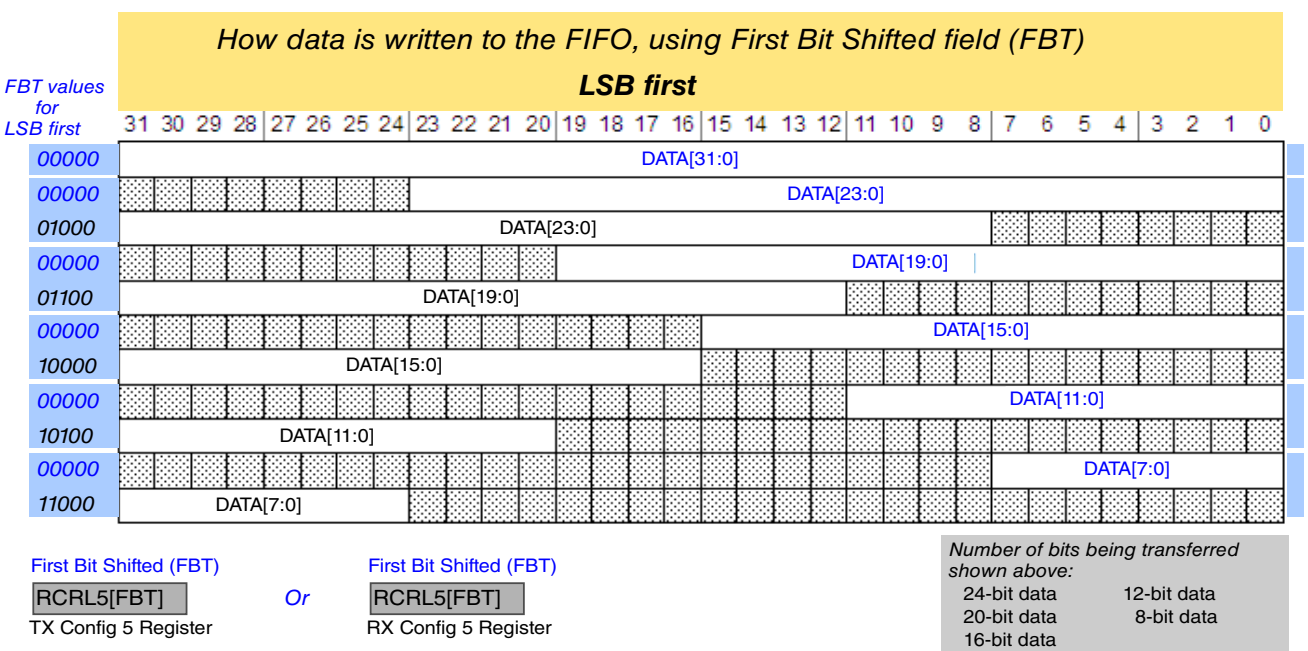

Figure 13-84. SAI first bit shifted, LSB first

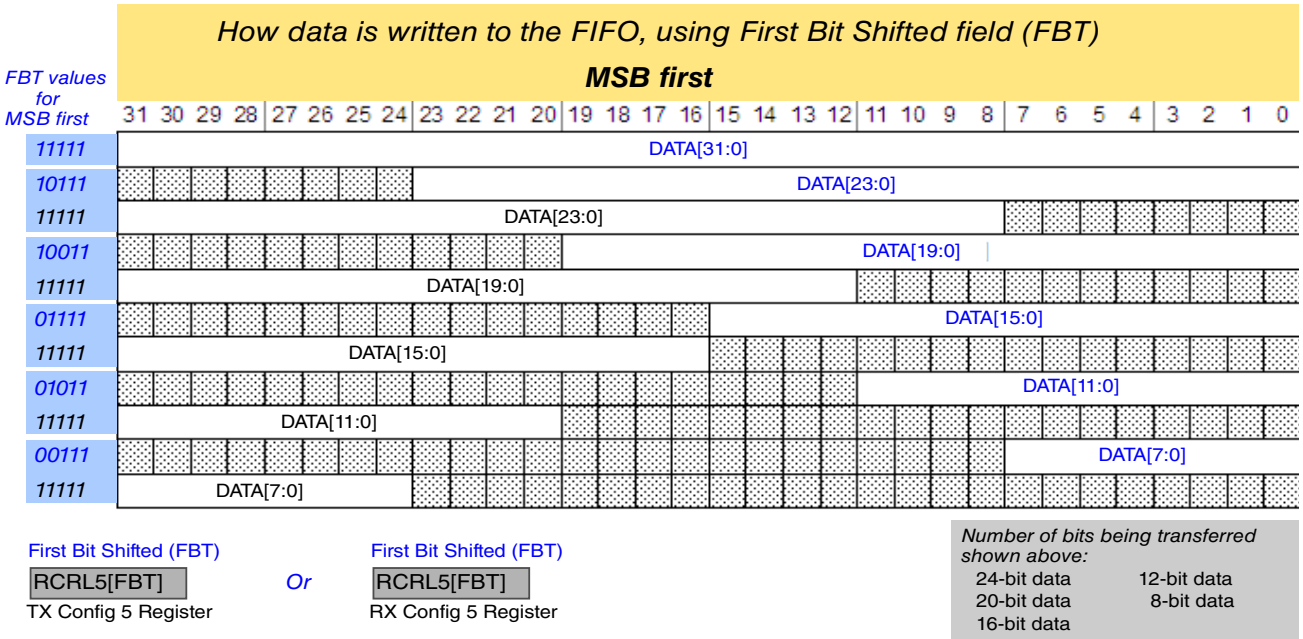

Figure 13-85. SAI first bit shifted, MSB first

13.10.3.5.2 FIFO pointers

When writing to a Transmit Data Register (TDR*n*), the Write FIFO Pointer (WFP) of the corresponding Transmit FIFO Register (TFR*n*) increments after each valid write. The SAI supports 8-bit, 16-bit and 32-bit writes to the Transmit Data Register and the FIFO pointer will increment after each individual write. Note that 8-bit writes should only be used when transmitting up to 8-bit data; 16-bit writes should only be used when transmitting up to 16-bit data.

- If the Transmit FIFO is full, then writes to a Transmit Data Register are ignored.
- If the Transmit FIFO is empty, then to avoid a FIFO underrun, the Transmit Data Register must be written at least 3 bit clocks before the start of the next unmasked word. Before enabling the transmitter, the Transmit FIFO should be initialized with data (since after the transmitter is enabled, the transmitter will start a new frame, and if no data is in the FIFO, then the transmitter will immediately give an error).

When reading a Receive Data Register (RDR*n*), the Read FIFO Pointer (RFP) of the corresponding Receive FIFO Register (RFR*n*) increments after each valid read. The SAI supports 8-bit, 16-bit and 32-bit reads from the RDR and the FIFO pointer will increment after each individual read. Note that 8-bit reads should only be used when receiving up to 8-bit data; 16-bit reads should only be used when receiving up to 16-bit data.

- If the Receive FIFO is empty, then reads from a Receive Data Register are ignored.
- If the Receive FIFO is full, then to avoid a FIFO overrun, the Receive Data Register must be read at least 3 bit clocks before the end of an unmasked word.

13.10.3.5.3 FIFO packing

FIFO packing supports storing multiple 8-bit or 16-bit data words in one 32-bit FIFO word for the transmitter and/or receiver. While this can be emulated by adjusting the number of bits per word and number of words per frame (for example, one 32-bit word per frame versus two 16-bit words per frame), FIFO packing does not require even multiples of words per frame and fully supports word masking. When FIFO packing is enabled, the FIFO pointers only increment when the full 32-bit FIFO word has been written (transmit) or read (receive) by software, supporting scenarios where different words within each frame are loaded/stored in different areas of memory.

When 16-bit FIFO packing is enabled for transmit, the transmit shift register is loaded at the start of each frame and after every second unmasked transmit word. The first word transmitted is taken from 16-bit word at byte offset $0 (first bit is selected by TCFG5[FBT] must be configured within this 16-bit word) and the second word transmitted is taken from the 16-bit word at byte offset $2 (first bit is selected by TCSR5[FBT][3:0]). The transmitter will transmit logic zero until the start of the next word once the 16-bit word has been transmitted.

When 16-bit FIFO packing is enabled for receive, the receive shift register is stored after every second unmasked received word, and at the end of each frame if there is an odd number of unmasked received words in each frame. The first word received is stored in the 16-bit word at byte offset $0 (first bit is selected by RCFG5[FBT] and must be configured within this 16-bit word) and the second word received is stored in the 16-bit word at byte offset $2 (first bit is selected by RCSR5[FBT][3:0]). The receiver will ignore received data until the start of the next word once the 16-bit word has been received.

The 8-bit FIFO packing is similar to 16-bit packing except four words are loaded or stored into each 32-bit FIFO word. The first word is loaded/stored in byte offset $0, second word in byte offset $1, third word in byte offset $2 and fourth word in byte offset $3. The TCFG5[FBT] and/or RCFG5[FBT] must be configured within byte offset $0.

13.10.3.5.4 FIFO Combine

FIFO combining mode allows the separate FIFOs for multiple data channels to be used as a single FIFO for either software accesses or a single data channel or both. Note that the enabled data channels must be contiguous and data channel 0 must be enabled when FIFO Combine mode is enabled.

Combining FIFOs for software access (writing transmit FIFO registers, reading receive FIFO registers) allows a DMA controller or software to read or write multiple FIFOs without incrementing the address that is accessed. Once enabled, the first software access

to a FIFO register will access the first enabled channel FIFO, while the second access to a FIFO register will access the second enabled channel FIFO. This continues until software accesses the last enabled channel FIFO and the pointer resets back to the first enabled channel FIFO. To reset the pointer manually, software can reset the FIFOs or disable the FIFO combining on software accesses.

Combining FIFOs for transmit data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with identical data output on each enabled data channel. The transmit shift registers for all enabled data channels are loaded at the start of each frame and every N unmasked words (where N is the number of enabled data channels). The first word transmitted is loaded from the first enabled channel FIFO, while the second word transmitted is loaded from the second enabled channel FIFO, and so on until the end of the frame. Since the first word in each frame is always loaded from the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Combining FIFOs for receive data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with received data from channel 0 stored into each enabled data channel. The receive shift register for all enabled data channels are stored after every N unmasked words (where N is the number of enabled data channels). The first word received is stored to the first enabled channel FIFO, while the second word received is stored to the second enabled channel FIFO, and so on until the end of the frame. Since the first word in each frame is always stored the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Note that combining FIFOs for data channels will load or store each channel FIFO at the same time. This means that FIFO error conditions are only checked every N words (where N is the number of enabled data channels) and that the FIFO warning and request flags will assert if any of the enabled data channel meets the warning flag or request flag conditions.

13.10.3.6 Word mask register

The SAI transmitter and receiver each contain a word mask register, namely TMR and RMR, that can be used to mask any word in the frame. Because the word mask register is double buffered, software can update it before the end of each frame to mask a particular word in the next frame.

The TMR causes the Transmit Data pin to be tri-stated for the length of each selected word and the transmit FIFO is not read for masked words.

The RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

13.10.3.7 Interrupts and DMA requests

The SAI transmitter and receiver generate separate interrupts and separate DMA requests, but support the same status flags.

13.10.3.7.1 FIFO request flag

The FIFO request flag is set based on the number of entries in the FIFO and the FIFO watermark configuration.

The transmit FIFO request flag is set when the number of entries in any of the enabled transmit FIFOs is less than or equal to the transmit FIFO watermark configuration and is cleared when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag is set when the number of entries in any of the enabled receive FIFOs is greater than the receive FIFO watermark configuration and is cleared when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt or a DMA request.

13.10.3.7.2 FIFO warning flag

The FIFO warning flag is set based on the number of entries in the FIFO.

The transmit warning flag is set when the number of entries in any of the enabled transmit FIFOs is empty and is cleared when the number of entries in each enabled transmit FIFO is not empty.

The receive warning flag is set when the number of entries in any of the enabled receive FIFOs is full and is cleared when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an Interrupt or a DMA request.

13.10.3.7.3 FIFO error flag

The transmit FIFO error flag is set when the any of the enabled transmit FIFOs underflow. After it is set, all enabled transmit channels will transmit zero data before TCSR[FEF] is cleared.

When TCR4[FCONT] is set, the FIFO will continue transmitting data following an underflow without software intervention. To ensure that data is transmitted in the correct order, the transmitter will continue from the same word number in the frame that caused the FIFO to underflow, but only after new data has been written to the transmit FIFO. Software should still clear the TCSR[FEF] flag, but without reinitializing the transmit FIFOs.

RCSR[FEF] is set when the any of the enabled receive FIFOs overflow. After it is set, all enabled receive channels discard received data until RCSR[FEF] is cleared and the next next receive frame starts. All enabled receive FIFOs should be emptied before RCSR[FEF] is cleared.

When RCR4[FCONT] is set, the FIFO will continue receiving data following an overflow without software intervention. To ensure that data is received in the correct order, the receiver will continue from the same word number in the frame that caused the FIFO to overflow, but only after data has been read from the receive FIFO. Software should still clear the RCSR[FEF] flag, but without emptying the receive FIFOs.

The FIFO error flag can generate only an interrupt.

13.10.3.7.4 Sync error flag

The sync error flag, TCSR[SEF] or RCSR[SEF], is set when configured for an externally generated frame sync and the external frame sync asserts when the transmitter or receiver is busy with the previous frame. The external frame sync assertion is ignored and the sync error flag is set. When the sync error flag is set, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

The sync error flag can generate an interrupt only.

13.10.3.7.5 Word start flag

The word start flag is set at the start of the second bit clock for the selected word, as configured by the Word Flag register field.

The word start flag can generate an interrupt only.

13.10.4 Memory map and register definition

A read or write access to an address from offset 0x100 and above will result in a bus error.

13.10.4.1 I2S register descriptions

13.10.4.1.1 I2S Memory map

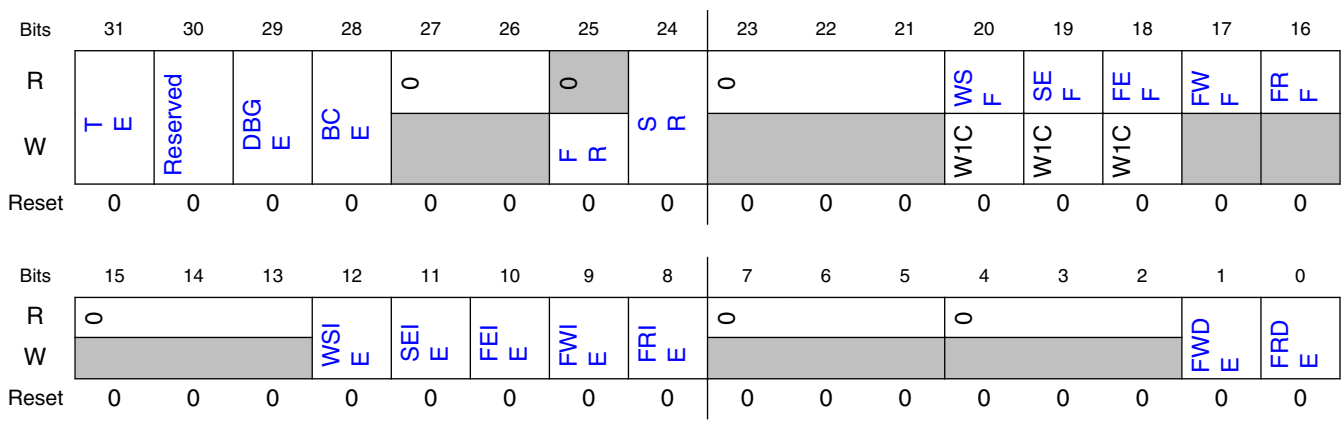
13.10.4.1.4.1 Offset

Register	Offset
TCSR	8h

13.10.4.1.4.2 Diagram



13.10.4.1.4.3 Fields

Field	Function
31 TE	Transmitter Enable Enables/disables the transmitter. When software clears this field, the transmitter remains enabled, and this bit remains set, until the end of the current frame. 0b - Transmitter is disabled. 1b - Transmitter is enabled, or transmitter has been disabled and has not yet reached end of frame.
30 —	Reserved. Software should only write zero to this reserved bit.
29 DBGE	Debug Enable

Table continues on the next page...

Field	Function
	Enables/disables transmitter operation in Debug mode. The transmit bit clock is not affected by debug mode. 0b - Transmitter is disabled in Debug mode, after completing the current frame. 1b - Transmitter is enabled in Debug mode.
28 BCE	Bit Clock Enable Enables the transmit bit clock, separately from the TE. This field is automatically set whenever TE is set. When software clears this field, the transmit bit clock remains enabled, and this bit remains set, until the end of the current frame. 0b - Transmit bit clock is disabled. 1b - Transmit bit clock is enabled.
27-26 —	Reserved
25 FR	FIFO Reset Empties the FIFO, and sets the FIFO read and write pointers to the same value, which may or may not be zero. Reading this field will always return zero. FIFO pointers should only be reset when the transmitter is disabled or the FIFO error flag is set. 0b - No effect. 1b - FIFO reset.
24 SR	Software Reset When set, resets the internal transmitter logic including the FIFO read and write pointers. Software-visible registers are not affected, except for the status registers. 0b - No effect. 1b - Software reset.
23-21 —	Reserved
20 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0b - Start of word not detected. 1b - Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0b - Sync error not detected. 1b - Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled transmit FIFO has underrun. Write a logic 1 to this field to clear this flag. 0b - Transmit underrun not detected. 1b - Transmit underrun detected.
17 FWF	FIFO Warning Flag Indicates that an enabled transmit FIFO is empty. 0b - No enabled transmit FIFO is empty. 1b - Enabled transmit FIFO is empty.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled transmit channel FIFO is less than or equal to the transmit FIFO watermark. 0b - Transmit FIFO watermark has not been reached. 1b - Transmit FIFO watermark has been reached.

Table continues on the next page...

Field	Function
15-13 —	Reserved
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
7-5 —	Reserved
4-2 —	Reserved
1 FWDE	FIFO Warning DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.
0 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.

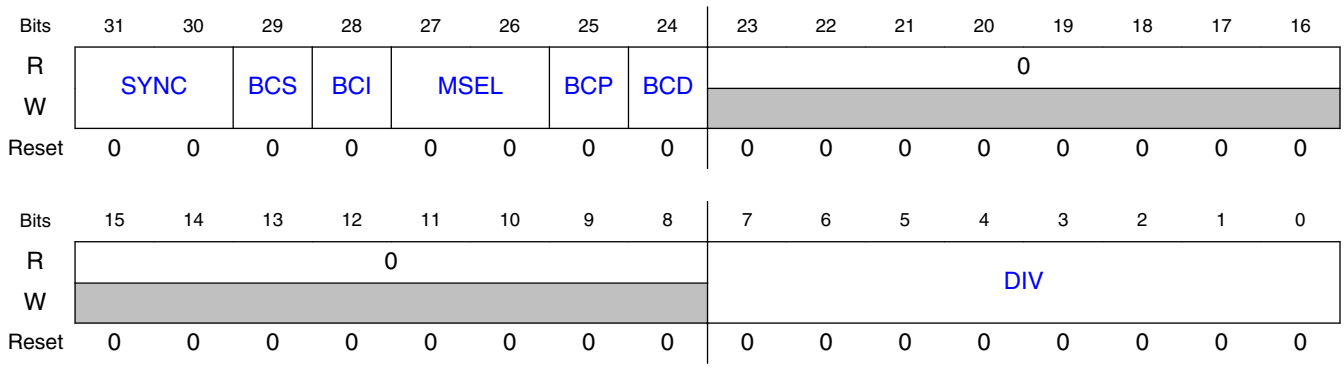
13.10.4.1.6.1 Offset

Register	Offset
TCR2	10h

13.10.4.1.6.2 Function

This register must not be altered when TCSR[TE] is set.

13.10.4.1.6.3 Diagram



13.10.4.1.6.4 Fields

Field	Function
31-30 SYNC	Synchronous Mode Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the receiver must be configured for asynchronous operation. 00b - Asynchronous mode. 01b - Synchronous with receiver. 10b - Reserved. 11b - Reserved.
29 BCS	Bit Clock Swap This field swaps the bit clock used by the transmitter. When the transmitter is configured in asynchronous mode and this bit is set, the transmitter is clocked by the receiver bit clock (RX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the transmitter continues to use the transmit frame sync (TX_SYNC). When the transmitter is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the transmitter bit clock (TX_BCLK) but use the receiver frame sync (RX_SYNC). 0b - Use the normal bit clock source. 1b - Swap the bit clock source.
28 BCI	Bit Clock Input When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the transmitter is delayed by the pad output delay (the transmitter is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the transmitter when this bit is set. In synchronous mode, this bit allows the transmitter to use the slave mode timing from the datasheet, while the receiver uses the master mode timing. This field has no effect when configured for an externally generated bit clock . 0b - No effect. 1b - Internal logic is clocked as if bit clock was externally generated.
27-26 MSEL	MCLK Select Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock.

Table continues on the next page...

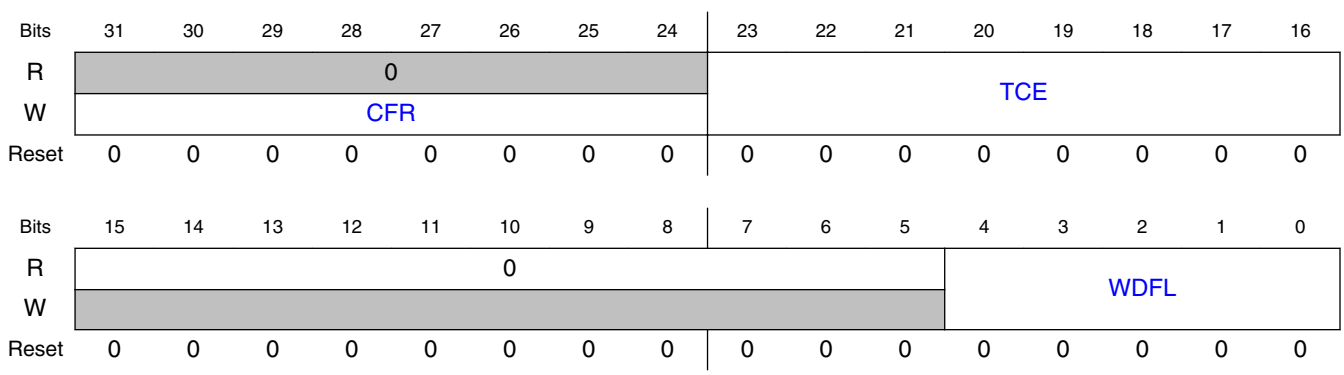
Field	Function
	NOTE: Depending on the device, some Master Clock options might not be available. See the chip-specific information for the meaning of each option. 00b - Bus Clock selected. 01b - Master Clock (MCLK) 1 option selected. 10b - Master Clock (MCLK) 2 option selected. 11b - Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0b - Bit clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1b - Bit clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0b - Bit clock is generated externally in Slave mode. 1b - Bit clock is generated internally in Master mode.
23-8 —	Reserved
7-0 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.

13.10.4.1.7 SAI Transmit Configuration 3 Register (TCR3)

13.10.4.1.7.1 Offset

Register	Offset
TCR3	14h

13.10.4.1.7.2 Diagram



13.10.4.1.7.3 Fields

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td>31-24
CFR</td><td>Channel FIFO Reset

Resets the FIFO pointers for a specific channel. Reading this field will always return zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is set.

The width of CFR field = the number of transmit channels (call it N). For example, if CFR is 2 bits wide, then bit position 24 refers to transmit channel 1 FIFO pointer and bit position 25 refers to transmit channel 2 FIFO pointer. Setting bit 24 resets transmit channel 1 FIFO pointer, and setting bit 25 enables transmit channel 2 FIFO pointer. Setting bit N will reset transmit channel N FIFO pointer.

0b - No effect.
1b - Transmit data channel N FIFO is reset.

NOTE: This field is not supported in every instance. The following table includes only supported registers.

<table>
<tr><th>Field supported in</th><th>Field not supported in</th></tr>
<tr><td>SAI1_TCR3</td><td>—</td></tr>
<tr><td>—</td><td>SAI2_TCR3</td></tr>

<tr><td>—</td><td>SAI5_TCR3</td></tr>
<tr><td>—</td><td>SAI6_TCR3</td></tr>
</table>
</td></tr>
<tr><td>23-16
TCE</td><td>Transmit Channel Enable

Enables the corresponding data channel for transmit operation. Changing TCE field will take effect immediately for generating the FIFO request and warning flags, but at the end of each frame for transmit operation.

The width of TCE field = the number of transmit channels (call it N). For example, if TCE field is 2 bits wide, then bit position 16 refers to transmit channel 1 and bit position 17 refers to transmit channel 2. Setting bit 16 enables transmit channel 1, and setting bit 17 enables transmit channel 2. Setting bit N will enable transmit channel N.

0b - Transmit data channel N is disabled.
1b - Transmit data channel N is enabled.

NOTE: This field is not supported in every instance. The following table includes only supported registers.

<table>
<tr><th>Field supported in</th><th>Field not supported in</th></tr>
<tr><td>SAI1_TCR3</td><td>—</td></tr>
<tr><td>SAI2_TCR3[16]</td><td>SAI2_TCR3[23–17]</td></tr>
<tr><td>SAI3_TCR3[16]</td><td>SAI3_TCR3[23–17]</td></tr>
<tr><td>SAI4_TCR3[16]</td><td>SAI4_TCR3[23–17]</td></tr>
<tr><td>SAI5_TCR3[16]</td><td>SAI5_TCR3[23–17]</td></tr>
<tr><td>SAI6_TCR3[16]</td><td>SAI6_TCR3[23–17]</td></tr>
</table>
</td></tr>
<tr><td>15-5</td><td>Reserved</td></tr>
</table>

Table continues on the next page...

Field	Function
—	
4-0 WDFL	Word Flag Configuration Configures which word sets the start of word flag. The value written must be one less than the word number. For example, writing 0 configures the first word in the frame. When configured to a value greater than TCR4[FRSZ], then the start of word flag is never set.

13.10.4.1.8 SAI Transmit Configuration 4 Register (TCR4)

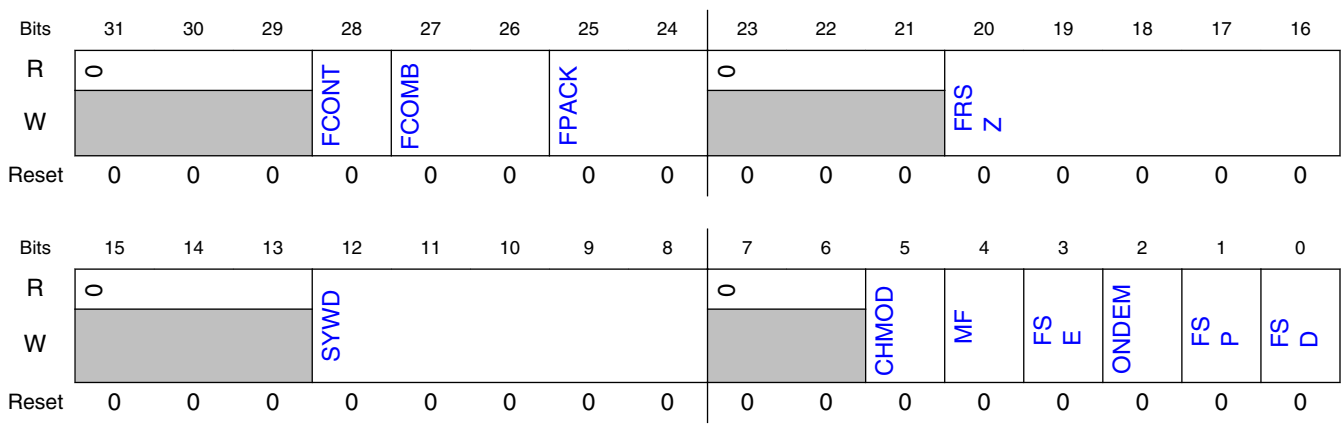
13.10.4.1.8.1 Offset

Register	Offset
TCR4	18h

13.10.4.1.8.2 Function

This register must not be altered when TCSR[TE] is set.

13.10.4.1.8.3 Diagram



13.10.4.1.8.4 Fields

Field	Function
31-29 —	Reserved
28 FCONT	FIFO Continue on Error Configures when the SAI will continue transmitting after a FIFO error has been detected.

Table continues on the next page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>0b - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared.
1b - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.</td></tr>
<tr><td>27-26
FCOMB</td><td>FIFO Combine Mode
When FIFO combine mode is enabled for FIFO writes, software writing to any FIFO data register will alternate the write among the enabled data channel FIFOs. For example, if two data channels are enabled then the first write will be performed to the first enabled data channel FIFO and the second write will be performed to the second enabled data channel FIFO. Reseting the FIFO or disabling FIFO combine mode for FIFO writes will reset the pointer back to the first enabled data channel.
When FIFO combine mode is enabled for FIFO reads from the transmit shift registers, the transmit data channel output will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked word will be transmitted from the first enabled data channel FIFO and the second unmasked word will be transmitted from the second enabled data channel FIFO. Since the first word of the frame is always transmitted from the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels.
NOTE: This field is not supported in every instance. The following table includes only supported registers.
<table><tr><th>Field supported in</th><th>Field not supported in</th></tr><tr><td>SAI1_TCR4</td><td>—</td></tr><tr><td>—</td><td>SAI2_TCR4</td></tr><tr><td>—</td><td>SAI3_TCR4</td></tr><tr><td>—</td><td>SAI4_TCR4</td></tr><tr><td>—</td><td>SAI5_TCR4</td></tr><tr><td>—</td><td>SAI6_TCR4</td></tr></table>
00b - FIFO combine mode disabled.
01b - FIFO combine mode enabled on FIFO reads (from transmit shift registers).
10b - FIFO combine mode enabled on FIFO writes (by software).
11b - FIFO combine mode enabled on FIFO reads (from transmit shift registers) and writes (by software).</td></tr>
<tr><td>25-24
FPACK</td><td>FIFO Packing Mode
Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are loaded from the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO write pointer will only increment when the full 32-bit FIFO word has been written by software.
00b - FIFO packing is disabled
01b - Reserved
10b - 8-bit FIFO packing is enabled
11b - 16-bit FIFO packing is enabled</td></tr>
<tr><td>23-21
—</td><td>Reserved</td></tr>
<tr><td>20-16
FRSZ</td><td>Frame size
Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.</td></tr>
</table>

Table continues on the next page...

Field	Function
15-13 —	Reserved
12-8 SYWD	Sync Width Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
7-6 —	Reserved
5 CHMOD	Channel Mode Configures if transmit data pins are configured for TDM mode or Output mode. 0b - TDM mode, transmit data pins are tri-stated when slots are masked or channels are disabled. 1b - Output mode, transmit data pins are never tri-stated and will output zero when slots are masked or channels are disabled.
4 MF	MSB First Configures whether the LSB or the MSB is transmitted first. 0b - LSB is transmitted first. 1b - MSB is transmitted first.
3 FSE	Frame Sync Early 0b - Frame sync asserts with the first bit of the frame. 1b - Frame sync asserts one bit before the first bit of the frame.
2 ONDEM	On Demand Mode When set, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is clear. 0b - Internal frame sync is generated continuously. 1b - Internal frame sync is generated when the FIFO warning flag is clear.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0b - Frame sync is active high. 1b - Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0b - Frame sync is generated externally in Slave mode. 1b - Frame sync is generated internally in Master mode.

13.10.4.1.12.4 Fields

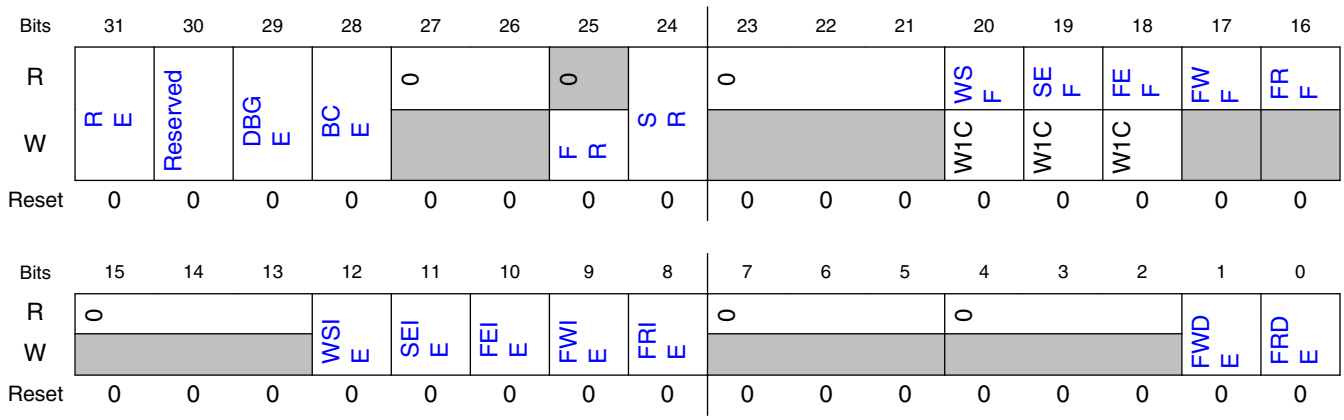
Field	Function
31-0 TWM	Transmit Word Mask Configures whether the transmit word is masked (transmit data pins are tri-stated or drive zero and transmit data not read from FIFO) for the corresponding word in the frame. 00000000000000000000000000000000b - Word N is enabled. 00000000000000000000000000000001b - Word N is masked. The transmit data pins are tri-stated or drive zero when masked.

13.10.4.1.13 SAI Receive Control Register (RCSR)

13.10.4.1.13.1 Offset

Register	Offset
RCSR	88h

13.10.4.1.13.2 Diagram



13.10.4.1.13.3 Fields

Field	Function
31 RE	Receiver Enable Enables/disables the receiver. When software clears this field, the receiver remains enabled, and this bit remains set, until the end of the current frame. 0b - Receiver is disabled. 1b - Receiver is enabled, or receiver has been disabled and has not yet reached end of frame.
30 —	Reserved. Software should only write zero to this reserved bit.
29 DBGE	Debug Enable Enables/disables receiver operation in Debug mode. The receive bit clock is not affected by Debug mode. 0b - Receiver is disabled in Debug mode, after completing the current frame. 1b - Receiver is enabled in Debug mode.
28 BCE	Bit Clock Enable Enables the receive bit clock, separately from RE. This field is automatically set whenever RE is set. When software clears this field, the receive bit clock remains enabled, and this field remains set, until the end of the current frame. 0b - Receive bit clock is disabled. 1b - Receive bit clock is enabled.
27-26 —	Reserved
25 FR	FIFO Reset Empties the FIFO, and sets the FIFO read and write pointers to the same value, which may or may not be zero. Reading this field will always return zero. FIFO pointers should only be reset when the receiver is disabled or the FIFO error flag is set. 0b - No effect. 1b - FIFO reset.
24 SR	Software Reset Resets the internal receiver logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers. 0b - No effect.

Table continues on the next page...

Field	Function
	1b - Software reset.
23-21 —	Reserved
20 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0b - Start of word not detected. 1b - Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0b - Sync error not detected. 1b - Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled receive FIFO has overflowed. Write a logic 1 to this field to clear this flag. 0b - Receive overflow not detected. 1b - Receive overflow detected.
17 FWF	FIFO Warning Flag Indicates that an enabled receive FIFO is full. 0b - No enabled receive FIFO is full. 1b - Enabled receive FIFO is full.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled receive channel FIFO is greater than the receive FIFO watermark. 0b - Receive FIFO watermark not reached. 1b - Receive FIFO watermark has been reached.
15-13 —	Reserved
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts.

Table continues on the next page...

Field	Function
	0b - Disables the interrupt. 1b - Enables the interrupt.
7-5 —	Reserved
4-2 —	Reserved
1 FWDE	FIFO Warning DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.
0 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.

13.10.4.1.15.4 Fields

Field	Function
31-30 SYNC	Synchronous Mode Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the transmitter must be configured for asynchronous operation. 00b - Asynchronous mode. 01b - Synchronous with transmitter. 10b - Reserved. 11b - Reserved.
29	Bit Clock Swap

Table continues on the next page...

Field	Function
BCS	This field swaps the bit clock used by the receiver. When the receiver is configured in asynchronous mode and this bit is set, the receiver is clocked by the transmitter bit clock (TX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the receiver continues to use the receiver frame sync (RX_SYNC). When the receiver is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the receiver bit clock (RX_BCLK) but use the transmitter frame sync (TX_SYNC). 0b - Use the normal bit clock source. 1b - Swap the bit clock source.
28 BCI	Bit Clock Input When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the receiver is delayed by the pad output delay (the receiver is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the receiver when this bit is set. In synchronous mode, this bit allows the receiver to use the slave mode timing from the datasheet, while the transmitter uses the master mode timing. This field has no effect when configured for an externally generated bit clock . 0b - No effect. 1b - Internal logic is clocked as if bit clock was externally generated.
27-26 MSEL	MCLK Select Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE:** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the availability and chip-specific meaning of each option. 00b - Bus Clock selected. 01b - Master Clock (MCLK) 1 option selected. 10b - Master Clock (MCLK) 2 option selected. 11b - Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0b - Bit Clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1b - Bit Clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0b - Bit clock is generated externally in Slave mode. 1b - Bit clock is generated internally in Master mode.
23-8 —	Reserved
7-0 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.

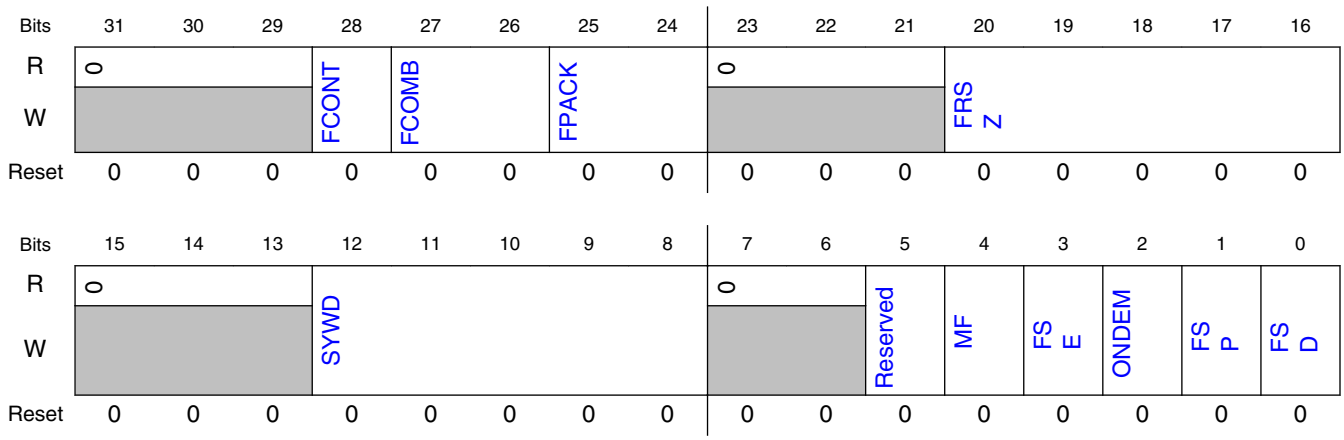
This register must not be altered when RCSR[RE] is set.

13.10.4.1.17.3 Diagram



13.10.4.1.17.4 Fields

Field	Function
31-29 —	Reserved
28 FCONT	FIFO Continue on Error Configures when the SAI will continue receiving after a FIFO error has been detected. 0b - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared. 1b - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.
27-26 FCOMB	FIFO Combine Mode When FIFO combine mode is enabled for FIFO reads, software reading any FIFO data register will alternate the read among the enabled data channel FIFOs. For example, if two data channels are enabled then the first read will be performed to the first enabled data channel FIFO and the second read will be performed to the second enabled data channel FIFO. Reseting the FIFO or disabling FIFO combine mode for FIFO reads will reset the pointer back to the first enabled data channel. When FIFO combine mode is enabled for FIFO writes from the receive shift registers, the first enabled data channel input will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked received word will be stored in the first enabled data channel FIFO and the second unmasked received word will be stored in the second enabled data channel FIFO. Since the first word of the frame is always stored in the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels. **NOTE:** This field is not supported in every instance. The following table includes only supported registers. **Field supported in** / **Field not supported in** SAI1_RCR4 / — — / SAI2_RCR4 — / SAI3_RCR4

Table continues on the next page...

Field	Function
	<table><tr><th>Field supported in</th><th>Field not supported in</th></tr><tr><td>—</td><td>SAI4_RCR4</td></tr><tr><td>—</td><td>SAI5_RCR4</td></tr><tr><td>—</td><td>SAI6_RCR4</td></tr></table> 00b - FIFO combine mode disabled. 01b - FIFO combine mode enabled on FIFO writes (from receive shift registers). 10b - FIFO combine mode enabled on FIFO reads (by software). 11b - FIFO combine mode enabled on FIFO writes (from receive shift registers) and reads (by software).
25-24 FPACK	FIFO Packing Mode Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are stored to the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO read pointer will only increment when the full 32-bit FIFO word has been read by software. 00b - FIFO packing is disabled 01b - Reserved. 10b - 8-bit FIFO packing is enabled 11b - 16-bit FIFO packing is enabled
23-21 —	Reserved
20-16 FRSZ	Frame Size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.
15-13 —	Reserved
12-8 SYWD	Sync Width Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
7-6 —	Reserved
5 —	Reserved. Software should only write zero to this bit.
4 MF	MSB First Configures whether the LSB or the MSB is received first. 0b - LSB is received first. 1b - MSB is received first.
3 FSE	Frame Sync Early 0b - Frame sync asserts with the first bit of the frame. 1b - Frame sync asserts one bit before the first bit of the frame.
2 ONDEM	On Demand Mode When set, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is clear.

Table continues on the next page...

Field	Function
	0b - Internal frame sync is generated continuously. 1b - Internal frame sync is generated when the FIFO warning flag is clear.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0b - Frame sync is active high. 1b - Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0b - Frame Sync is generated externally in Slave mode. 1b - Frame Sync is generated internally in Master mode.

Field	Function
31-0 RWM	Receive Word Mask Configures whether the receive word is masked (received data ignored and not written to receive FIFO) for the corresponding word in the frame. 00000000000000000000000000000000b - Word N is enabled. 00000000000000000000000000000001b - Word N is masked.

Chapter 14
Video Processing Unit (VPU)

14.1 VPU G1 (VPU_G1)

14.1.1 Overview

This block details the VPU G1 hardware based decoders and API. The decoders are able to decode H.264, VP8. The decoders conform to the H.264 Baseline, Main and High profile, and VP8 Main Profile

NOTE

The overall performance and capabilities of the decoders is system dependent. Formats and features that are presented depend on the chip configuration.

14.1.2 Features (G1)

The API is implemented on top of the VPU G1 decoder H.264 and VP8. The features of the decoders are noted in the following sections.

14.1.2.1 Decoder Features

The VPU G1 decoder has the following features:

- H.264 baseline profile, levels 1-4.1 decoding
  - Byte stream input
  - NAL unit input
- VP8 decoding
- Video post-processing features
  - Frame rotation 90 degrees left/right
  - Frame mirroring horizontally/vertically
  - Frame cropping

- Frame conversion from YCbCr formats to 16-bit or 32-bit RGB formats
- Frame scaling with maximum up-scaling factor of 3
- Two rectangular or alpha blending masks for output frame

The post-processing features can be used in pipeline with the decoder. The post-processing features can also be used as stand-alone, without performing any decoding.

- H.264 main and high profile, levels 1-4.1 decoding
- VP8 decoding

14.1.3 Video Frame Storage Format

This chapter describes the different input and output picture storage formats supported by the decoder and post-processor. Notice that some of the formats are only used for input or output.

14.1.3.1 YCbCr 4:2:0 Planar Format

In the planar format each video sample component forms one memory plane. The luminance and both chrominance planes must be stored in a linear and contiguous memory block as shown in Figure 3. The luminance samples are stored in raster-scan order (Y0Y1Y2Y3Y4….). The chrominance samples are stored in two planes also in raster scan order (Cb0Cb1Cb2Cb3… and Cr0Cr1Cr2Cr3…).

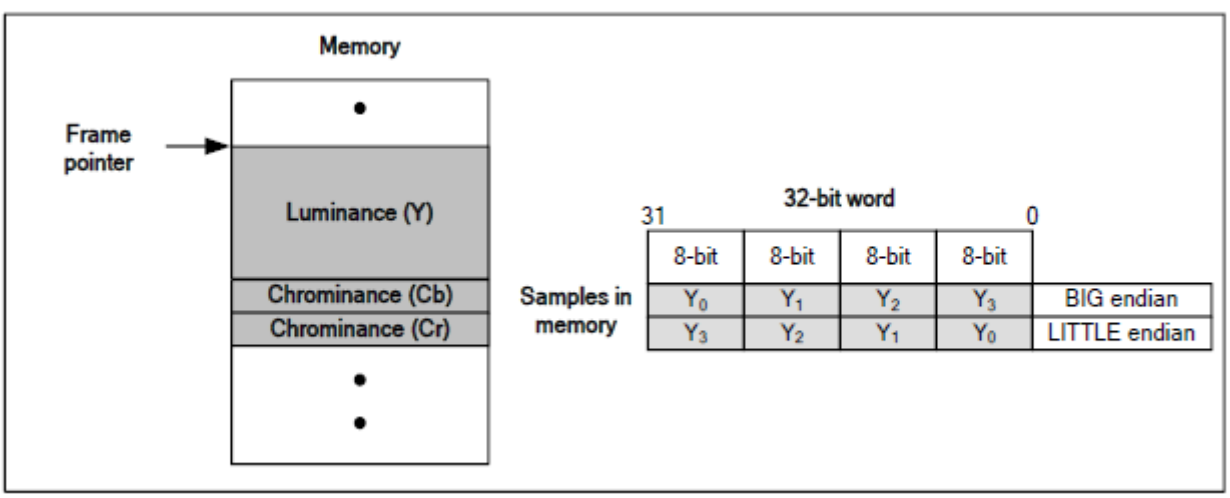

Figure 14-1. YCBCR 4:2:0 Planar Format External Memory Usage

The YCbCr 4:2:0 planar format is supported only as an input format for the postprocessor. In this format each pixel takes 12 bits of memory.

14.1.3.2 YCbCr 4:2:0 Semi-Planar Format

In semi-planar YCbCr 4:2:0 format the luminance samples form one plane in memory, and chrominance samples form another. The luminance and chrominance planes must be stored in a linear and contiguous memory block as presented in the following figure. The luminance pixels are stored in raster-scan order Y0Y1Y2Y3Y4…. The interleaved chrominance CbCr samples are stored in raster-scan order in memory as Cb0Cr0Cb1Cr1Cb2Cr2Cb3....

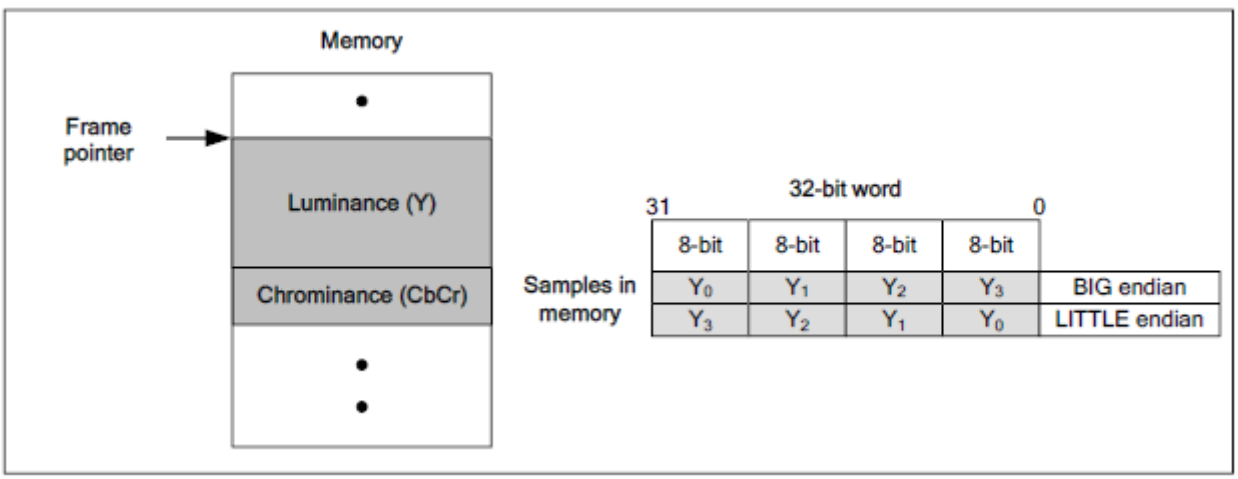

Figure 14-2. YCBCR 4:2:0 Planar Format External Memory Usage

The YCbCr 4:2:0 semi-planar format is supported both as an input and as an output format for the post-processor. In this format each pixel takes 12 bits of memory. As the chrominance components are interleaved, the bus load caused by this format can be slightly lower than with the planar format due to the reduced amount of non-sequential memory addressing.

14.1.3.3 YCbCr 4:2:2 Interleaved Format

In the interleaved YCbCr 4:2:2 format the pixel samples form a single plane in which the data has to be stored linearly and contiguously as shown in Figure 5. The pixel data is in raster scan order and the chrominance samples are interleaved between the luminance samples as Y0Cb0Y1Cr0Y2Cb1Y3Cr1….

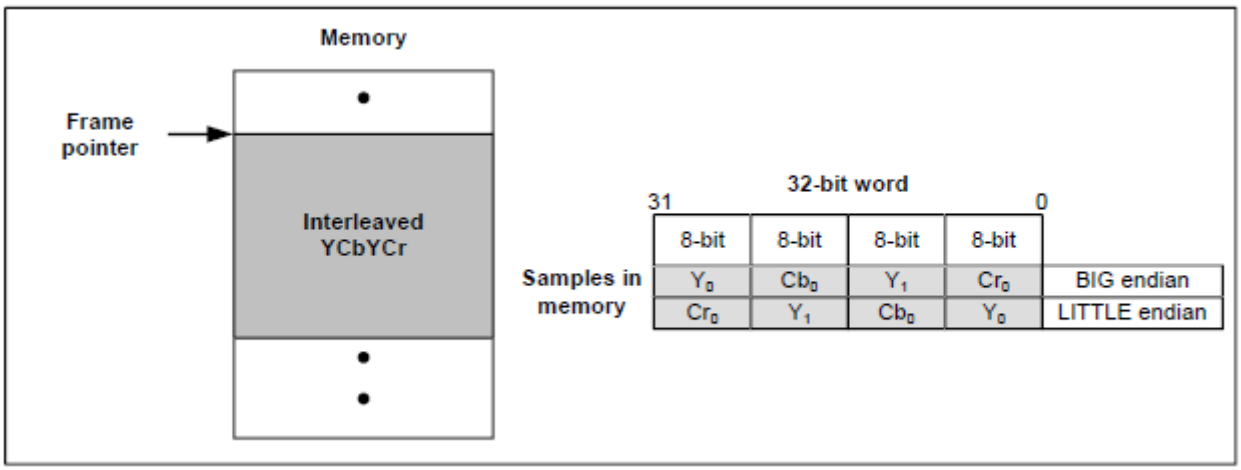

Figure 14-3. YCBCR 4:2:2 Interleaved Format External Memory Usage

The YCbCr 4:2:2 interleaved format is supported both as an input and as an output format for the post-processor. In this format each pixel takes 16 bits of memory. Although there is more data to be transferred than in the 4:2:0 formats, the interleaved format is bus effective as there are no non-sequential memory accesses caused by the plane changes.

14.1.3.4 G2 Decoder Tiled 4x4 Format

The output picture of the decoder is in semi-planar YCbCr 4:2:0 4x4 tiled format, i.e. luminance data forms one plane in memory, and chrominance data forms another. The distinction from raster scan format is that the output picture is grouped into tiles, which are then stored linearly and contiguously in the memory. The chrominance tiles have to be stored right after the luminance tiles in external memory as shown in Figure 6.

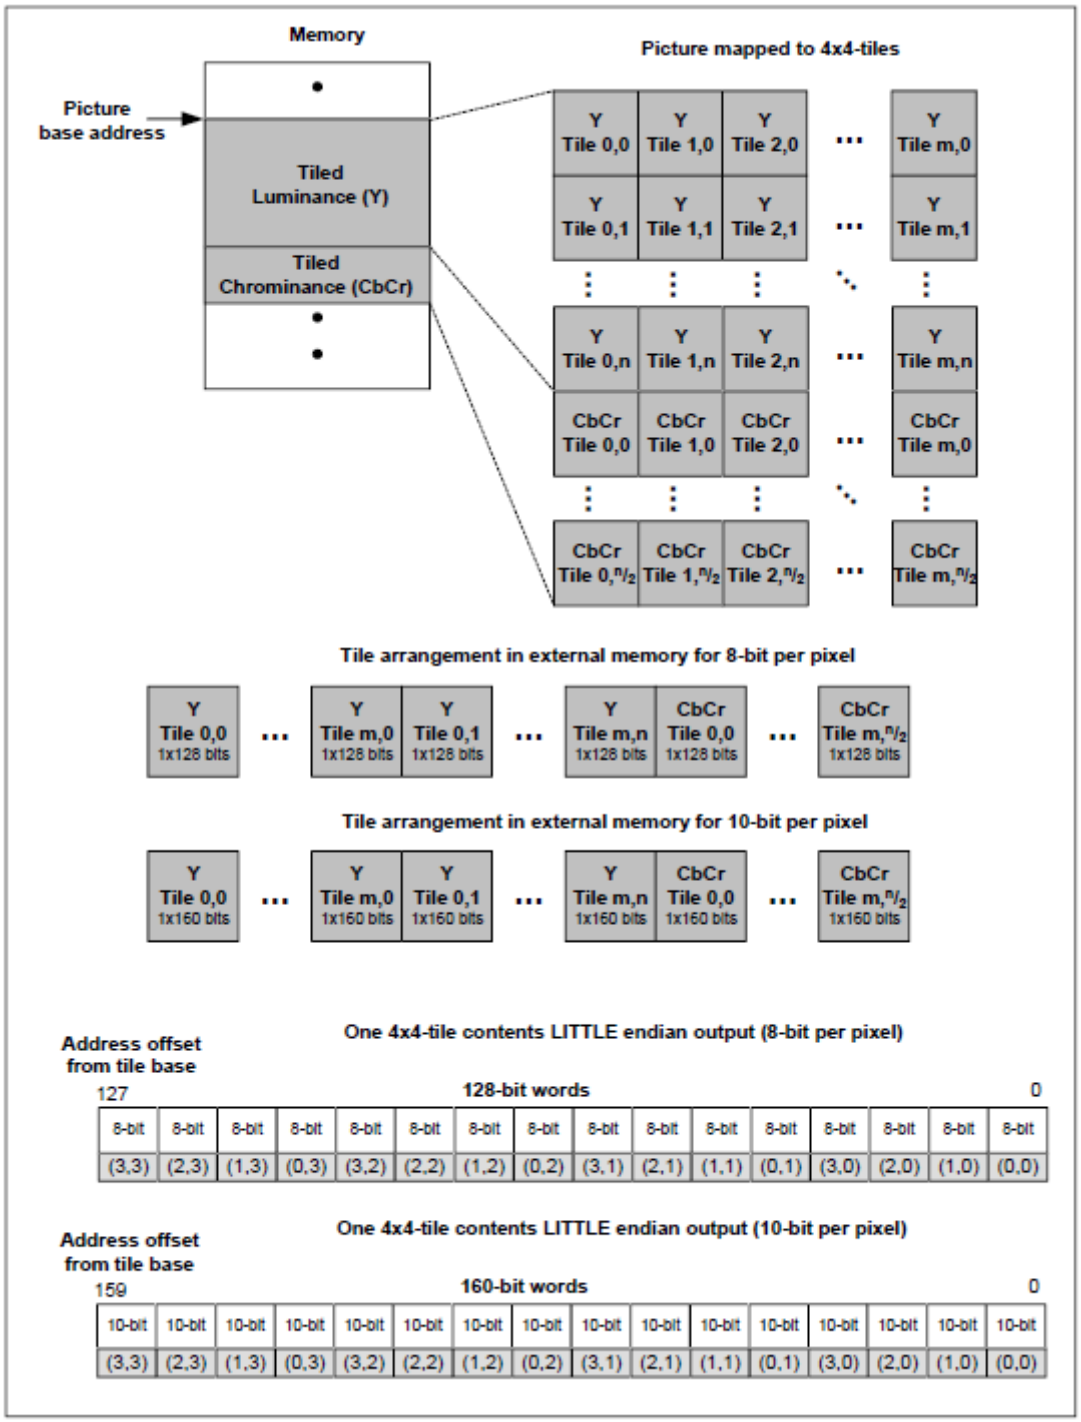

Figure 14-4. Tiled 4x4 Format External Memory Usage

14.1.3.5 RGB 16bpp Format

In this format each pixel is represented by 16 or less bits containing the red, blue and green samples. There are several 16bpp formats which use different number of bits for each sample. For example the RGB 5-5-5 format uses 5 bits for each sample and 1 bit is left unused or can represent a transparency flag, where RGB 5-6-5 uses 6 bits for the G sample and 5 bits for R and B samples. Common for all 16bpp types is that two pixels fit into one 32-bit space.

The data has to be stored linearly and contiguously in the memory as shown in Figure 7. The order of the sample bytes is always defined with a 16 bit word which will define the byte order in the memory. The pixel samples are stored in raster-scan order.

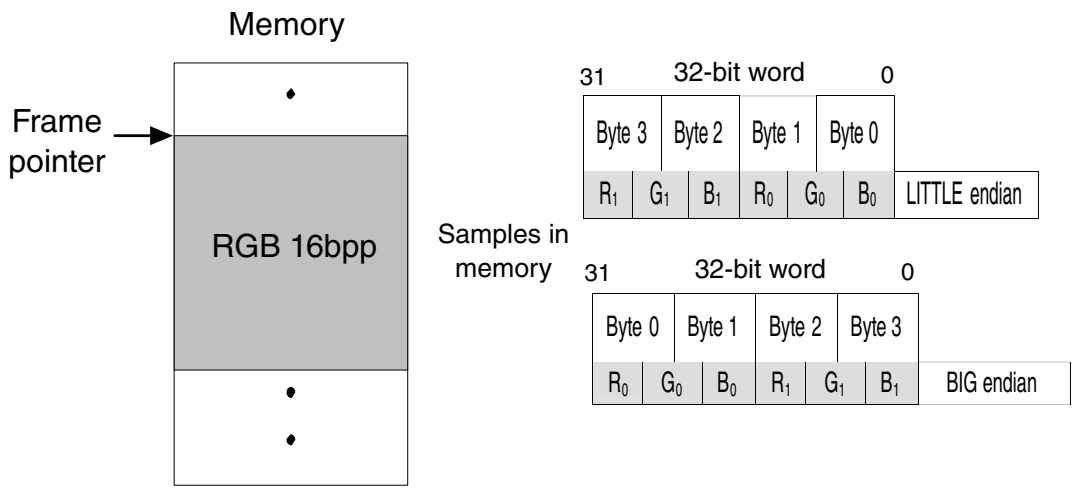

Figure 14-5. RGB 16bpp Format External Memory Usage

The RGB 16bpp formats are supported only as post-processor output formats.

14.1.3.6 RGB 32bpp Format

Any RGB format that has its pixels represented by more than 16 bits each is considered to be of 32bpp type. Typically in this format each pixel is represented by three bytes containing a red, blue and green sample and a 4th byte which can be empty or hold an alpha blending value. Common for all 32bpp types is that only one pixel fit into one 32-bit space.

The data has to be stored linearly and contiguously in the memory as shown in Figure 8. The order of the sample bytes is always defined on a 32 bit word and that will define the byte order in the memory (for example, ARGB order means that on a little endian system

the B sample will be stored in the lowest offset byte followed by the G, R and A samples. In a big endian system the A sample will be on the lowest offset byte). The pixel samples are stored in raster-scan order.

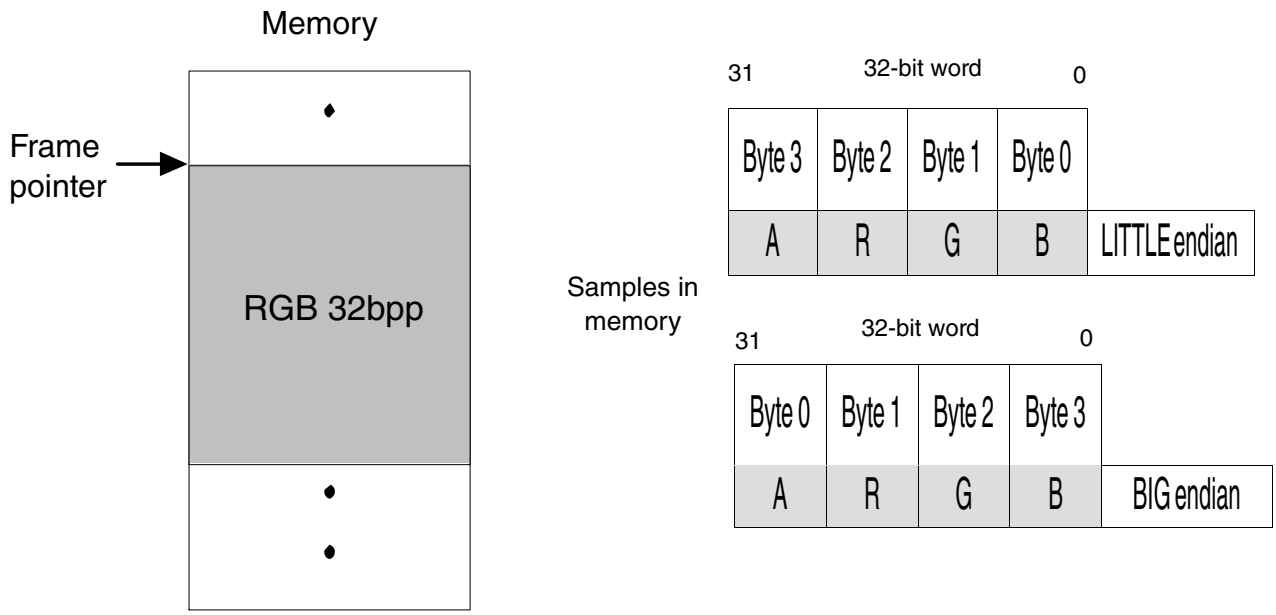

Figure 14-6. RGB 32bpp Format External Memory Usage

14.1.4 G1 Register Decoder

14.1.5 VPU G1 Memory Map/Register Definition

14.1.5.1 VPU_G1 common registers descriptions

14.1.5.1.1 VPU_G1 common registers memory map

VPU_G1 base address: 3830_0000h

Offset	Register	Width (In bits)	Access	Reset value
4h	Interrupt register decoder (SWREG1)	32	RW	0000_0000h
8h	Device configuration register decoder (SWREG2)	32	RW	0000_0000h

Table continues on the next page...

Offset	Register	Width (In bits)	Access	Reset value
Ch	Decoder control register 0 (decmode,picture type etc) (SWREG3)	32	RW	0000_0000h
30h	Base address for RLC data (RLC) / stream start address/decoded end addr register (VLC) (SWREG12)	32	RW	0000_0000h
34h	Base address for decoded picture (SWREG13)	32	RW	0000_0000h
A0h	Base address for standard dependent tables (SWREG40)	32	RW	0000_0000h
A4h	Base address for direct mode motion vectors (SWREG41)	32	RW	0000_0000h
C0h	Error concealment register (SWREG48)	32	RW	0000_0000h
C4h	Prediction filter tap register for H264 (SWREG49)	32	RW	0000_0000h
C8h	Synthesis configuration register decoder 0 (SWREG50)	32	RO	Table 14-
CCh	Reference picture buffer control register (SWREG51)	32	RW	0000_0000h
D0h	Reference picture buffer information register 1 (SWREG52)	32	RO	0000_0000h
D4h	Reference picture buffer information register 2 (SWREG53)	32	RO	0000_0000h
D8h	Synthesis configuration register decoder 1 (SWREG54)	32	RO	0000_0000h
DCh	Reference picture buffer 2 / Advanced prefetch control register (SWREG55)	32	RW	0000_0000h
E0h	Reference buffer information register 3 (SWREG56)	32	RO	0000_0000h
E4h	Decoder fuse register (SWREG57)	32	RO	Table 14-
E8h	Device configuration register decoder 2 + Multi core control register (SWREG58)	32	RW	0000_0000h
ECh	H264 Chrominance 8 pixel interleaved data base (SWREG59)	32	RW	0000_0000h
F0h	Interrupt register post-processor (SWREG60)	32	RW	0000_0000h
F4h	Device configuration register post-processor (SWREG61)	32	RW	0000_0100h
F8h	Deinterlace control register (SWREG62)	32	RW	0000_0000h
FCh	Base address for reading post-processing input picture luminance (top field/frame) (SWREG63)	32	RW	0000_0000h
100h	Base address for reading post-processing input picture Cb/Ch (top field/frame) (SWREG64)	32	RW	0000_0000h
104h	Base address for reading post-processing input picture Cr (SWRE G65)	32	RW	0000_0000h
108h	Base address for writing post-processed picture luminance/RGB (SWREG66)	32	RW	0000_0000h
10Ch	Base address for writing post-processed picture Ch (SWREG67)	32	RW	0000_0000h
110h	Register for contrast adjusting (SWREG68)	32	RW	0000_0000h
114h	Register for colour conversion and contrast adjusting/YUYV 422 channel orders (SWREG69)	32	RW	0000_0000h
118h	Register for colour conversion 0 (SWREG70)	32	RW	0000_0000h
11Ch	Register for colour conversion 1 + rotation mode (SWREG71)	32	RW	0000_0000h
120h	PP input size and -cropping register (SWREG72)	32	RW	0000_0000h
124h	PP input picture base address for Y bottom field (SWREG73)	32	RW	0000_0000h
128h	PP input picture base for Ch bottom field (SWREG74)	32	RW	0000_0000h
13Ch	Scaling register 0 ratio and padding for R and G (SWREG79)	32	RW	0000_0000h
140h	Scaling ratio register 1 and padding for B (SWREG80)	32	RW	0000_0000h

Table continues on the next page...

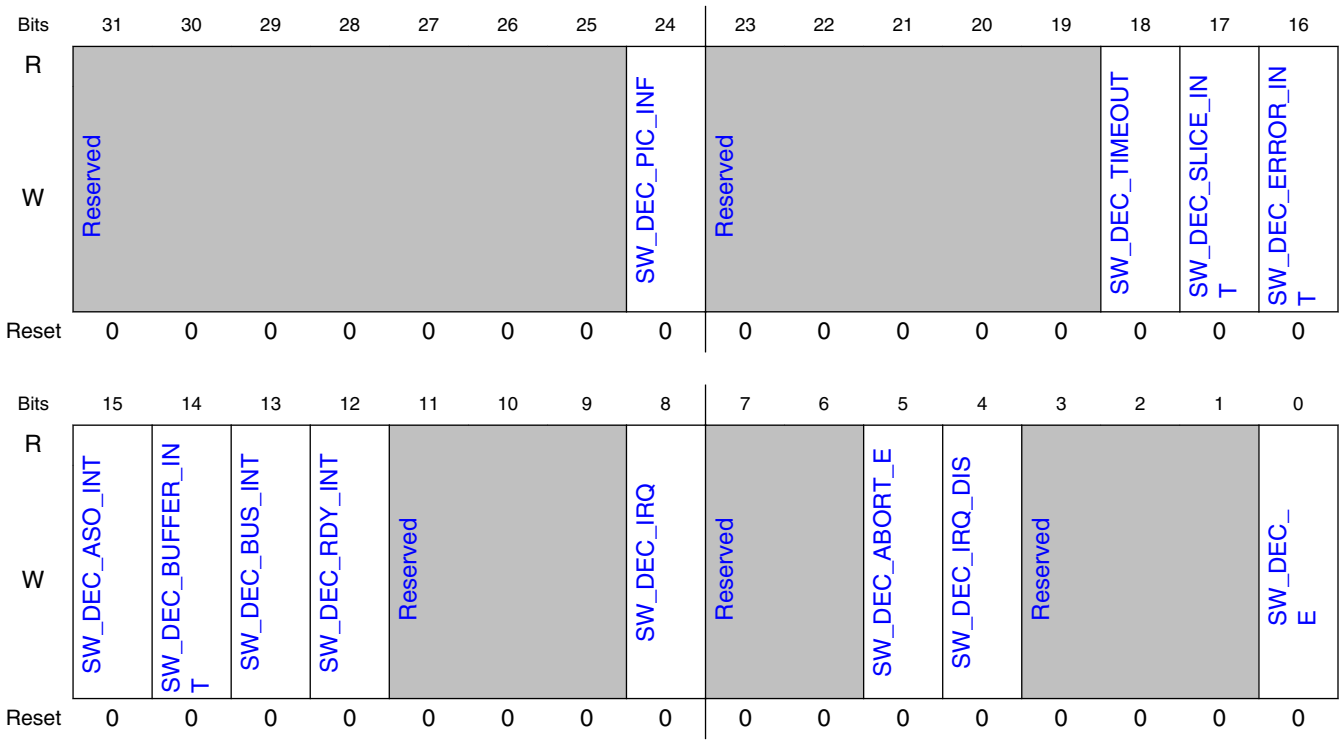
Offset	Register	Width (In bits)	Access	Reset value
144h	Scaling ratio register 2 (SWREG81)	32	RW	0000_0000h
148h	Rmask register (SWREG82)	32	RW	0000_0000h
14Ch	Gmask register (SWREG83)	32	RW	0000_0000h
150h	Bmask register (SWREG84)	32	RW	0000_0000h
154h	Post-processor control register (SWREG85)	32	RW	0000_0000h
158h	Mask 1 start coordinate register (SWREG86)	32	RW	0000_0000h
15Ch	Mask 2 start coordinate register + Mask extensions (SWREG87)	32	RW	0000_0000h
160h	Mask 1 size and PP original width register (SWREG88)	32	RW	0000_0000h
164h	Mask 2 size register + mask extensions (SWREG89)	32	RW	0000_0000h
168h	PiP register 0 (SWREG90)	32	RW	0000_0000h
16Ch	PiP register 1 and dithering control (SWREG91)	32	RW	0000_0000h
170h	Display width and PP input size extension register (SWREG92)	32	RW	0000_0000h
174h	Base address for alpha blend 1 gui component (SWREG93)	32	RW	0000_0000h
178h	Base address for alpha blend 2 gui component (SWREG94)	32	RW	0000_0000h
17Ch	Alpha blend input cropping register (scanline for cropping) (SWREG95)	32	RW	0000_0000h
18Ch	PP fuse register (SWREG99)	32	RO	Table 14-
190h	Synthesis configuration register post-processor (SWREG100)	32	RO	Table 14-
198h	Base address for H264 decoded chroma picture (SWREG102)	32	RW	0000_0000h
19Ch	Base address for reference chroma picture index 0 (SWREG103)	32	RW	0000_0000h
1A0h	Base address for reference chroma picture index 1 (SWREG104)	32	RW	0000_0000h
1A4h	Base address for reference chroma picture index 2 (SWREG105)	32	RW	0000_0000h
1A8h	Base address for reference chroma picture index 3 (SWREG106)	32	RW	0000_0000h
1ACh	Base address for reference chroma picture index 4 (SWREG107)	32	RW	0000_0000h
1B0h	Base address for reference chroma picture index 5 (SWREG108)	32	RW	0000_0000h
1B4h	Base address for reference chroma picture index 6 (SWREG109)	32	RW	0000_0000h
1B8h	Base address for reference chroma picture index 7 (SWREG110)	32	RW	0000_0000h
1BCh	Base address for reference chroma picture index 8 (SWREG111)	32	RW	0000_0000h
1C0h	Base address for reference chroma picture index 9 (SWREG112)	32	RW	0000_0000h
1C4h	Base address for reference chroma picture index 10 (SWREG113)	32	RW	0000_0000h
1C8h	Base address for reference chroma picture index 11 (SWREG114)	32	RW	0000_0000h
1CCh	Base address for reference chroma picture index 12 (SWREG115)	32	RW	0000_0000h
1D0h	Base address for reference chroma picture index 13 (SWREG116)	32	RW	0000_0000h
1D4h	Base address for reference chroma picture index 14 (SWREG117)	32	RW	0000_0000h
1D8h	Base address for reference chroma picture index 15 (SWREG118)	32	RW	0000_0000h

14.1.5.1.2 Interrupt register decoder (SWREG1)

14.1.5.1.2.1 Offset

Register	Offset
SWREG1	4h

14.1.5.1.2.2 Diagram



14.1.5.1.2.3 Fields

Field	Function
31-25 —	Reserved.
24 SW_DEC_PIC_INF	B slice detected. This signal is driven high during picture ready interrupt if B-type slice is found. This bit does not launch interrupt but is used to inform SW about h264 tools.
23-19 —	Reserved.
18 SW_DEC_TIMEOUT	Interrupt status bit decoder timeout. When high the decoder has been idling for too long. HW will self reset. Possible only if timeout interrupt is enabled

Table continues on the next page...

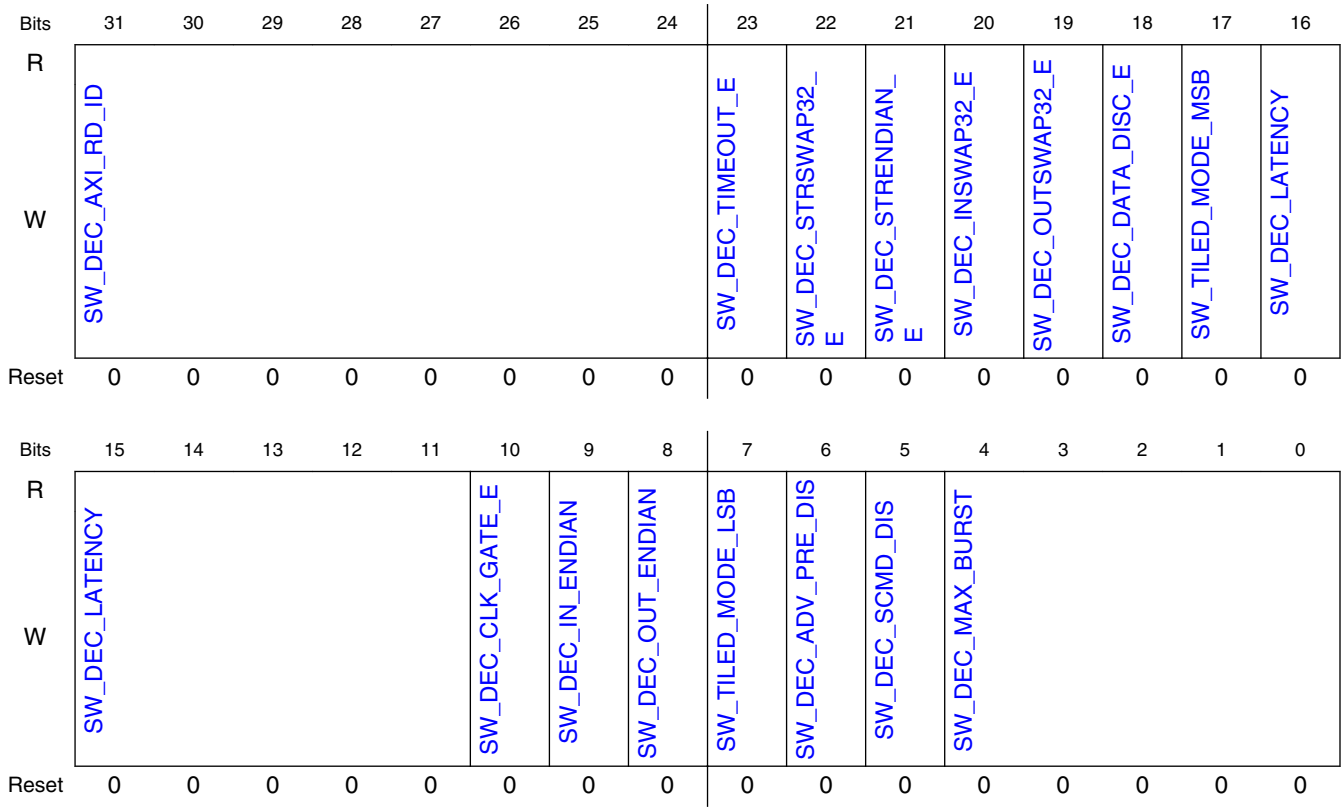
Field	Function
17 SW_DEC_SLICE_INT	Interrupt status bit dec_slice_decoded. When high SW must set new base addresses for sw_dec_out_base and sw_jpg_ch_out_base before resetting this status bit. Used for VP8 web-p modes
16 SW_DEC_ERROR_INT	Interrupt status bit input stream error. When high, an error is found in input data stream decoding. HW will self reset.
15 SW_DEC_ASO_INT	H264: Interrupt status bit ASO (Arbitrary Slice Ordering) detected. When high, ASO detected in input data stream decoding. HW will self reset. VP8: Error detected in Residual data. HW returns MB number in error concealment register for MB it detected it
14 SW_DEC_BUFFER_INT	Interrupt status bit input buffer empty. When high, input stream buffer is empty but picture is not ready. HW will not self reset.
13 SW_DEC_BUS_INT	Interrupt status bit bus. Error response from bus.
12 SW_DEC_RDY_INT	Interrupt status bit decoder. When this bit is high decoder has decoded a picture. HW will self reset.
11-9 —	Reserved.
8 SW_DEC_IRQ	Decoder IRQ. When high, decoder requests an interrupt. SW will reset this after interrupt is handled.
7-6 —	Reserved.
5 SW_DEC_ABORT_E	Abort decoding enable. Setting this bit high will cause HW to abort decoding and safely to reset itself down. After abort is complete the corresponding interrupt status is set and this bit is set low as well as the decoder enable.
4 SW_DEC_IRQ_DIS	Decoder IRQ disable. When high, there are no interrupts concerning decoder from HW. Polling must be used to see the interrupt statuses.
3-1 —	Reserved.
0 SW_DEC_E	Decoder enable. Setting this bit high will start the decoding operation. HW will reset this when picture is processed or ASO or stream error is detected or bus error or timeout interrupt is given.

14.1.5.1.3 Device configuration register decoder (SWREG2)

14.1.5.1.3.1 Offset

Register	Offset
SWREG2	8h

14.1.5.1.3.2 Diagram



14.1.5.1.3.3 Fields

Field	Function
31-24 SW_DEC_AXI_RD_ID	Read ID used for decoder reading services in AXI bus (if connected to AXI).
23 SW_DEC_TIMEOUT_E	Timeout interrupt enable. If enabled HW may return timeout interrupt in case HW gets stuck while decoding picture.
22 SW_DEC_STRSWAP32_E	Decoder input 32bit data swap for stream data (may be used for 64 bit environment): 0b - no swapping of 32 bit words 1b - 32 bit data words are swapped (needed in 64 bit environment to achieve 7-6-5-4-3-2-1-0 byte order(also little endian should be enabled))
21 SW_DEC_STRENDIAN_E	Decoder input endian mode for stream data: 0b - Big endian (0-1-2-3 order) 1b - Little endian (3-2-1-0 order)
20	Decoder input 32bit data swap for other than stream data (may be used for 64 bit environment): 0b - no swapping of 32 bit words

Table continues on the next page...

Field	Function
SW_DEC_INSWAP32_E	1b - 32 bit data words are swapped (needed in 64 bit environment to achieve 7-6-5-4-3-2-1-0 byte order(also little endian should be enabled))
19 SW_DEC_OUTSWAP32_E	Decoder output 32bit data swap (may be used for 64 bit environment): 0b - no swapping of 32 bit words 1b - 32 bit data words are swapped (needed in 64 bit environment to achieve 7-6-5-4-3-2-1-0 byte order(also little endian should be enabled))
18 SW_DEC_DATA_DISC_E	Data discard enable. Precise burst lengths are used with reading services. Extra data is discarded internally. Note. If AHB maxburst 17 is used data discard cannot be enabled (causes conflict)
17 SW_TILED_MODE_MSB	Tiled mode msb. Concatenated to Tiled mode lsb which form 2 bit tiled mode. 0b - Tiled mode not enabled 1b - Tiled mode enabled for 8x4 tile size
16-11 SW_DEC_LATENCY	Decoder master interface additional latency. Can be used to slow down decoder HW between services in steps of 8 clock cycles: 0 = no latency 1 = minimum 8 cycles of IDLE between services 2 = minimum 16 cycles of IDLE between services . . . 63 = minimum latency of 504 cycles of IDLE between services
10 SW_DEC_CLK_GATE_E	Decoder dynamic clock gating enable: 0b - Clock is running for all structures 1b - Clock is gated for decoder structures that are not used. Note: Clock gating value can be changed only when decoder is disabled.
9 SW_DEC_IN_ENDIAN	Decoder input endian mode for other than stream data: 0b - Big endian (0-1-2-3 order) 1b - Little endian (3-2-1-0 order)
8 SW_DEC_OUT_ENDIAN	Decoder output endian mode: 0b - Big endian (0-1-2-3 order) 1b - Little endian (3-2-1-0 order)
7 SW_TILED_MODE_LSB	Tiled mode lsb. Concatenated to Tiled mode msb which form 2 bit tiled mode. Defined in tiled_mode_msb
6 SW_DEC_ADV_PRE_DIS	Advanced PREFETCH mode disable (advanced reference picture reading mode for video)
5 SW_DEC_SCMD_DIS	9170 decoder and later->: AXI Single Command Multiple Data disable. 9170 axi wrapper supports this mode by default (where only the first addresses of the burst are given from address generator). This bit is used to disable the feature (possible SW workaround if something is not working correctly)
4-0 SW_DEC_MAX_BURST	Maximum burst length for decoder bus transactions. Valid values: AHB: 1, 4, 8, 16 and 17. Other values will result in INCR type (undefined length) for all transfers. INCR used for lengths 2 and 3.

Field	Function
	17 = fixed bursts are used when possible. INCR bursts are used for lengths 2, 3, 5, 6, 7, 9, 10, 11, 12, 13, 14 and 15. OCP: 16-31 AXI: 1-16

14.1.5.1.4 Decoder control register 0 (decmode,picture type etc) (SWREG3)

14.1.5.1.4.3 Fields

Field	Function
31-28 SW_DEC_MODE	Decoding mode: 0000b - H.264 0001b - Reserved 0010b - Reserved 0011b - Reserved 0100b - Reserved 0101b - Reserved 0110b - Reserved 0111b - Reserved 1000b - Reserved 1001b - Reserved 1010b - VP8 1011b - Reserved 1100b - Reserved 1101b - Reserved 1110b - Reserved 1111b - Reserved
27 SW_RLC_MODE_E	RLC mode enable: 0b - HW decodes video from bit stream (VLC mode) + side information 1b - HW decodes video from RLC input data + side information (Differential MV's, separate DC coeffs, Intra 4x4 modes, MB control). Valid only for H.264 Baseline.
26 SW_SKIP_MODE	VP8: • 0 : HW decodes mb_coeff_skip -flag • 1 : HW does not decode mb_coeff_skip -flag
25 —	Reserved.
24 —	Reserved.
23 SW_PIC_INTERLACE_E	Coding mode of the current picture: 0b - progressive 1b - interlaced
22 SW_PIC_FIELDMODE_E	Structure of the current picture (residual structure) 0b - Frame structure. For H264, this means MBAFF structured picture for interlaced sequence 1b - Field structure
21 SW_PIC_B_E	B picture enable for current picture: 0b - picture type is I or P depending on sw_pic_inter_e 1b - picture type is B depending on sw_pic_inter_e (not valid for H264 since it is slice based information)
20 SW_PIC_INTER_E	Picture type. Please also see SW_PIC_B_E. 0b - Intra type (I) 1b - Inter type (P)
19 SW_PIC_TOPFIELD_E	If field structure is enabled, this bit informs which one of the fields is being decoded: 0b - bottom field 1b - top field
18 SW_FWD_INTERLACE_E	Coding mode of forward reference picture **NOTE:** For backward reference picture, the coding mode is always the same as for current picture. 0b - progressive

Table continues on the next page...

Field	Function
	1b - interlaced
17 —	Reserved.
16 SW_REF_TOPFIELD_E	Indicates which field should be used as reference if sw_ref_frames = '0': 0b - bottom field 1b - top field
15 SW_DEC_OUT_DIS	Disable decoder output picture writing: 0b - Decoder output picture is written to external memory 1b - Decoder output picture is not written to external memory
14 SW_FILTERING_DIS	De-block filtering disable: 0b - filtering is enabled for current picture 1b - filtering is disabled for current picture
13 SW_WEBP_E	SW_WEBP_E: Webp enable for VP8: • '0' = Normal VP8 • '1' = WEBP picture SW_MVC_E: Multi View Coding enable. Possible for H264 only.
12 SW_WRITE_MVS_E	Direct mode motion vector write enable for current picture / VPX motion vector write enable for error concealment purposes: 0b - Writing disabled for current picture 1b - The direct mode motion vectors are written to external memory. H264 direct mode motion vectors are written to DPB aside with the corresponding reference picture. Other decoding mode dir mode mvs are written to external memory starting from sw_dir_mv_base.
11 SW_REFTOPFIRST_E	Indicates which FWD reference field has been decoded first. 0b - FWD reference bottom field 1b - FWD reference top field
10 SW_SEQ_MBAFF_E	Sequence includes MBAFF coded pictures
9 SW_PICORD_COUNT_E	h264_high config: Picture order count table read enable. If enabled HW will read picture order counts from memory in the beginning of picture
8 SW_DEC_AHB_HLOCK_E	AHB master HLOCK enable. When high the service is locked to decoder as long as it needs the bus (whenever decoder requests the bus it will be granted)
7-0 SW_DEC_AXI_WR_ID	Write ID used for decoder writing services in AXI bus (if connected to AXI)

14.1.5.1.5 Base address for RLC data (RLC) / stream start address/ decoded end addr register (VLC) (SWREG12)

14.1.5.1.5.1 Offset

Register	Offset
SWREG12	30h

14.1.5.1.5.2 Diagram

14.1.5.1.5.3 Fields

Field	Function
31-0 SW_RLC_VLC_BASE	RLC mode: Base address for RLC data (swreg3.sw_rlc_mode_e = 1). VLC mode: Stream start address / end addr+I288ess with byte precision (swreg4.rlc_mode_en = 0), start bit number in swreg5.stream_start_bit. When sw_dec_buffer_int is high or sw_dec_e is low this register contains HW return value of last_byte_address where stream has been read (and used) in accuracy of byte. For debug purposes the last_byte_address is also written when stream error/ASO is detected even though it may not be accurate. VP8: This base address is used as sw_dct_strm0_base including DCT stream for MB rows 0,2n.

14.1.5.1.6 Base address for decoded picture (SWREG13)

14.1.5.1.6.1 Offset

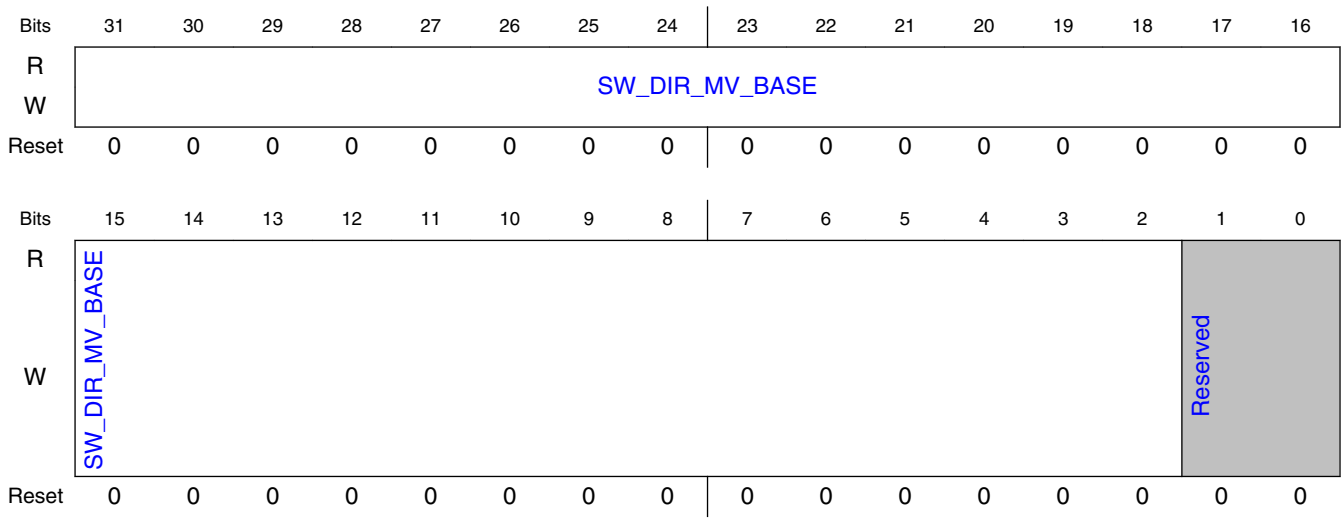
SWREG41	A4h

14.1.5.1.8.2 Diagram



14.1.5.1.8.3 Fields

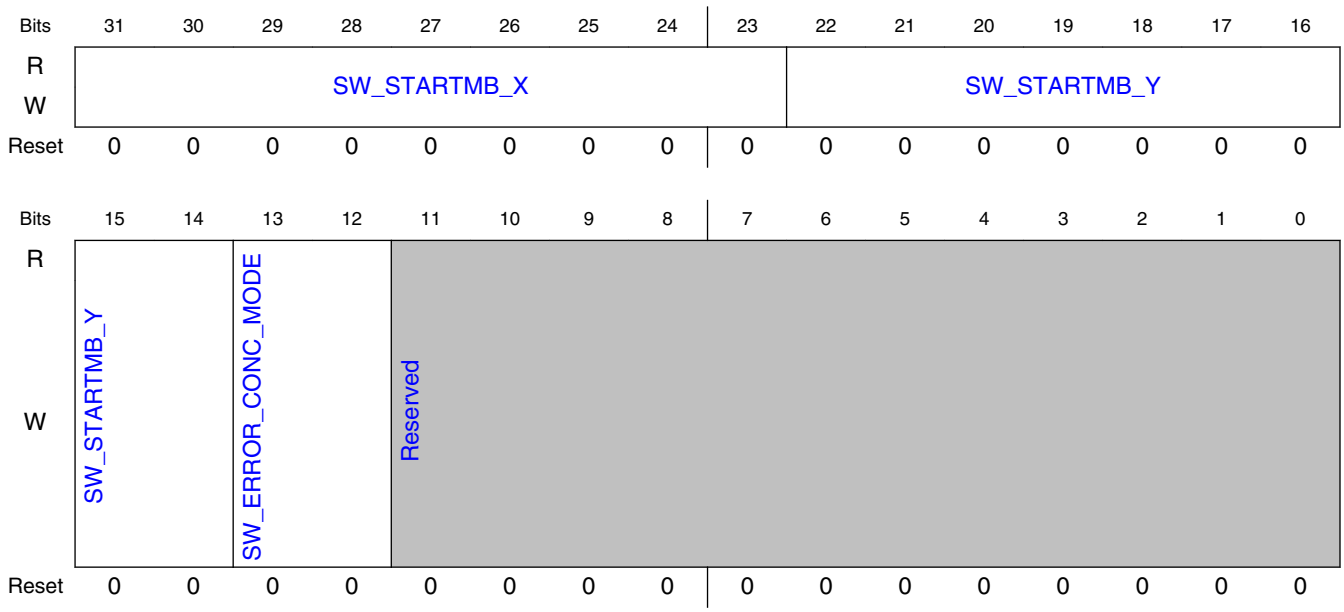
Field	Function
31-2 SW_DIR_MV_BASE	Direct mode motion vector write/read base address. For H264 this is used only for direct mode motion vector write base. VP8: Motion vectors are written for error concealment purposes if sw_write_mvs is high. In error concealment mode motion vectors are read from this base address
1-0 —	Reserved.

14.1.5.1.9 Error concealment register (SWREG48)

14.1.5.1.9.1 Offset

Register	Offset
SWREG48	C0h

14.1.5.1.9.2 Diagram



14.1.5.1.9.3 Fields

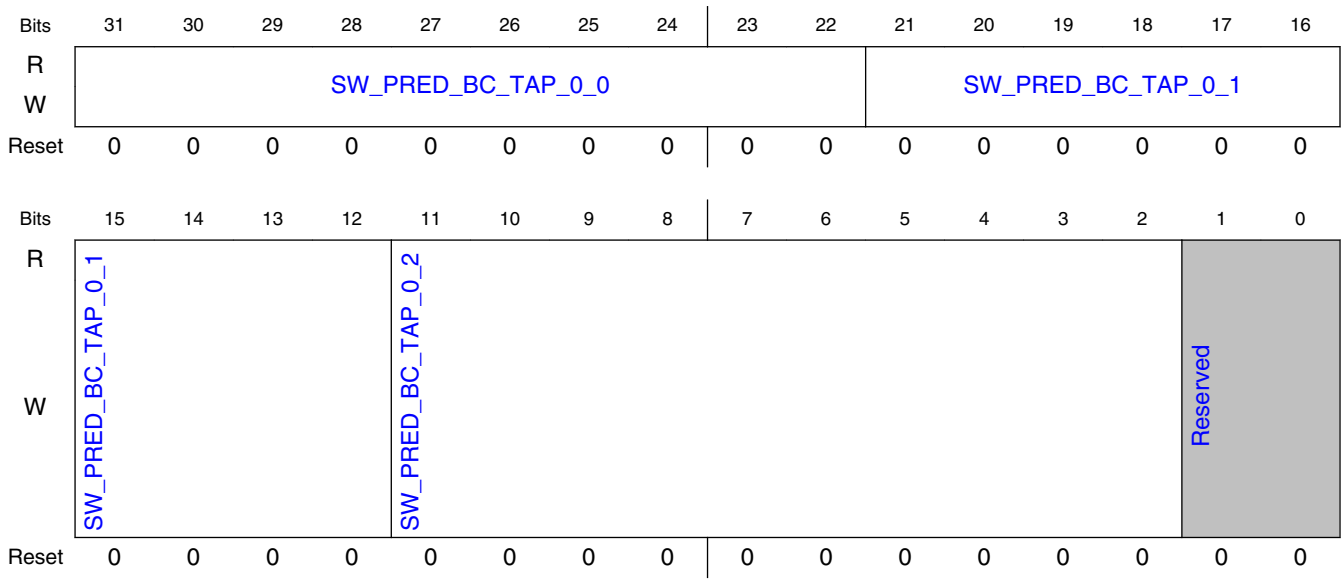
Field	Function
31-23 SW_STARTMB_X	Start MB from SW for X dimension. Used in error concealment case as HW return value if HW founds an error or in HW init mb for error concealment if SW enables error concealment
22-14 SW_STARTMB_Y	Start MB from SW for Y dimension. Used in error concealment case as HW return value if HW founds an error or in HW init mb for error concealment if SW enables error concealment
13-12 SW_ERROR_CONC_MODE	Error concealment mode: 00b - disabled (normal decoding mode) 01b - enabled for direct mode MV usage starting from MB defined by sw_startmb_x, sw_startmb_y
11-0 —	Reserved.

14.1.5.1.10 Prediction filter tap register for H264 (SWREG49)

14.1.5.1.10.1 Offset

Register	Offset
SWREG49	C4h

14.1.5.1.10.2 Diagram



14.1.5.1.10.3 Fields

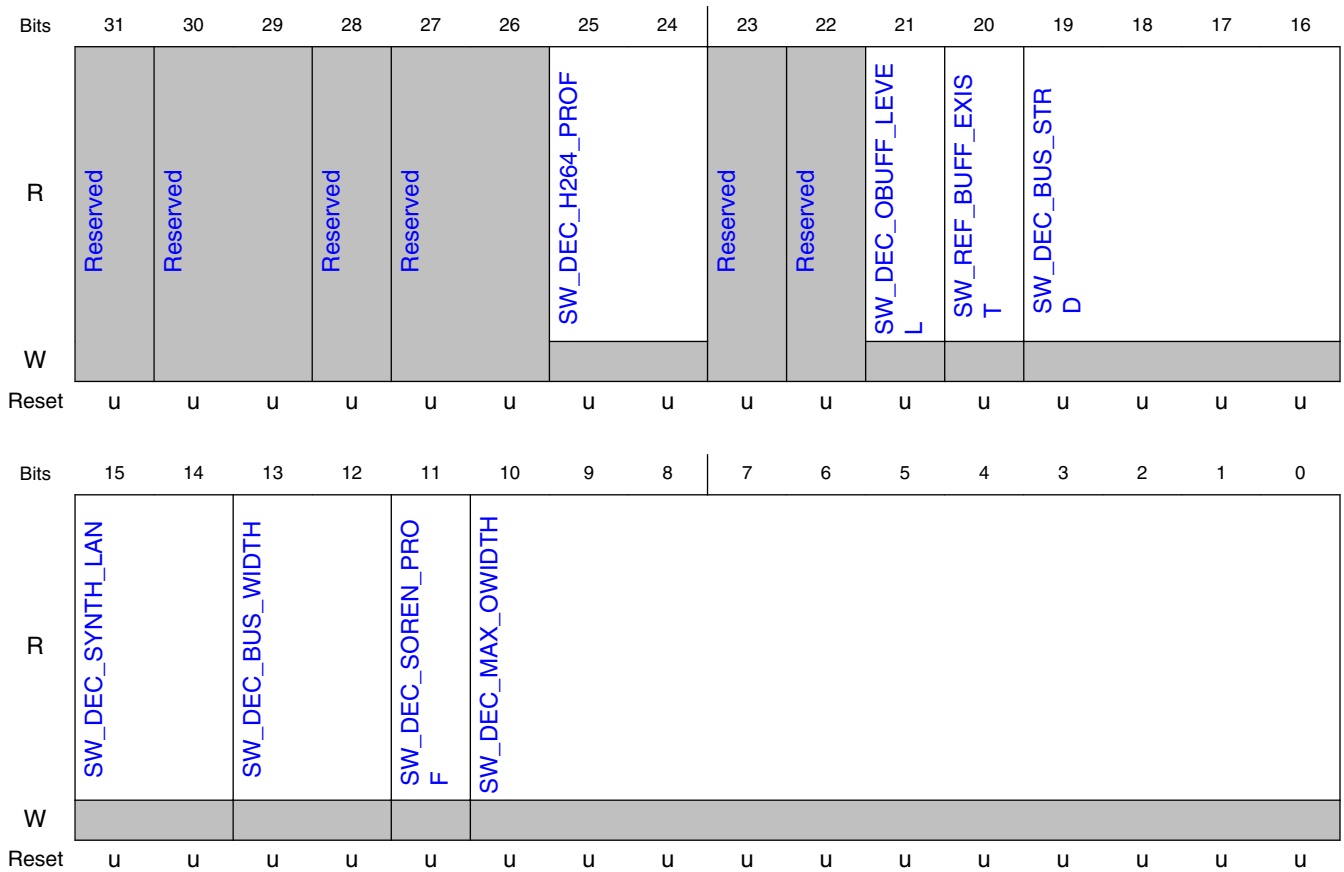
Field	Function
31-22 SW_PRED_BC_TAP_0_0	Prediction filter set 0, tap 0
21-12 SW_PRED_BC_TAP_0_1	Prediction filter set 0, tap 1
11-2 SW_PRED_BC_TAP_0_2	Prediction filter set 0, tap 2
1-0 —	Reserved.

14.1.5.1.11 Synthesis configuration register decoder 0 (SWREG50)

14.1.5.1.11.1 Offset

Register	Offset
SWREG50	C8h

14.1.5.1.11.2 Diagram



14.1.5.1.11.3 Fields

Field	Function
31 —	Reserved.
30-29 —	Reserved.
28 —	Reserved.
27-26 —	Reserved.
25-24 SW_DEC_H264_PROF	Decoding format support, H.264 00b - not supported 01b - supported up to baseline profile 10b - supported up to high profile labeled stream with restricted high profile tools (Tools that are used in Hantro 7280, 8270 encoder) 11b - supported up to high profile

Table continues on the next page...

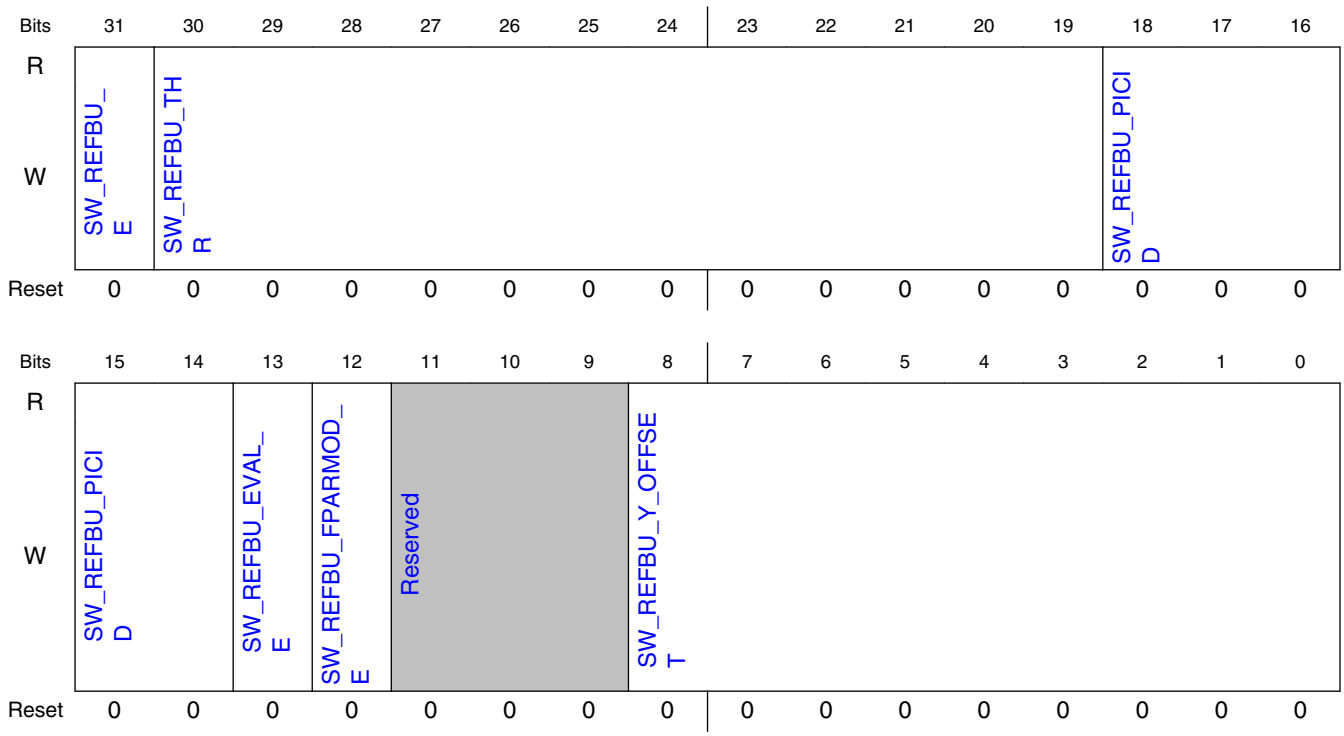
Field	Function
23 —	Reserved.
22 —	Reserved.
21 SW_DEC_OBUFF_LEVEL	Decoder output buffer level: 0b - 1 MB buffering is used 1b - 4 MB buffering is used
20 SW_REF_BUFF_EXIST	Reference picture buffer usage: 0b - not supported 1b - reference buffer is used
19-16 SW_DEC_BUS_STRD	Connected to standard bus: 0000b - error 0001b - AHB master, AHB slave 0010b - OCP master, OCP slave 0011b - AXI master, AXI slave 0100b - AXI master, APB slave 0101b - AXI master, AHB slave
15-14 SW_DEC_SYNTH_LAN	00b - error 01b - vhdl 10b - verilog
13-12 SW_DEC_BUS_WIDTH	00b - error 01b - 32 bit bus 10b - 64 bit bus 11b - 128 bit bus
11 SW_DEC_SOREN_PROF	Decoding format support, Sorenson 0b - not supported 1b - supported
10-0 SW_DEC_MAX_OWIDTH	Max configured decoder video resolution that can be decoded. Informed as width of the picture in pixels.

14.1.5.1.12 Reference picture buffer control register (SWREG51)

14.1.5.1.12.1 Offset

Register	Offset
SWREG51	CCh

14.1.5.1.12.2 Diagram



14.1.5.1.12.3 Fields

Field	Function
31 SW_REFBU_E	Refer picture buffer enable: 0b - refer picture buffer disabled 1b - refer picture buffer enabled. Valid if picture size is QVGA or more.
30-19 SW_REFBU_THR	Reference buffer disable threshold value (cache miss amount). Used to buffer shut down (if more misses than allowed)
18-14 SW_REFBU_PICID	The used reference picture ID for reference buffer usage
13 SW_REFBU_EVAL_E	Enable for HW internal reference ID calculation. If given threshold level is reached by any picture_id after first MB row, that picture_id is used for reference buffer fill for rest of the picture
12 SW_REFBU_FPARMOD_E	Field parity mode enable. Used in refbufferd evaluation mode. 0b - use the result field of the evaluation 1b - use the parity mode field
11-9 —	Reserved.
8-0 SW_REFBU_Y_OFFSET	Y offset for refbufferd. This coordinate is used to compensate the global motion of the video for better buffer hit rate

14.1.5.1.13 Reference picture buffer information register 1 (SWREG52)

14.1.5.1.13.1 Offset

Register	Offset
SWREG52	D0h

14.1.5.1.13.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

14.1.5.1.14.3 Fields

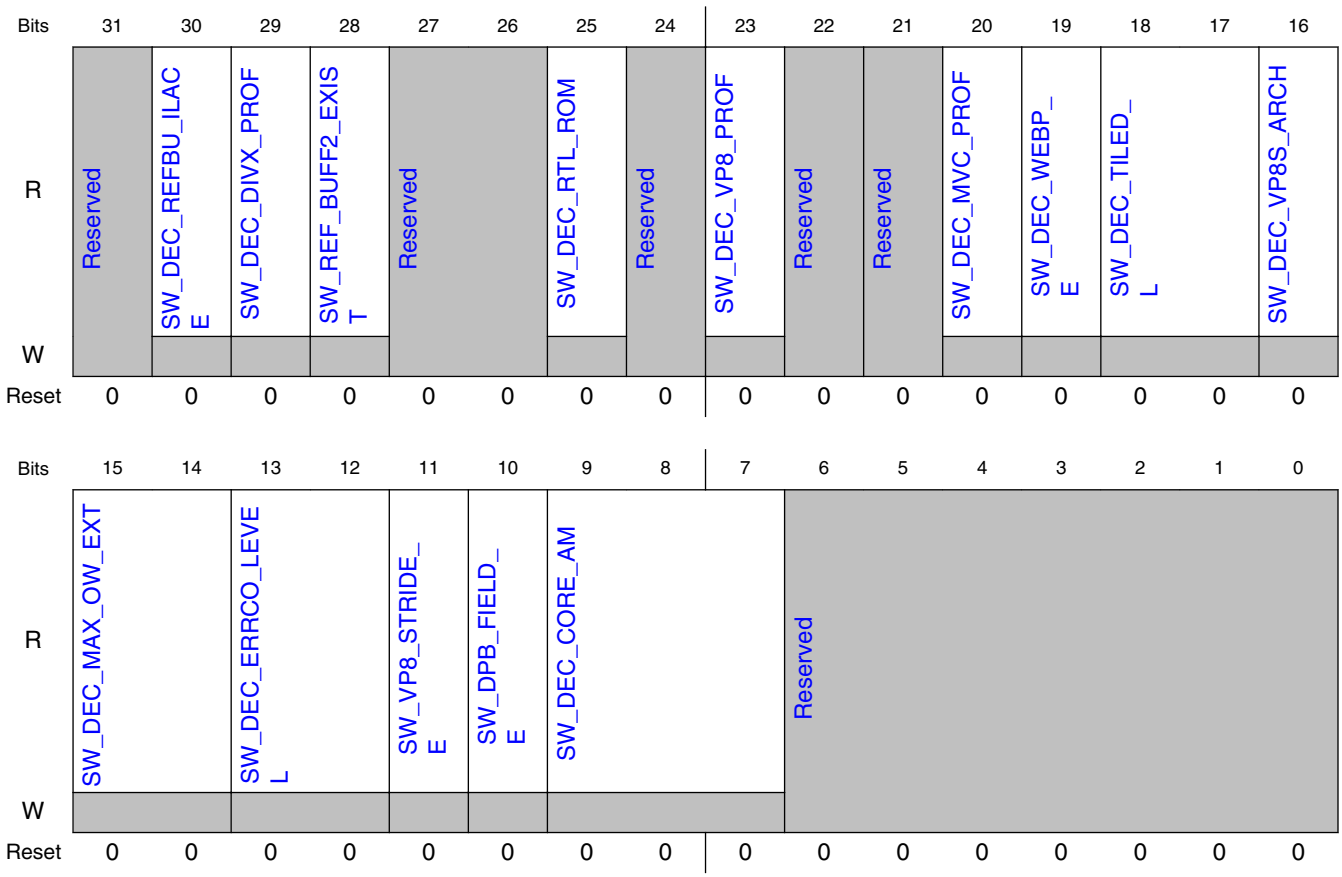
Field	Function
31-22 —	Reserved.
21-0 SW_REFBU_Y_MV_SUM	The sum of the decoded motion vector y-components of the picture. The first luminance motion vector of each MB is used in calculation. Other motion vectors of the MB are discarded. Each motion vector is saturated between -256 - 255 before calculation. The proceeding of the HW calculation can be read during HW decoding.

14.1.5.1.15 Synthesis configuration register decoder 1 (SWREG54)

14.1.5.1.15.1 Offset

Register	Offset
SWREG54	D8h

14.1.5.1.15.2 Diagram



14.1.5.1.15.3 Fields

Field	Function
31 —	Reserved.
30 SW_DEC_REFBU_ILACE	Refbufferd support for interlaced content: 0b - not supported 1b - supported
29 SW_DEC_DIVX_PROF	DIVX Support: 0b - not supported 1b - supported
28 SW_REF_BUFF2_EXIST	Reference picture buffer 2 usage: 0b - not supported 1b - reference buffer 2 is used
27-26 —	Reserved.
25	ROM implementation type (If design includes ROMs) 0b - ROMs are implemented from actual ROM units

Table continues on the next page...

Field	Function
SW_DEC_RTL_ROM	1b - ROMs are implemented from RTL
24 —	Reserved.
23 SW_DEC_VP8_PROF	Decoding format support, VP8 0b - not supported 1b - supported
22 —	Reserved.
21 —	Reserved.
20 SW_DEC_MVC_PROF	Decoding format support, MVC 0b - not supported 1b - supported
19 SW_DEC_WEBP_E	Decoding format support, Web-p 0b - not supported bigger than 1080p resolution 1b - supported upto 16kx16k pixel resolution (defined max)
18-17 SW_DEC_TILED_L	Tiled mode support level 00b - not supported 01b - supported with 8x4 tile size for progressive content 10b - supported with 8x4 tile size for progressive/ilaced content
16 SW_DEC_VP8S_ARCH	VP8 Architecture type (for prediction) 0b - Same prediction architecture as for other decoding formats 1b - Dedicated small architecture for VP8 (refbuffer cannot be used either)
15-14 SW_DEC_MAX_OW_EXT	Max configured decoder video resolution that can be decoded. This is the MSB part of the configuration signal
13-12 SW_DEC_ERRCO_LEVEL	Decoder error concealment support level: 00b - Error concealment not supported (only error detection) 01b - VP8 direct mode motion vector error concealment supported
11 SW_VP8_STRIDE_E	Decoder output stride support for VP8. Separate base addresses for Y/C data and possibility to set scanline bigger than picture width: 0b - not supported, Y and C tables attached. 1b - supported, Y and C tables can be set freely.
10 SW_DPB_FIELD_E	DPB field separate mode support for ilaced content: 0b - Not supported. For ilaced content, DPB is ilaced frame order. 1b - Supported. For ilaced content, DPB can consist of ilaced frames or separate fields (TOP/BOT).
9-7 SW_DEC_CORE_AM	Decoder core amount. If other than 0, the multicore can be used. Each individual cores can be identified from corresponding core ID register: 000b - single core decoder 001b - dual core decoder 010b - 3 core decoder 011b - 4 core decoder 100b - 5 core decoder 101b - 6 core decoder 110b - 7 core decoder 111b - 8 core decoder

Table continues on the next page...

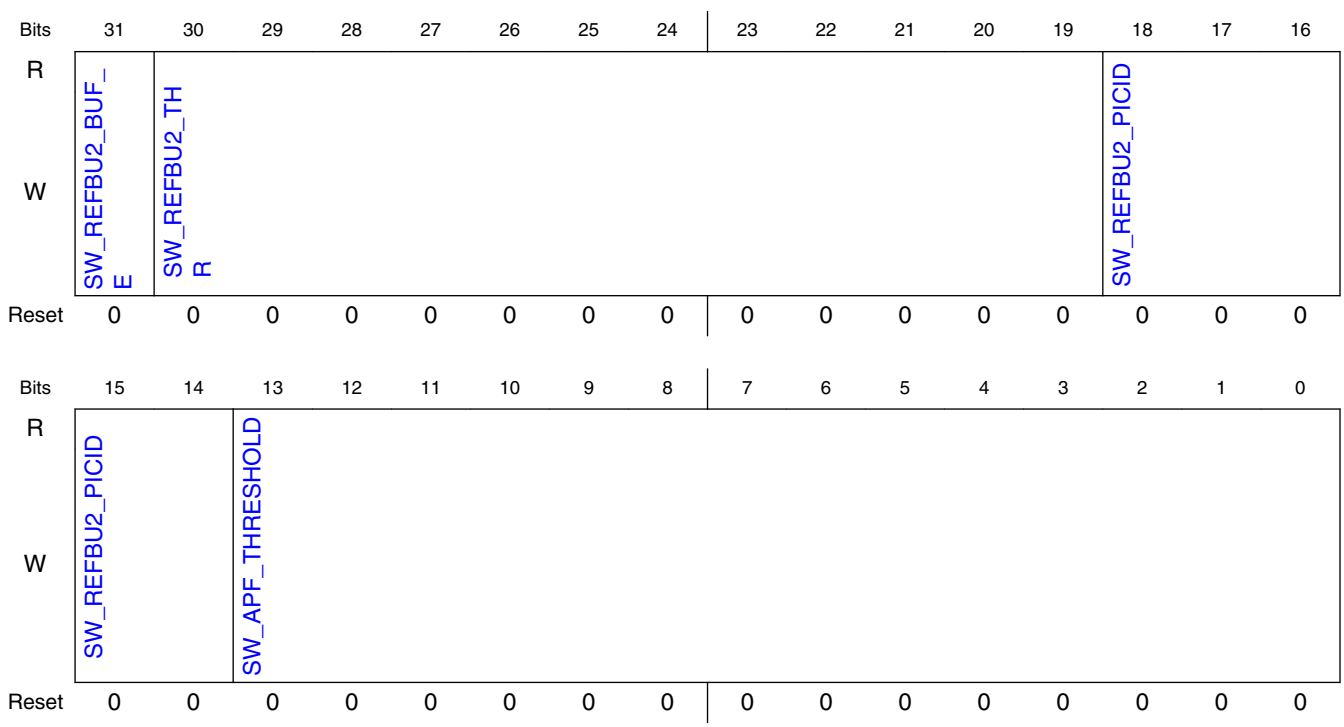
Field	Function
6-0 —	Reserved.

14.1.5.1.16 Reference picture buffer 2 / Advanced prefetch control register (SWREG55)

14.1.5.1.16.1 Offset

Register	Offset
SWREG55	DCh

14.1.5.1.16.2 Diagram



14.1.5.1.16.3 Fields

Field	Function
31 SW_REFBU2_BUF_E	Refer picture buffer 2 enable: 0b - refer picture buffer disabled

Table continues on the next page...

Field	Function
	1b - refer picture buffer enabled. Valid if picture size is QVGA or more (can be turned of by HW if threshold value reached).
30-19 SW_REFBU2_THR	Reference buffer disable threshold value (buffer miss amount). Used to buffer shut down (if more misses than allowed)
18-14 SW_REFBU2_PICID	The used reference picture ID for reference buffer usage
13-0 SW_APF_THRESHOLD	G1 decoder and later :Advanced prefetch threshold value. If current MB exceeds the threshold the advanced mode is not used. Value 0 disables threshold usage and advanced prefetch usage is restricted by internal memory limitation only

14.1.5.1.17 Reference buffer information register 3 (SWREG56)

14.1.5.1.17.1 Offset

Register	Offset
SWREG56	E0h

18 FUSE_DEC_MVC	1 = MVC enabled (requires also H264 to be enabled)
17 —	Reserved.
16 FUSE_DEC_MAXW_4K	1 = Max video width up to 4096 pixels enabled. Priority coded with priority 1.
15 FUSE_DEC_MAXW_1920	1 = Max video width up to 1920 pixels enabled. Priority coded with priority 2.

Table continues on the next page...

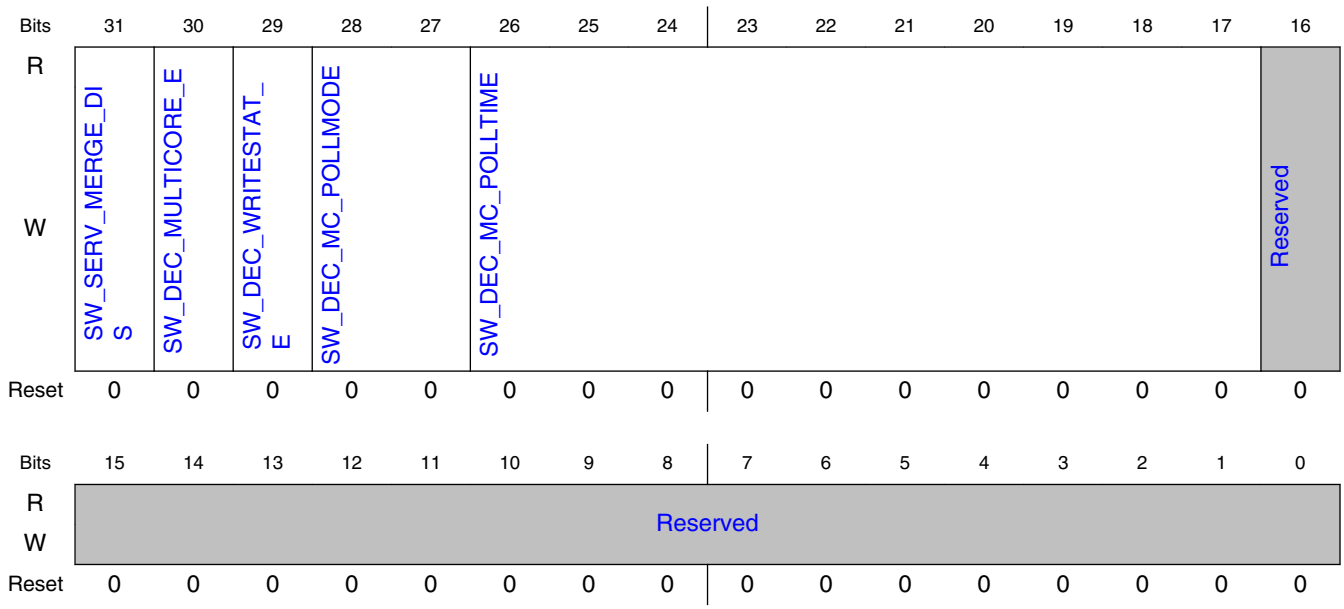
Field	Function
14 FUSE_DEC_MAXW_1280	1 = Max video width up to 1280 pixels enabled. Priority coded with priority 3.
13 FUSE_DEC_MAXW_720	1 = Max video width up to 720 pixels enabled. Priority coded with priority 4.
12 FUSE_DEC_MAXW_352	1 = Max video width up to 352 pixels enabled. Priority coded with priority 5.
11-8 —	Reserved.
7 FUSE_DEC_REFBUFFER	1 = reference buffer used
6-0 —	Reserved.

14.1.5.1.19 Device configuration register decoder 2 + Multi core control register (SWREG58)

14.1.5.1.19.1 Offset

Register	Offset
SWREG58	E8h

14.1.5.1.19.2 Diagram



14.1.5.1.19.3 Fields

Field	Function
31 SW_SERV_MERGE_DIS	Decoder service merge disable: 0b - HW merges simultaneous sub-block requests internally if they are same type (read or write). 1b - decoder serves one sub-block per service and merging is disabled.
30 SW_DEC_MULTICORE_E	Decoder multi core enable: 0b - Multi core disabled or only one core exists in design. 1b - Multi core enable. Each reference picture status must be verified from external memory status field before usage. 128 bits status word exists after each reference picture and include picture proceeding coordinates Y and X.
29 SW_DEC_WRITESTAT_E	Decoder write statusword enable. Must be high if multi core decoding enabled. HW writes output picture data proceeding to external memory after picture data (and after H264 direct mode MVS if they exist)
28-27 SW_DEC_MC_POLLMODE	Decoder multicore status reading mode: 00b - HW internal status polling mechanism is used. Status of reference picture is read only when required coordinate for the reference picture is not big enough. If the status is still not big enough after reading it the HW waits N clock cycles per pixel from the coordinate difference. The N is defined by the sw_dec_mc_polltime (range 0...4). 01b - Dummy status polling mechanism is used for all reference pictures. HW reads status of all reference pictures at frequency defined by sw_dec_mc_polltime.
26-17 SW_DEC_MC_POLLTIME	sw_dec_mc_polltime definition depends on sw_dec_mc_mode. if mode is 0 (HW internal mechanism) the sw_dec_mc_polltime: • 0 = 1/4 cycles per pixel • 1 = wait 1/2 cycles per pixel • 2 = wait one cycle per pixel • 3 = wait 2 cycles per pixel • 4=wait 4 cycles per pixel

Table continues on the next page...

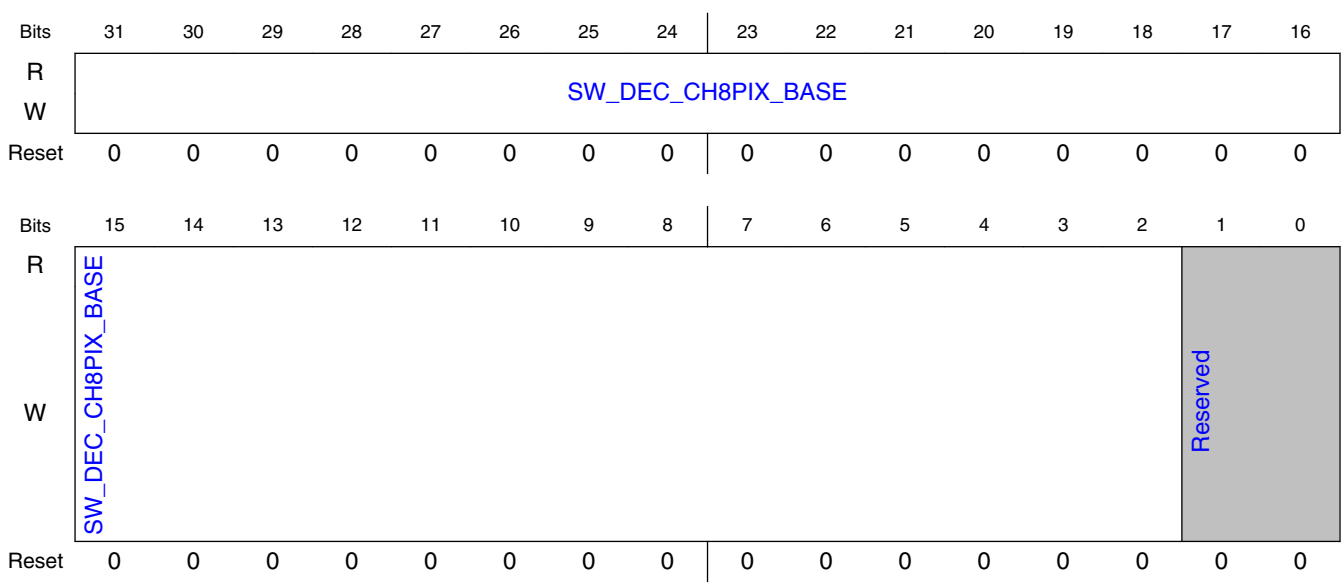
Field	Function
	For dummy polling mechanism the sw_dec_mc_polltime defines the amount cycles between status reads x1024: • 0 = wait 1024 cycles between status reading • 1 = wait 2048 cycles between status reading • 2 = wait 3072 cycles between status reading • N = wait (N+1)x1024 cycles
16-0 —	Reserved.

14.1.5.1.20 H264 Chrominance 8 pixel interleaved data base (SWREG59)

14.1.5.1.20.1 Offset

Register	Offset
SWREG59	ECh

14.1.5.1.20.2 Diagram



14.1.5.1.20.3 Fields

Field	Function
31-2	Base address for additional chrominance data format where chrominance is interleaved in group of 8 pixels. The usage is enabled by sw_ch_8pix_ileav_e

Table continues on the next page...

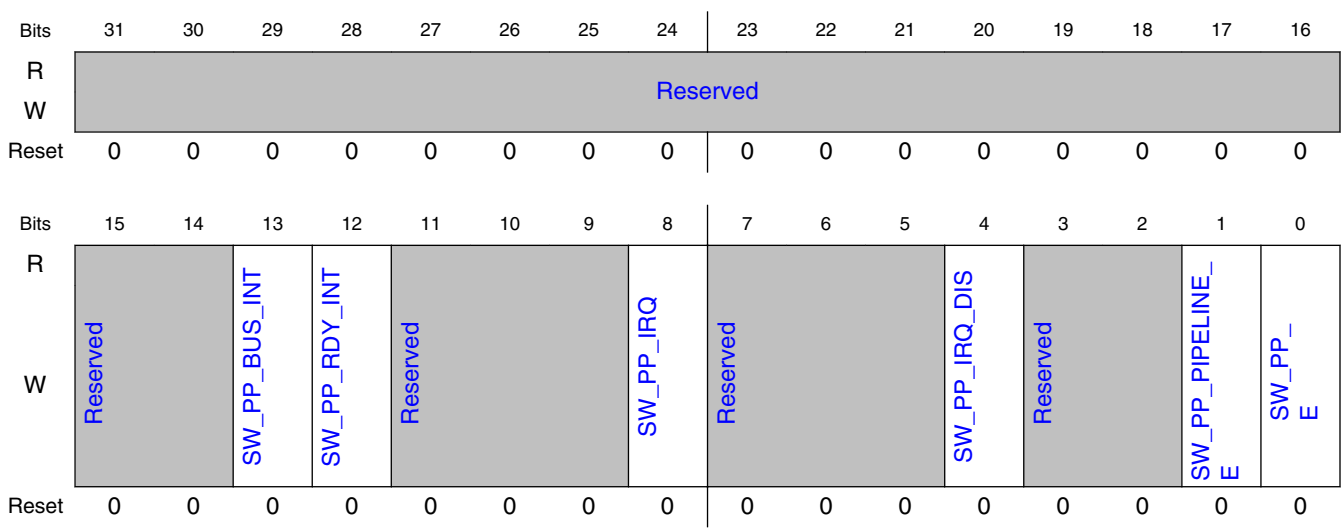
Field	Function
SW_DEC_CH8PIX_BASE	
1-0 —	Reserved.

14.1.5.1.21 Interrupt register post-processor (SWREG60)

14.1.5.1.21.1 Offset

Register	Offset
SWREG60	F0h

14.1.5.1.21.2 Diagram



14.1.5.1.21.3 Fields

Field	Function
31-14 —	Reserved.
13 SW_PP_BUS_INT	Interrupt status bit bus. Error response from bus. In pipeline mode this bit is not used

Table continues on the next page...

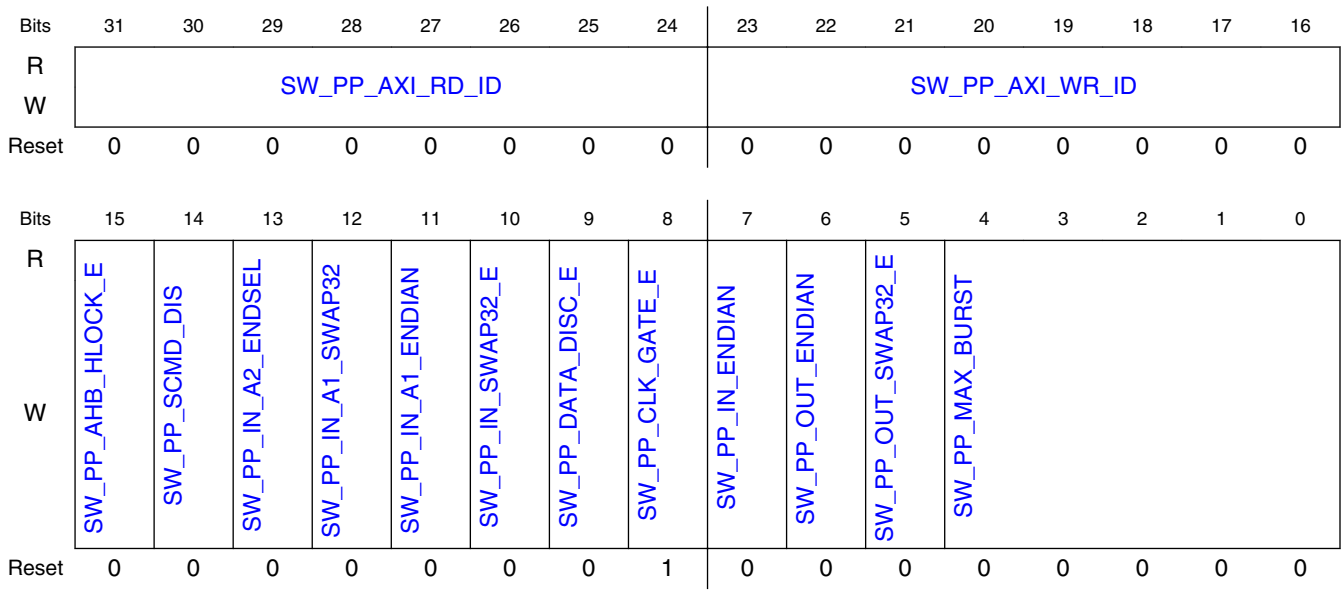
Field	Function
12 SW_PP_RDY_INT	Interrupt status bit pp. When this bit is high post processor has processed a picture in external mode. In pipeline mode this bit is not used.
11-9 —	Reserved.
8 SW_PP_IRQ	Post-processor IRQ. SW will reset this after interrupt is handled. HINTpp is not used for pp if IRQ disable pp is high (sw_pp_irq_n_e = 1). In pipeline mode this bit is not used
7-5 —	Reserved.
4 SW_PP_IRQ_DIS	Post-processor IRQ disable. When high, there are no interrupts from HW concerning post processing. Polling must be used to see the interrupt
3-2 —	Reserved.
1 SW_PP_PIPELINE_E	Decoder – post-processing pipeline enable: 0b - Post-processing is processing different picture than decoder or is disabled 1b - Post-processing is performed in pipeline with decoder
0 SW_PP_E	External mode post-processing enable. This bit will start the post-processing operation. Not to be used if PP is in pipeline with decoder (sw_pp_pipeline_e = 1). HW will reset this when picture is post-processed.

14.1.5.1.22 Device configuration register post-processor (SWREG61)

14.1.5.1.22.1 Offset

Register	Offset
SWREG61	F4h

14.1.5.1.22.2 Diagram



14.1.5.1.22.3 Fields

Field	Function
31-24 SW_PP_AXI_RD_ID	Read ID used for AXI PP read services (if connected to AXI)
23-16 SW_PP_AXI_WR_ID	Write ID used for AXI PP write services (if connected to AXI)
15 SW_PP_AHB_HLOCK_E	AHB master HLOCK enable. When high the service is locked to pp as long as it needs the bus (whenever pp requests the bus it will be granted)
14 SW_PP_SCMD_DIS	9170 decoder: AXI Single Command Multiple Data disable. 9170 axi wrapper supports this mode by default (where only the first addresses of the burst are given from address generator). This bit is used to disable the feature (possible SW workaround if something is not working correctly)
13 SW_PP_IN_A2_ENDSEL	Endian/swap select for Alpha blend input source 2: 0b - Use PP in endian/swap definitions (sw_pp_in_endian, sw_pp_in_swap) 1b - Use Ablend source 1 endian/swap definitions (sw_pp_in_a1_endian, sw_pp_in_a1_swap)
12 SW_PP_IN_A1_SWAP32	Alpha blend source 1 input 32bit data swap (may be used for 64 bit environment): 0b - no swapping of 32 bit words 1b - 32 bit data words are swapped (needed in 64 bit environment to achieve 7-6-5-4-3-2-1-0 byte order(also little endian should be enabled))
11 SW_PP_IN_A1_ENDIAN	Alpha blend source 1 input data byte endian mode. 0b - Big endian (0-1-2-3 order) 1b - Little endian (3-2-1-0 order)
10	PP input 32bit data swap (may be used for 64 bit environment):

Table continues on the next page...

Field	Function
SW_PP_IN_SWAP32_E	0b - no swapping of 32 bit words 1b - 32 bit data words are swapped (needed in 64 bit environment to achieve 7-6-5-4-3-2-1-0 byte order(also little endian should be enabled))
9 SW_PP_DATA_DISC_E	PP data discard enable. Precise burst lengths are used with reading services. Extra data is discarded internally. Note. If AHB maxburst 17 is used data discard cannot be enabled (causes conflict)
8 SW_PP_CLK_GATE_E	PP dynamic clock gating enable. **NOTE:** Clock gating value can be changed only when PP is not enabled. 0b - Clock is running for all PP structures 1b - Clock is gated from PP structures that are not used
7 SW_PP_IN_ENDIAN	PP input picture byte endian mode. Used only if PP is in standalone mode. If PP is running pipelined with the decoder, this bit has no effect. 0b - Big endian (0-1-2-3 order) 1b - Little endian (3-2-1-0 order)
6 SW_PP_OUT_ENDIAN	PP output picture endian mode for YCbCr data or for any data if config value SW_PP_OEN_VERSION = 1. **NOTE:** For SW_PP_OEN_VERSION=0, 16 bit RGB data, this bit works as pixel swapping bit. For 32 bit RGB, this bit has no meaning. 0b - Big endian (0-1-2-3 order) 1b - Little endian (3-2-1-0 order)
5 SW_PP_OUT_SWAP32_E	PP output data word swap (may be used for 64 bit environment): 0b - no swapping of 32 bit words 1b - 32 bit data words are swapped (needed in 64 bit environment to achieve 7-6-5-4-3-2-1-0 byte order (also little endian should be enabled))
4-0 SW_PP_MAX_BURST	Maximum burst length for PP bus transactions. Valid values: AHB: 1, 4, 8 , 16 and 17. Other values will result in INCR type (undefined length) transfers. 17 = fixed bursts are used when possible. INCR bursts for others. OCP: 16-31 AXI: 1-16

14.1.5.1.23 Deinterlace control register (SWREG62)

14.1.5.1.30.3 Fields

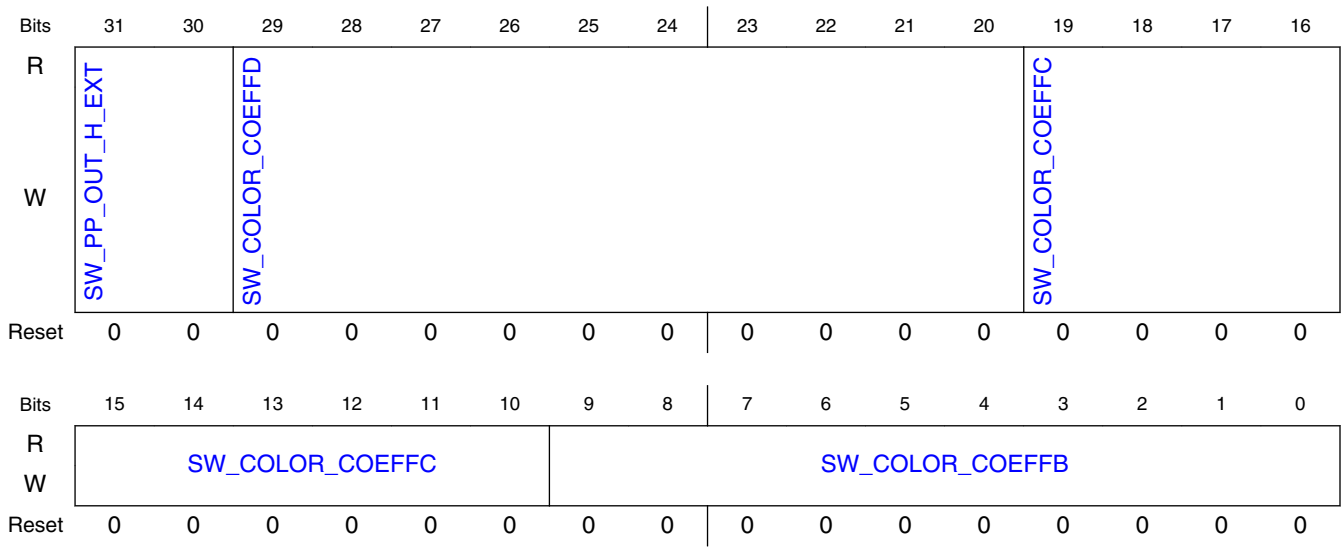
Field	Function
31 SW_PP_IN_START_CH	For YUYV 422 input format. Enable for start_with_chrominance. 0b - the order is Y0CbY0Cr or Y0CrY0Cb 1b - the order is CbY0CrY0 or CrY0CbY0
30 SW_PP_IN_CR_FIRST	For YUYV 422 input format. Enable for Cr first (before Cb). 0b - the order is Y0CbY0Cr or CbY0CrY0 (if 420 semiplanar chrominance: CbCrCbCr) 1b - the order is Y0CrY0Cb or CrY0CbY0 (if 420 semiplanar chrominance: CrCbCrCb)
29 SW_PP_OUT_START_CH	For YUYV 422 output format. Enable for start_with_chrominance. 0b - the order is Y0CbY0Cr or Y0CrY0Cb 1b - the order is CbY0CrY0 or CrY0CbY0
28 SW_PP_OUT_CR_FIRST	For YUYV 422 output format. Enable for Cr first (before Cb). 0b - the order is Y0CbY0Cr or CbY0CrY0 1b - the order is Y0CrY0Cb or CrY0CbY0
27-18 SW_COLOR_COEFFA2	Coefficient a2, used with Y pixel to calculate all color components
17-8 SW_COLOR_COEFFA1	Coefficient a1, used with Y pixel to calculate all color components
7-0 SW_CONTRAST_THR2	Threshold value 2, used with contrast adjusting

14.1.5.1.31 Register for colour conversion 0 (SWREG70)

14.1.5.1.31.1 Offset

Register	Offset
SWREG70	118h

14.1.5.1.31.2 Diagram



14.1.5.1.31.3 Fields

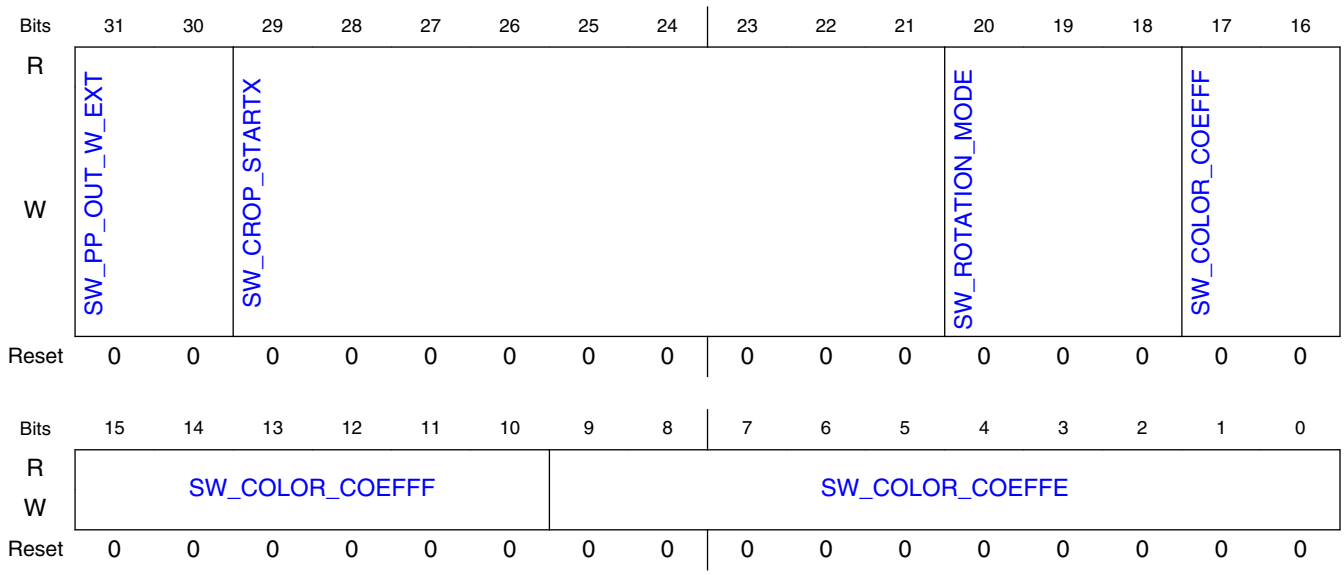
Field	Function
31-30 SW_PP_OUT_H_EXT	Extended output height for 4k resolution
29-20 SW_COLOR_COEFFD	Coefficient d, used with Cb to calculate green component value
19-10 SW_COLOR_COEFFC	Coefficient c, used with Cr to calculate green component value
9-0 SW_COLOR_COEFFB	Coefficient b, used with Cr to calculate red component value

14.1.5.1.32 Register for colour conversion 1 + rotation mode (SWREG71)

14.1.5.1.32.1 Offset

Register	Offset
SWREG71	11Ch

14.1.5.1.32.2 Diagram



14.1.5.1.32.3 Fields

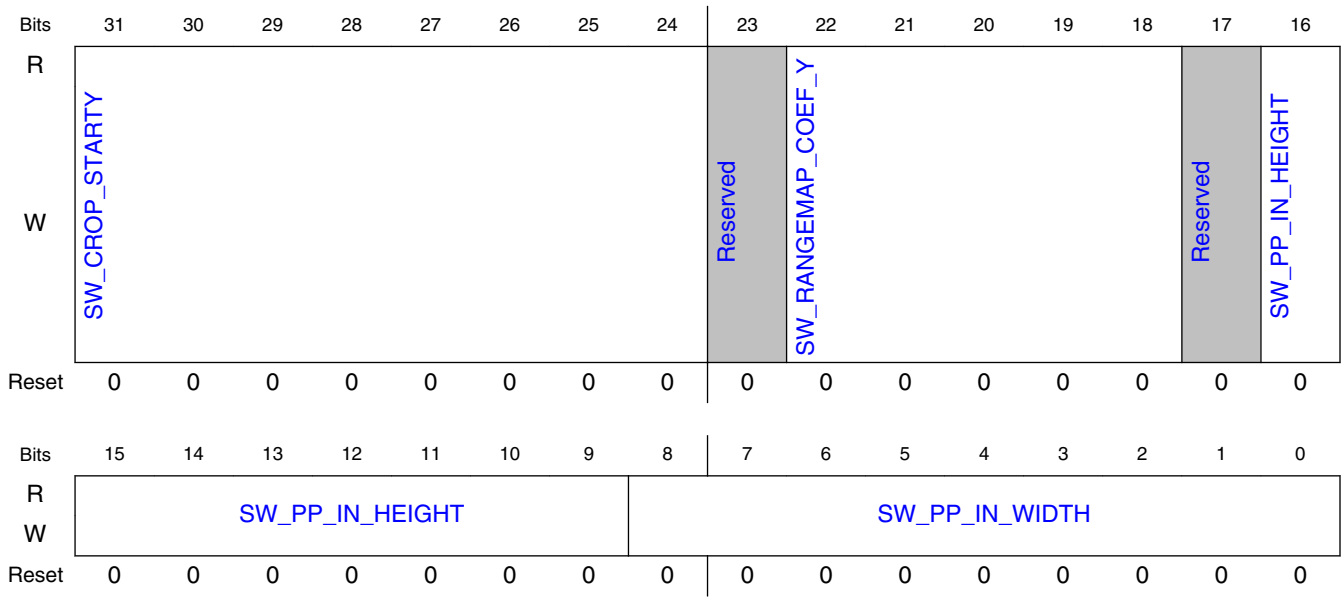
Field	Function
31-30 SW_PP_OUT_W_EXT	Extended output width for 4k resolution
29-21 SW_CROP_STARTX	Start coordinate x for the cropped area in macroblocks.
20-18 SW_ROTATION_MODE	Rotation mode: 000b - rotation disabled 001b - rotate + 90 010b - rotate – 90 011b - horizontal flip (mirror) 100b - vertical flip 101b - rotate 180
17-10 SW_COLOR_COEFFF	Coefficient f, used with Y to adjust brightness
9-0 SW_COLOR_COEFFE	Coefficient e, used with Cb to calculate blue component value

14.1.5.1.33 PP input size and -cropping register (SWREG72)

14.1.5.1.33.1 Offset

Register	Offset
SWREG72	120h

14.1.5.1.33.2 Diagram



14.1.5.1.33.3 Fields

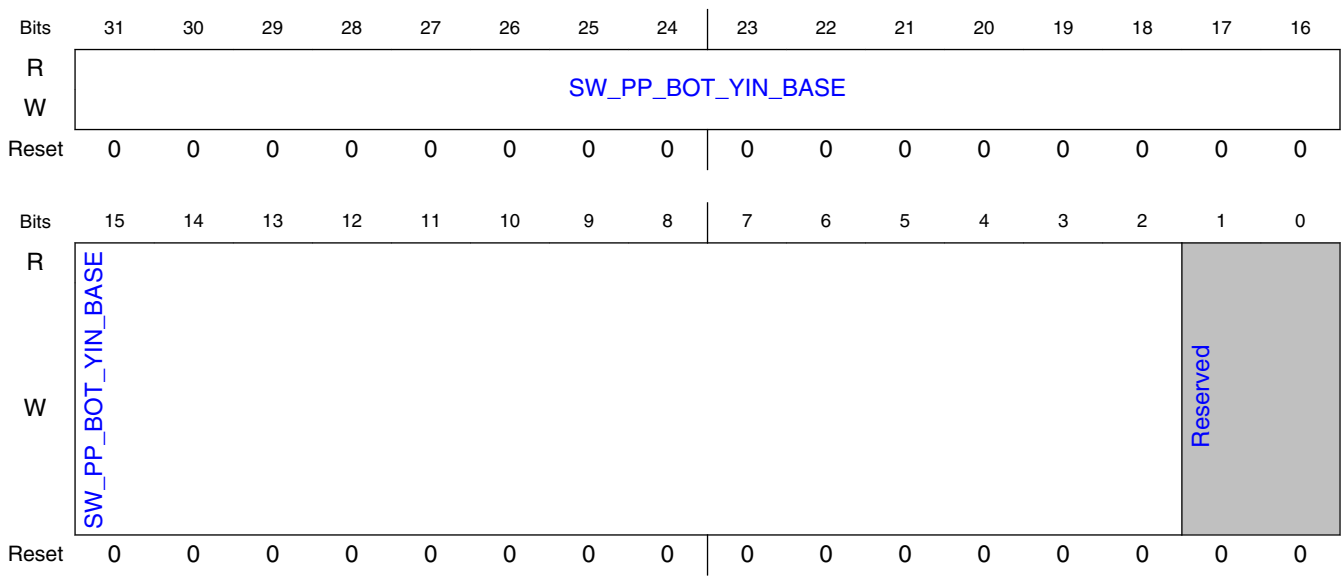
Field	Function
31-24 SW_CROP_STARTY	Start coordinate y for the cropped area in macroblocks.
23 —	Reserved.
22-18 SW_RANGEMAP_COEF_Y	Range map value for Y component
17 —	Reserved.
16-9 SW_PP_IN_HEIGHT	PP input picture height in MBs. Can be cropped from a bigger input picture in external mode
8-0 SW_PP_IN_WIDTH	PP input picture width in MBs. Can be cropped from a bigger input picture in external mode

14.1.5.1.34 PP input picture base address for Y bottom field (SWREG73)

14.1.5.1.34.1 Offset

Register	Offset
SWREG73	124h

14.1.5.1.34.2 Diagram



14.1.5.1.34.3 Fields

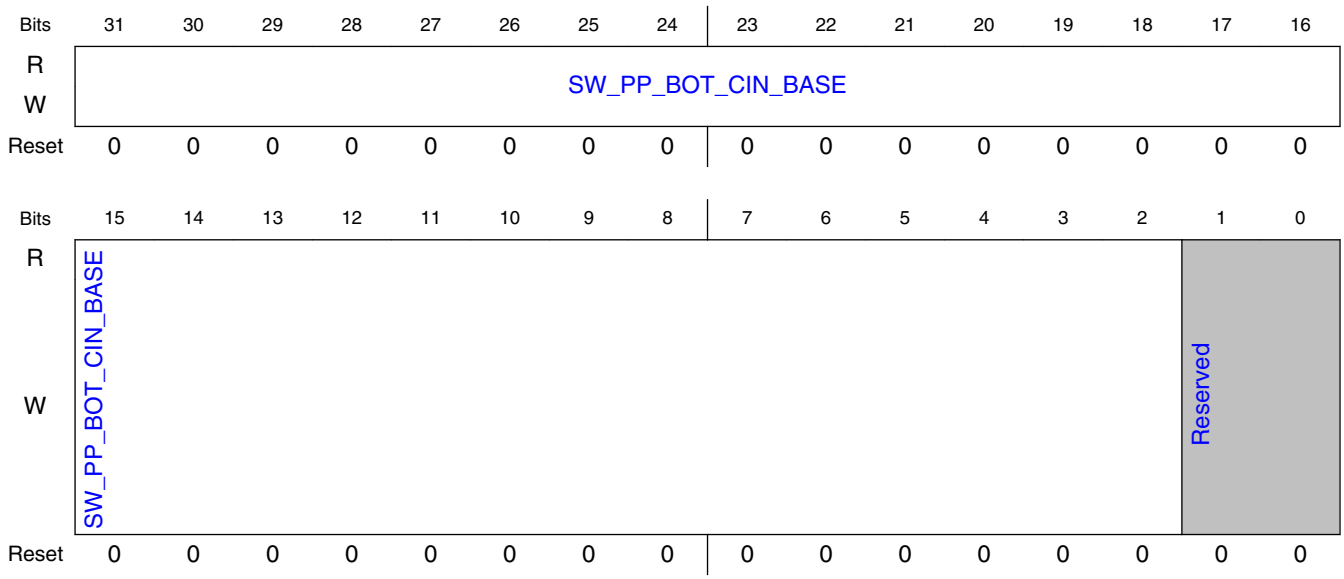
Field	Function
31-2 SW_PP_BOT_YIN_BASE	PP input Y base for bottom field
1-0 —	Reserved.

14.1.5.1.35 PP input picture base for Ch bottom field (SWREG74)

14.1.5.1.35.1 Offset

Register	Offset
SWREG74	128h

14.1.5.1.35.2 Diagram



14.1.5.1.35.3 Fields

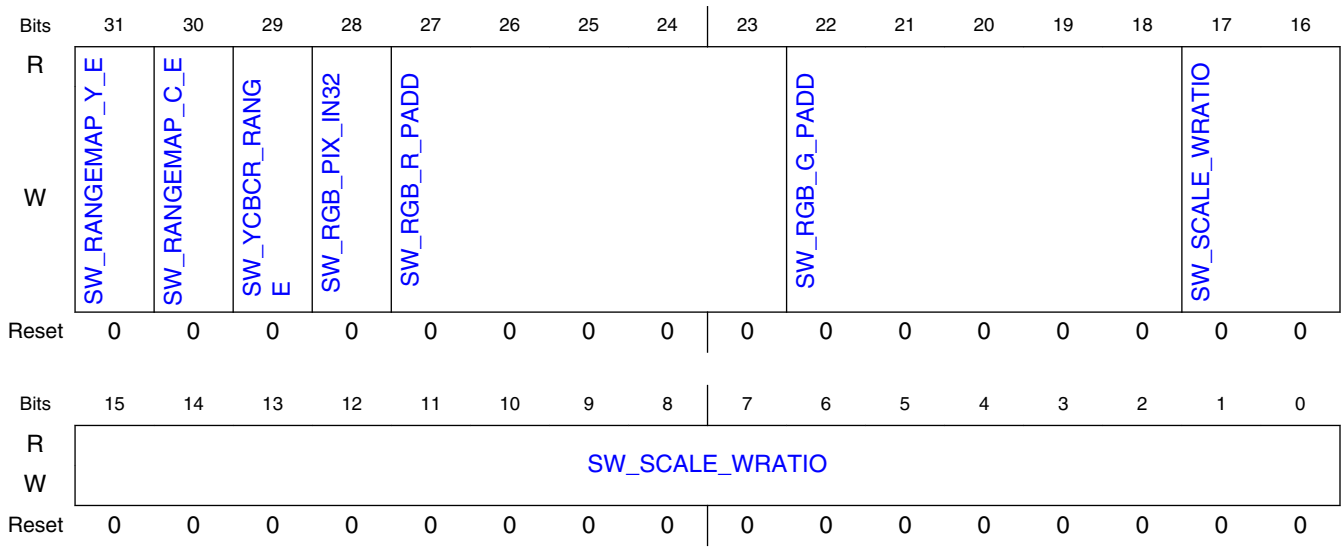
Field	Function
31-2 SW_PP_BOT_CIN_BASE	PP input C base for bottom field (mixed chrominance)
1-0 —	Reserved.

14.1.5.1.36 Scaling register 0 ratio and padding for R and G (SWREG79)

14.1.5.1.36.1 Offset

Register	Offset
SWREG79	13Ch

14.1.5.1.36.2 Diagram



14.1.5.1.36.3 Fields

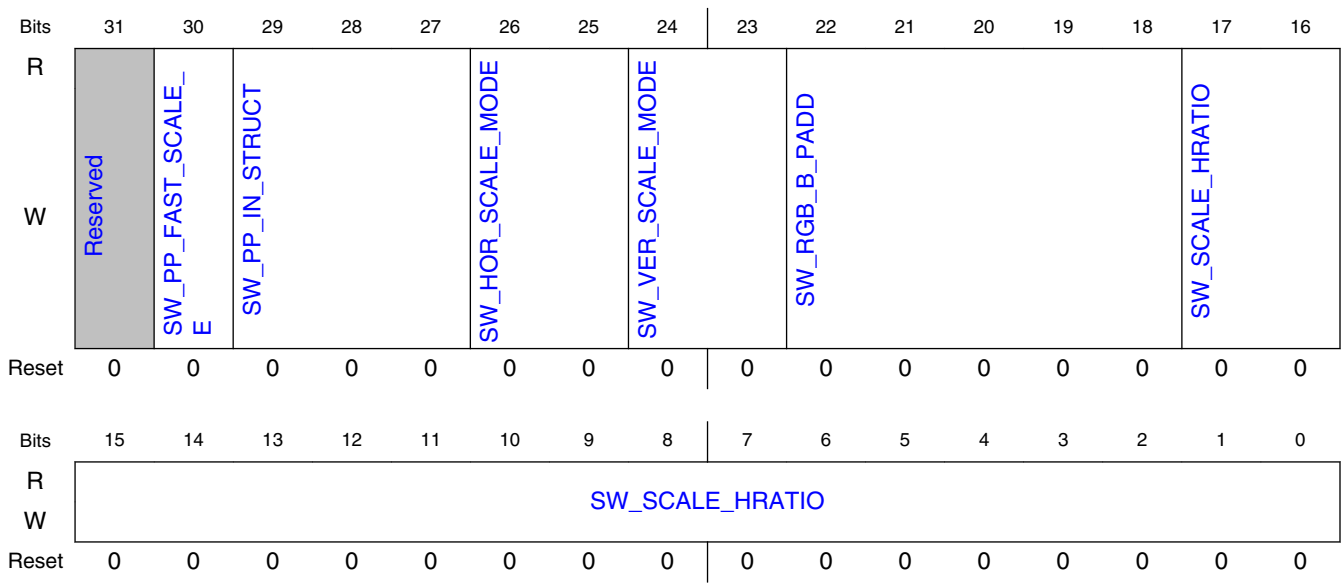
Field	Function
31 SW_RANGEMAP_Y_E	Range map enable for Y component
30 SW_RANGEMAP_C_E	Range map enable for chrominance component
29 SW_YCBCR_RANGE	Defines the YCbCr range in RGB conversion: 0b - 16…235 for Y, 16…240 for Chrominance. 1b - 0…255 for all components
28 SW_RGB_PIX_IN32	RGB pixel amount/ 32 bit word 0b - 1 RGB pixel/32 bit 1b - 2 RGB pixels/32 bit
27-23 SW_RGB_R_PADD	Amount of ones that will be padded in front of the R-component
22-18 SW_RGB_G_PADD	Amount of ones that will be padded in front of the G-component
17-0 SW_SCALE_WRATIO	Scaling ratio for width (outputw-1/inputw-1)

14.1.5.1.37 Scaling ratio register 1 and padding for B (SWREG80)

14.1.5.1.37.1 Offset

Register	Offset
SWREG80	140h

14.1.5.1.37.2 Diagram



14.1.5.1.37.3 Fields

Field	Function
31 —	Reserved.
30 SW_PP_FAST_SCALE_E	0b - fast downscaling is not enabled 1b - fast downscaling is enabled. The quality of the picture is decreased but performance is improved.
29-27 SW_PP_IN_STRUCT	PP input data picture structure: 000b - Top field / progressive frame structure: Read input data from top field base address /frame base address and read every line. 001b - Bottom field structure: Read input data from bottom field base address and read every line. 010b - Interlaced field structure: Read input data from both top and bottom field base address and take every line from each field. 011b - Interlaced frame structure: Read input data from both top and bottom field base address and take every second line from each field. 100b - Ripped top field structure: Read input data from top field base address and read every second line.

Table continues on the next page...

Field	Function
	101b - Ripped bottom field structure: Read input data from bottom field base address and read every second line.
26-25 SW_HOR_SCALE_MODE	Horizontal scaling mode: 00b - Off 01b - Upscale 10b - Downscale
24-23 SW_VER_SCALE_MODE	Vertical scaling mode: 00b - Off 01b - Upscale 10b - Downscale
22-18 SW_RGB_B_PADD	Amount of ones that will be padded in front of the B-component
17-0 SW_SCALE_HRATIO	Scaling ratio for height (outputh-1/inputh-1)

14.1.5.1.38 Scaling ratio register 2 (SWREG81)

14.1.5.1.38.1 Offset

14.1.5.1.41.3 Fields

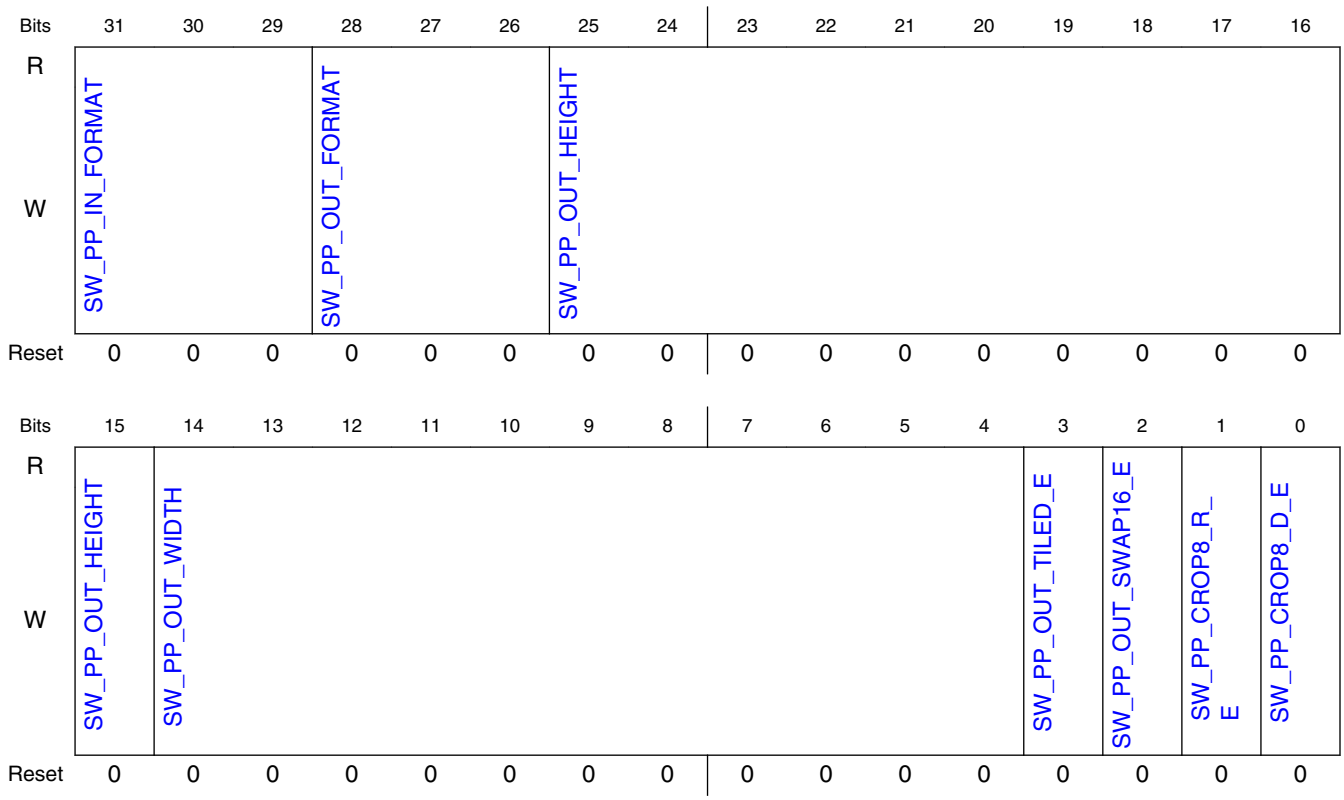
Field	Function
31-0 SW_B_MASK	Bit mask for B component (and alpha channel)

14.1.5.1.42 Post-processor control register (SWREG85)

14.1.5.1.42.1 Offset

Register	Offset
SWREG85	154h

14.1.5.1.42.2 Diagram



14.1.5.1.42.3 Fields

Field	Function
31-29 SW_PP_IN_FORMAT	PP input picture data format 000b - YUYV 4:2:2 interleaved (supported only in external mode) 001b - YCbCr 4:2:0 Semi-planar in linear raster-scan format 010b - YCbCr 4:2:0 planar (supported only in external mode) 011b - YCbCr 4:0:0 (supported only in pipelined mode) 100b - YCbCr 4:2:2 Semi-planar (supported only in pipelined mode) 101b - YCbCr 4:2:0 Semi-planar in tiled format (supported only in external mode (8170 decoder only) 110b - Reserved 111b - Escape pp input data format. Defined in swreg86.
28-26 SW_PP_OUT_FORMAT	PP output picture data format: 000b - RGB 001b - YCbCr 4:2:0 planar (Not supported) 010b - YCbCr 4:2:2 planar (Not supported) 011b - YUYV 4:2:2 interleaved 100b - YCbCr 4:4:4 planar (Not supported) 101b - YCh 4:2:0 chrominance interleaved 110b - YCh 4:2:2 (Not supported) 111b - YCh 4:4:4 (Not supported)

Table continues on the next page...

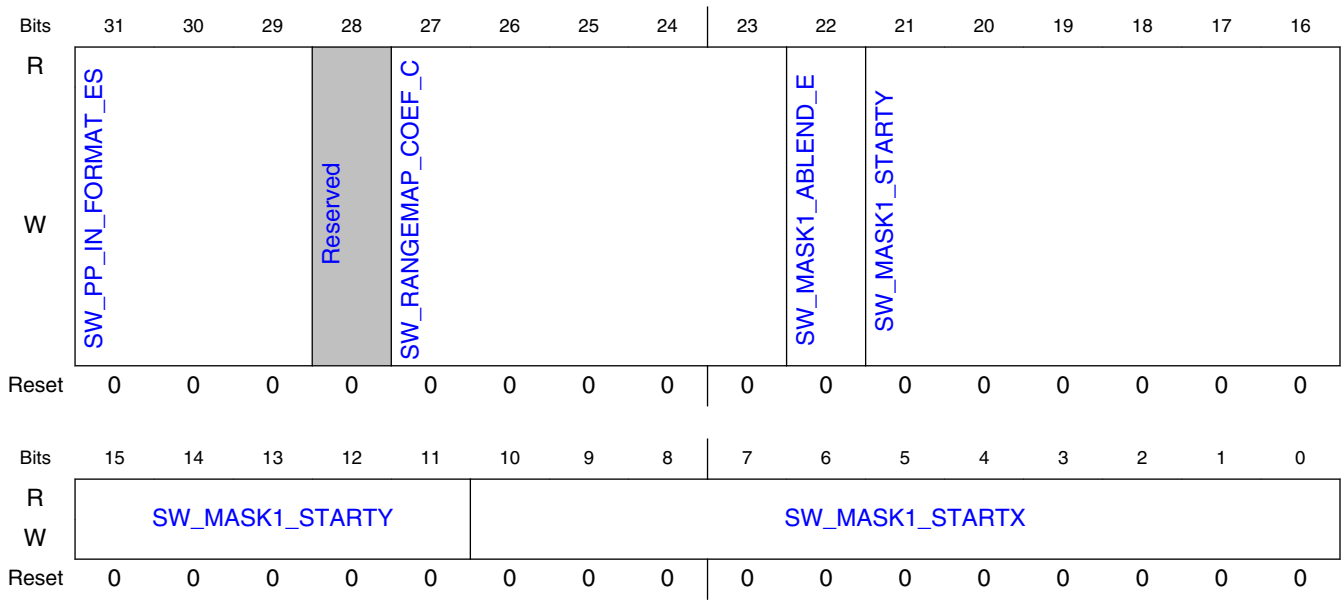
Field	Function
25-15 SW_PP_OUT_HEIGHT	Scaled picture height in pixels (Must be dividable by 2 or by any if Pixel Accurate PP output configuration is enabled) Max scaled picture height is 1920 pixels or maximum three times the input source height minus 8 pixels
14-4 SW_PP_OUT_WIDTH	Scaled picture width in pixels. Must be dividable by 8 or by any if Pixel Accurate PP output configuration is enabled. Max scaled picture width is 1920 pixels or maximum three times the input source width minus 8 pixels
3 SW_PP_OUT_TILED_E	Tiled mode enable for PP output. Can be used only for YCbYCr 422 output format. Can be used only if corresponding configuration supports this feature. Tile size is 4x4 pixels.
2 SW_PP_OUT_SWAP16_E	PP output swap 16, swaps 16 bit half inside of 32 bit word. Can be used for 16 bit RGB to change pixel orders but is valid also for any output format. NOTE: requires that configuration of SW_PPD_OEN_VERSION=1
1 SW_PP_CROP8_R_E	PP input picture width is not 16 pixels multiple. Only 8 pixels of the most right MB of the unrotated input picture is used for PP input.
0 SW_PP_CROP8_D_E	PP input picture height is not 16 pixels multiple. Only 8 pixel rows of the most down MB of the unrotated input picture is used for PP input.

14.1.5.1.43 Mask 1 start coordinate register (SWREG86)

14.1.5.1.43.1 Offset

Register	Offset
SWREG86	158h

14.1.5.1.43.2 Diagram



14.1.5.1.43.3 Fields

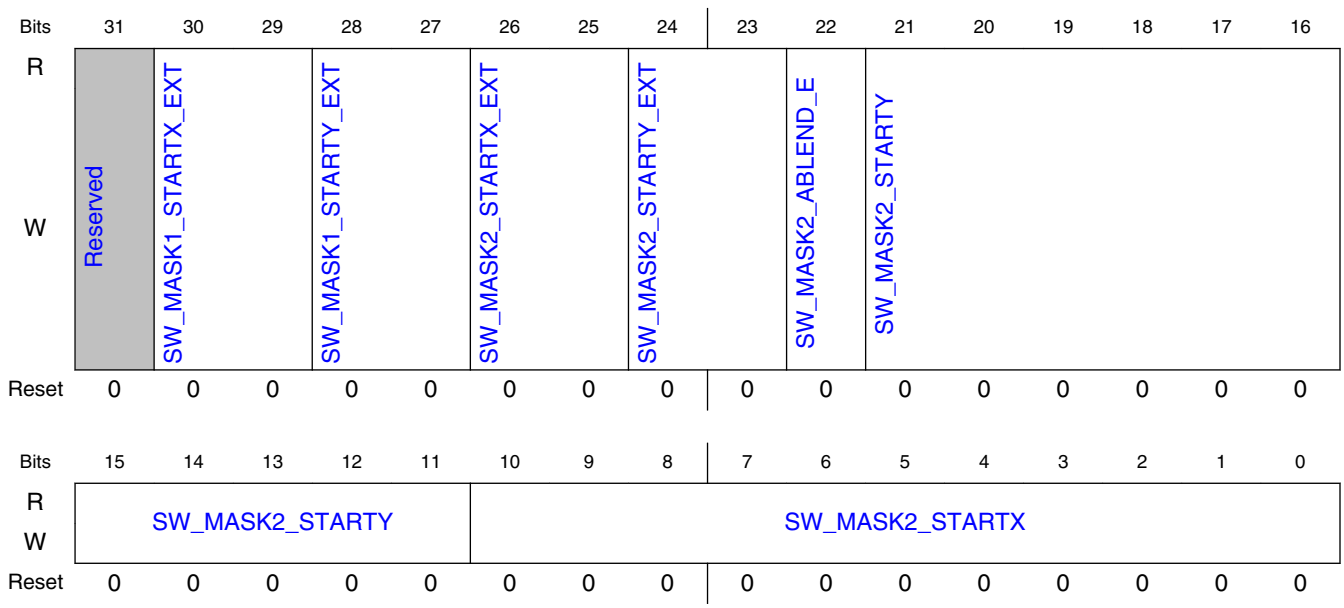
Field	Function
31-29 SW_PP_IN_FORMAT_ES	Escape PP in format. Used if sw_pp_in_format is defined to 7. 000b - YCbCr 4:4:4 001b - YCbCr 4:1:1
28 —	Reserved.
27-23 SW_RANGEMAP_COEF_C	Range map value for chrominance component
22 SW_MASK1_ABLEND_E	Mask 1 alpha blending enable. Instead of masking the output picture the alpha blending is performed. Alpha blending source can be found from alpha blend 1 base address. Alpha blending can be enabled only for RGB/ YUYV 422 data.
21-11 SW_MASK1_STARTY	Vertical start pixel for mask area 1. Defines the y coordinate. Coordinate 0,0 means the up-left corner in PP output luminance picture. See Table 47 for restrictions
10-0 SW_MASK1_STARTX	Horizontal start pixel for mask area 1. Defines the x coordinate. Coordinate 0,0 means the up-left corner in PP output luminance picture. See Table 47 for restrictions

14.1.5.1.44 Mask 2 start coordinate register + Mask extensions (SWREG87)

14.1.5.1.44.1 Offset

Register	Offset
SWREG87	15Ch

14.1.5.1.44.2 Diagram



14.1.5.1.44.3 Fields

Field	Function
31 —	Reserved.
30-29 SW_MASK1_STARTX_EXT	Extended coordinate upto 4k resolution
28-27 SW_MASK1_STARTY_EXT	Extended coordinate upto 4k resolution
26-25 SW_MASK2_STARTX_EXT	Extended coordinate upto 4k resolution

Table continues on the next page...

Field	Function
24-23 SW_MASK2_STARTY_EXT	Extended coordinate upto 4k resolution
22 SW_MASK2_ABLEND_E	Mask 2 alpha blending enable. Instead of masking the output picture the alpha blending is performed. Alpha blending source can be found from alpha blend 2 base address. Alpha blending can be enabled only for RGB/YUYV 422 data.
21-11 SW_MASK2_STARTY	Vertical start pixel for mask area 2. Defines the y coordinate. Coordinate 0,0 means the up-left corner in PP output Y picture. See Table 47 for restrictions
10-0 SW_MASK2_STARTX	Horizontal start pixel for mask area 2. Defines the x coordinate. Coordinate 0,0 means the up-left corner in PP output Y picture. See Table 47 for restrictions

14.1.5.1.45 Mask 1 size and PP original width register (SWREG88)

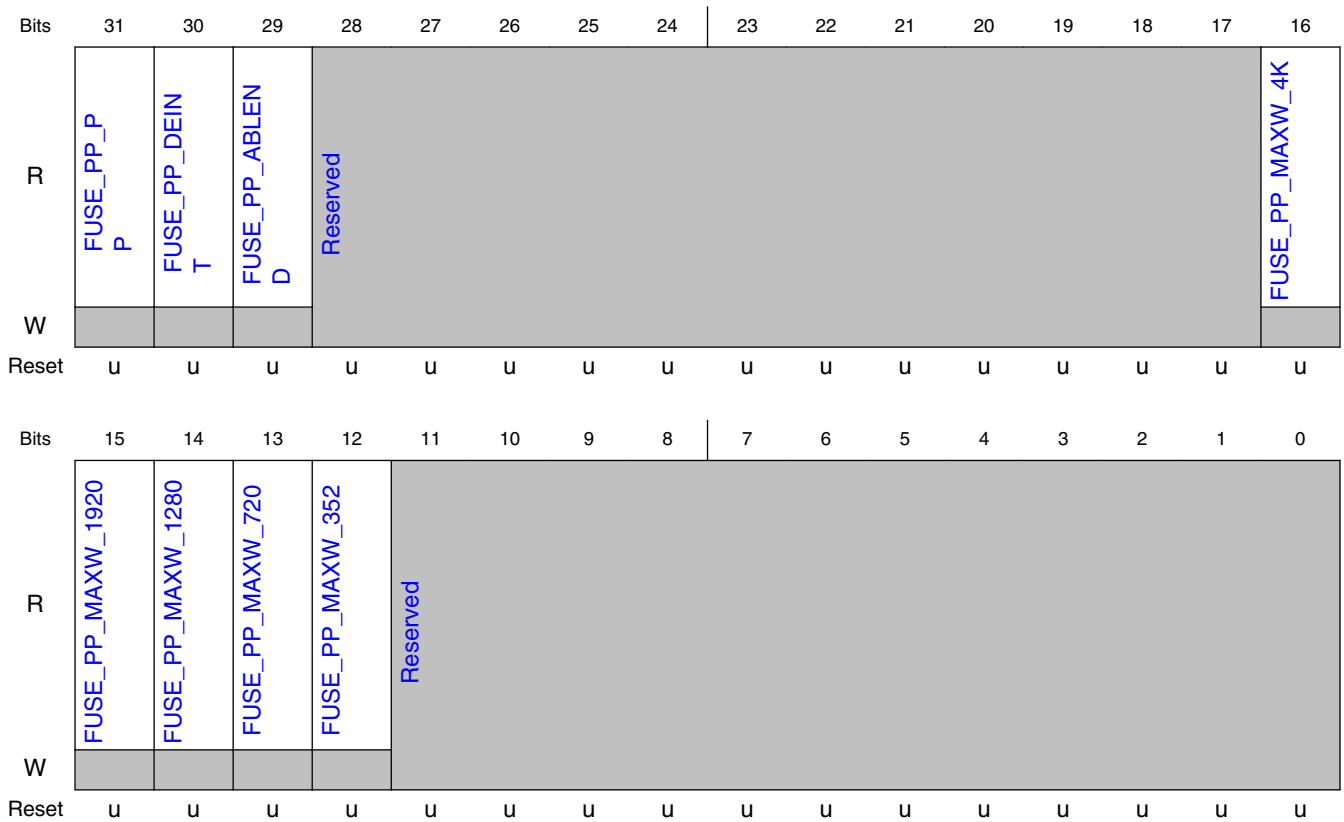
14.1.5.1.53.2 Diagram



14.1.5.1.53.3 Fields

Field	Function
31 FUSE_PP_PP	1 = PP enabled
30 FUSE_PP_DEINT	1 = Deinterlacing enabled
29 FUSE_PP_ABLEND	1 = Alpha Blending enabled
28-17 —	Reserved.
16 FUSE_PP_MAXW_4K	1 = Max PP output width up to 4096 pixels enabled. Priority coded with priority 1
15 FUSE_PP_MAXW_1920	1 = Max PP output width up to 1920 pixels enabled. Priority coded with priority 2

Table continues on the next page...

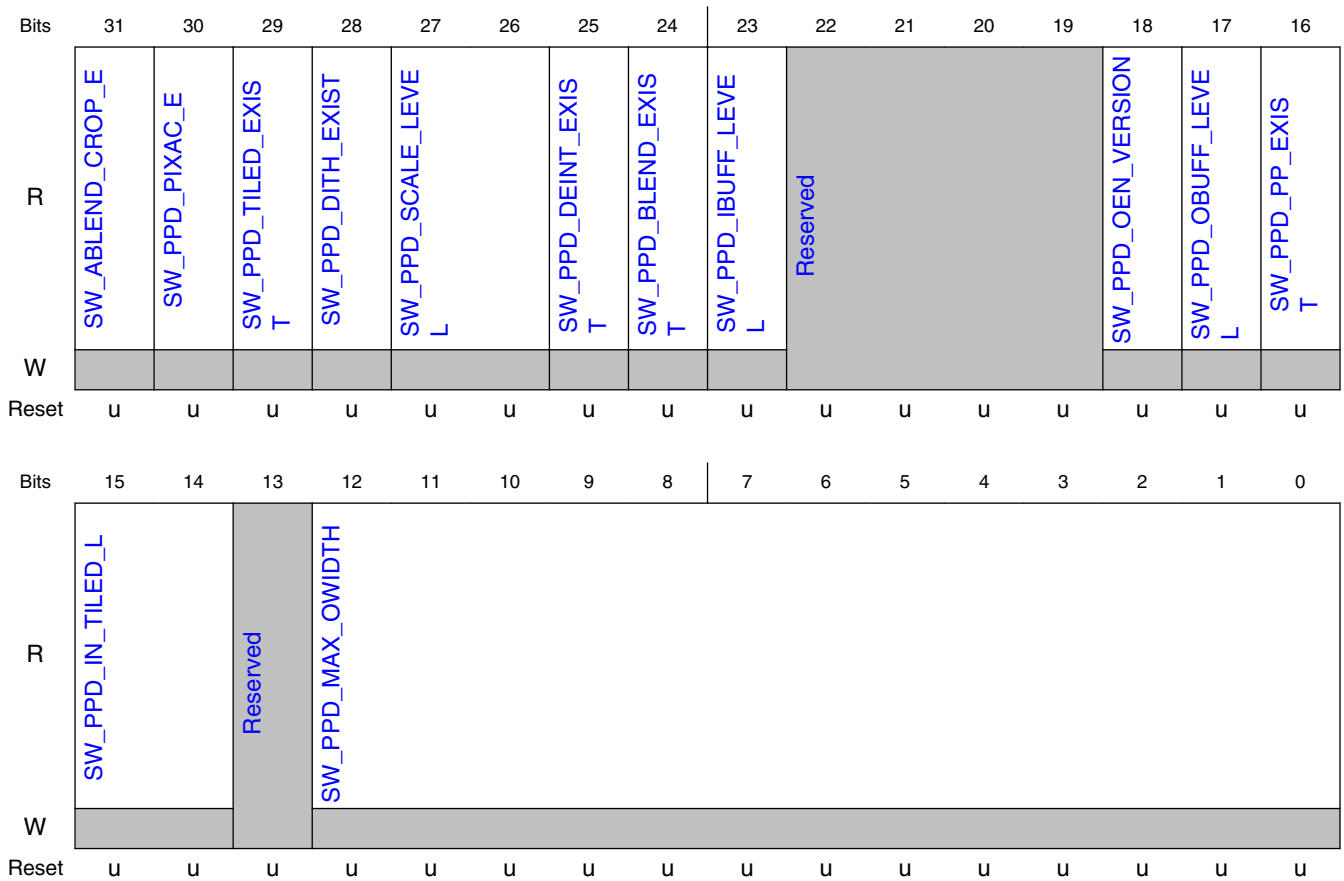
Field	Function
14 FUSE_PP_MAXW_1280	1 = Max PP output width up to 1280 pixels enabled. Priority coded with priority 3
13 FUSE_PP_MAXW_720	1 = Max PP output width up to 720 pixels enabled. Priority coded with priority 4
12 FUSE_PP_MAXW_352	1 = Max PP output width up to 352 pixels enabled. Priority coded with priority 5
11-0 —	Reserved.

14.1.5.1.54 Synthesis configuration register post-processor (SWREG100)

14.1.5.1.54.1 Offset

Register	Offset
SWREG100	190h

14.1.5.1.54.2 Diagram



14.1.5.1.54.3 Fields

Field	Function
31 SW_ABLEND_CROP_E	Alpha blending support for input cropping: 0b - Not supported. External memory must include the exact image of the area being alpha blended. 1b - Supported. External memory can include a picture from blended area can be cropped. Requires usage of swreg95.
30 SW_PPD_PIXAC_E	Pixel Accurate PP output mode exists: 0b - PIP, Scaling and masks can be adjusted by steps of 8 pixels (width) or 2 pixels (height) 1b - PIP, Scaling and masks can be adjusted by steps of 1 pixel for RGB and 2 pixels for subsampled chroma formats (by using bus specific write strobe functionality)
29 SW_PPD_TILED_EXIST	PP output YCbYCr 422 tiled support (4x4 pixel tiles) 0b - Not supported 1b - Supported
28 SW_PPD_DITH_EXIST	Dithering exists: 0b - No 1b - Yes
27-26	Scaling support:

Table continues on the next page...

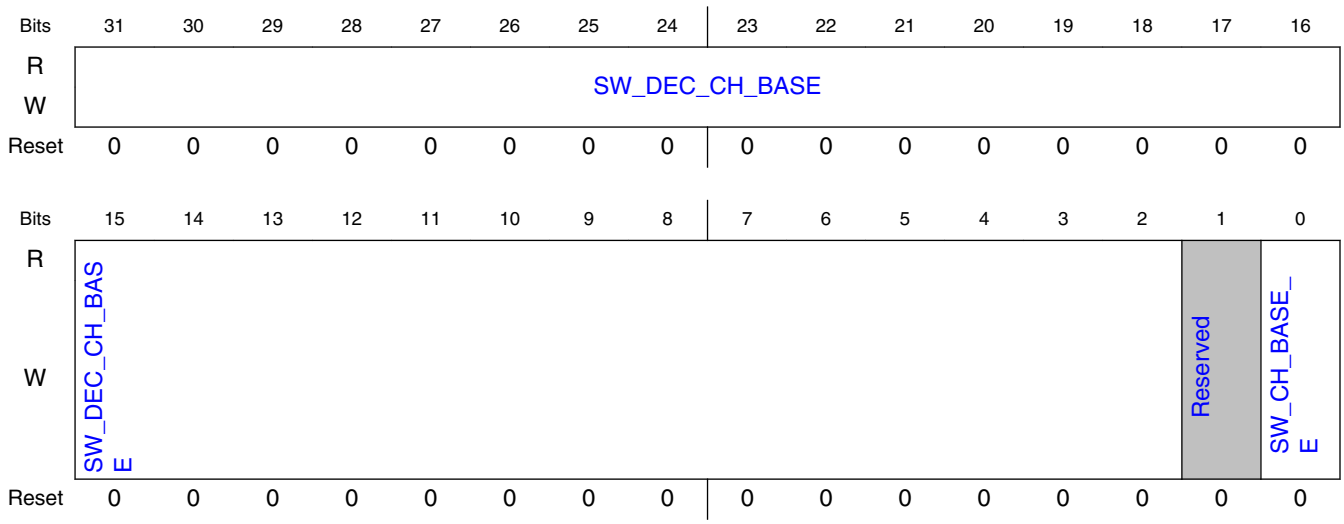
Field	Function
SW_PPD_SCALE_LEVEL	00b - No scaling 01b - Scaling with lo performance architecture 10b - Scaling with high performance architecture 11b - Scaling with high performance architecture + fast downscaling enabled
25 SW_PPD_DEINT_EXIST	De-interlacing exits: 0b - No 1b - Yes
24 SW_PPD_BLEND_EXIST	Alpha blending exists: 0b - No 1b - Yes
23 SW_PPD_IBUFF_LEVEL	PP input buffering level: 0b - 1 MB input buffering is used 1b - 4 MB input buffering is used
22-19 —	Reserved.
18 SW_PPD_OEN_VERSION	PP output endian version: 0b - Endian mode supported for other than RGB 1b - Endian mode supported for any output format
17 SW_PPD_OBUFF_LEVEL	PP output buffering level: 0b - 1 unit output buffering is used 1b - 4 unit output buffering is used
16 SW_PPD_PP_EXIST	PPD exists: 0b - No 1b - Yes
15-14 SW_PPD_IN_TILED_L	PPD input tiled mode support level 00b - not supported 01b - 8x4 tile size supported
13 —	Reserved.
12-0 SW_PPD_MAX_OWIDTH	Max supported PP output width in pixels

14.1.5.1.55 Base address for H264 decoded chroma picture (SWREG102)

14.1.5.1.55.1 Offset

Register	Offset
SWREG102	198h

14.1.5.1.55.2 Diagram



14.1.5.1.55.3 Fields

Field	Function
31-2 SW_DEC_CH_BASE	Valid only if chroma address separate mode is enabled. H264: Base address for decoder output chroma picture. Points directly to start of decoder output chroma picture or field.
1 —	Reserved.
0 SW_CH_BASE_E	chroma address separate mode enable: 0b - HW outputs decoded chroma picture to the end of decoded luma picture. HW calculates the chroma picture address according to sw_dec_base and luma data length. 1b - HW outputs decoded chroma picture to independent memory address

14.1.5.1.56 Base address for reference chroma picture index 0 (SWREG103)

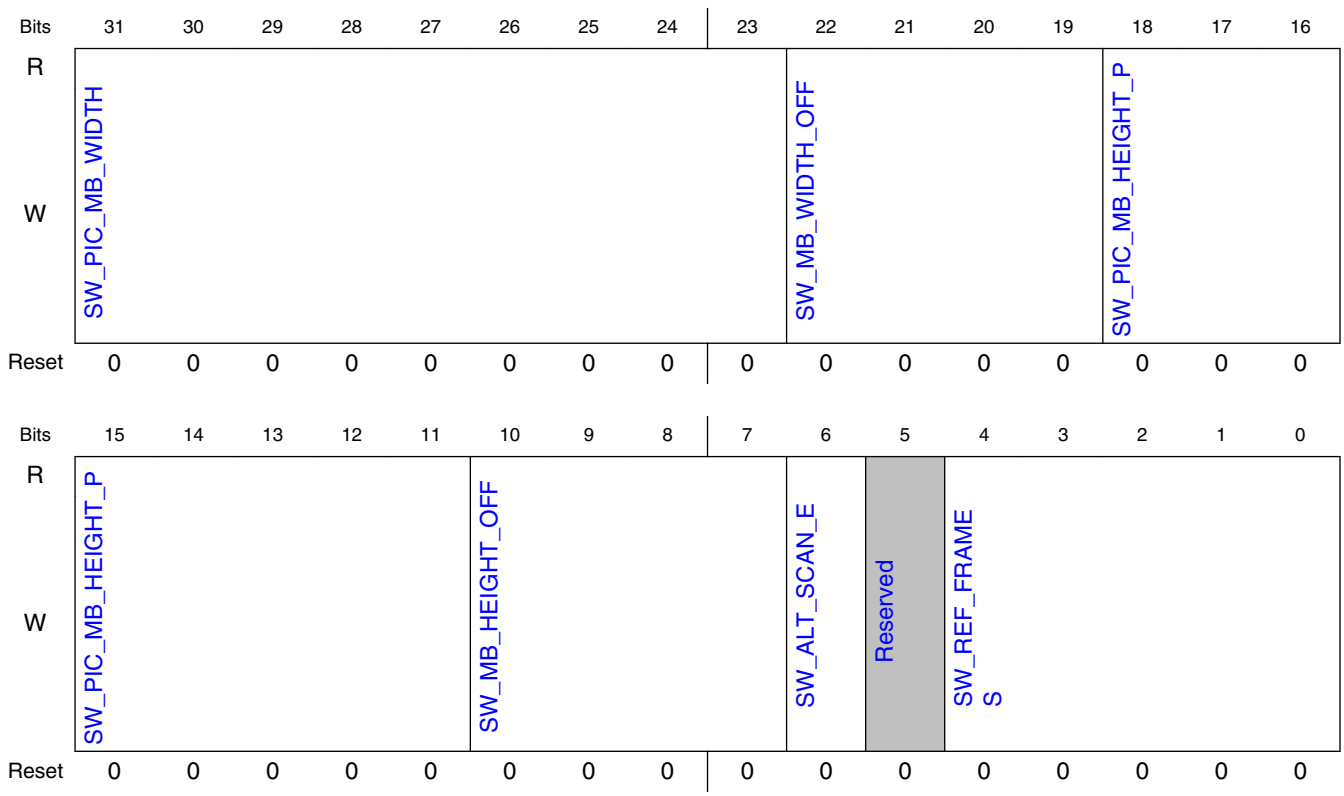
B8h	bi-dir initial ref pic list register (12-14) / VP7,VP8 quantization values (SWREG46)	32	RW	0000_0000h
BCh	bi-dir and P fwd initial ref pic list register (15 and P 0-3) / VP7,VP8 quantization values (SWREG47)	32	RW	0000_0000h

14.1.5.2.2 Decoder control register 1 (picture parameters) (SWREG4)

14.1.5.2.2.1 Offset

Register	Offset
SWREG4	10h

14.1.5.2.2.2 Diagram



14.1.5.2.2.3 Fields

Field	Function
31-23 SW_PIC_MB_WIDTH	Picture width in macroblocks = ((width in pixels + 15) /16)
22-19 SW_MB_WIDTH_OFF	The amount of meaningfull horizontal pixels in last MB (width offset) 0 if exactly 16 pixels multiple picture and all the horizontal pixels in last MB are meaningfull
18-11	Picture height in macroblocks =((height in pixels+15)/16). Picture height is informed as size of the (progressive) frame also for single field (of interlaced content) is being decoded

Table continues on the next page...

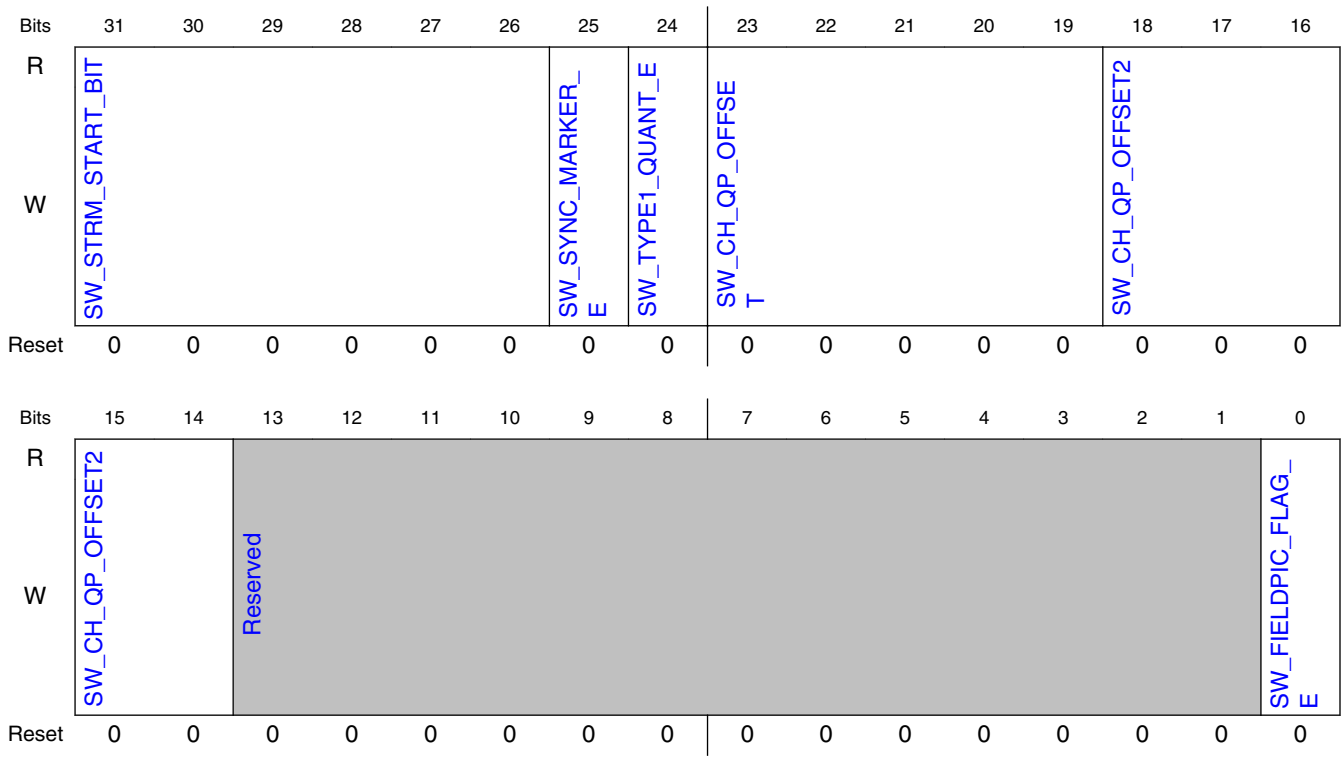
Field	Function
SW_PIC_MB_HEIGHT_P	
10-7 SW_MB_HEIGHT_OFF	The amount of meaningful vertical pixels in last MB (height offset 0 if exactly 16 pixels multiple picture and all the vertical pixels in last MB are meaningfull
6 SW_ALT_SCAN_E	indicates alternative vertical scan method used for interlaced frames
5 —	Reserved.
4-0 SW_REF_FRAMES	H.264: num_ref_frames, maximum number of short and long term reference frames in decoded picture buffer VC-1: num_ref semantics

14.1.5.2.3 Decoder control register 2 (stream decoding table selects) (SWREG5)

14.1.5.2.3.1 Offset

Register	Offset
SWREG5	14h

14.1.5.2.3.2 Diagram



14.1.5.2.3.3 Fields

Field	Function
31-26 SW_STRM_START_BIT	Exact bit of stream start word where decoding can be started (assosiates with sw_rlc_vlc_base)
25 SW_SYNC_MARKER_E	Sync markers enable For progressive JPEG, this indicates that there are restart markers in the stream after restart interval steps. 0b - synch markers are not used 1b - synch markers are used.
24 SW_TYPE1_QUANT_E	MPEG4: Type 1 quantization enable • '0' = type 2 inverse Q method • '1' = type 1 inverse Q method (Q-tables used) H264 (h264_high config): scaling matrix enable • '0' = normal transform • '1' = use scaling matrix for transform (read from external memory)
23-19 SW_CH_QP_OFFSET	Chroma Qp filter offset. (For H.264 this offset concerns Cb only)
18-14	Chroma Qp filter offset for cr type

Table continues on the next page...

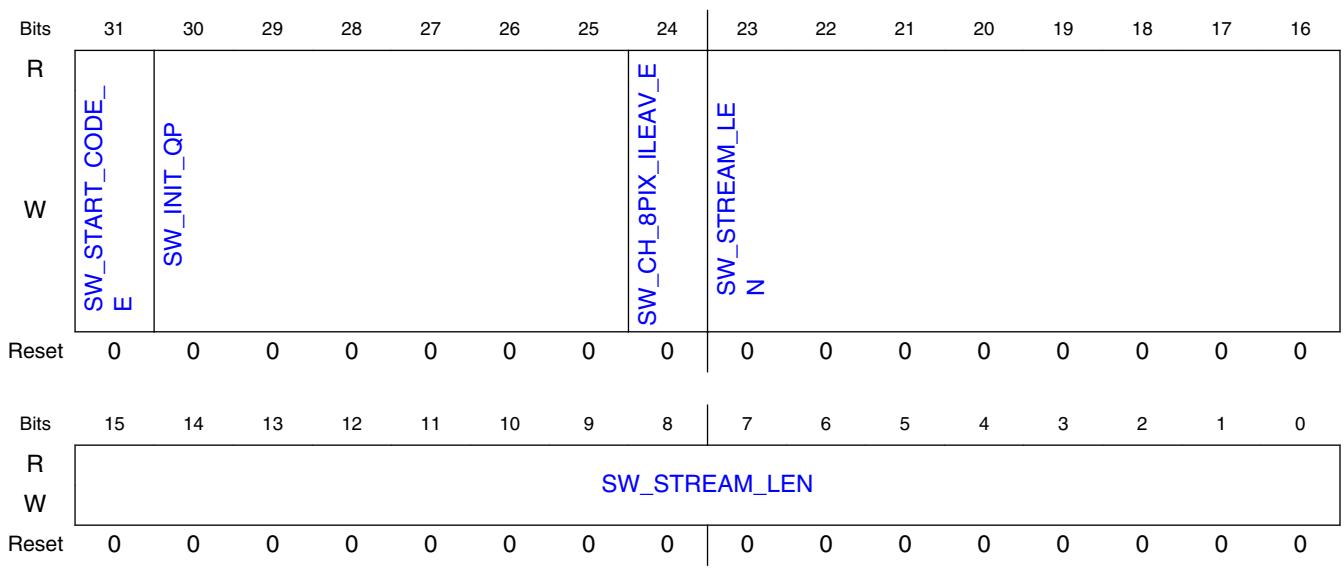
Field	Function
SW_CH_QP_OFFSET2	
13-1 —	Reserved.
0 SW_FIELDPIC_FLAG_E	Flag for streamd that field_pic_flag exists in stream

14.1.5.2.4 Decoder control register 3 (stream buffer information) (SWREG6)

14.1.5.2.4.1 Offset

Register	Offset
SWREG6	18h

14.1.5.2.4.2 Diagram



14.1.5.2.4.3 Fields

Field	Function
31	Bit for indicating stream start code existence: 0b - stream doesn't contain start codes

Table continues on the next page...

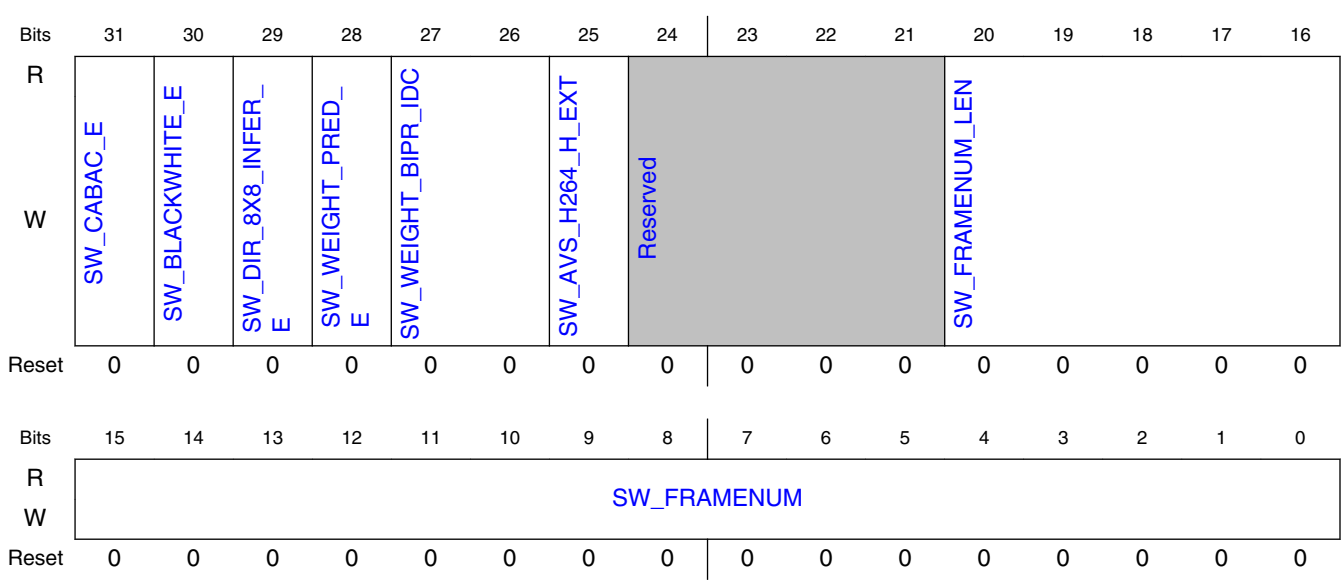
Field	Function
SW_START_CODE_E	1b - stream contains start codes
30-25 SW_INIT_QP	Initial value for quantization parameter (picture quantizer).
24 SW_CH_8PIX_ILEAV_E	Enable for additional chrominance data format writing where decoder writes chrominance in group of 8 pixels of Cb and then corresponding 8 pixels of Cr. Data is written to sw_dec_ch8pix_base. Cannot be used if tiled mode is enabled
23-0 SW_STREAM_LEN	Amount of stream data bytes in input buffer. If the given buffer size is not enough for finishing the picture the corresponding interrupt is given and new stream buffer base address and stream buffer size information should be given (assosiates with sw_rlc_vlc_base). For VC-1/VP6 the buffer must include data for one picture/slice of the picture For H264/MPEG4/H263/MPEG2/MPEG1 the buffer must include at least data for one slice/VP of the picture For JPEG the buffer size must be a multiple of 256 bytes or the amount of data for one picture.

14.1.5.2.5 Decoder control register 4 (H264, VC-1, VP6 and progressive JPEG control) (SWREG7)

14.1.5.2.5.1 Offset

Register	Offset
SWREG7	1Ch

14.1.5.2.5.2 Diagram



14.1.5.2.5.3 Fields

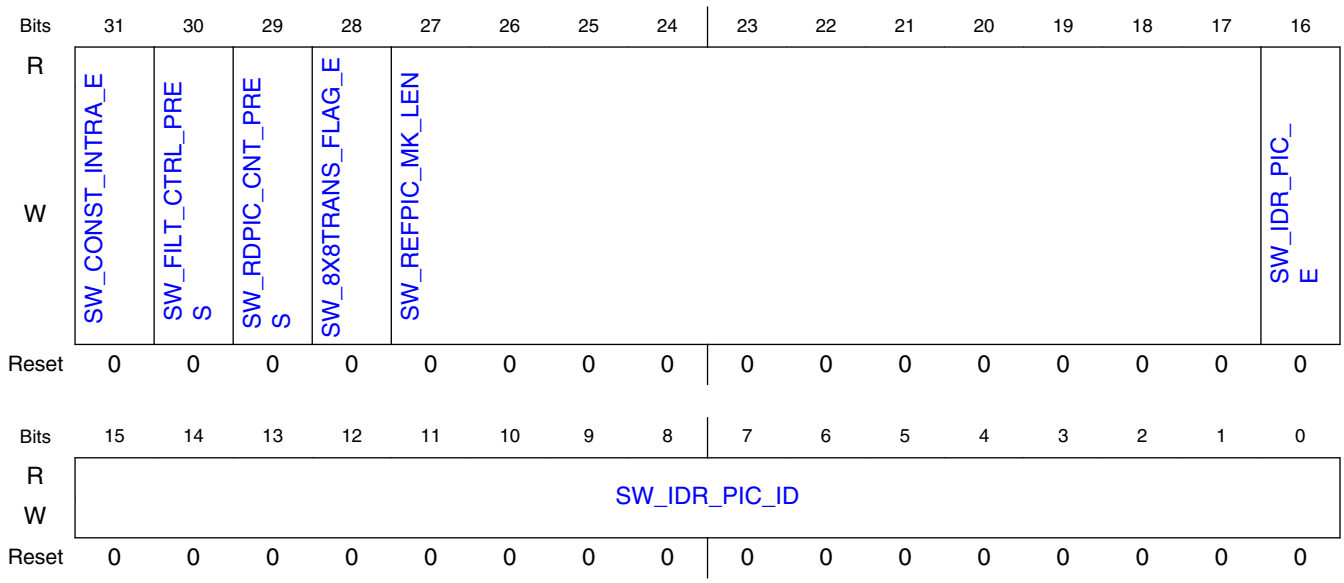
Field	Function
31 SW_CABAC_E	CABAC enable
30 SW_BLACKWHITE_E	0b - 4:2:0 sampling format 1b - 4:0:0 sampling format (H264 monochroma)
29 SW_DIR_8X8_INFER_E	Specifies the method to use to derive luma motion vectors in B_skip, B_Direct_16x16 and B_direct_8x8_inference_flag (see direct_8x8_inference flag)
28 SW_WEIGHT_PRED_E	Weighted prediction enable for P slices
27-26 SW_WEIGHT_BIPR_IDC	weighted prediction specification for B slices: 00b - default weighted prediction is applied to B slices 01b - explicit weighted prediction shall be applied to B slices 10b - implicit weighted prediction shall be applied to B slices
25 SW_AVS_H264_H_EXT	Resolution extension to support 4k resolution for AVS/H264. Used as MSB of sw_pic_mb_height
24-21 —	Reserved.
20-16 SW_FRAMENUM_LEN	H.264: Bit length of frame_num in data stream RV: frame size length. Informs how many bits in stream are used for frame size (HW discards these bits)
15-0 SW_FRAMENUM	current frame_num, used to identify short-term reference frames. Used in reference picture reordering

14.1.5.2.6 Decoder control register 5 (H264, VC-1, VP6, Progressive JPEG and RV control) (SWREG8)

14.1.5.2.6.1 Offset

Register	Offset
SWREG8	20h

14.1.5.2.6.2 Diagram



14.1.5.2.6.3 Fields

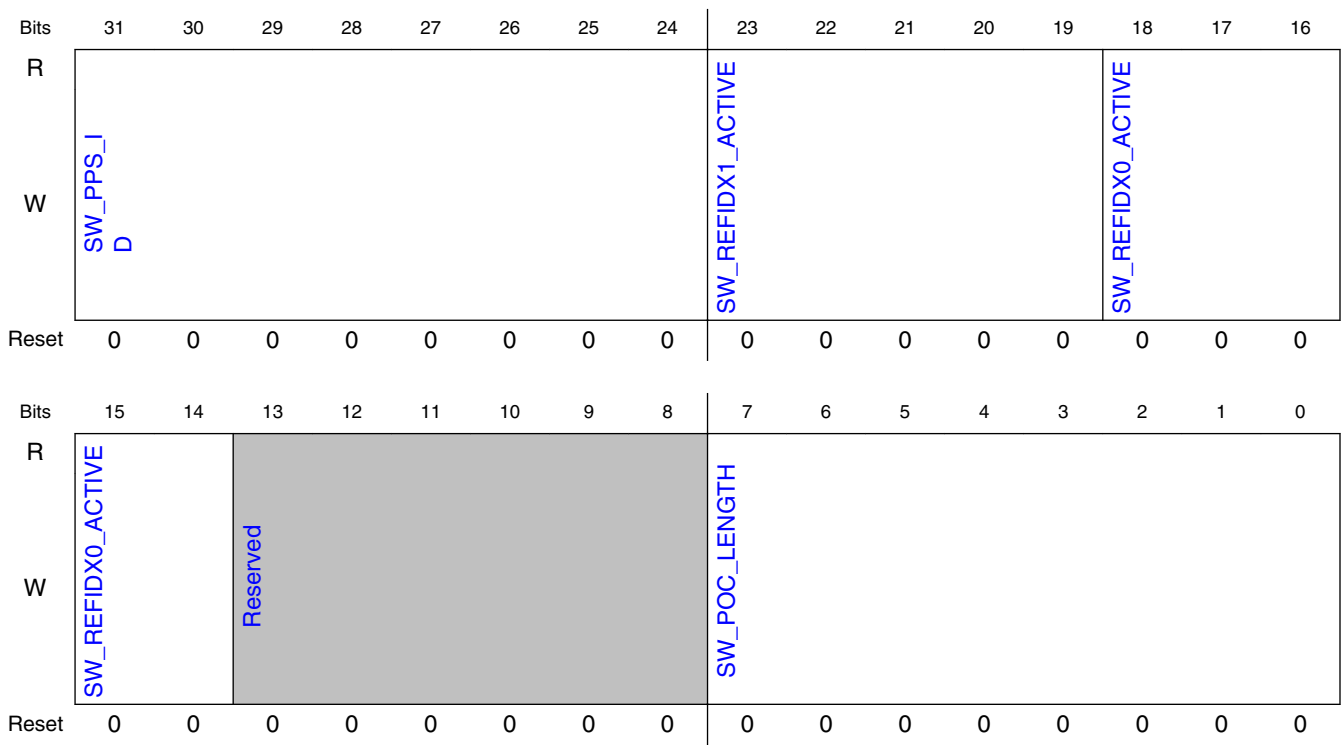
Field	Function
31 SW_CONST_INTRA_E	constrained_intra_pred_flag equal to 1 specifies that intra prediction uses only neighbouring intra macroblocks in prediction. When equal to 0 also neighbouring inter macroblocks are used in intra prediction process.
30 SW_FILT_CTRL_PRES	deblocking_filter_control_present_flag indicates whether extra variables controlling characteristics of the deblocking filter are present in the slice header.
29 SW_RDPIC_CNT_PRES	redundant_pic_cnt_present_flag specifies whether redundant_pic_cnt syntax elements are present in the slice header.
28 SW_8X8TRANS_FLAG_E	8x8 transform flag enable for stream decoding
27-17 SW_REFPIC_MK_LEN	Length of decoded reference picture marking bits
16 SW_IDR_PIC_E	IDR (instantaneous decoding refresh) picture flag.
15-0 SW_IDR_PIC_ID	idr_pic_id, identifies IDR (instantaneous decoding refresh) picture

14.1.5.2.7 Decoder control register 6 / base address for MB-control (RLC) / VC-1 intensity control 0/ VP6,VP7,VP8 ctrl-stream length/ RV pic slice amount (SWREG9)

14.1.5.2.7.1 Offset

Register	Offset
SWREG9	24h

14.1.5.2.7.2 Diagram



14.1.5.2.7.3 Fields

Field	Function
31-24 SW_PPS_ID	pic_parameter_set_id, identifies the picture parameter set that is referred to in the slice header.
23-19 SW_REFIDX1_ACTIVE	Specifies the maximum reference index that can be used while decoding inter predicted macro blocks.

Table continues on the next page...

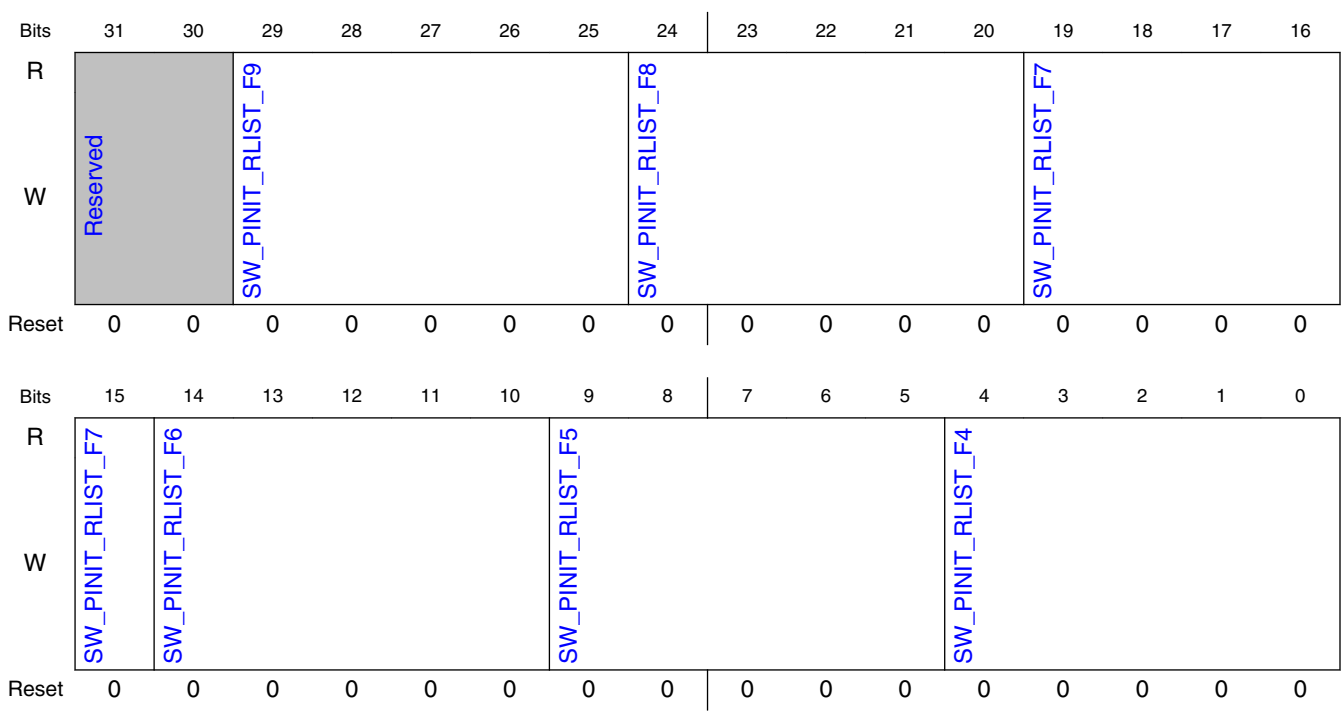
Field	Function
18-14 SW_REFIDX0_ACTIVE	Specifies the maximum reference index that can be used while decoding inter predicted macro blocks. This is same as in previous decoders (width increased with q bit)
13-8 —	Reserved.
7-0 SW_POC_LENGTH	Length of picture order count field in stream

14.1.5.2.8 Base address for differential motion vector base address (RLC-mode) /H264 P initial fwd ref pic list register (4-9)/ VC-1 intensity control 1/ VP7 and VP8 segmentation base register (SWREG10)

14.1.5.2.8.1 Offset

Register	Offset
SWREG10	28h

14.1.5.2.8.2 Diagram



14.1.5.2.8.3 Fields

Field	Function
31-30 —	Reserved.
29-25 SW_PINIT_RLIST_F9	Initial reference picture list for P forward picid 9
24-20 SW_PINIT_RLIST_F8	Initial reference picture list for P forward picid 8
19-15 SW_PINIT_RLIST_F7	Initial reference picture list for P forward picid 7
14-10 SW_PINIT_RLIST_F6	Initial reference picture list for P forward picid 6
9-5 SW_PINIT_RLIST_F5	Initial reference picture list for P forward picid 5
4-0 SW_PINIT_RLIST_F4	Initial reference picture list for P forward picid 4

14.1.5.2.9 Decoder control register 7 (VLC) / base address for H.264 intra prediction 4x4 / base address for MPEG-4 DC component (RLC) / H264 P initial fwd ref pic list register (10-15) / VC-1 intensity control 2 (SWREG11)

14.1.5.2.9.1 Offset

Register	Offset
SWREG11	2Ch

14.1.5.2.9.2 Diagram

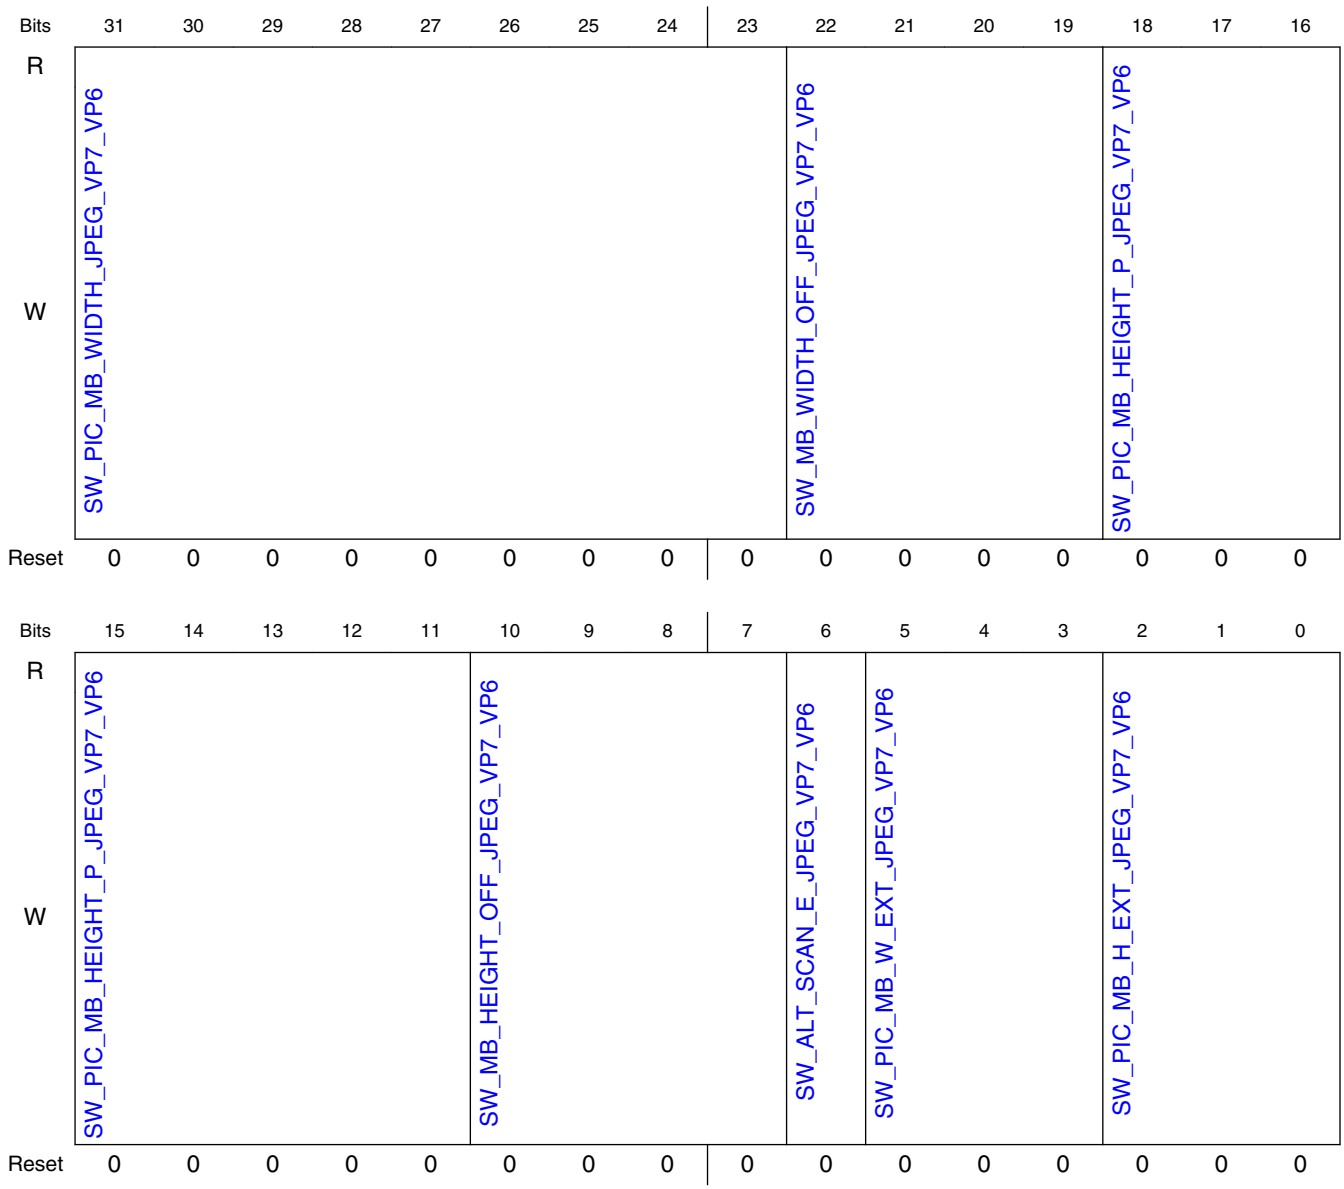
SWREG4_JPEG_VP7_VP8	10h

14.1.5.4.2.2 Diagram



14.1.5.4.2.3 Fields

Field	Function
31-23 SW_PIC_MB_WIDTH_JPEG_VP7_VP6	Picture width in macroblocks = ((width in pixels + 15) /16)
22-19	The amount of meaningfull horizontal pixels in last MB (width offset) 0 if exactly 16 pixels multiple picture and all the horizontal pixels in last MB are meaningfull

Table continues on the next page...

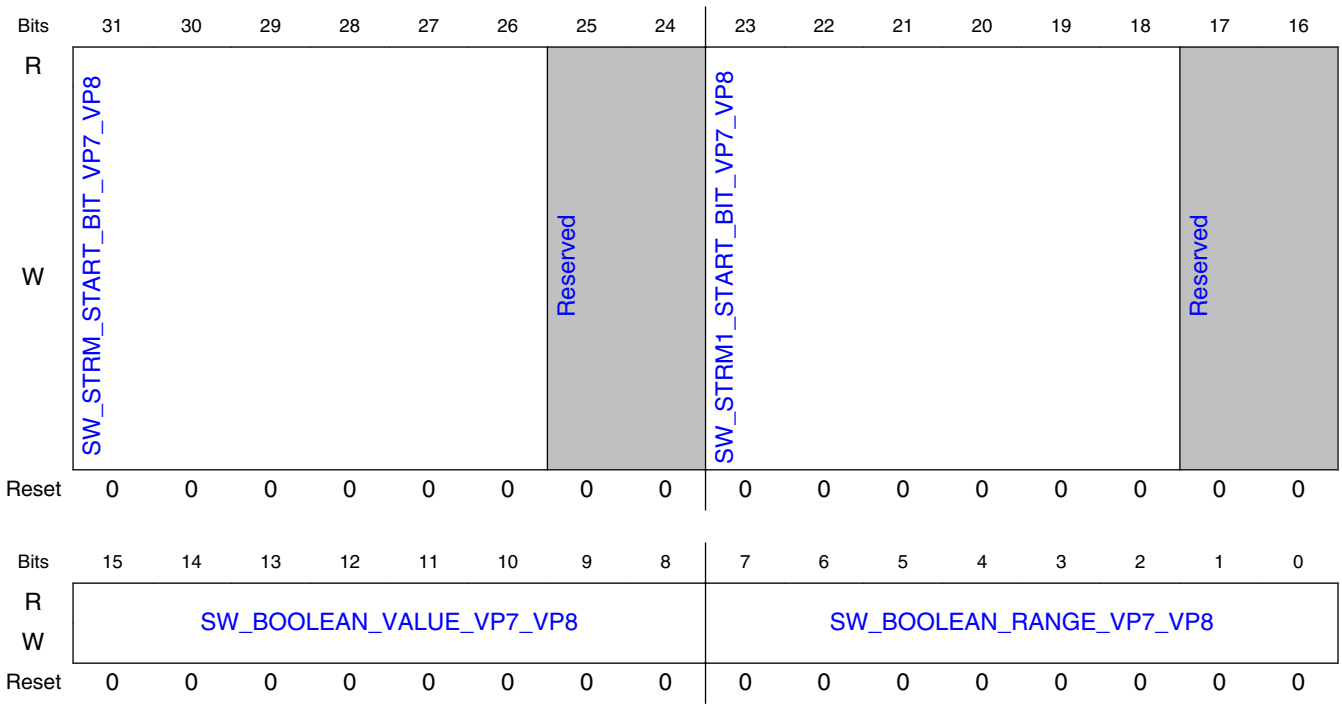
Field	Function
SW_MB_WIDTH_OFF_JPEG_VP7_VP6	
18-11 SW_PIC_MB_HEIGHT_P_JPEG_VP7_VP6	Picture height in macroblocks =((height in pixels+15)/16). Picture height is informed as size of the (progressive) frame also for single field (of interlaced content) is being decoded
10-7 SW_MB_HEIGHT_OFF_JPEG_VP7_VP6	The amount of meaningful vertical pixels in last MB (height offset 0 if exactly 16 pixels multiple picture and all the vertical pixels in last MB are meaningfull
6 SW_ALT_SCAN_E_JPEG_VP7_VP6	indicates alternative vertical scan method used for interlaced frames
5-3 SW_PIC_MB_W_EXT_JPEG_VP7_VP6	Picture mb width extension. If sw_pic_mb_width does not fit to 9 bits then these bits are used to increase the range upto 11 bits (used as 3 msb)
2-0 SW_PIC_MB_H_EXT_JPEG_VP7_VP6	Picture mb height extension. If sw_pic_mb_height_p does not fit to 9 bits then these bits are used to increase the range upto 11 bits (used as 3 msb). For 4k video one bit is used for extension (bit 0)

14.1.5.4.3 Decoder control register 2 (stream decoding table selects) (SWREG5_VP7_VP8)

14.1.5.4.3.1 Offset

Register	Offset
SWREG5_VP7_VP8	14h

14.1.5.4.3.2 Diagram



14.1.5.4.3.3 Fields

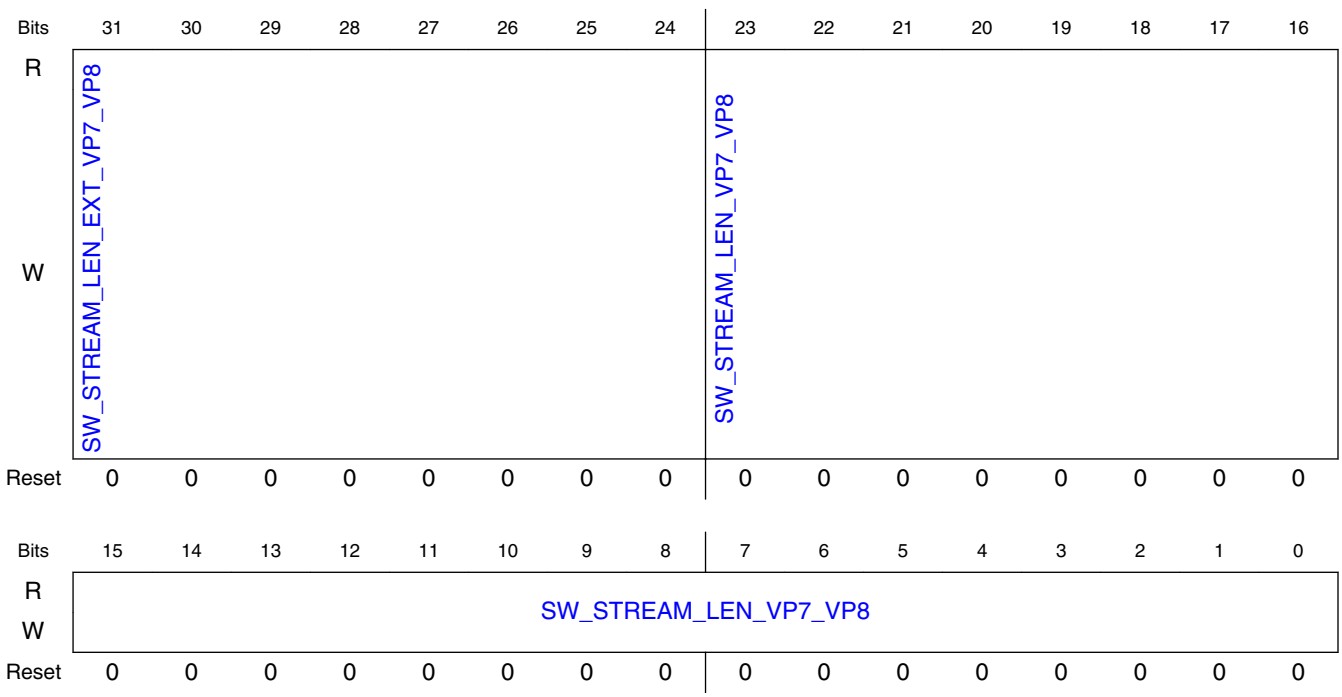
Field	Function
31-26 SW_STRM_START_BIT_VP7_VP8	Exact bit of stream start word where decoding can be started (assosiates with sw_rlc_vlc_base)
25-24 —	Reserved.
23-18 SW_STRM1_START_BIT_VP7_VP8	Start bit for ctrl-stream (needed if multistream is enabled, assosiates with sw_bitpl_ctrl_base)
17-16 —	Reserved.
15-8 SW_BOOLEAN_VALUE_VP7_VP8	Initial value for boolean dec
7-0 SW_BOOLEAN_RANGE_VP7_VP8	Initial range for boolean dec

14.1.5.4.4 Decoder control register 3 (stream buffer information) (SWREG6_VP7_VP8)

14.1.5.4.4.1 Offset

Register	Offset
SWREG6_VP7_VP8	18h

14.1.5.4.4.2 Diagram



14.1.5.4.4.3 Fields

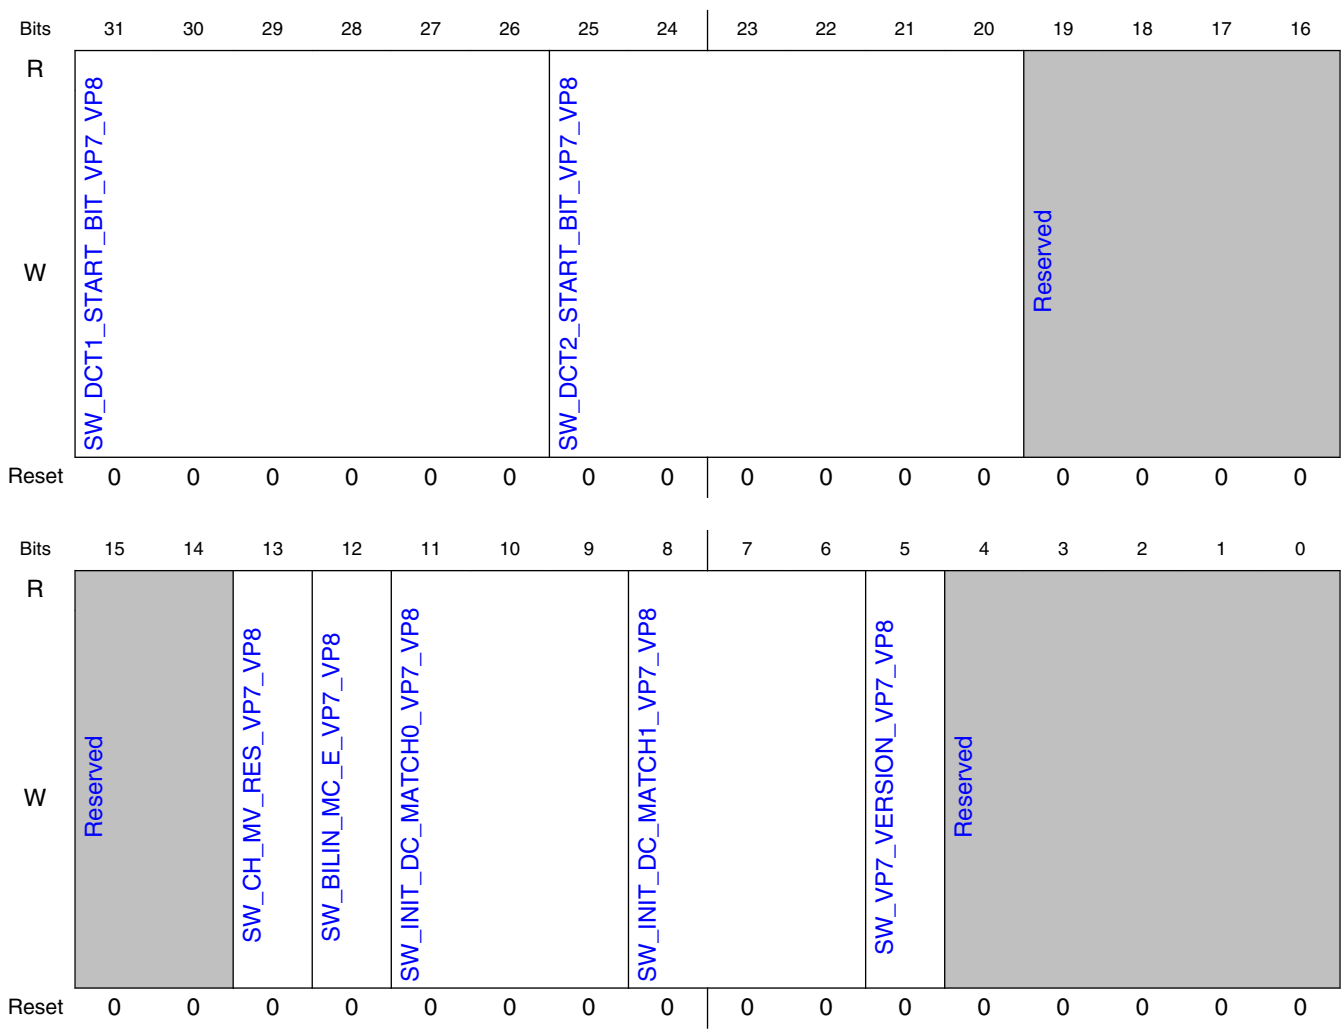
Field	Function
31-24 SW_STREAM_LEN_EXT_VP7_VP8	Extended stream length for WEBP/VP8
23-0 SW_STREAM_LEN_VP7_VP8	Amount of stream data bytes in input buffer. If the given buffer size is not enough for finishing the picture the corresponding interrupt is given and new stream buffer base address and stream buffer size information should be given (assosiates with sw_rlc_vlc_base). For VC-1/VP6 the buffer must include data for one picture/slice of the picture For H264/MPEG4/H263/MPEG2/MPEG1 the buffer must include at least data for one slice/VP of the picture For JPEG the buffer size must be a multiple of 256 bytes or the amount of data for one picture.

14.1.5.4.5 Decoder control register 4 (H264, VC-1, VP6 and progressive JPEG control) (SWREG7_VP7_VP8)

14.1.5.4.5.1 Offset

Register	Offset
SWREG7_VP7_VP8	1Ch

14.1.5.4.5.2 Diagram



14.1.5.4.5.3 Fields

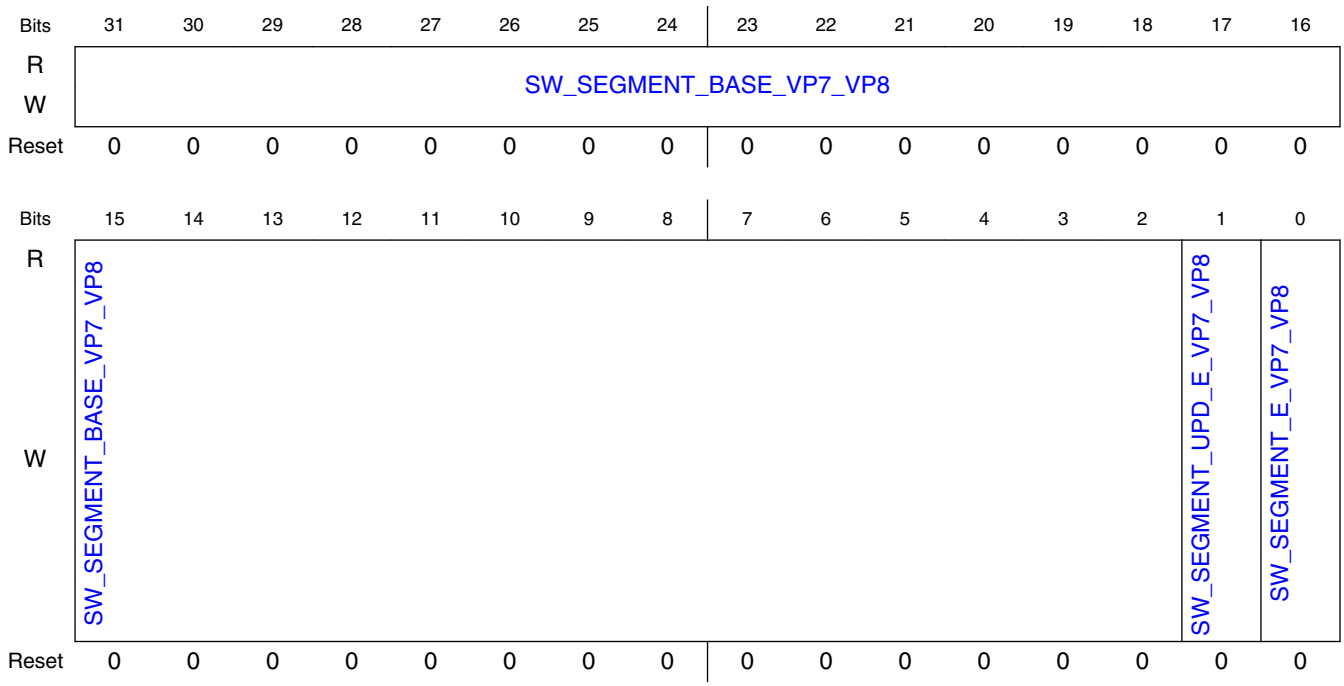
Field	Function
31-26 SW_DCT1_START_BIT_VP7_VP8	Start bit for VP7/VP8 DCT stream partition index 1
25-20 SW_DCT2_START_BIT_VP7_VP8	Start bit for VP7/VP8 DCT stream partition index 2
19-14 —	Reserved.
13 SW_CH_MV_RES_VP7_VP8	VP7/VP8 Chrominance motion vector resolution: 0b - Full pixel 1b - 1/8 pixel
12 SW_BILIN_MC_E_VP7_VP8	Bilinear motion compensation enable: 0b - Bicubic interpolation used 1b - Bilinear interpolation used
11-9 SW_INIT_DC_MATCH0_VP7_VP8	Initial DC prediction mach count 0. After HW has decoded a picture HW returns the final match count0 information which is read by SW
8-6 SW_INIT_DC_MATCH1_VP7_VP8	Initial DC prediction mach count 1. After HW has decoded a picture HW returns the final match count1 information which is read by SW
5 SW_VP7_VERSION_VP7_VP8	VP7 version information to streamd: 0b - VP7 version 7.0 1b - VP7 version 7.1 or better
4-0 —	Reserved.

14.1.5.4.6 Base address for differential motion vector base address (RLC-mode) /H264 P initial fwd ref pic list register (4-9)/ VC-1 intensity control 1/ VP7 and VP8 segmentation base register (SWREG10_VP7_VP8)

14.1.5.4.6.1 Offset

Register	Offset
SWREG10_VP7_VP8	28h

14.1.5.4.6.2 Diagram



14.1.5.4.6.3 Fields

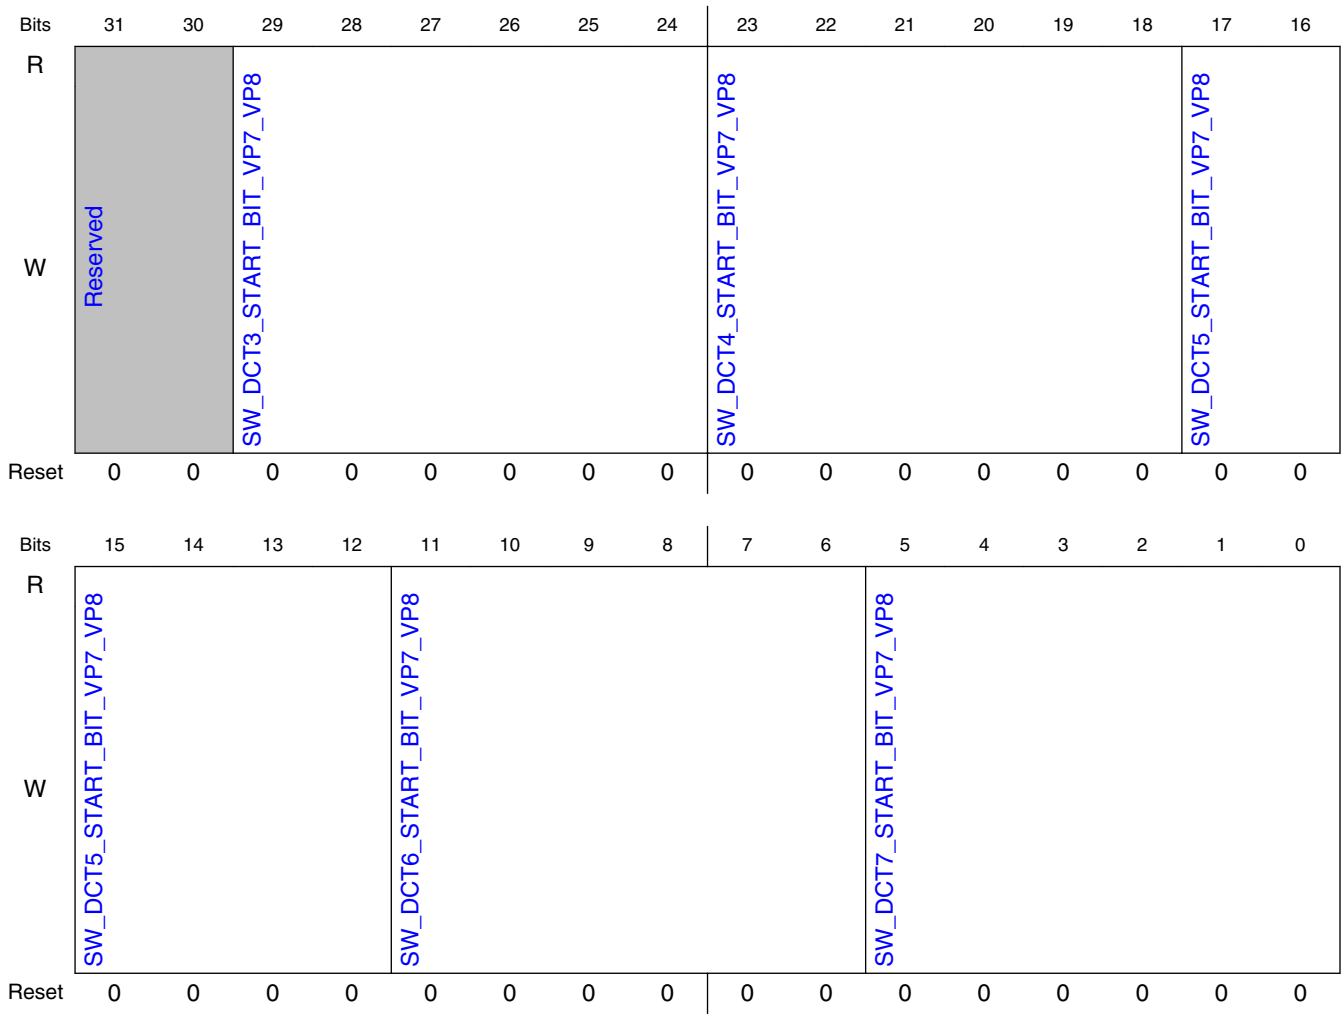
Field	Function
31-2 SW_SEGMENT_BASE_VP7_VP8	VP7/VP8: base address for segmentation map values
1 SW_SEGMENT_UPD_E_VP7_VP8	VP7/VP8 Segmentation map update enable: '0': segmentation values are read from external memory (from segment_base) '1': segmentation update is included in stream
0 SW_SEGMENT_E_VP7_VP8	Segmentation enable: '0': segmentation is not enabled '1': segmentation is enabled (sw_segment_upd_e value is used)

14.1.5.4.7 Decoder control register 7 (VLC) / base address for H.264 intra prediction 4x4 / base address for MPEG-4 DC component (RLC) / H264 P initial fwd ref pic list register (10-15) / VC-1 intensity control 2 (SWREG11_VP7_VP8)

14.1.5.4.7.1 Offset

Register	Offset
SWREG11_VP7_VP8	2Ch

14.1.5.4.7.2 Diagram



14.1.5.4.7.3 Fields

Field	Function
31-30 —	Reserved.
29-24	Start bit for VP7/VP8 DCT stream partition index 3

Table continues on the next page...

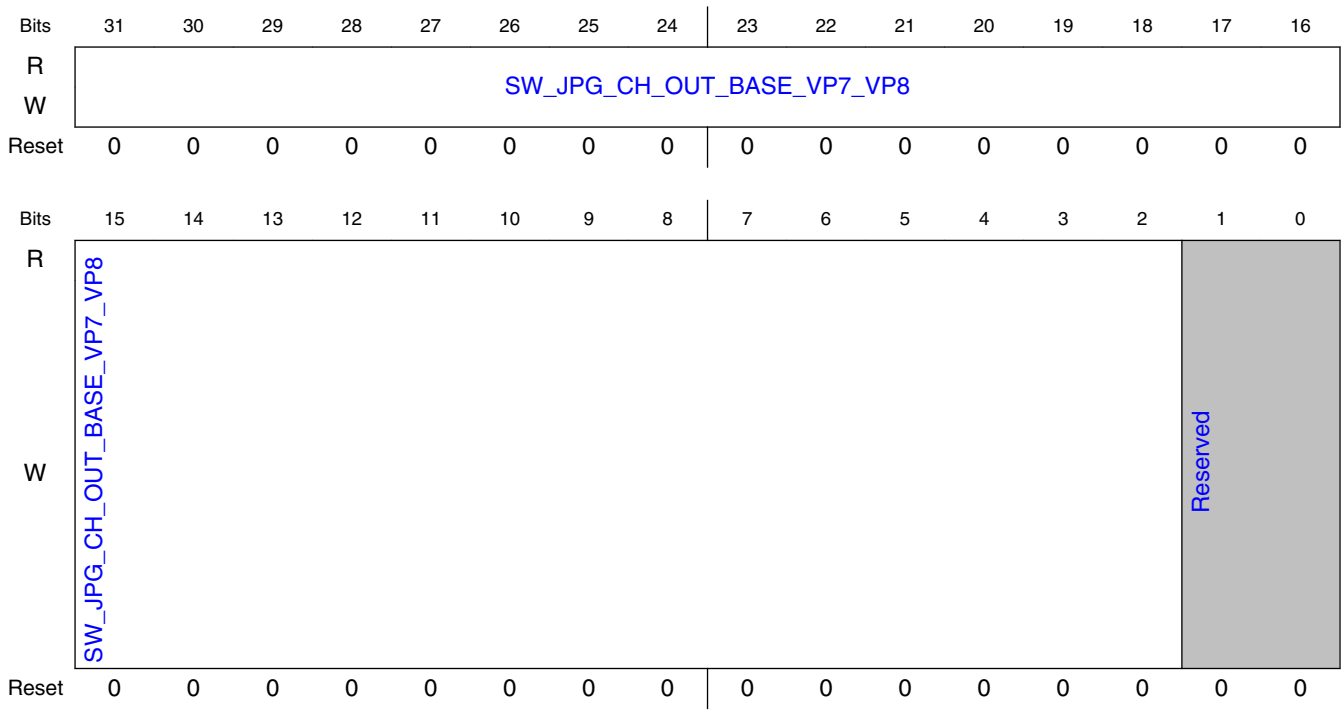
Field	Function
SW_DCT3_START_BIT_VP7_VP8	
23-18 SW_DCT4_START_BIT_VP7_VP8	Start bit for VP7/VP8 DCT stream partition index 4
17-12 SW_DCT5_START_BIT_VP7_VP8	Start bit for VP7/VP8 DCT stream partition index 5
11-6 SW_DCT6_START_BIT_VP7_VP8	Start bit for VP7/VP8 DCT stream partition index 6
5-0 SW_DCT7_START_BIT_VP7_VP8	Start bit for VP7/VP8 DCT stream partition index 7

14.1.5.4.8 Base address for reference picture index 0 / base address for JPEG decoder output chrominance picture (SWREG14_VP7_VP8)

14.1.5.4.8.1 Offset

Register	Offset
SWREG14_VP7_VP8	38h

14.1.5.4.8.2 Diagram



14.1.5.4.8.3 Fields

Field	Function
31-2 SW_JPG_CH_OUT_BASE_VP7_VP8	Base address for decoder output chrominance picture. Used in JPEG and web-p picture mode (not needed if decoder output is not written)
1-0 —	Reserved.

14.1.5.4.9 Base address for reference picture index 1 / JPEG control (SWREG15_VP7_VP8)

14.1.5.4.9.1 Offset

Register	Offset
SWREG15_VP7_VP8	3Ch

14.1.5.4.9.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved								SW_JPEG_SLICE_H_VP7_VP8							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

14.1.5.4.9.3 Fields

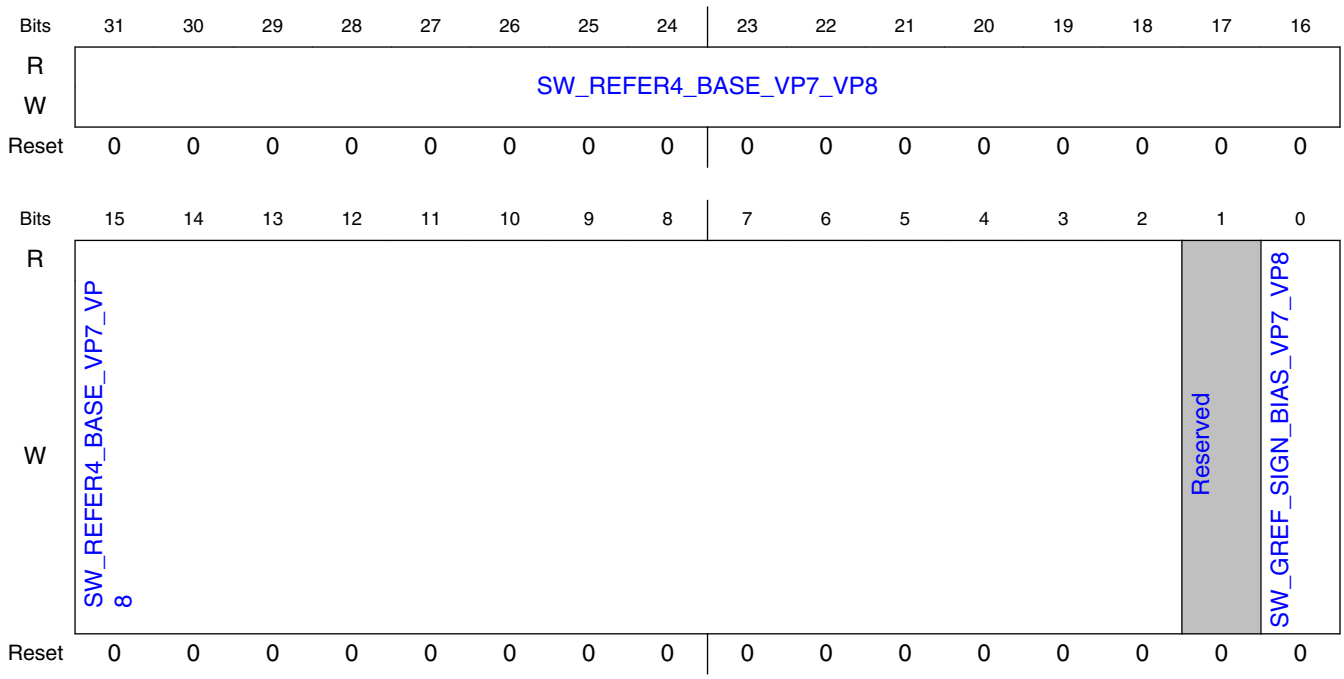
Field	Function
31-8 —	Reserved.
7-0 SW_JPEG_SLICE_H_VP7_VP8	JPEG/Web-p. Height of the slice (multiple of 16 pixels) that HW decodes before interrupt. When slice is decoded HW will rise an interrupt and reset external addresses back to base address. Note, value 0 disables slice mode. Slice mode must be used if picture size is more than 16 Mpixels. However for bigger than 4096 MBs the slice mode usage is recommended.

14.1.5.4.10 Base address for reference picture index 4 / VC1 control / MPEG4 MVD control/ List of VLC code lengths in first JPEG AC table / VC-1 intensity control 4 / VP6/VP7, VP8 Golden refer picture base (SWREG18_VP7_VP8)

14.1.5.4.10.1 Offset

Register	Offset
SWREG18_VP7_VP8	48h

14.1.5.4.10.2 Diagram



14.1.5.4.10.3 Fields

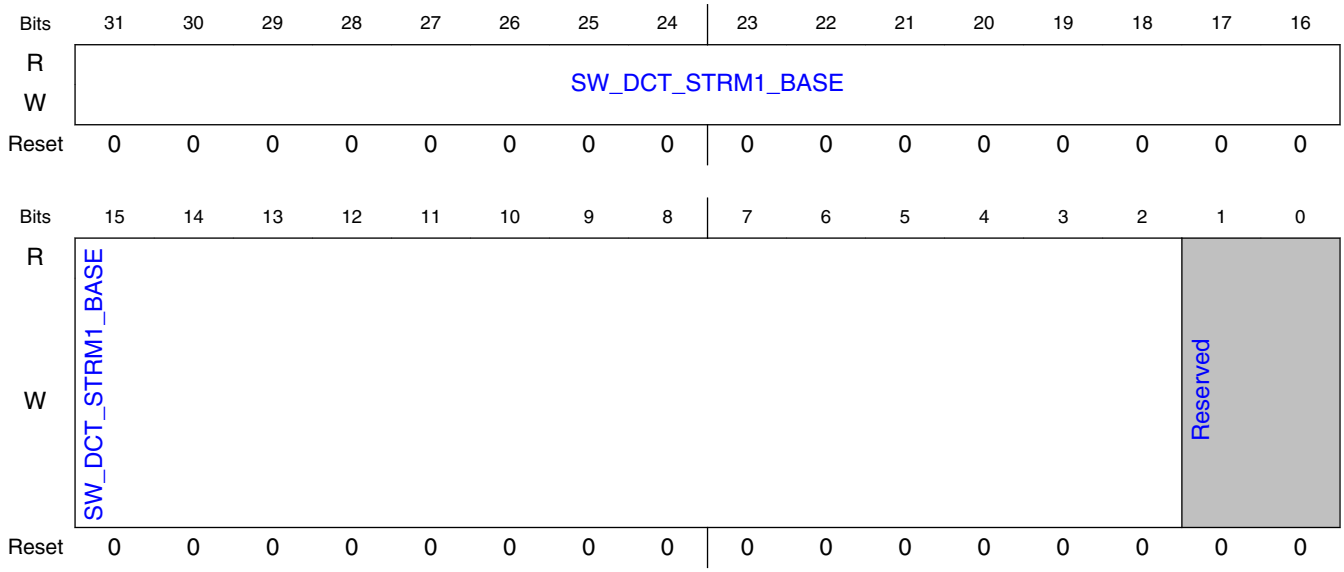
Field	Function
31-2 SW_REFER4_BASE_VP7_VP8	H264: Base address for reference picture index 4 VP6/VP7/VP8: Base address for Golden reference picture (corresponds picid 4)
1 —	Reserved.
0 SW_GREF_SIGN_BIAS_VP7_VP8	Reference picture sign bias for Golden reference frame

14.1.5.4.11 Base address for reference picture index 8 / List of VLC code lengths in second JPEG AC table / VP6 scan maps / VP7,VP8 DCT stream 1 base (SWREG22_VP7_VP8)

14.1.5.4.11.1 Offset

Register	Offset
SWREG22_VP7_VP8	58h

14.1.5.4.11.2 Diagram



14.1.5.4.11.3 Fields

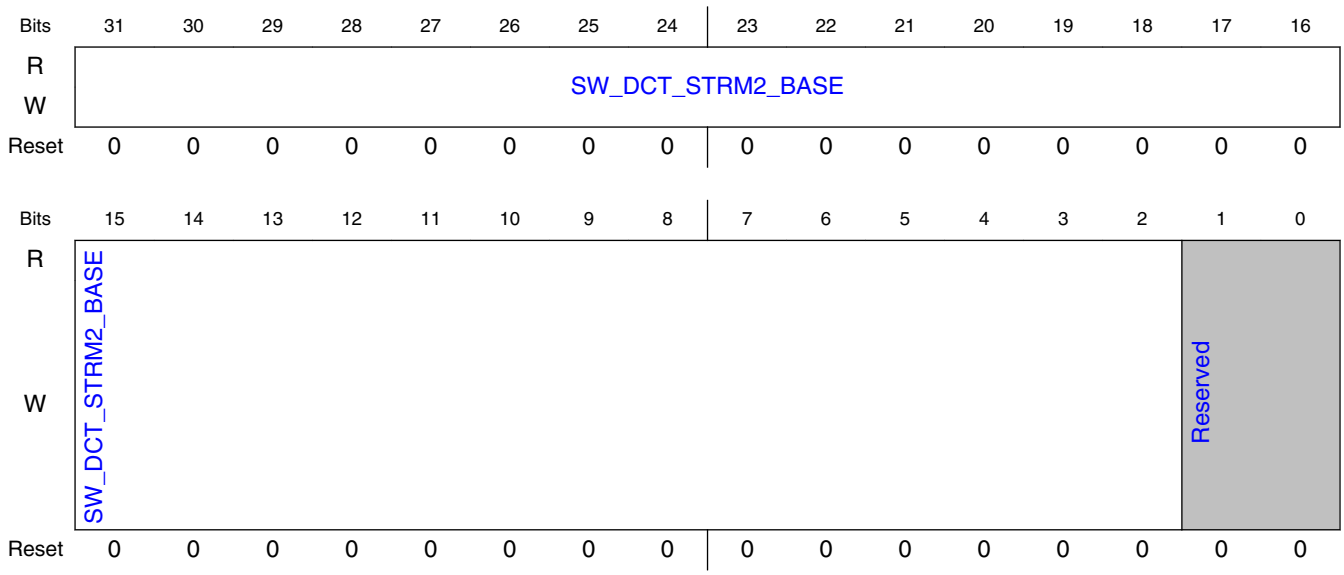
Field	Function
31-2 SW_DCT_STRM1_BASE	Base address for VP7/VP8 DCT stream MB row 1,2n+1
1-0 —	Reserved.

14.1.5.4.12 Base address for reference picture index 9 / List of VLC code lengths in first JPEG DC table / VP6 scan maps / VP7,VP8 DCT stream 2 base (SWREG23_VP7_VP8)

14.1.5.4.12.1 Offset

Register	Offset
SWREG23_VP7_VP8	5Ch

14.1.5.4.12.2 Diagram



14.1.5.4.12.3 Fields

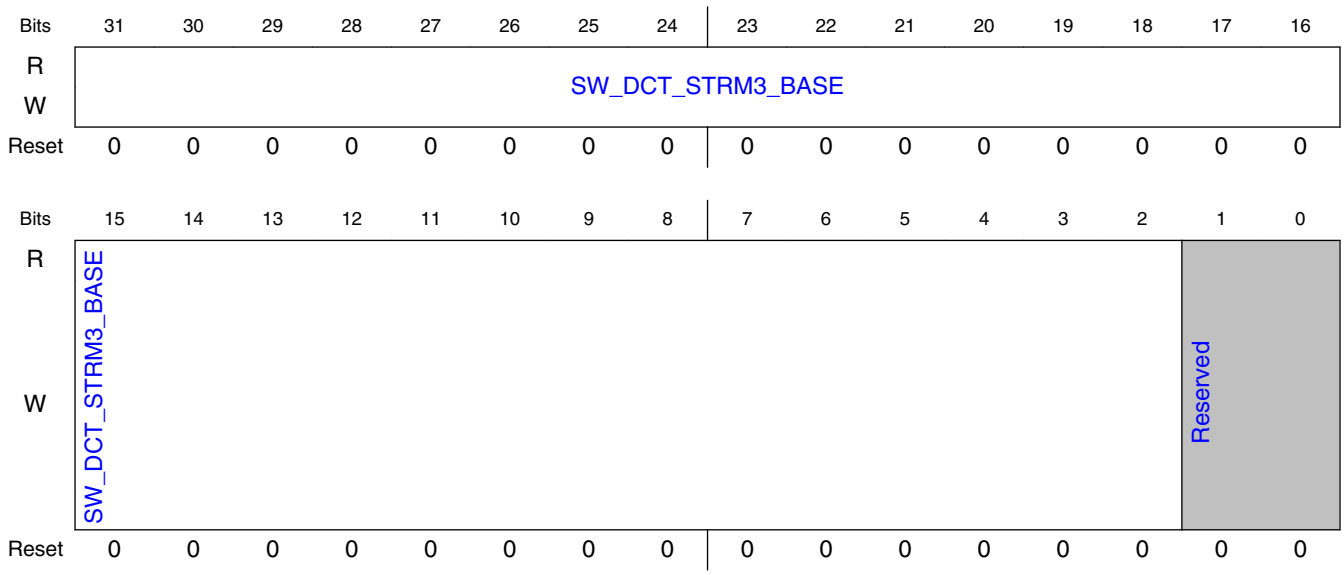
Field	Function
31-2 SW_DCT_STRM2_BASE	Base address for VP7/VP8 DCT stream MB row 2,2n+2
1-0 —	Reserved.

14.1.5.4.13 Base address for reference picture index 10 / List of VLC code lengths in first JPEG DC table / VP6 scan maps / VP7,VP8 DCT stream 3 base (SWREG24_VP7_VP8)

14.1.5.4.13.1 Offset

Register	Offset
SWREG24_VP7_VP8	60h

14.1.5.4.13.2 Diagram



14.1.5.4.13.3 Fields

Field	Function
31-2 SW_DCT_STRM3_BASE	Base address for VP7/VP8 DCT stream MB row 3,2n+3
1-0 —	Reserved.

14.1.5.4.14 Base address for reference picture index 11 / List of VLC code lengths in second JPEG DC table / VP6 scan maps / VP7,VP8 DCT stream 4 base (SWREG25_VP7_VP8)

14.1.5.4.14.1 Offset

Register	Offset
SWREG25_VP7_VP8	64h

14.2 VPU G2 (VPU_G2)

14.2.1 Overview

This block details the G2 hardware-based decoder and API. The decoder is able to decode HEVC standard Main/Main 10 profile compatible video streams, and Google's VP9 Profile 0 compatible video streams. The G2 decoder conforms to the HEVC Main/ Main 10 profiles and can decode streams up to level 5.1.

14.2.2 Video Frame Storage Format

The HW decoder may support two storage formats for frames, raster-scan, tiled without being compressed and compressed output. The application using the decoder may specify upon initialization which format is preferred, depending on HW support. The tiled format generally speaking offers better bus utilization and performance, however the decoder output must be converted back to raster-scan format prior to displaying it, except that GPU supports tiled format displaying. This postprocessing is beyond the scope of G2 decoder.

14.2.2.1 Raster-scan format

The output picture of the decoder is in semi-planar YCbCr 4:2:0 format, i.e. luminance data forms one plane in memory, and chrominance data forms the other. The output picture has to be stored linearly and contiguously in the memory. The interleaved

chrominance block has to be stored right after the luminance block in external memory as shown in Figure . The number of bytes in one luminance row must be divisible by 16, which means there will be padded 0 in the right edge when necessary.

The interleaved chrominance is stored raster-scanned in memory in Cb0Cr0Cb1Cr1Cb2Cr2Cb3… format.

The decoder output picture for interlaced sequence is always stored as an interlaced frame where even lines belongs to top field and odd lines belongs to bottom field of the frame.

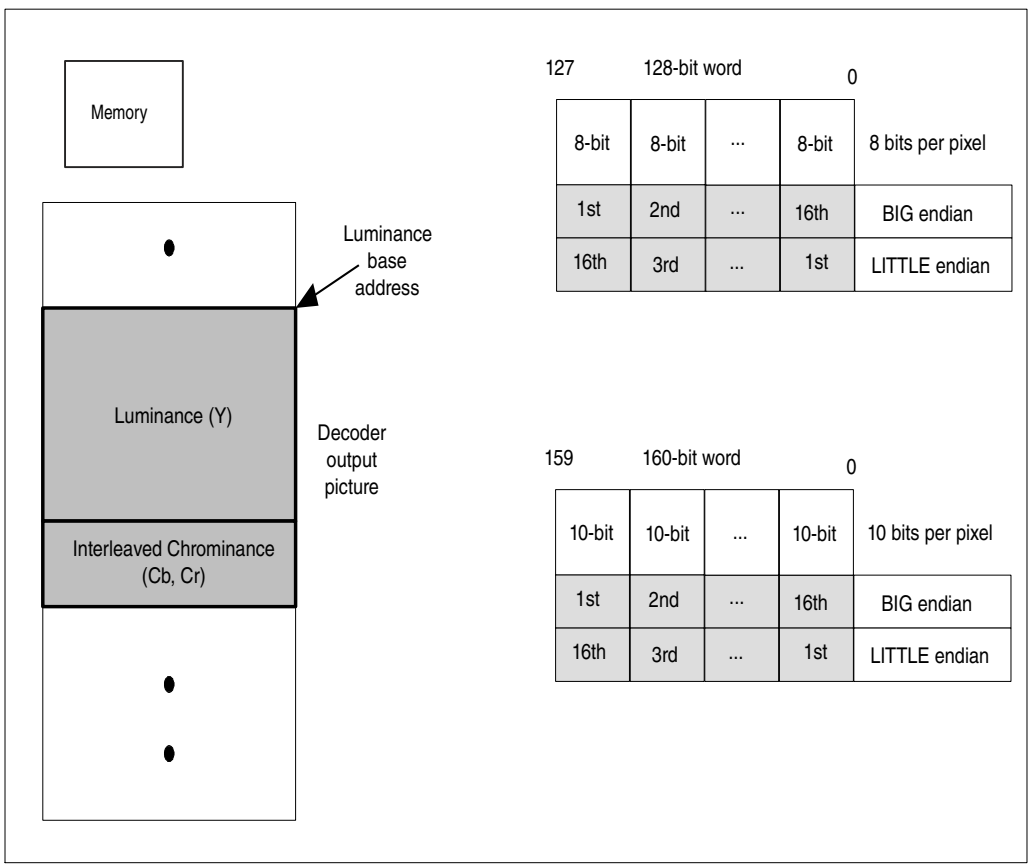

Figure 14-7. External Memory Usage

As an example the luminance pixels of a QCIF sized (176 x 144) frame with each pixel in 8 bits are numbered as presented in Table 1. Table 2 shows the storage of the luminance pixel data of the QCIF sized video frame in raster-scan order (in little endian mode).

Table 14-1. Pixel numbers of the luminance data of the QCIF video frame

0	1	2	3	4	5	6	7	…	172	173	174	175
176	177	178	179	180	181	182	183	…	348	349	350	351
::												::
25200	25201	25202	25203	25204	25205	25206	25207	…	25340	25341	25342	25343

The storage of the luminance pixel data of a QCIF video frame in raster-scan order. All pixels of a pixel row are stored in consecutive memory locations.

Table 14-2. Pixel Memory Locations

Address offset (decimal)	128-bit words(Pixel data of the luminance component. Each byte contains data for one pixel. Number in table are pixel numbers)			
0	15	...	1	0

25312	25327	...	25313	25312
25328	25343	...	25329	25328

14.2.2.2 Tiled format

The output picture of the decoder is in semi-planar YCbCr 4:2:0 4x4 tiled format, i.e. luminance data forms one plane in memory, and chrominance data forms another. The distinction from raster scan format is that the output picture is grouped into tiles, which are then stored linearly and contiguously in the memory. The chrominance tiles have to be stored right after the luminance tiles in external memory as shown in Figure . The number of luminance pixels in one row must be divisible by 16.

The chrominance is stored into tiles in interleaved Cb0Cr0Cb1Cr1Cb2Cr2Cb3… format.

Figure contains example external memory usage when using 4x4 tiles, which is used in G2 decoder.

Below is an example code of converting tiled YCbCr 4:2:0 output picture back to raster scan format. The code is in generalized form, i.e. can function on arbitrary tile sizes as long as the picture dimensions are multiple of tile sizes. In the example, chrominance data is interleaved into 4x4 tile so that one 4x4 tile contains one 2x4 block of Cb and Cr each. Output is YCbCr 4:2:0 semiplanar.

```
void ConvertTiledToRaster( DecPicture decPicture, u32 tileWidth,
            u32 tileHeight, u8 *pOutput )
            {
            u32 i, j;
            u32 k, l;
            u32 s, t;
            u8 *pIn;
            pIn = decPicture.pOutputPicture;
            /* loop all tile rows for luminance */
            for( i = 0 ; i < decPicture.frameHeight ; i += tileHeight )
```

```
{
t = 0;
s = 0;
/* loop all tiles in one row */
for( j = 0 ; j < decPicture.frameWidth ; j += tileWidth )
{
/* copy one tile */
for( k = 0 ; k < tileHeight ; ++k )
{
for( l = 0 ; l < tileWidth ; ++l )
{
pOutput[ k*decPicture.frameWidth + l + s ] = pIn[t++];
}
}
/* move to next horizontal tile */
s += tileWidth;
}
/* move to next tile row */
pOutput += decPicture.frameWidth * tileHeight;
pIn += decPicture.frameWidth * tileHeight;
}
/* setup pointers to chrominance data */
pIn = decPicture.pOutputPicture +
decPicture.frameWidth * decPicture.frameHeight;
/* loop all tile rows for chrominance */
for( i = 0 ; i < decPicture.frameHeight/2 ; i += tileHeight )
{
t = 0;
s = 0;
/* loop all tiles in one row */
for( j = 0 ; j < decPicture.frameWidth ; j += tileWidth )
{
/* copy one tile */
for( k = 0 ; k < tileHeight ; ++k )
{
for( l = 0 ; l < tileWidth ; ++l )
{
pOutput[ k*decPicture.frameWidth + l + s ] = pIn[t++];
}
}
/* move to next horizontal tile */
s += tileWidth;
}
/* move to next tile row */
pOutput += decPicture.frameWidth * tileHeight;
pIn += decPicture.frameWidth * tileHeight;
}
}
```

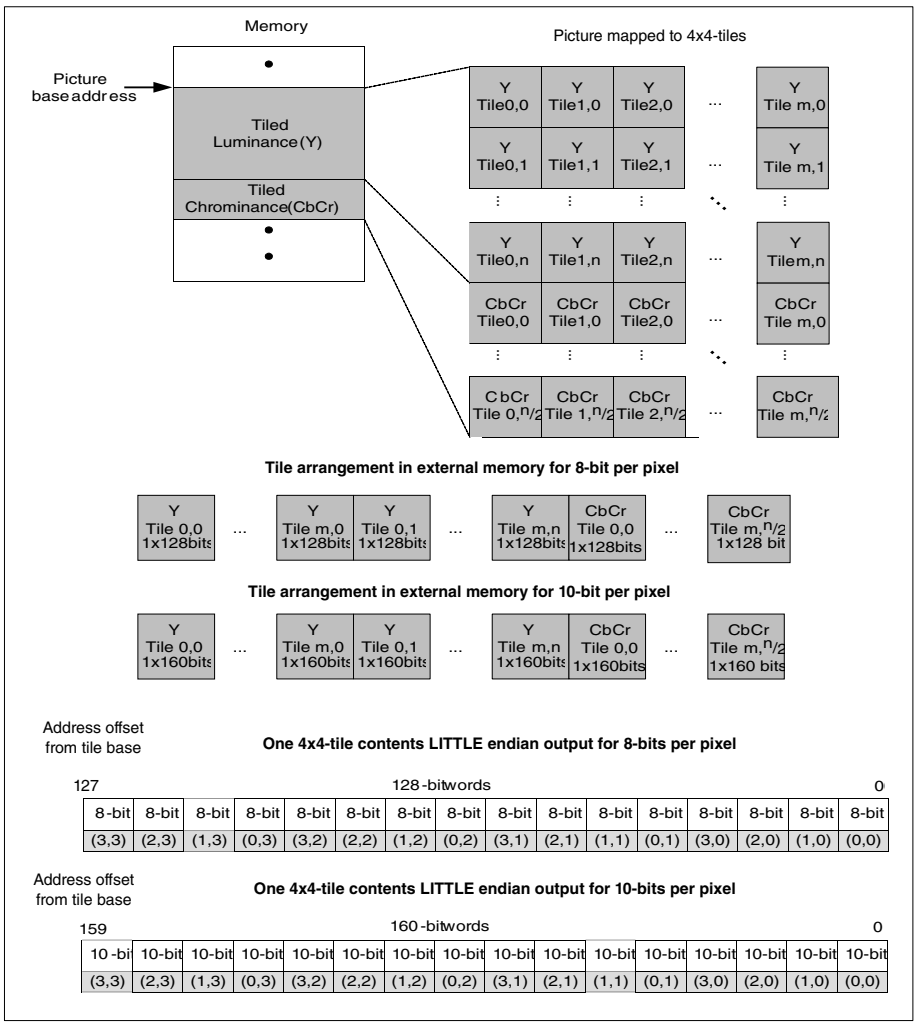

Figure 14-8. External Memory Usage in 4x4 Tiled Reference Picture Mode

14.2.2.3 Compressed format

G2 decoder supports compressed tiled output, when reference buffer compression (RFC) is enabled when synthesis, and user allows compressed reference frame output directly.

Reference frame compression is a feature added in G2 decoder to compress frame buffer so that the bandwidth of storing/loading reference frame can be reduced, especially when the resolution of decoded stream is of high definition.

When compression is enabled, the picture is divided into CBS rows, which is further divided into continuous CBS groups. Each CBS group is composed of 16 CBS. The luminance CBS is composed of 1 8x8 coded block (CB), which one chrominance CBS is composed of two 8x4 coded blocks, with cb CB first then cr CB following. The compression is performed to each CB in the CBS. The first CB's compressed data is

saved from the same offset of that CBS in raster scan buffer. And the compressed output of following CBs in the CBS row is saved continuously. That means there may be gaps between the compressed data of each CBS row.

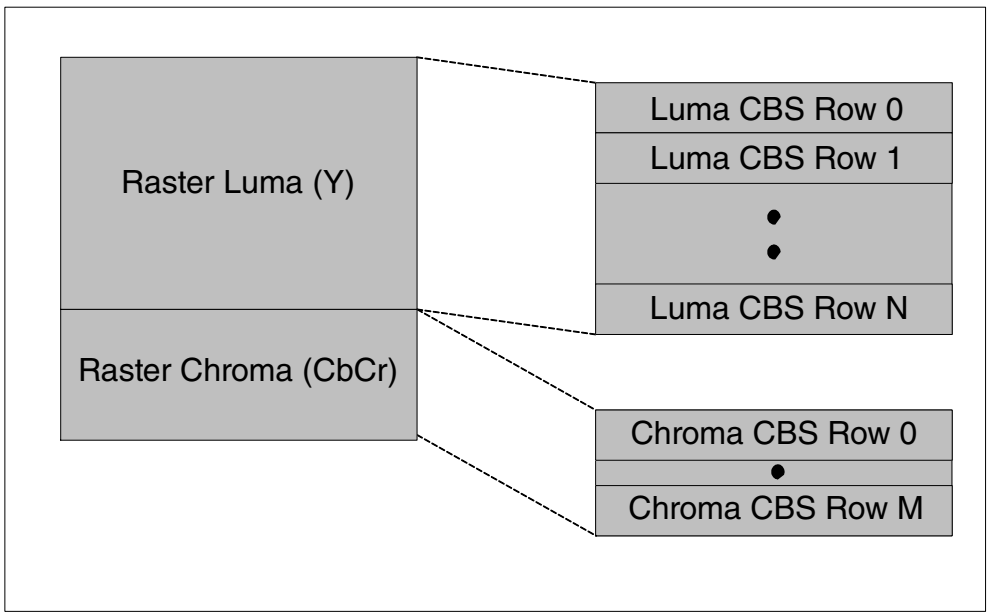

Figure 14-9. Raster scan picture mapped to CBS rows

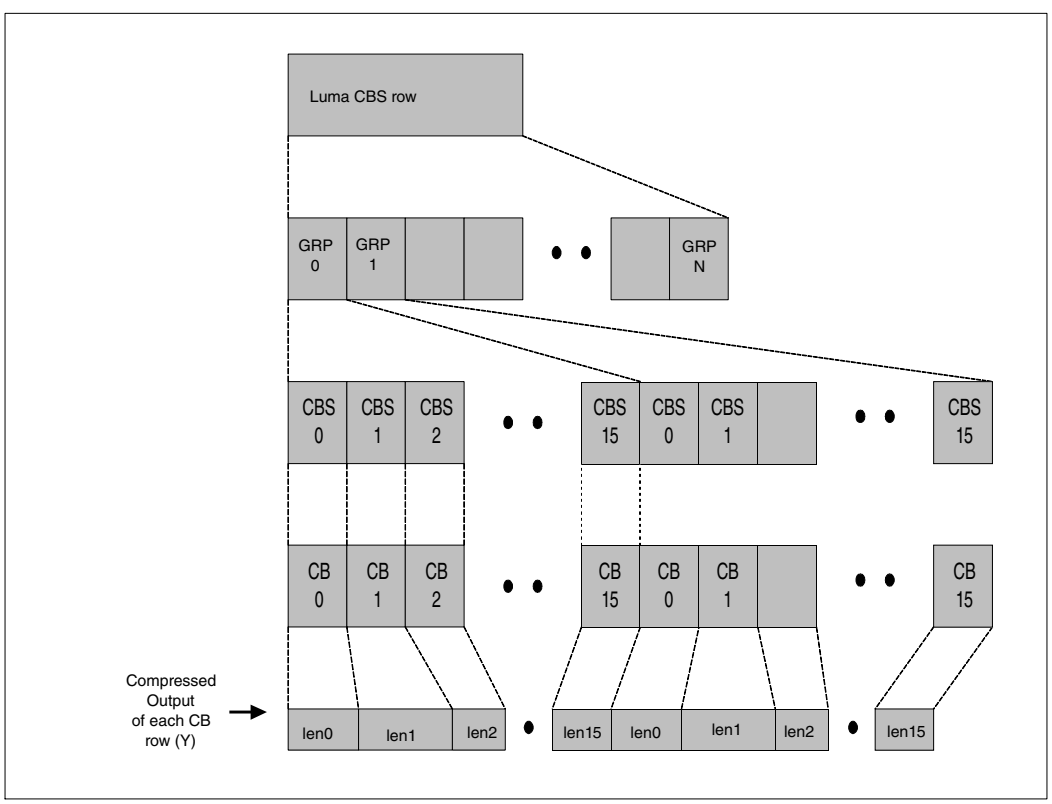

Figure 14-10. Compression performed to each Luma CBS row

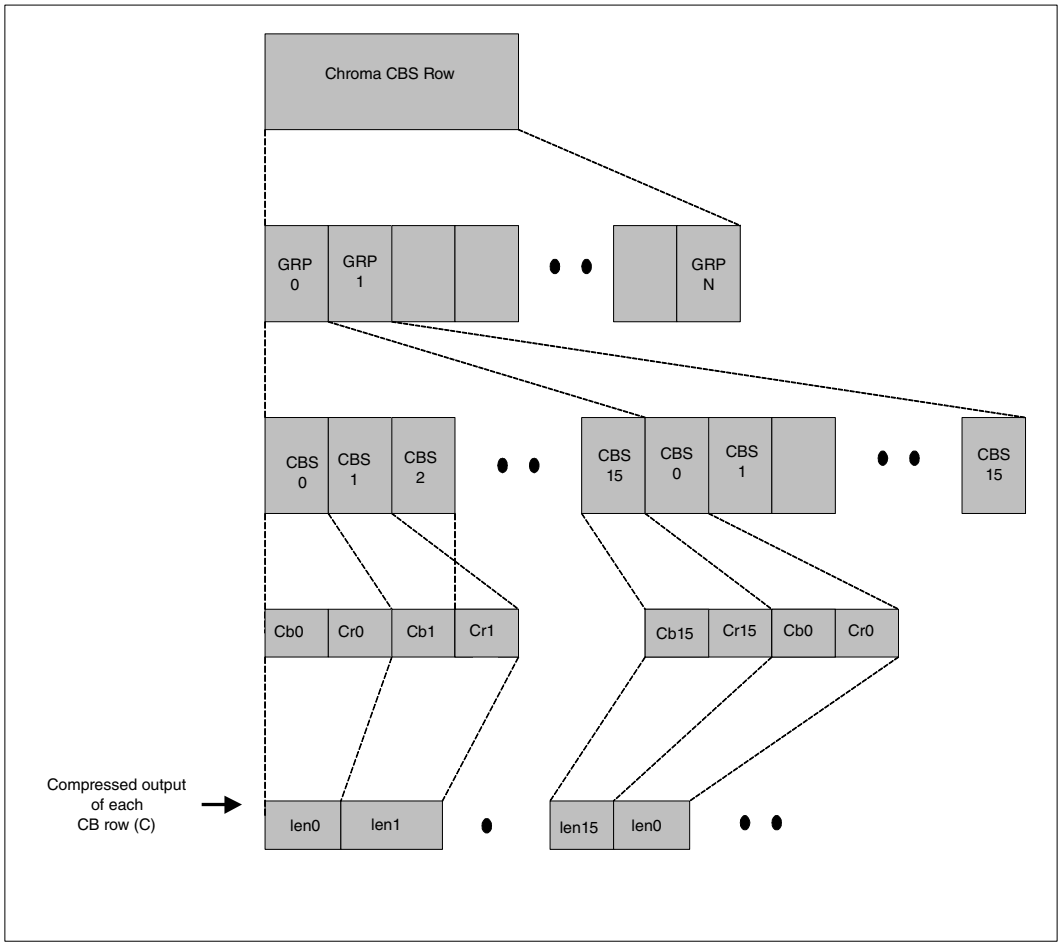

Figure 14-11. Compression performed to each Chroma CBS row

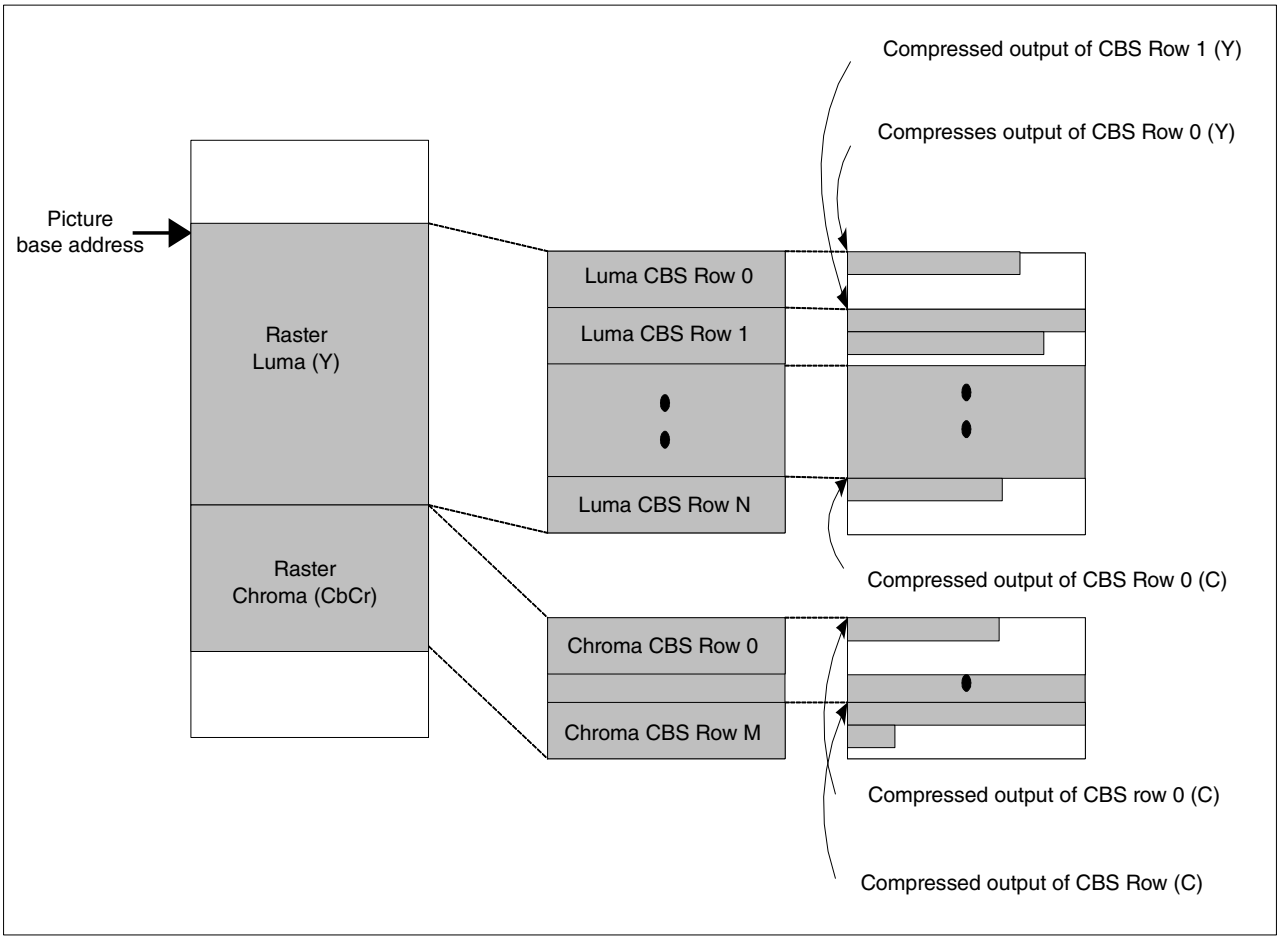

Figure 14-12. Map of external memory in RFC output buffer

Corresponding to each CBS group the starting offset of first compressed CBS output is saved in two bytes in CBS table, followed by the length of each CBS compress output, which is saved in 7 bits. So the table length of each CBS group information is 2+7*16/8=16 bytes.

This 16 bytes for each CBS group in compression table is mapped as shown in the following table. Here, X[n] means the bit-n of the length of CBS X in CBS group.

Table 14-3. Storage of the compression cache table for each CBS group

Byte	Bit7	Bit6	Bit5	Bit4	Bit 3	Bit 2	Bit 1	Bit 0
0	Offset[7:0]							
1	Offset[15:8]							
2	1[0]	0[6]	0[5]	0[4]	0[3]	0[2]	0[1]	0[0]

14.2.3 Interface Functions

This chapter describes the API declared in decapi.h, the definition of API in “software \source\common\decapi.c” of the release package.

Common numeric data types are declared in basetype.h as follows:

- **u8** – unsigned 8 bits integer value
- **i8** – signed 8 bits integer value
- **u16** – unsigned 16 bits integer value
- **i16** – signed 16 bits integer value
- **u32** – unsigned 32 bits value
- **i32** – signed 32 bits value

14.2.3.1 DecGetBuild

Syntax

```
struct DecSwHwBuild DecGetBuild(void)
```

Purpose

Returns the hardware and software build information of the decoder. Does not require the creation of a decoder instance.

Parameters

None.

Return value

DecSwHwBuild -- A structure containing the build information of the decoder.

```
struct DecSwHwBuild {
        u32 sw_build;                                   /* Software build ID */
        u32 hw_build;                                   /* Hardware build ID */
        struct DecHwConfig hw_config;          /* Hardware configuration */
};
```

Function	Description
sw_build	The internal release version of the Hantro HW HEVC software.
hw_build	The internal release version of the Hantro HW hardware.

DecHwConfig -- A structure containing the hardware-supported configuration.

```
struct DecHwConfig {
     u32 mpeg4_support;
     u32 custom_mpeg4_support;
     u32 h264_support;
     u32 vc1_support;
     u32 mpeg2_support;
     u32 jpeg_support;
     u32 jpeg_prog_support;
     u32 max_dec_pic_width;
     u32 max_dec_pic_height;
     u32 pp_support;
     u32 pp_config;
     u32 max_pp_out_pic_width;
     u32 sorenson_spark_support;
     u32 ref_buf_support;
     u32 tiled_mode_support;
     u32 vp6_support;
     u32 vp7_support;
     u32 vp8_support;
     u32 vp9_support;
     u32 avs_support;
     u32 jpeg_esupport;
     u32 rv_support;
     u32 mvc_support;
     u32 webp_support;
     u32 ec_support;
     u32 stride_support;
     u32 field_dpb_support;
     u32 hevc_support;
     u32 double_buffer_support;
     u32 hevc_main10_support;
     u32 vp9_10bit_support;
     u32 ds_support;
     u32 rfc_support;
     u32 ring_buffer_support;
};
```

Function	Description
mpeg4_support	Hardware support for MPEG-4 decoding. Possible values: • MPEG4_NOT_SUPPORTED – decoding not supported • MPEG4_SIMPLE_PROFILE – simple profile decoder • MPEG4_ADVANCED_SIMPLE_PROFILE – advanced simple profile decoder (includes • simple profile)
custom_mpeg4_support	Hardware support for DivX®decoding. Possible values:

Table continues on the next page...

Function	Description
	• MPEG4_CUSTOM_NOT_SUPPORTED – decoding not supported • MPEG4_CUSTOM - DivX Home Theater Profile QualifiedTM decoder available
h264_support	Hardware support for H.264 decoding. Possible values: • H264_NOT_SUPPORTED – decoding not supported • H264_BASELINE_PROFILE – baseline profile decoder • H264_MAIN_PROFILE – main profile decoder (includes baseline profile) • H264_HIGH_PROFILE – high profile decoder (includes baseline and main profile)
vc1_support	Hardware support for VC-1 decoding. Possible values: • VC1_NOT_SUPPORTED – decoding not supported. • VC1_SIMPLE_PROFILE – simple profile decoder • VC1_MAIN_PROFILE – main profile decoder (includes simple profile) • VC1_ADVANCED_PROFILE – advanced profile decoder (includes main profile)
mpeg2_support	Hardware support for MPEG-2 (includes MPEG-1) decoding. Possible values: • MPEG2_NOT_SUPPORTED – decoding not supported • MPEG2_MAIN_PROFILE – main profile decoder
jpeg_support	Hardware support for JPEG decoding. Possible values: • JPEG_NOT_SUPPORTED – decoding not supported • JPEG_BASELINE – baseline decoder
jpeg_prog_support	Hardware support for progressive JPEG decoding. Possible values: • JPEG_NOT_SUPPORTED – decoding not supported • JPEG_PROGRESSIVE – progressive decoder available
max_dec_pic_width	Maximum decoded picture's width for video decoders. The value is given in pixel units.
max_dec_pic_height	Maximum decoded picture's height for video decoders. The value is given in pixel units.
pp_support	Hardware support for video post-processing. Possible values: • PP_NOT_SUPPORTED – post-processing not supported. • PP_SUPPORTED – post-processing supported in hardware.
pp_config	Post-processing functions available. This is a bitwise list of the following values: • PP_DITHERING, PP_SCALING, PP_DEINTERLACING, and • PP_ALPHA_BLENDING. The availability of all these post-processor functions is • dependent on the hardware build.
max_pp_out_pic_width	Maximum output picture's width for the post-processor. The value is given in pixel units.

Table continues on the next page...

Function	Description
sorenson_spark_support	Hardware support for Sorenson Spark decoding. Possible values: • SORENSON_SPARK_NOT_SUPPORTED – decoding not supported • SORENSON_SPARK_SUPPORTED – decoder available
ref_buf_support	Hardware includes reference buffer handling speedup logic. Possible values: • REF_BUF_NOT_SUPPORTED – logic not available • REF_BUF_SUPPORTED – logic available for progressive pictures (flag) • REF_BUF_INTERLACED – logic available for interlaced pictures (flag) • REF_BUF_DOUBLE – logic available for buffering two reference pictures (flag) • Multiple values are possible using bitwise OR operation of valid flags.
tiled_mode_support	Hardware includes support for handling reference pictures in tiled mode to optimize bus utilization. Possible values: • TILED_NOT_SUPPORTED – tiled reference picture support not available • TILED_8x4_SUPPORTED – tiled reference picture support for 8x4 tiles available • TILED_8x4_ILACED_SUPPORTED – tiled reference picture support for 8x4 tiles • available also for interlaced pictures.
vp6_support	Hardware support for VP6 decoding. Possible values: • VP6_NOT_SUPPORTED – decoding not supported • VP6_SUPPORTED – decoder available
vp7_support	Hardware support for VP7 decoding. Possible values: • VP7_NOT_SUPPORTED – decoding not supported • VP7_SUPPORTED – decoder available
vp8_support	Hardware support for VP8 decoding. Possible values: • VP8_NOT_SUPPORTED – decoding not supported • VP8_SUPPORTED – decoder available
vp9_support	Hardware support for VP9 decoding. Possible values: • VP9_NOT_SUPPORTED – decoding not supported • VP9_SUPPORTED – decoder available
avs_support	Hardware support for AVS decoding. Possible values: • AVS_NOT_SUPPORTED – decoding not supported • AVS_SUPPORTED – decoder available
jpeg_esupport	Hardware support for baseline JPEG decoding up to 67 Mpixel images, and 4:1:1 and 4:4:4 sampling. Possible values: • JPEG_EXT_NOT_SUPPORTED – decoding not supported • JPEG_EXT_SUPPORTED – decoder available
rv_support	Hardware support for RV decoding. Possible values:

Table continues on the next page...

Function	Description
	• RV_NOT_SUPPORTED – decoding not supported • RV_SUPPORTED – decoder available
mvc_support	Hardware support for MVC decoding. Possible values: • MVC_NOT_SUPPORTED – decoding not supported • MVC_SUPPORTED – decoder available
webp_support	Hardware support for WebP decoding. Possible values: • WEBP_NOT_SUPPORTED – decoding not supported • WEBP_SUPPORTED – decoder available
ec_support	Hardware support for error concealment. Possible values: • EC_NOT_SUPPORTED – error concealment not supported • EC_SUPPORTED – error concealment available
stride_support	Hardware support for separate Y and C strides. Possible values: • STRIDE_NOT_SUPPORTED – strides not supported • STRIDE_SUPPORTED – strides available
field_dpb_support	Hardware support for field-mode DPB. Possible values: • FIELD_DPB_NOT_SUPPORTED – field-mode DPB not supported • FIELD_DPB_SUPPORTED –field-mode DPB available
hevc_support	Hardware support for HEVC decoding. Possible values: • HEVC_NOT_SUPPORTED – decoding not supported • HEVC_SUPPORTED – decoder available
double_buffer_support	Hardware support for decoder internal reference double buffering. Possible values: • DOUBLE_BUFFER_NOT_SUPPORTED – internal reference double buffering not • supported • DOUBLE_BUFFER_SUPPORTED – internal reference double buffering available
hevc_main10_support	Hardware support for HEVC main10 profile decoding. Possible values: • 0 – decoding not supported • 1 – decoder available
vp9_10bit_support	Hardware support for VP9 10 bits decoding. Possible values: • 0 – decoding not supported • 1 – decoder available
ds_support	Hardware support for decoder down scale outputting. Possible values: • 0 – decoding not supported • 1 – decoder available
rfc_support	Hardware support for reference frame compression. Possible values: • 0 – decoding not supported • 1 – decoder available
ring_buffer_support	Hardware support for ring buffer. Possible values:

Function	Description
	• 0 – decoding not supported • 1 – decoder available

14.2.3.2 DecInit

Syntax

```
enum DecRet DecInit(enum DecCodec codec,
                                  DecInst* decoder,
                                  struct DecConfig config,
                                  struct DecClientHandle callbacks)
```

Purpose

DecInit initializes a new decoder instance based on the given codec type. If parameter noOutputReordering is set to a non-zero value the decoder will not provide output pictures in display order but in decoding order (unless decoding order and display order is the same). Outputting pictures in decode order will lower the memory consumption of the decoder in case the number of reference frames used by the stream is less than the maximum number allowed by the profile and level of the stream.

Parameters

```
enum DecCodec codec
                  Codec type to be initialized.
                  enum DecCodec {
                  DEC_VP9,
                  DEC_HEVC
                  };
             DecInst * decoder
                  Pointer to the location where DecInit returns a decoder instance. This
instance is later
                  passed to other decoder API functions.
             struct DecConfig config
                  Decoder initialization parameters.
                    struct DecConfig {
                    u32 disable_picture_reordering;
                    enum DecPictureFormat output_format;
                    struct DWL dwl;
                    const void* dwl_inst;
                    u32 max_num_pics_to_decode;
                    enum DecErrorConcealment concealment_mode;
                    struct DecDownscaleCfg dscale_cfg;
                    u32 use_video_compressor;
                    u32 use_ringbuffer;
                    u32 use_8bits_output;
             }
             u32 disable_picture_reordering
                 Flag to disable the reordering of output frames. When set to a non-zero
value the
                 decoder will not provide output pictures in display order but in decoding
order (unless
                 decoding order and display order is the same).
             enum DecPictureFormat output_format
                  Format of the output picture.
```

```
                    enum DecPictureFormat {
                     DEC_OUT_FRM_TILED_4X4 = 0,
                     DEC_OUT_FRM_RASTER_SCAN = 1,
                     DEC_OUT_FRM_PLANAR_420 = 2
                     };
                    DEC_OUT_FRM_TILED_4X4 - Tiled 4x4 format
                    DEC_OUT_FRM_RASTER_SCAN - raster scan format (a.k.a semi-planar)
                    DEC_OUT_FRM_PLANAR_420 - planar format
               struct DWL dwl
                    Decoder wrapper layer functionality.
               const void* dwl_inst
                    Pointer to a DWL instance, which should be instantiated by calling DWLInit
in
                    advance.
               u32 max_num_pics_to_decode
                    Limits the maximum pictures number to be decoded, 0 for unlimited.
               enum DecErrorConcealment concealment_mode
                    Flag to determine which error concealment method to use. When set to
                    DEC_INTRA_FREEZE the decoder will conceal every frame after an error has
been
                    detected in the bitstream, until the next IDR (key frame) frame is
decoded. When set to
                    DEC_PICTURE_FREEZE, the decoder will conceal only the frames having errors
in the
                    bitstream.

                    enum DecErrorConcealment {
                    DEC_PICTURE_FREEZE = 0,
                    DEC_INTRA_FREEZE = 1
                    };
               struct DecDownscaleCfg dscale_cfg
                    Down scale parameters.
                    struct DecDownscaleCfg {
                      u32 down_scale_x;
                      u32 down_scale_y;
                    };
                    u32 down_scale_x
                        Down scale ratio in horizontal direction. Possible value: 2, 4, 8.
Available
                        value:2, 4, 8, which means down scaled to 1/2, 1/4 or 1/8
respectively. 1
                        means no scaling.
                    u32 down_scale_y
                        Down scale ratio in vertical direction. Possible value: 2, 4, 8.
Available value:2,
                        4, 8, which means down scaled to 1/2, 1/4 or 1/8 respectively. 1 means
no
                        scaling.
```

NOTE

If the down scale ratio in one direction is set to 1, no matter what the value is in the other direction, no down scale will be performed in both directions.

```
               u32 use_video_compressor
                   Flag to enable reference buffer compression. Set 0 to bypass reference
buffer
                   compression, or when reference buffer compression is not supported. When
set to 1,
                   the decoded reference buffer will be saved in compressed format.
               u32 use_ringbuffer
                   Flag to indicate decoder use ring buffer or not. Set 1 to enable ring
buffer. When set to
                   0, ring buffer will be disabled.
                   Stream ring buffer mode is an alternative storage for stream. In this mode,
frame
```

stream data usually doesn’t start from buffer head but follow a previous frame stream
data. When stream data goes to stream buffer end, it must turnaround to buffer head to
save left stream data. It requires a whole frame stream data saved in stream buffer and
stream data start address is byte-aligned.
Below figure shows how stream data is stored in stream buffer if ring buffer mode.

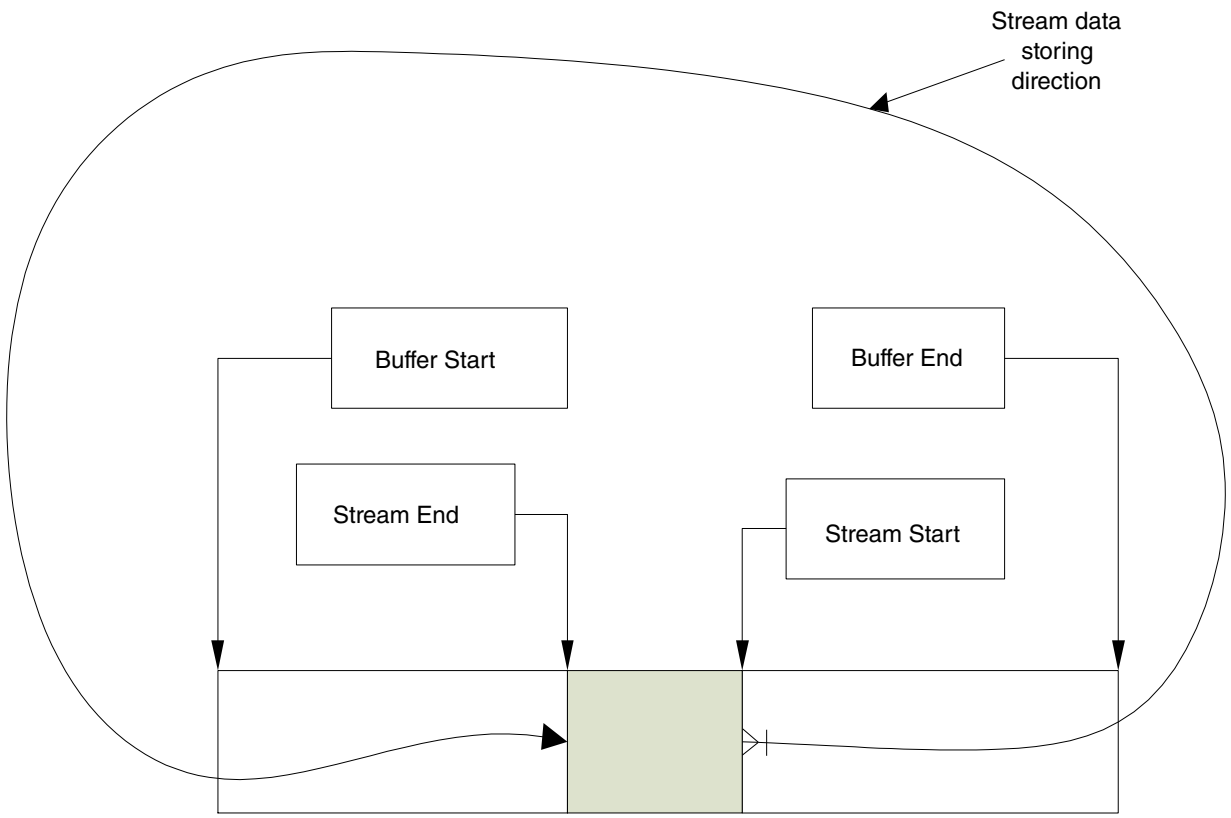

Figure 14-13. Data storage in Stream buffer in Ring Buffer Mode

u32 use_8bits_output
Flag to force 8 bit per pixel output when it's a stream with higher bit depth, e.g., HEVC
Main10 profile stream. The conversion is based on following rule:

Table 14-4. Rule for conversion

Bit depth of original pixel	Original pixel	8bit output
9	XXXXXXXX0	XXXXXXXX
	XXXXXXXX1	XXXXXXXX+1
10	XXXXXXXX00	XXXXXXXX
	XXXXXXXX01	XXXXXXXX
	XXXXXXXX10	XXXXXXXX+1
	XXXXXXXX11	XXXXXXXX+1

struct DecClientHandle callbacks
Callback interfaces that client should provide to facilitate the decoder

```
to inform the client that
                    there is any events or state changing in decoder.
                    struct DecClientHandle {
                           ClientInst client;
                           ClientInitialized* Initialized;
                           ClientHeadersDecoded* HeadersDecoded;
                           ClientBufferDecoded* BufferDecoded;
                           ClientPictureReady* PictureReady;
                           ClientEndOfStream* EndOfStream;
                           ClientReleased* Released;
                           ClientNotifyError* NotifyError;
                    };
                    typedef const void* ClientInst;
                           Opaque pointer to the client.
                    typedef void ClientInitialized(ClientInst inst);
                           Function to notify the client that decoder has successfully
initialized.
                    typedef void ClientHeadersDecoded(ClientInst inst,
                                struct DecSequenceInfo sequence_info);
                           Function to notify about successful decoding of the stream
parameters. Decoder
                           expects client to provide needed buffers through
DecSetPictureBuffers function to
                           continue decoding the actual stream.
                    typedef void ClientBufferDecoded(ClientInst inst,
                                                     struct DecInput* input);
                           Function to notify client that a buffer has been consumed by the
decoder and it can be
                           handled freely by the client.
                    typedef void ClientPictureReady(ClientInst inst,
                                                    struct DecPicture picture);
                           Function to notify about picture that is ready to be outputted.
Client is expected to notify
                           the decoder when it has finished processing the picture, so
decoder can reuse the
                           picture buffer for another picture.
                    typedef void ClientEndOfStream(ClientInst inst);
                            Function to notify the client that all the pending pictures
have been outputted and
                            decoder can be safely shut down.
                    typedef void ClientReleased(ClientInst inst);
                           Function to notify the client that decoder has shut down.
                    typedef void ClientNotifyError(ClientInst inst,
                                                   u32 pic_id,
                                                   enum DecRet rv);
                           Function to notify client about error in the decoding process.
```

Return

```
DEC_OK
                 API function returned successfully.
             DEC_PARAM_ERROR
                 Bad input parameters.
             DEC_MEMFAIL
                 The decoder was not able to allocate memory.
             DEC_FORMAT_NOT_SUPPORTED
                 Format is not supported in hardware. See DecGetBuild.
```

14.2.3.3 DecDecode

Syntax

```
enum DecRet DecDecode(DecInst decInst,
        DecInput *pInput)
```

Purpose

This function will push a COMMAND_DECODE command to the decoding thread, along with the input stream parameters, which will inform the decoding thread to decode one or more NAL units from the current stream for HEVC or element stream for VP9. The input buffer should contain one of the following:

1. Exactly one NAL unit and nothing else.
2. One or more NAL units in byte stream format, as defined in Annex B of the standard [1].
3. Or for VP9 at least one whole frame bit stream data.

The decoder automatically detects the format of the stream data and decodes NAL units until the whole buffer is processed or decoding of a picture is finished for HEVC. For VP9 if there is not enough bit stream data in input buffer, HW decoder will return TIMEOUT error.

Parameters

DecInst*decInst* - A decoder instance created earlier with an DecInit call.

DecInput **pInput* - Pointer to the decoder input structure.

```
struct DecInput {
               struct DWLLinearMem buffer; /* Pointer to the input buffer. */
               u32 data_len;
        };
```

struct DWLLinearMem buffer -- Linear buffer descriptor.

```
struct DWLLinearMem {
                  u32 *virtual_address;
                  u32 bus_address;
                  u32 size;
                  u32 logical_size;
          };
```

Function	Description
*virtual_address	Pointer to the virtual address of stream linear buffer.
bus_address	Bus address of the linear buffer. NOTE: The start of the stream buffer must be in a 128-bit aligned position or accessible for reading from the previous 128-bit aligned position.
size	Physical size of the linear buffer, which is rounded to page multiple.
logical_size	Physical size of the linear buffer, which is rounded to page multiple.

Table continues on the next page...

Function	Description
datalen	Number of bytes contained in the buffer stream buffer. The length can be represented on maximum 32 bits. Valid range: [0, (2^32-1)]

Return value

DEC_OK - The COMMAND_DECODE is successfully pushed to decoder thread's input queue.

DEC_PARAM_ERROR - Error in calling parameters.

DEC_NOT_INITIALIZED - Decoder instance is not initialized. Stream decoding is not started. DecInit must be called before decoding can be started.

14.2.3.4 DecSetPictureBuffers

Syntax

```
enum DecRet DecSetPictureBuffers(DecInst dec_inst,
               const struct DWLLinearMem* buffers,
               u32 num_of_buffers)
```

Purpose

DecSetPictureBuffers assigns picture buffers for the decoder. When decoder has finished decoding the stream headers and knows which types of buffers and how many of them it will need, it will inform that through the HeadersDecoded callback. Buffers must not be written into until client has successfully called DecRelease or decoder has requested new set of buffers through HeadersDecoded callback.

Parameters

DecInst*decInst* - A decoder instance created earlier with an DecInit call.

const struct DWLLinearMem* buffers - Linear buffer to be assigned to the decoder.

u32 num_of_buffers - Number of buffers to be assigned to the decoder.

Return value

DEC_OK - Successfully set picture buffers.

DEC_PARAM_ERROR - Error in calling parameters.

14.2.3.5 DecPictureConsumed

Syntax

```
enum DecRet DecPictureConsumed(DecInst decInst,
        struct DecPicture picture)
```

Purpose

DecPictureConsumed informs the decoder that the client has finished processing a specific picture, which was previously sent to client through the PictureReady callback.

Parameters

DecInst*decInst* - A decoder instance.

DecPicture *pOutput - Pointer to the location used to return the picture parameters. The picture parameters are valid only when the return value indicates that an output picture is available.

```
struct DecPicture {
               struct DecSequenceInfo sequence_info;
               struct DWLLinearMem luma;
               struct DWLLinearMem chroma;
               struct DecPictureInfo picture_info;
               struct DWLLinearMem dscale_luma;
               struct DWLLinearMem dscale_chroma;
               u32 dscale_width;
               u32 dscale_height;
               u32 dscale_stride;
          };
          struct DecSequenceInfo sequence_info
                struct DecSequenceInfo {
                   u32 pic_width;
                   u32 pic_height;
                   u32 sar_width;
                   u32 sar_height;
                   struct DecCropParams crop_params;
                   enum DecVideoRange video_range;
                   u32 matrix_coefficients;
                   u32 is_mono_chrome;
                   u32 is_interlaced;
                   u32 num_of_ref_frames;
                   u32 bit_depth_luma;
                   u32 bit_depth_chroma;
                   u32 pic_stride;
               };
```

Function	Description
picture_width	Decoded picture width in pixels.
picture_height	Decoded picture height in pixels.
sar_width	Horizontal size of the sample aspect ratio.
sar_height	Vertical size of the sample aspect ratio.
struct DecCropParams crop_param	Cropping parameters for the picture.

Table continues on the next page...

Function	Description

	struct DecCropParams {
	u32 crop_left_offset;
	u32 crop_out_width;
	u32 crop_top_offset;
	u32 crop_out_height;
	};

crop_left_offset	Left offset for cropping process, i.e. number of luminance samples removed from the left edge of the picture (always a multiple of 2).
crop_out_width	Width of the picture in luminance samples after cropping is performed.
crop_top_offset	Top offset for cropping process, i.e. number of luminance samples removed from the top edge of the picture (always a multiple of 2).
crop_out_height	Height of the picture in luminance samples after cropping is performed.
Enum DecVideoRange video_range	YUV sample video range. Possible value: • DEC_VIDEO_RANGE_NORMAL - sample range [16, 235] • DEC_VIDEO_RANGE_FULL - sample range [0, 255]
matrix_coefficients	Matrix coefficients RGB->YUV conversion.
is_mono_chrome	Flag to indicate whether sequence is of monochrome.
is_interlaced	Flag to indicate whether sequence is interlaced.
num_of_ref_frames	Maximum number of reference frames.
bit_depth_luma	Bit depth of stored pixels for luma plane.
bit_depth_chroma	Bit depth of stored pixels for chroma plane.
pic_stride	Stride of the picture as stored in memory in bytes.
struct DWLLinearMem luma	Linear buffer for luma pixels.
struct DWLLinearMem chroma	Linear buffer for chroma pixels.

struct DecPictureInfo picture_info	Picture specific information.
	struct DecPictureInfo {
	enum DecPicCodingType pic_coding_type;
	u32 is_corrupted;
	enum DecPictureFormat format;
	u32 cycles_per_mb;
	u32 pic_id;
	};

enum DecPicCodingType pic_coding_type	Picture coding type. Possible value: • DEC_PIC_TYPE_I - key frame • DEC_PIC_TYPE_P - P frame • DEC_PIC_TYPE_B - B frame
is_corrupted	Flag indicates whether picture is corrupted.
enum DecPictureFormat format	Color format of the picture. Refer to DecPictureFormat in 4.2.
cycles_per_mb	Average decoding time in cycles per mb.

Table continues on the next page...

Function	Description
pic_id	Identifier for the picture to be decoded.
struct DWLLinearMem dscale_luma	Linear buffer for luma pixels in down scaled output.
struct DWLLinearMem dscale_chroma	Linear buffer for chroma pixels in down scaled output.
dscale_width	Width of down scaled output in pixels.
dscale_height	Height of down scaled output in pixels.
dscale_stride	Stride of a pixel line in down scaled output in bytes.

Return value

DEC_OK - No pictures available for display.

DEC_PARAM_ERROR - Error in calling parameters.

DEC_NOT_INITIALIZED - Decoder instance is not initialized. DecInit must be called before decoding can be started.

14.2.3.6 DecEndOfStream

Syntax

```
enum DecRet DecEndOfStream (DecInst decInst)
```

Purpose

DecEndOfStream sends a COMMAND_END_OF_STREAM command to the decoder thread to inform the decoder that it should not be expecting any more input stream and finish decoding and outputting all the buffers that are currently pending in the component. Once decoder has finished outputting the pending pictures it will notify the client about it by calling the EndOfStream callback.

Parameters

DecInst*decInst* - A decoder instance.

Return value

DEC_OK - API function returned successfully

DEC_PARAM_ERROR - Error in calling parameters.

DEC_INITFAIL - Decoder instance is not initialized.

14.2.3.7 DecRelease

Syntax

```
void DecRelease(DecInst decInst)
```

Purpose

DecRelease sends a COMMAND_RELEASE command to decoder thread, which will finally close the decoder instance decInst and releases all internally allocated resources. This function must not be called twice for the same instance.

Parameters

DecInst*decInst* - A decoder instance to be released.

Return value

None.

14.2.4 Decoder Application Examples

Purpose

The purpose of the following examples is to show how to implement client's callback functions, as long as using G2 decoder API to implement a simple decoder with demuxer to decode both HEVC and VP9 streams. InitializedCb, HeadersDecodedCb, BufferDecodedCb, PictureReadyCb, EndOfStreamCb, ReleasedCb, and NotifyErrorCb are the system/application dependent callback functions, which are provided by client to the decoder wrapper.

The examples are simplified, e.g. they do not take errors into consideration.

NOTE

Program code in the examples should be considered as pseudo code and may not compile as such.

```
            void SetupDefaultParams(struct TestParams* params);
            int ParseParams(int argc, char* argv[], struct TestParams* params);
            void* CreateDemuxer(struct Client* client);
            void ReleaseDemuxer(struct Client* client);
            void PostProcessPicture(struct Client* client, struct DecPicture* picture);

            static void DispatchBufferForDecoding(struct Client* client, struct DecInput*
buffer)
            {
             enum DecRet rv;
             i32 size = buffer->buffer.size;
             memset(buffer->buffer.virtual_address, 0, size);
             i32 len = client->demuxer.ReadPacket(client->demuxer.inst, (u8*)buffer-
>buffer.virtual_address, &size);
             if (len <= 0) {/* EOS or error. */
```

```
              /* If reading was due to insufficient buffer size, try to realloc with
sufficient size. */
              if (size > buffer->buffer.size) {
               i32 i;
               for (i = 0; i < GetStreamBufferCount(client); i++) {
                if (client->buffers[i].buffer.virtual_address == buffer-
>buffer.virtual_address) {
                  DWLFreeLinear(client->dwl, &client->buffers[i].buffer);
                  if (DWLMallocLinear(client->dwl, size, &client->buffers[i].buffer))
                  {
                    DispatchEndOfStream(client);
                    return;
                  }
                  DispatchBufferForDecoding(client, &client->buffers[i]);
                  return;
                 }
                }
               }
               else {
                DispatchEndOfStream(client);
                return;
               }
              }
              buffer->data_len = len;
              if (client->eos) return; /* Don't dispatch new buffers if EOS already done. */
              /* Decode the contents of the input stream buffer. */
              switch (rv = DecDecode(client->decoder, buffer)) {
               case DEC_OK:
                /* Everything is good, keep on going. */
                break;
               default:
                DispatchEndOfStream(client);
                break;
              }
             }

             static void InitializedCb(ClientInst inst)
             {
              struct Client* client = (struct Client*)inst;
              /* Internal testing feature: Override HW configuration parameters */
              HwconfigOverride(client->decoder,  &tb_cfg);
              /* Start the output handling thread, if needed. */
              if (client->test_params.extra_output_thread)
               pthread_create(&client->parallel_output_thread, NULL, ParallelOutput, client);
               for (int i = 0; i < GetStreamBufferCount(client); i++) {
                if (DWLMallocLinear(client->dwl, DEFAULT_STREAM_BUFFER_SIZE,&client-
>buffers[i].buffer)) {
                 DecRelease(client->decoder);
                 return;
                }
                /* Dispatch the first buffers for decoding. When decoder finished
                * decoding each buffer it will be refilled within the callback. */
                DispatchBufferForDecoding(client, &client->buffers[i]);
               }
             }

             static void HeadersDecodedCb(ClientInst inst, struct DecSequenceInfo info)
             {

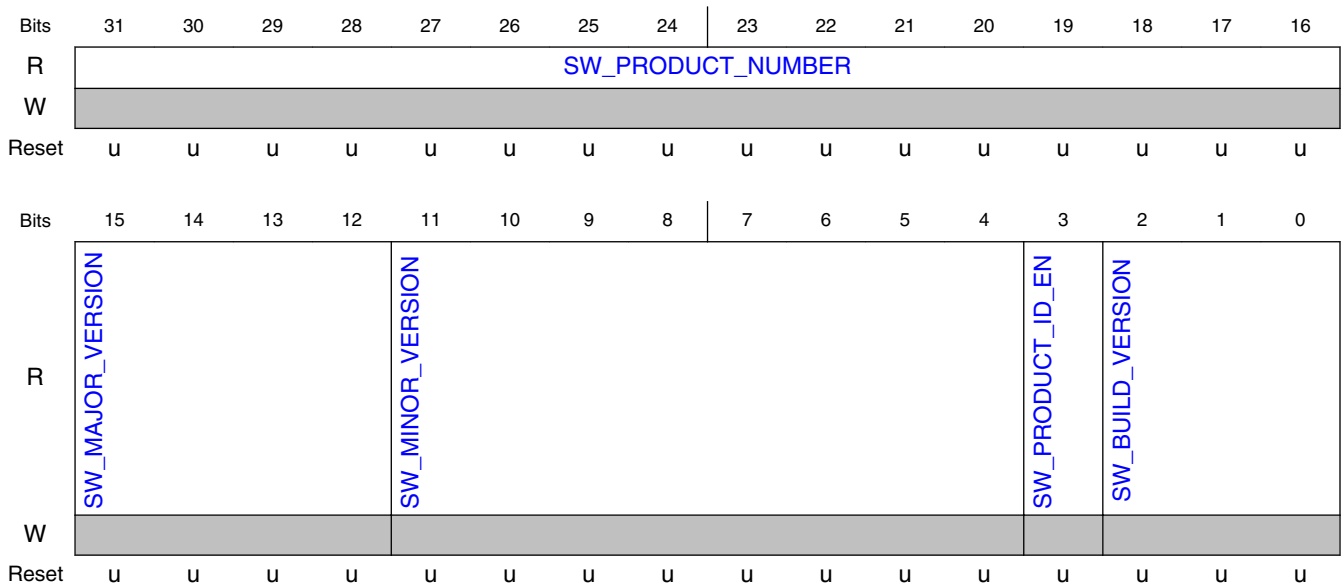
14.2.5.1.2 ID register (read only) (SWREG0)

14.2.5.1.2.1 Offset

Register	Offset
SWREG0	0h

14.2.5.1.2.2 Diagram



14.2.5.1.2.3 Fields

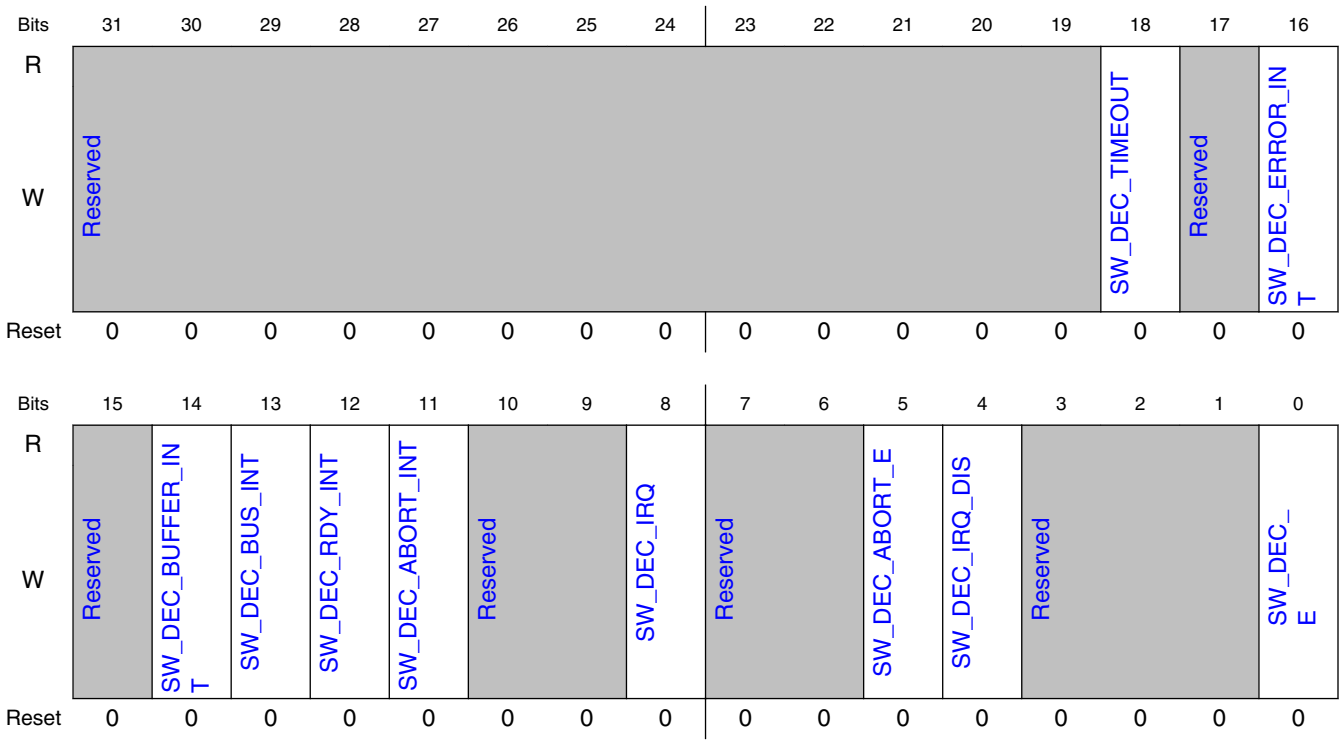
Field	Function
31-16 SW_PRODUCT_NUMBER	Product number (g2)
15-12 SW_MAJOR_VERSION	Major version
11-4 SW_MINOR_VERSION	Minor version
3 SW_PRODUCT_ID_EN	ASCII type product ID enable
2-0 SW_BUILD_VERSION	Build version (core number)

14.2.5.1.3 Interrupt register decoder (SWREG1)

14.2.5.1.3.1 Offset

Register	Offset
SWREG1	4h

14.2.5.1.3.2 Diagram



14.2.5.1.3.3 Fields

Field	Function
31-19 —	Reserved.
18 SW_DEC_TIMEOUT	Interrupt status bit decoder timeout. When high the decoder has been idling for too long. HW will self reset. Possible only if timeout interrupt is enabled
17 —	Reserved.
16 SW_DEC_ERROR_INT	Interrupt status bit input stream error. When high an error is found in input data stream decoding. HW will self reset.
15	Reserved.

Table continues on the next page...

Field	Function
—	
14 SW_DEC_BUFFER_INT	Interrupt status bit input buffer empty. When high input stream buffer is empty but picture is not ready. HW will not self reset.
13 SW_DEC_BUS_INT	Interrupt status bit bus. Error response from bus. HW will self reset.
12 SW_DEC_RDY_INT	Interrupt status bit decoder. When this bit is high decoder has decoded a picture. HW will self reset.
11 SW_DEC_ABORT_INT	Interrupt status bit decoding aborted. When this bit is high decoder has aborted the current picture decoding as SW requested (sw_dec_abort_e). Decoder self reset and sw_dec_abort_e written low
10-9 —	Reserved.
8 SW_DEC_IRQ	Decoder IRQ. When high decoder requests an interrupt. SW will reset this after interrupt is handled.
7-6 —	Reserved.
5 SW_DEC_ABORT_E	Abort decoding enable. Setting this bit high will cause HW to abort decoding and safely to reset itself down. After abort is complete the corresponding interrupt status is set and this bit is set low as well as the decoder enable.
4 SW_DEC_IRQ_DIS	Decoder IRQ disable. When high there are no interrupts concerning decoder from HW. Polling must be used to see the interrupt statuses.
3-1 —	Reserved.
0 SW_DEC_E	Decoder enable. Setting this bit high will start the decoding operation. HW will reset this when picture is processed or ASO or stream error is detected or bus error or timeout interrupt is given.

14.2.5.1.4.3 Fields

Field	Function
31-28 SW_DEC_STRM_SWAP	Byte swap configuration for stream data 4 Bit byte order vector to control byte locations inside HW internal 128 bit data vector. For 64 and 32 bit external bus widths, the data is first gathered to 128 bit width and then bytes swapped accordingly: Bit 0: 8 bit swap Bit 1: 16 bit swap Bit 2: 32 bit swap Bit 3: 64 bit swap '0000' = 0-1-2-3-4-5-6-7-8-9-10-11-12-13-14-15 '0001' = 1-0-3-2-5-4-7-6... '0010' = 2-3-0-1-6-7-4-5... '0011' = 3-2-1-0-7-6-5-4... '0100' = 4-5-6-7-0-1-2-3... ... '0111' = 7-6-5-4-3-2-1-0 '1000' = 8-9-10-11-12-13-14-15-0-1-2-3-4-5-6-7... ...

Table continues on the next page...

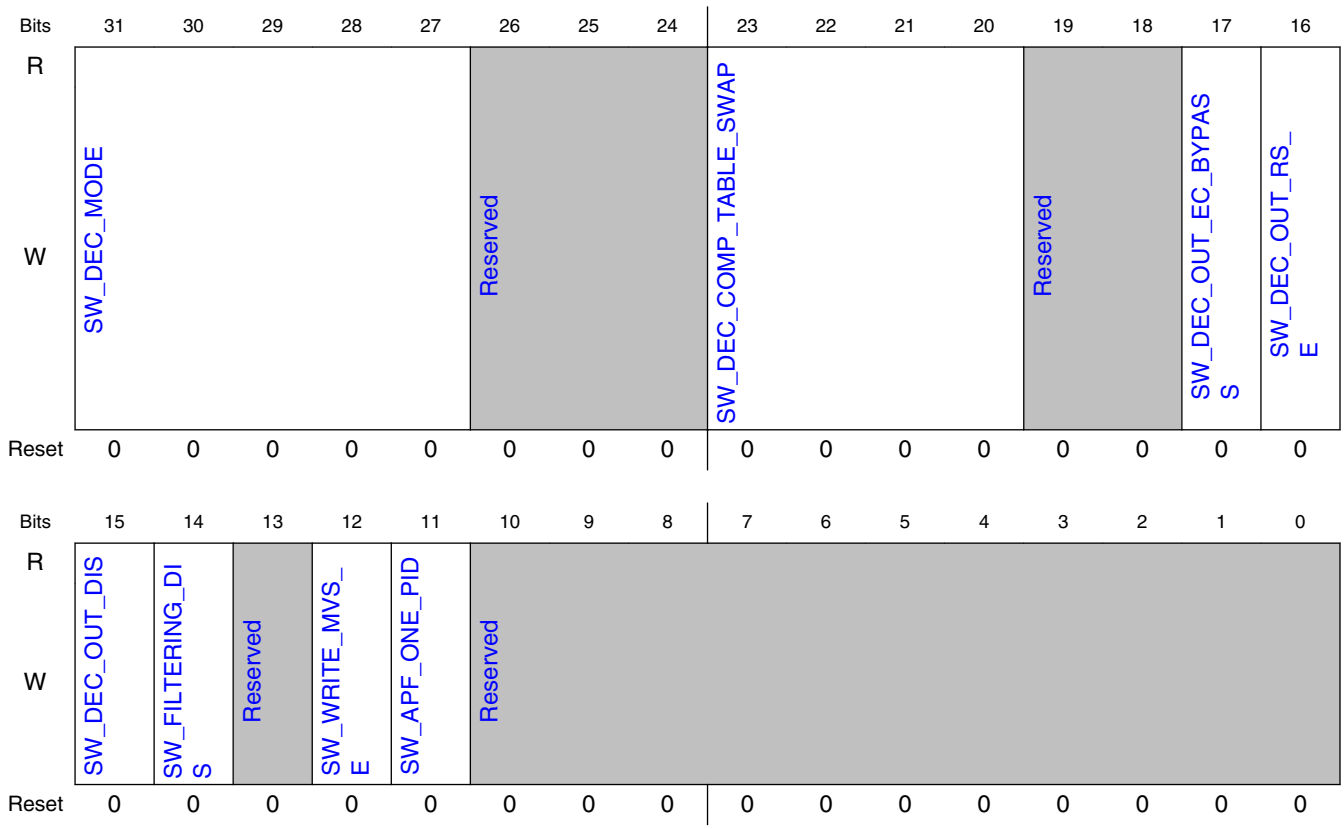
Field	Function
	'1111'=15-14-13-12-11-10-9-8-7-6-5-4-3-2-1-0
27-24 SW_DEC_PIC_SWAP	Byte swap configuration for decoder reference output picture data
23-20 SW_DEC_DIRMV_SWAP	Byte swap configuration for direct mode MV data (read/write)
19-16 SW_DEC_TAB0_SWAP	Byte swap configuration for VP9 stream propability tables
15-12 SW_DEC_TAB1_SWAP	Byte swap configuration for HEVC scaling lists / VP9 segmentation map read/write
11-8 SW_DEC_TAB2_SWAP	Byte swap configuration for VP9 CTX counter values
7-4 SW_DEC_TAB3_SWAP	Byte swap configuration for tile sizes
3-0 SW_DEC_RSCAN_SWAP	Byte swap for raster scan output picture data

14.2.5.1.5 Decoder control register 0 (SWREG3)

14.2.5.1.5.1 Offset

Register	Offset
SWREG3	Ch

14.2.5.1.5.2 Diagram



14.2.5.1.5.3 Fields

Field	Function
31-27 SW_DEC_MODE	Decoding mode: 00000-01011b - Reserved 01100b - HEVC 01101b - VP9 01110-11111b - Reserved
26-24 —	Reserved.
23-20 SW_DEC_COMP_TABLE_SWAP	Byte swap configuration for compress table data
19-18 —	Reserved.
17 SW_DEC_OUT_EC_BYPASS	Compress bypass

Table continues on the next page...

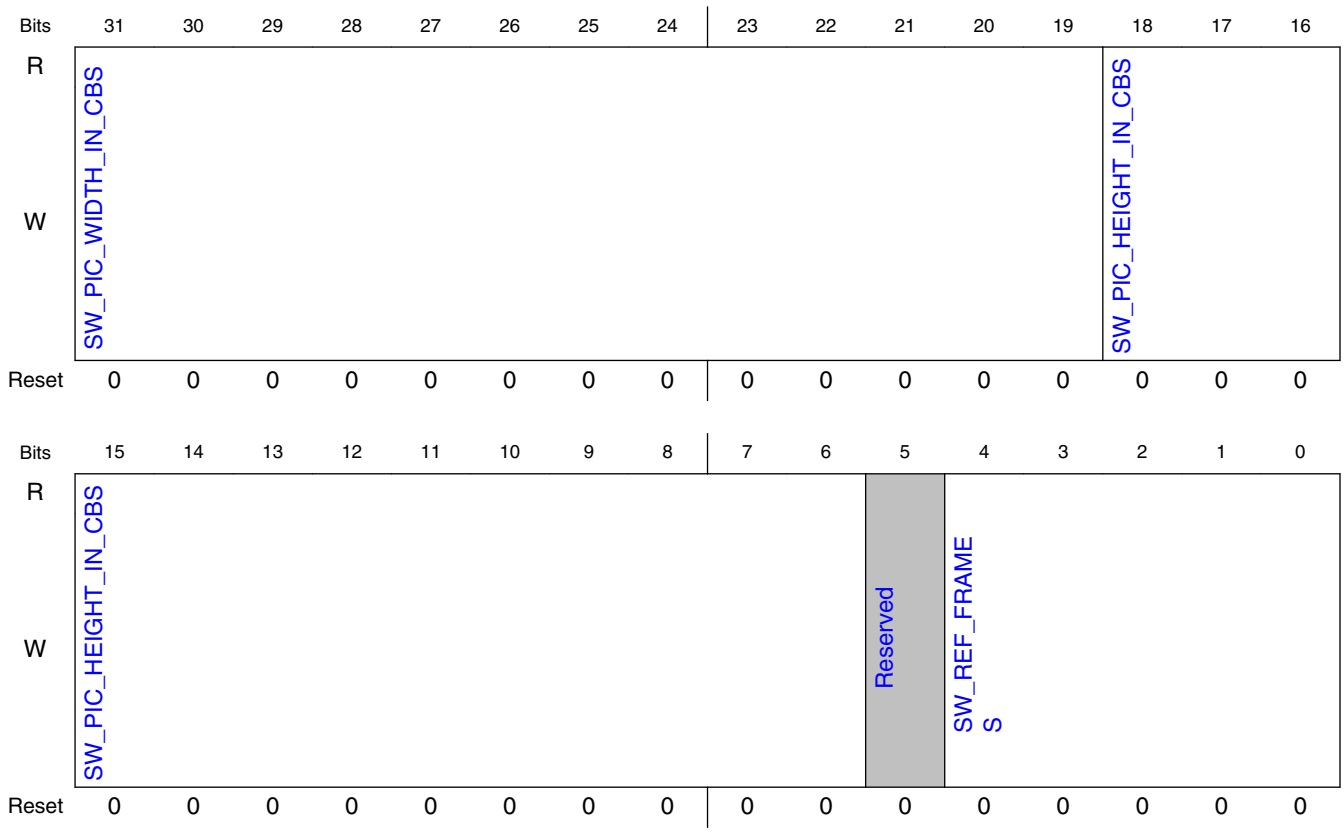
Field	Function
16 SW_DEC_OUT_RS_E	Raster scan output enable. If high decoder writes the raster scan output if the configuration of Decoder includes PP raster scan output
15 SW_DEC_OUT_DIS	Disable decoder output picture writing 0b - Decoder output picture is written to external memory 1b - Decoder output picture is not written to external memory
14 SW_FILTERING_DIS	De-block filtering disable 0b - Filtering is enabled for current picture 1b - Filtering is disabled for current picture
13 —	Reserved.
12 SW_WRITE_MVS_E	Direct mode motion vector write enable for current picture 0b - Writing disabled for current picture. 1b - The direct mode motion vectors are written to external memory. HEVC/VP9 direct mode motion vectors are written to DPB aside with the corresponding reference picture. Other decoding mode dir mode mvs are written to external memory starting from sw_dir_mv_base.
11 SW_APF_ONE_PID	Prefetch partitions that have the same pic_id together
10-0 —	Reserved.

14.2.5.1.6 Decoder control register 1 (SWREG4)

14.2.5.1.6.1 Offset

Register	Offset
SWREG4	10h

14.2.5.1.6.2 Diagram



14.2.5.1.6.3 Fields

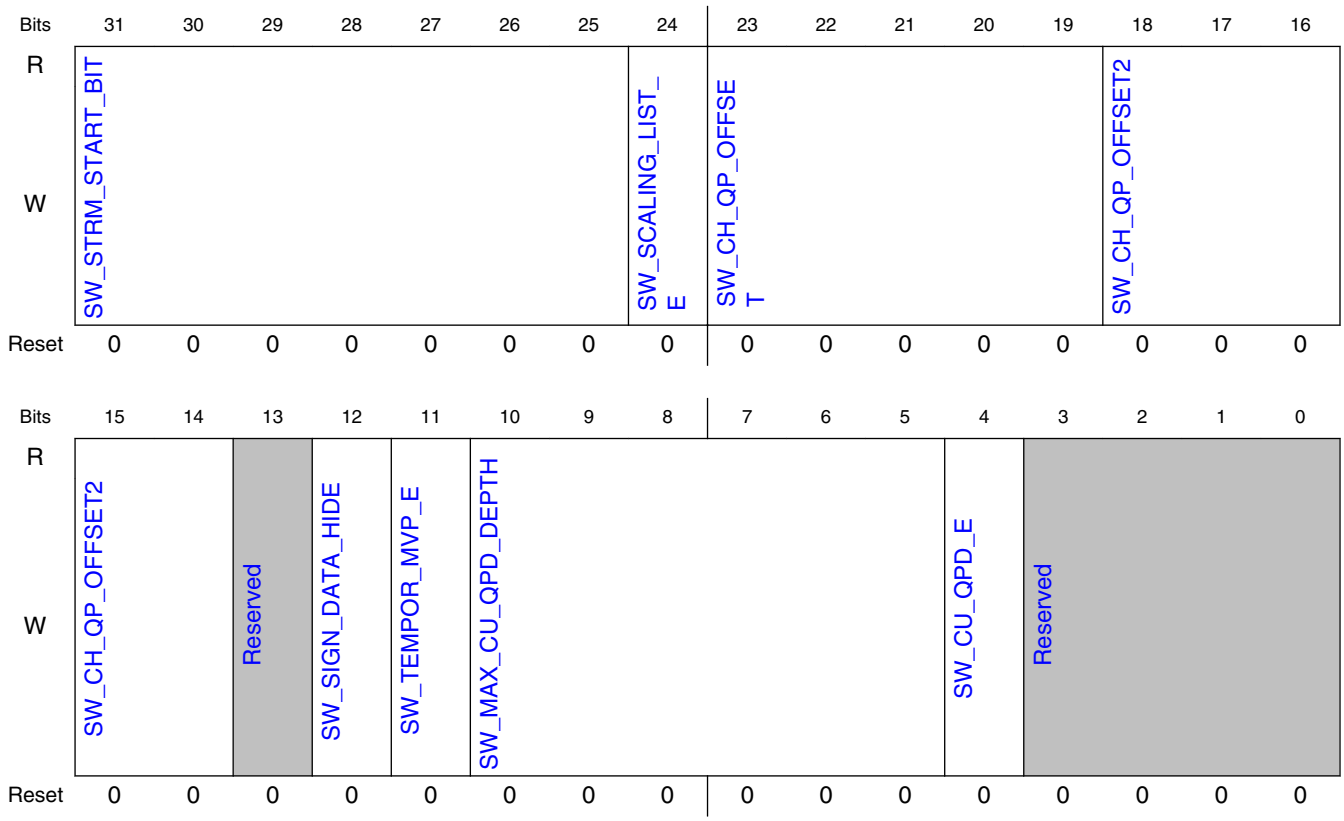
Field	Function
31-19 SW_PIC_WIDTH_IN_CBS	Picture width in min coded blocks (min = 8pix)
18-6 SW_PIC_HEIGHT_IN_CBS	Picture height in min coded blocks (min = 8pix)
5 —	Reserved.
4-0 SW_REF_FRAMES	HEVC: num_ref_frames maximum number of short and long term reference frames in decoded picture buffer

14.2.5.1.7 Decoder control register 2 (SWREG5)

14.2.5.1.7.1 Offset

Register	Offset
SWREG5	14h

14.2.5.1.7.2 Diagram



14.2.5.1.7.3 Fields

Field	Function
31-25 SW_STRM_START_BIT	Exact bit of stream start word where decoding can be started (assosiates with sw_rlc_vlc_base)
24 SW_SCALING_LIST_E	Scaling matrix enable 0b - Normal transform 1b - Use scaling matrix for transform (read from external memory)
23-19 SW_CH_QP_OFFSET	Chroma Qp filter offset. (For HEVC this offset concerns Cb only)

Table continues on the next page...

Field	Function
18-14 SW_CH_QP_OFFSET2	Chroma Qp filter offset for cr type
13 —	Reserved.
12 SW_SIGN_DATA_HIDE	Flag for stream decoding
11 SW_TEMPOR_MVP_E	Temporal mvp enable
10-5 SW_MAX_CU_QPD_DEPTH	Max CU qp delta depth
4 SW_CU_QPD_E	CU qp delta enable
3-0 —	Reserved.

14.2.5.1.8 Decoder control register 3 (SWREG6)

14.2.5.1.8.1 Offset

Register	Offset
SWREG6	18h

14.2.5.1.8.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SW_STREAM_LEN

R W	SW_STREAM_LEN															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

14.2.5.1.8.3 Fields

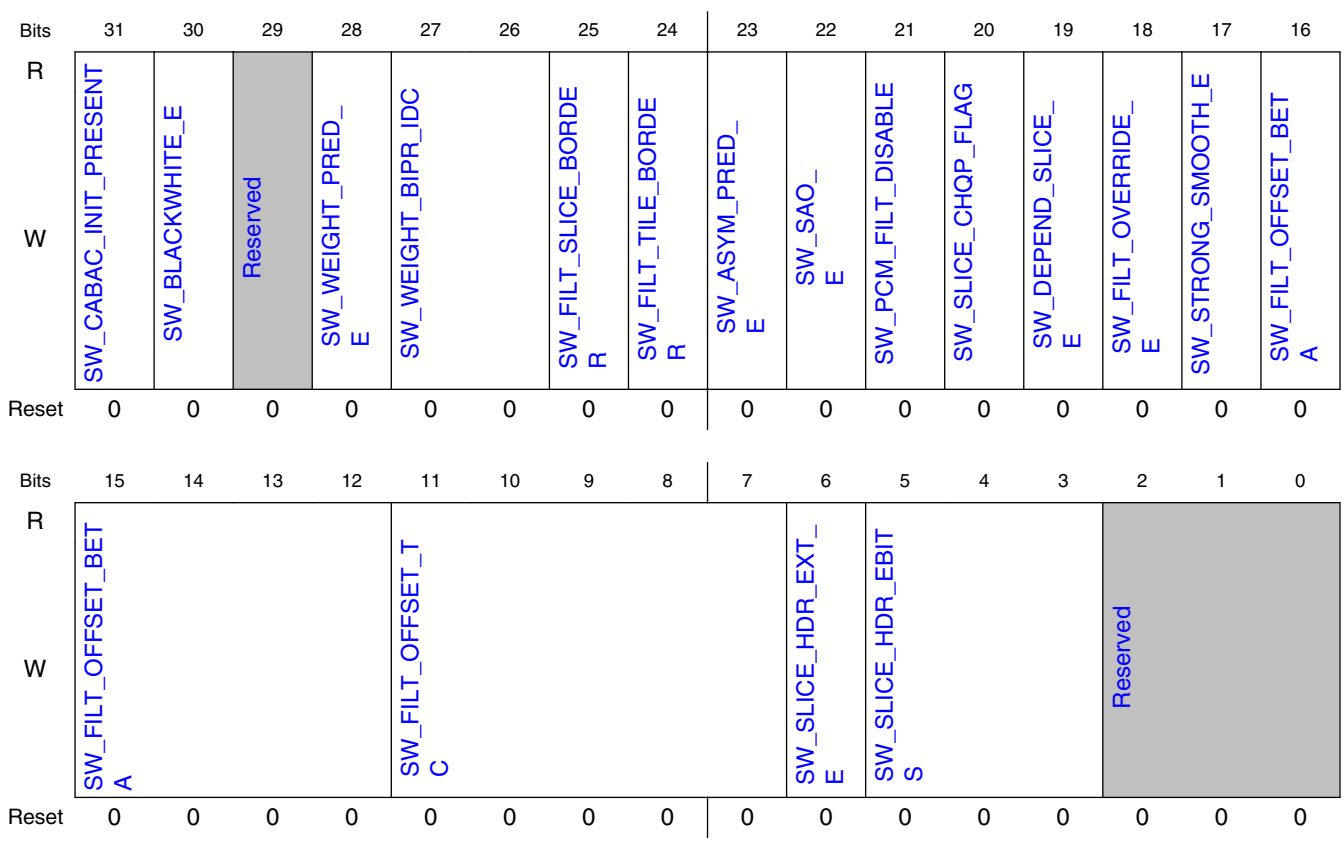
Field	Function
31-0 SW_STREAM_LEN	Amount of stream data bytes in input buffer. If the given buffer size is not enough for finishing the picture the corresponding interrupt is given and new stream buffer base address and stream buffer size information should be given (assosiates with sw_rlc_vlc_base). For HEVC the buffer must include at least data for one slice/VP of the picture

14.2.5.1.9 Decoder control register 4 (SWREG7)

14.2.5.1.9.1 Offset

Register	Offset
SWREG7	1Ch

14.2.5.1.9.2 Diagram



14.2.5.1.9.3 Fields

Field	Function
31 SW_CABAC_INIT_PRESENT	CABAC init present enable for stream decoding
30 SW_BLACKWHITE_E	Sampling 0b - 4:2:0 sampling format 1b - 4:0:0 sampling format (H264 monochroma)
29 —	Reserved.
28 SW_WEIGHT_PRED_E	Weighted prediction enable for P slices
27-26 SW_WEIGHT_BIPR_IDC	Weighted prediction specification 00b - Default weighted prediction is applied to B slices 01b - Explicit weighted prediction shall be applied to B slices 10b - NA 11b - NA
25 SW_FILT_SLICE_BORDER	Filter enable over slice border
24 SW_FILT_TILE_BORDER	Filter enable over tile border
23 SW_ASYM_PRED_E	Asymmetric prediction flag for stream decoding
22 SW_SAO_E	Sample Adaptive Offset enable for stream decoding
21 SW_PCM_FILT_DISABLE	Disable for PCM loop filtering
20 SW_SLICE_CHQP_FLAG	Slice header flag for chroma QP present (if it is included in slice header)
19 SW_DEPEND_SLICE_E	Dependent slice enable
18 SW_FILT_OVERRIDE_E	Filter override enable
17 SW_STRONG_SMOOTH_E	Strong smoothing enable
16-12	Filter beta offset (declared as div2)

Table continues on the next page...

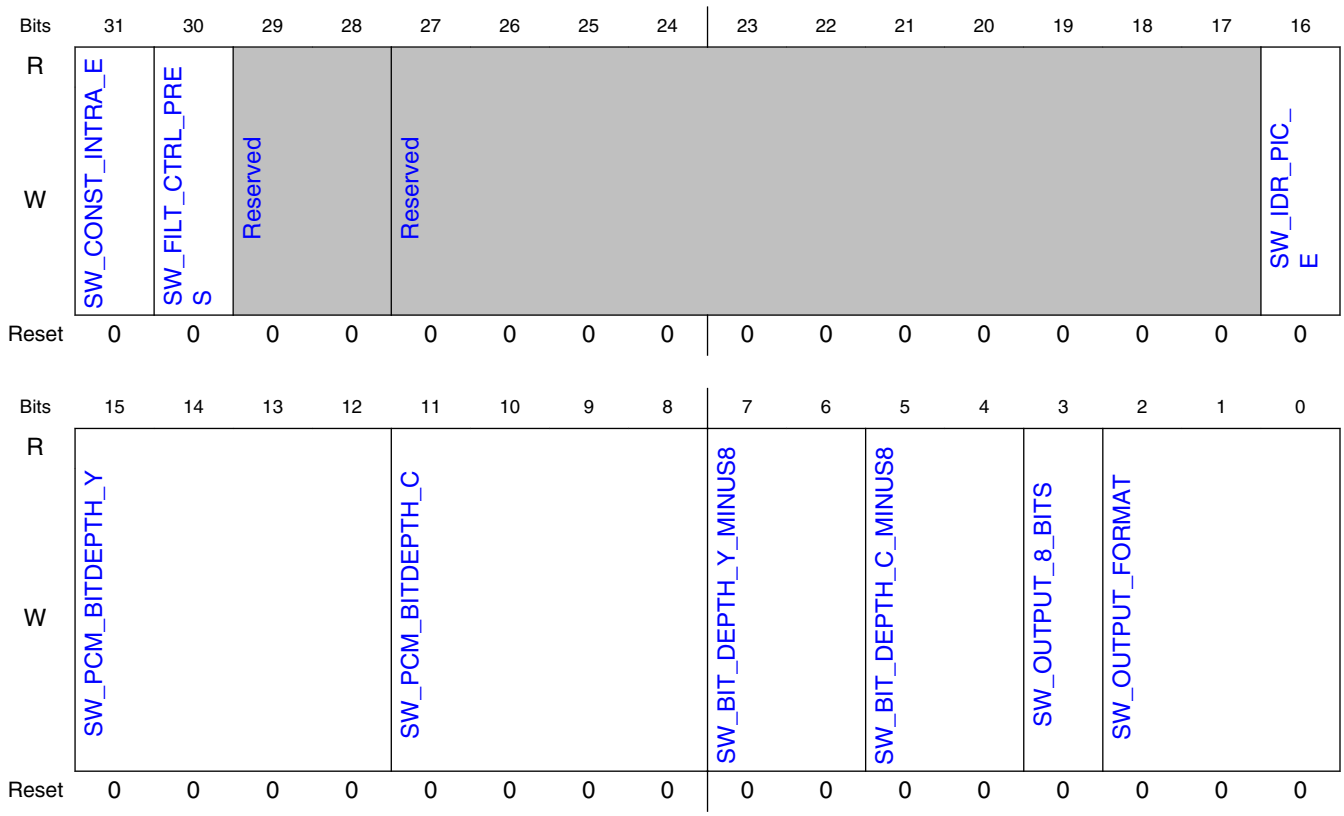
Field	Function
SW_FILT_OFFSET_BETA	
11-7 SW_FILT_OFFSET_TC	Filter tc offset (declared as div2)
6 SW_SLICE_HDR_EXT_E	Slice header extension enable. Reserved for future use
5-3 SW_SLICE_HDR_EBITS	Number of extra slice header bits (if enabled slice header extension)
2-0 —	Reserved.

14.2.5.1.10 Decoder control register 5 (SWREG8)

14.2.5.1.10.1 Offset

Register	Offset
SWREG8	20h

14.2.5.1.10.2 Diagram



14.2.5.1.10.3 Fields

Field	Function
31 SW_CONST_INTRA_E	constrained_intra_pred_flag equal to 1 specifies that intra prediction uses only neighbouring intra macroblocks in prediction. When equal to 0 also neighbouring inter macroblocks are used in intra prediction process.
30 SW_FILT_CTRL_PRES	deblocking_filter_control_present_flag indicates whether extra variables controlling characteristics of the deblocking filter are present in the slice header.
29-28 —	Reserved.
27-17 —	Reserved.
16 SW_IDR_PIC_E	IDR (instantaneous decoding refresh) picture flag.
15-12 SW_PCM_BITDEPTH_Y	Bit depth for PCM Y data
11-8	Bit depth for PCM C data

Table continues on the next page...

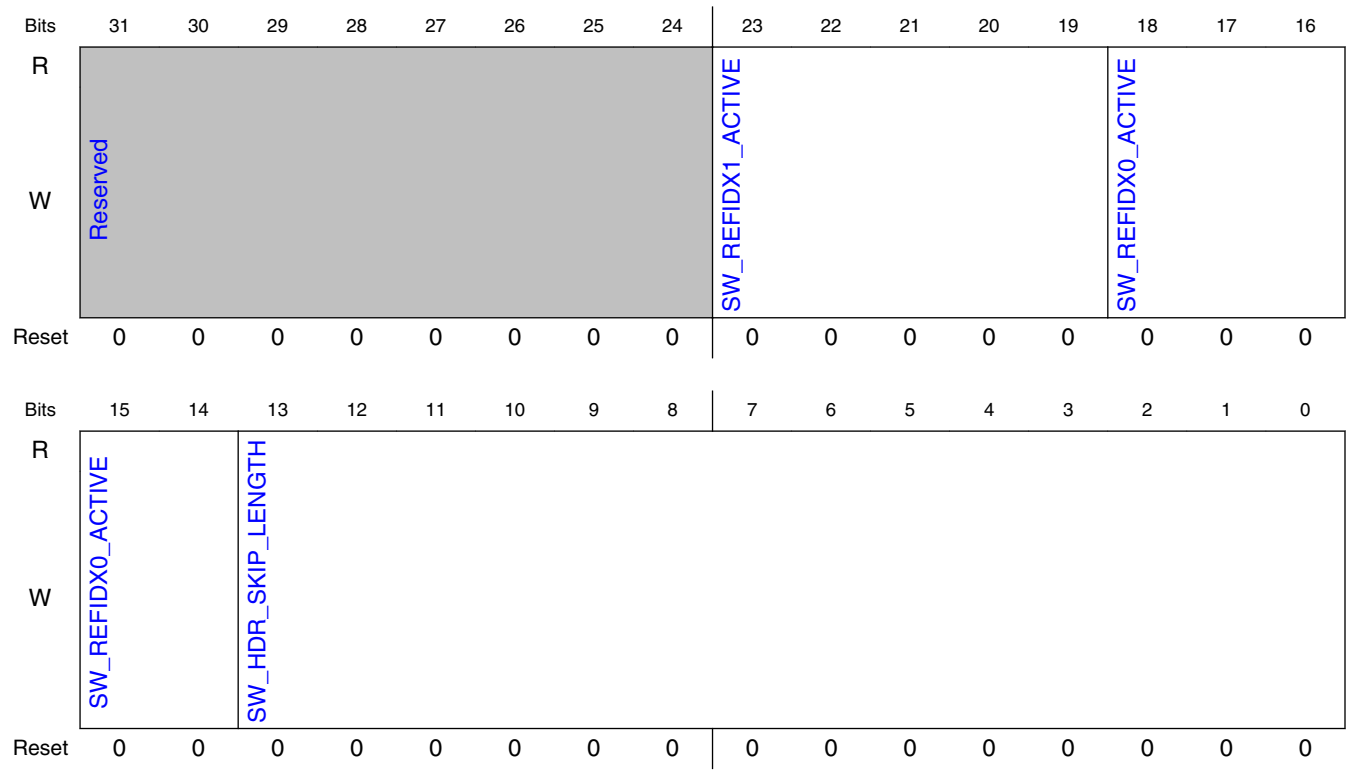
Field	Function
SW_PCM_BITDEPTH_C	
7-6 SW_BIT_DEPTH_Y_MINUS8	Bit depth of luma samples minus 8
5-4 SW_BIT_DEPTH_C_MINUS8	Bit depth of chroma samples minus 8
3 SW_OUTPUT_8_BITS	enable rasterscan output force to 8 bit(only for hevc main10 and vp9 10bit)
2-0 SW_OUTPUT_FORMAT	Raster scan and down scale output data format 000b - Each pixel in 10 bits when luma or chroma pixel bit depth is larger than 8; or 8 bits when both luma and chroma pixel bit depth are 8 bits. (default) 001b - Store in P010 format when luma or chroma pixel bit depth is larger than 8. 010b - A customized format: please refer to register SWREG23[6].

14.2.5.1.11 Decoder control register 6 (SWREG9)

14.2.5.1.11.1 Offset

Register	Offset
SWREG9	24h

14.2.5.1.11.2 Diagram



14.2.5.1.11.3 Fields

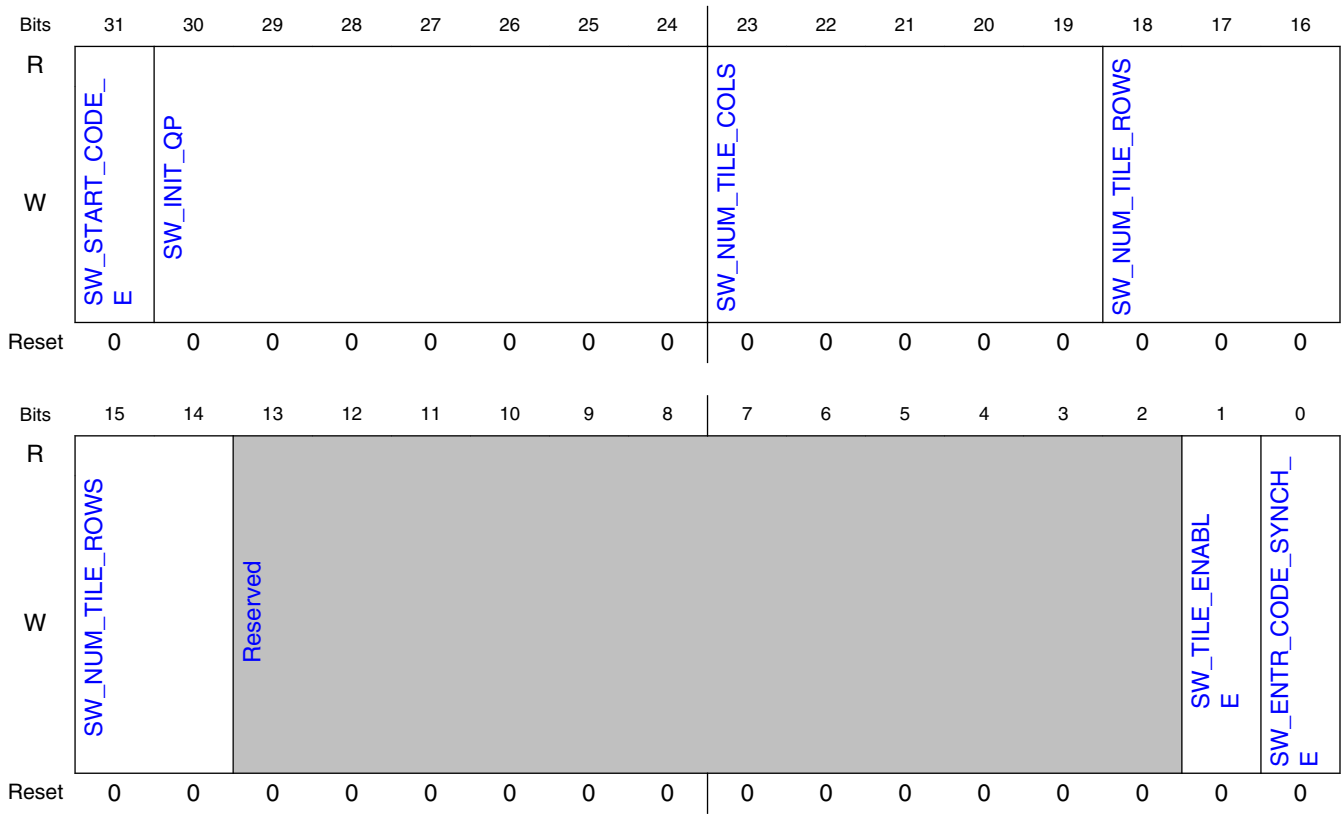
Field	Function
31-24 —	Reserved.
23-19 SW_REFIDX1_ACTIVE	Specifies the maximum reference index that can be used while decoding inter predicted macro blocks.
18-14 SW_REFIDX0_ACTIVE	Specifies the maximum reference index that can be used while decoding inter predicted macro blocks. This is same as in previous decoders (width increased with q bit)
13-0 SW_HDR_SKIP_LENGTH	Length of slice header skip length (bytes used by sw)

14.2.5.1.12 Decoder control register 7 (SWREG10)

14.2.5.1.12.1 Offset

Register	Offset
SWREG10	28h

14.2.5.1.12.2 Diagram



14.2.5.1.12.3 Fields

Field	Function
31 SW_START_CODE_E	Bit for indicating stream start code existence 0b - Stream does not contain start codes 1b - Stream contains start codes
30-24 SW_INIT_QP	Initial value for quantization parameter (picture quantizer).
23-19 SW_NUM_TILE_COLS	Number of tile columns in picture
18-14	Number of tile rows in picture

Table continues on the next page...

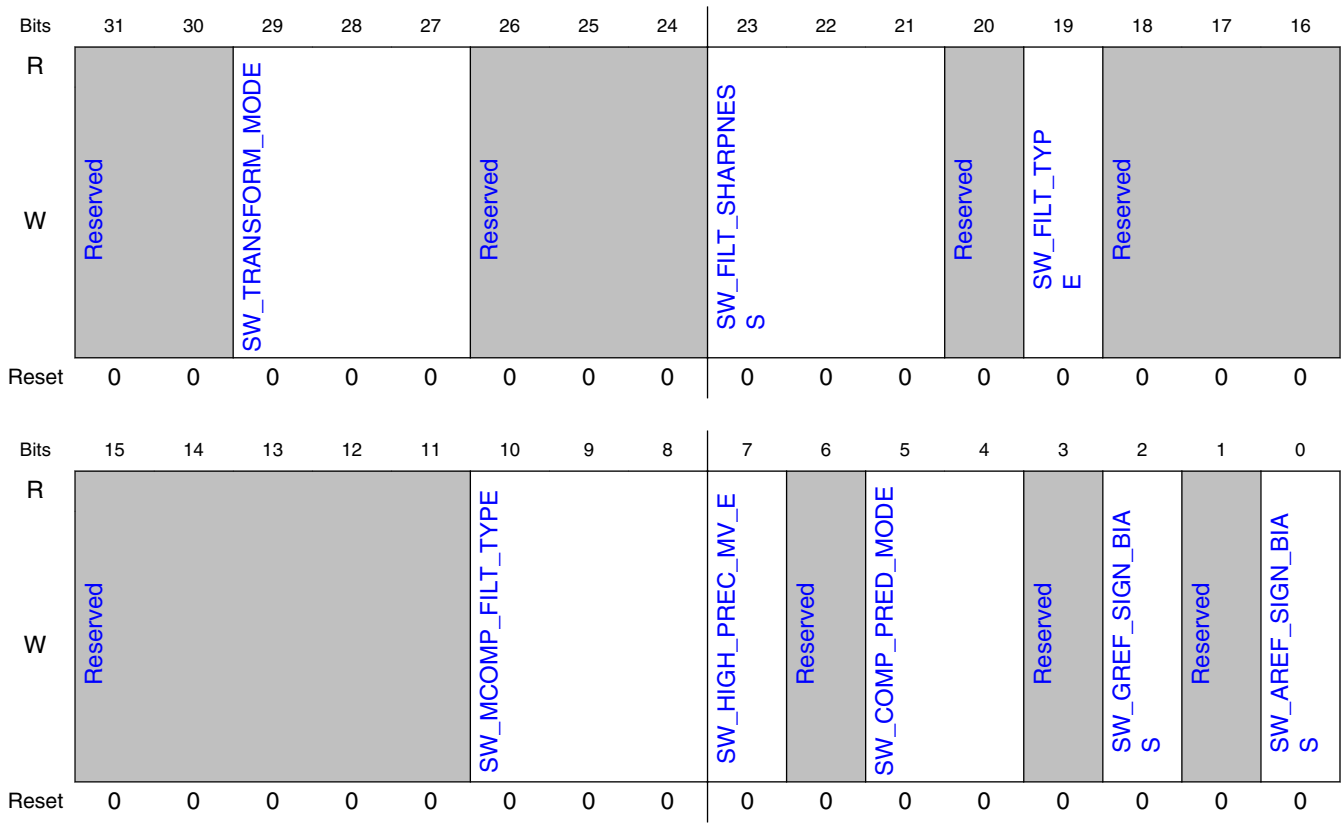
Field	Function
SW_NUM_TILE_ROWS	
13-2 —	Reserved.
1 SW_TILE_ENABLE	Tile enable
0 SW_ENTR_CODE_SYNCH_E	Entropy coding synchronization enable (Possible parallel cabac decoding)

14.2.5.1.13 Decoder control register 8 (SWREG11)

14.2.5.1.13.1 Offset

Register	Offset
SWREG11	2Ch

14.2.5.1.13.2 Diagram



14.2.5.1.13.3 Fields

Field	Function
31-30 —	Reserved.
29-27 SW_TRANSFORM_MODE	Transform modes 000b - 4x4 only 001b - Allow 8x8 010b - Allow 16x16 011b - Allow 32x32 100b - TX mode select
26-24 —	Reserved.
23-21 SW_FILT_SHARPNESS	Filter sharpness value
20 —	Reserved.
19 SW_FILT_TYPE	Filter Type

Table continues on the next page...

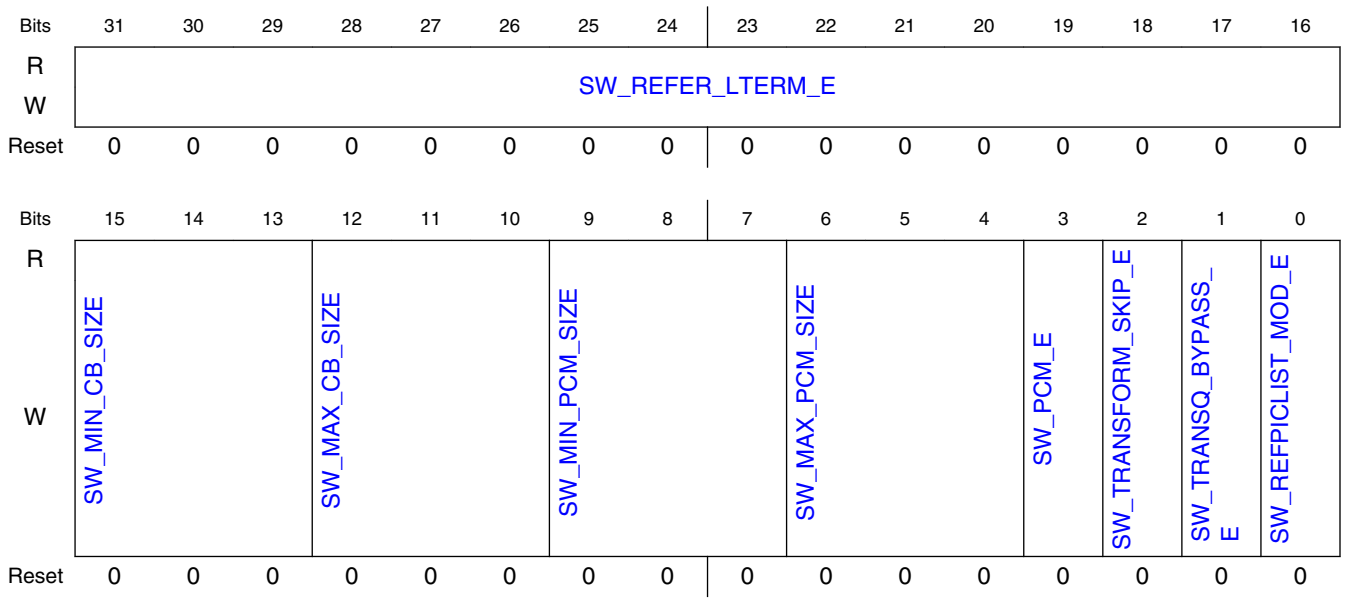
Field	Function
18-11 —	Reserved.
10-8 SW_MCOMP_FILT_TYPE	Inter prediction filter type to stream decoder 000b - Eight tap smooth 001b - Eight tap 010b - Eight tap sharp 011b - Bilinear 100b - Switchable
7 SW_HIGH_PREC_MV_E	High precision MV prediction enable
6 —	Reserved.
5-4 SW_COMP_PRED_MODE	Prediction Comp Type 00b - Single prediction only 01b - COMP prediction only 10b - Hybrid prediction
3 —	Reserved.
2 SW_GREF_SIGN_BIAS	Golden reference picture sign bias used for motion vector decoding
1 —	Reserved.
0 SW_AREF_SIGN_BIAS	Alternate reference picture sign bias used for motion vector decoding

14.2.5.1.14 Decoder control register 9 (SWREG12)

14.2.5.1.14.1 Offset

Register	Offset
SWREG12	30h

14.2.5.1.14.2 Diagram



14.2.5.1.14.3 Fields

Field	Function
31-16 SW_REFER_LTERM_E	Long term flag for reference picture index Definition: Bit 31 for picture index 0 Bit 30 for picture index 1 etc.
15-13 SW_MIN_CB_SIZE	CodedBlock min size (2^N): 011b - 8 pix 100b - 16 pix 101b - 32 pix 110b - 64 pix
12-10 SW_MAX_CB_SIZE	CodedBlock max size (2^N): 011b - 8 pix 100b - 16 pix 101b - 32 pix 110b - 64 pix
9-7 SW_MIN_PCM_SIZE	PCM min size (2^N): 011b - 8 pix 100b - 16 pix 101b - 32 pix 110b - 64 pix
6-4 SW_MAX_PCM_SIZE	PCM max size (2^N): 011b - 8 pix 100b - 16 pix 101b - 32 pix 110b - 64 pix
3 SW_PCM_E	IPCM MBs flag

Table continues on the next page...

Field	Function
2 SW_TRANSFORM_SKIP_E	Transform skipping flag
1 SW_TRANSQ_BYPASS_E	Transform bypass flag (lossless mode)
0 SW_REFPICLIST_MOD_E	Refpic list reordering flag

14.2.5.1.15 Decoder control register 10 (SWREG13)

14.2.5.1.15.1 Offset

Register	Offset
SWREG13	34h

14.2.5.1.15.2 Diagram

Chapter 15
Display Controller Subsystem (DCSS)

15.1 Display Controller Subsystem

15.1.1 Overview

The Display Controller Subsystem (DCSS) is used to source up to three display buffers, compose them, and drive a display using HDMI 2.0a with HDCP 2.2. The DCSS is intended to support up to 4kp60 displays. HDR10 image processing capabilities are included to provide a solution capable of driving next generation high dynamic range displays.

15.1.2 Features

The DCSS supports two major modes: HDR10 and Dolby Vision. These modes are mutually exclusive modes of operation. In HDR10 mode, there are 3 identical pipelines for video or graphics. In Dolby Vision mode, there are two pipelines, the Video pipeline (consists of 2 streams, base and enhanced layers) and the Overlay pipeline. The features of the DCSS include support for the following capabilities.

- Up to 4Kp60 video/graphics display over HDMI 2.0a with HDCP 2.2 encryption and audio formats including Dolby Digital, DTS, TrueHD, LPCM
- On-the-fly image composition of up to 3 source display buffers.
  - PIG (picture in GFX) overlay on video
  - PIP (picture in picture) scaled video on video with graphics
- On-the-fly decompression of compressed video or graphics frame buffers to optimize DRAM bandwidth.
- On-the-fly conversion of tile frame buffers to raster for display refresh.
- Integrated memory to store pre-fetched pixel data to manage DRAM access latencies.
- 3 independent 7x7 tap scaling to process 3 display buffers.

    - Supports x7 up and x1/7 down scaling ratios, UHD/HD/SD/PIP
    - PIP (picture in picture) scaled video on video with graphics
- Dolby or HDR10 image processing (see below for detailed feature list). These modes are mutually exclusive.
- Scaled output to DDR write back for 1 of three scaler engines (programmable). Used for large ratio downscaled images to manage dataflow from DDR and real time display processing.
- Read bus master to source raster frames from memory with direct input into Dolby and HDR10 pixel processing data pipes (bypass buffer conversion and scaling HW).
- CEA861 compatible display timing generator.
- Display state controller to manage display context changes.
- HDMI supporting HDCP output interface.
- YUV420/422/444 and ARGB with 8/10-bit per component source buffer formats

15.1.2.1 HDR10 Pixel Processing

In HDR10 mode, all three pixel processing pipelines are identical.

Each HDR10 pixel processing input pipeline supports
- 10-bit per component input
- Color space conversion
- LUT gamma correction per component

HDR10 Output Pipeline The HDR10 pixel processing output pipeline supports
- Linear to non-linear conversion per component
- Color space conversion
- 10-bit per component RGB/YUV444

15.1.2.2 Dolby Vision Pixel Processing

When the DCSS is configured to operate in Dolby Vision Mode, the follow capabilities are supported.

Dolby Vision Video pixel processing features supported.

- Algorithms
    - Dolby Vision base and enhanced layer processing and composition
    - Dolby Vision color space conversion
    - Dolby Vision color volume mapping
- Metadata and Tone Curve information processing.

- 422 10-bit pixel input
- Bypass supported for non-Dolby content

Dolby Overlay(Graphics) pixel processing features supported.

- Algorithms
  - Dolby Vision Input color volume conversion for overlay
  - Color space conversion
- Bypass supported for non-Dolby content
- Support for RGB and YUV422/444 8-bit pixel formats
- Tone Curve information processing

The overlay pipeline supports graphics and/or video overlay pixel processing. The video and graphics overlay pixels are composited at the output of these two Dolby pixel processing pipes. The overlay buffer can contain any content preprocessed by the SoC graphics accelerator or general purpose microprocessor. This can include preprocessed video and graphics composited buffers.

Dolby Output pixel processing features supported.

- Algorithms
  - Dolby Vision output color space mapping
  - Video+metadata scrambling
  - Dithering for 8/10 bit YUV output
- Output formats
  - Bypassed 8-bit RGB
  - 8/10-bit UV444

15.1.3 Use Cases

Some of the use cases the DCSS supports are decribed here:

- Video only – This can be optimized for power by turning off the CPUs and graphics and unused VPU decoders
- Graphics only - Supports GUI or gaming. This can be optimized for power by turning off the VPU
- Video with graphics overlay – Per pixel alpha blending supported
- PIG (picture in graphics) - Graphics with PIP video in corner
- PIP (picture in picture) – Full screen video with PIP video in corner
- Video with PIP and graphics – Full screen video with PIP video in corner and graphics overlay

Since the DCSS is a programmable display engine, the use cases are not limited to the cases listed above.

15.1.4 DCSS Block Diagram

The first diagram below contains the front end of the DCSS datapath, including all the busmaster components, decompression blocks, resolve memory, and scaler. All components feed the pixel processing components later in the DCSS pipeline.

The second diagram below contains the display pipeline, including the mutually exclusive Dolby and HDR10 processing pixel pipes, alpha blender, color subsampler, and HDMI controller and PHY.

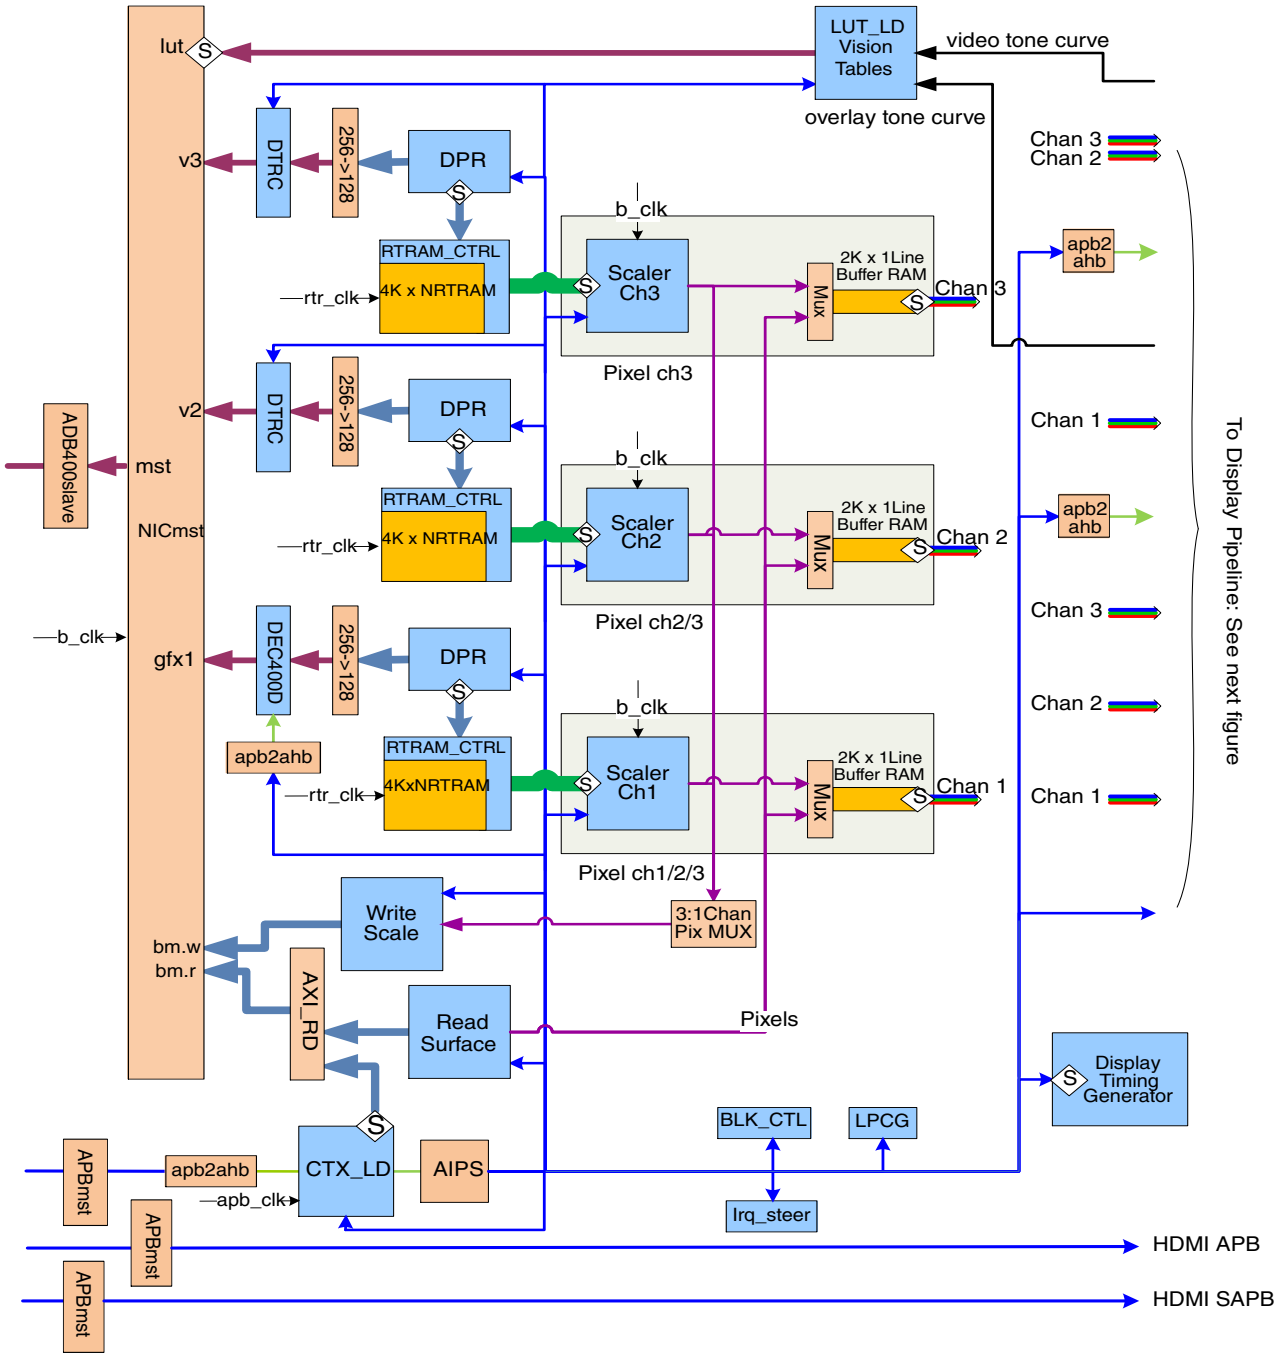

Figure 15-1. DCSS Front End Block Diagram

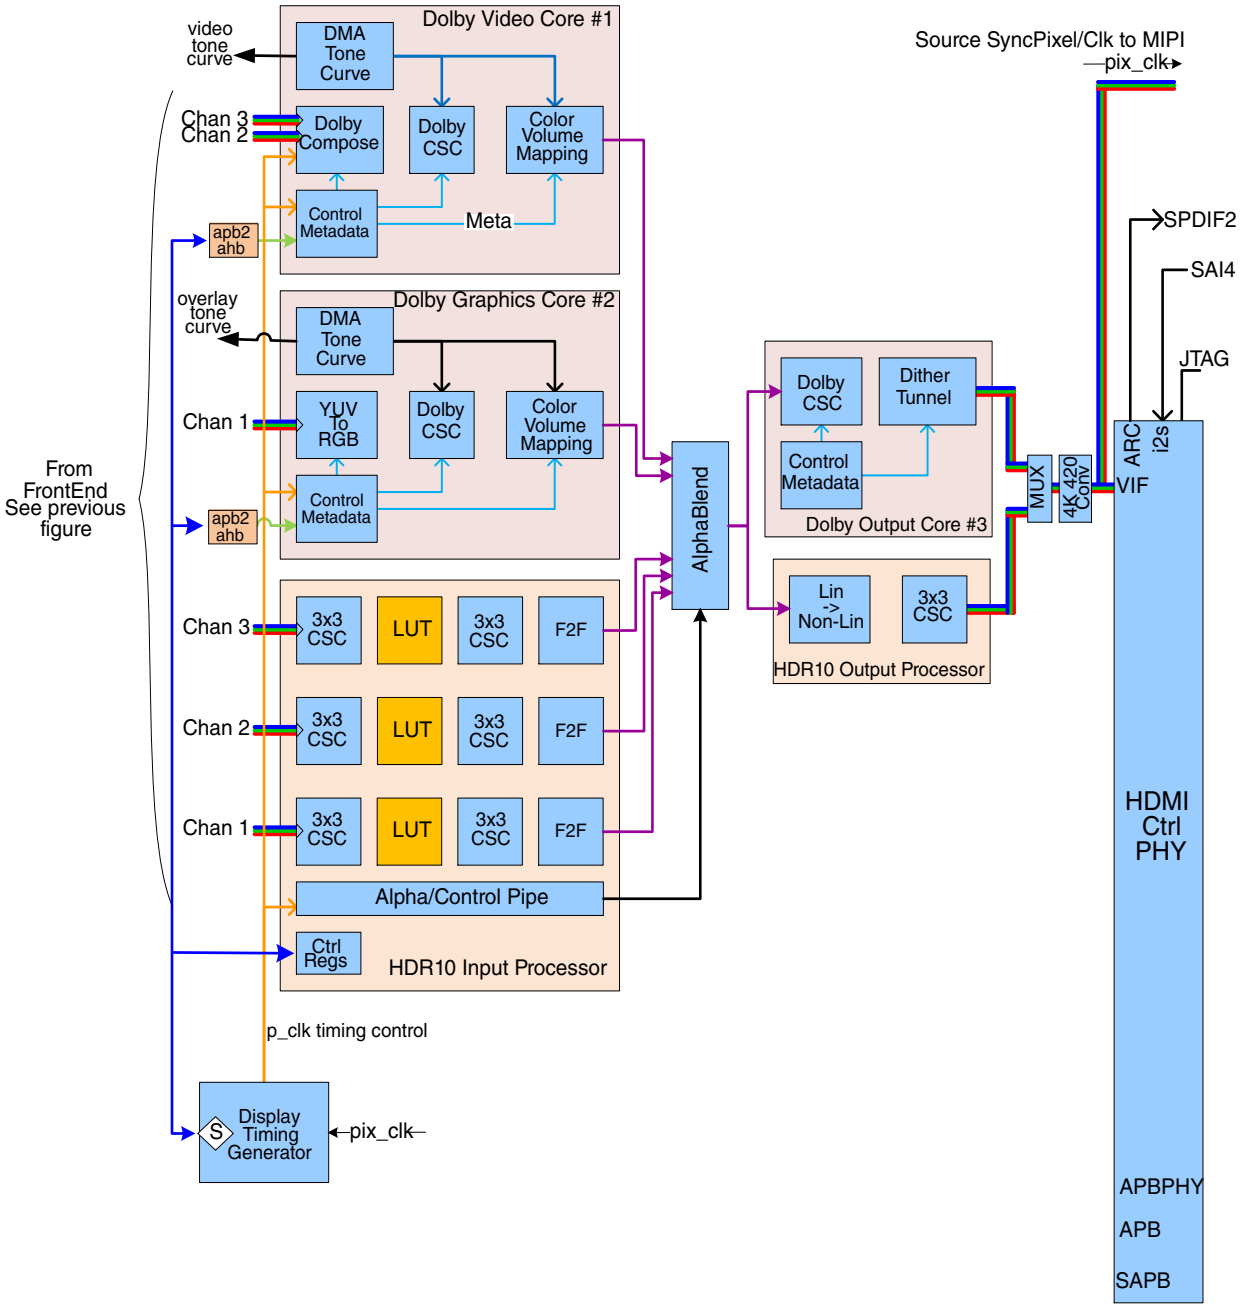

Figure 15-2. DCSS Pixel Processing Block Diagram

15.1.5 Memory Map and register definition

The HDMI controller has independent APB interfaces that are separate from the DCSS APB input bus. There is one HDMI APB for general purpose APB access, and another for secure SAPB access. Since they are separate DCSS input busses, their base address in the system is dependent on the address decoding outside of the DCSS. Refer to the top level memory map definition for the system.

The HDMI.APB interface uses 256KB of address space.

The HDMI.SAPB interface uses 64KB of address space.

The DCSS address space is configured as shown. All addresses are relative to the base address of the DCSS in the system. This memory map defines the offsets for all components from the base address which is defined outside of the DCSS.

Table 15-1. DCSS Memory Map

Start Address	End Address	Size	Allocation
0002_F000	0002_FFFF	4KB	BLK_CTL

0001_7000	0001_7FFF	4KB	DTRC-chan3
0001_6000	0001_7FFF	4KB	DTRC-chan2
0001_5000	0001_7FFF	4KB	DEC400D-chan1
		8KB	Reserved
0001_2000	0001_2FFF	4KB	Dolby Vision Output (Core3)
0001_1000	0001_1FFF	4KB	Dolby Vision Graphics (Core2)
0001_0000	0001_0FFF	4KB	Dolby Vision Video (Core1)
0000_C000	0000_FFFF	16KB	HDR10 Tables and Registers
0000_8000	0000_BFFF	16KB	HDR10 Chan3 LUT
0000_4000	0000_7FFF	16KB	HDR10 Chan2 LUT
0000_0000	0000_3FFF	16KB	HDR10 Chan1 LUT

Note 1: The LPCG registers are at the base address in the table above. Each LPCG(i) register is located at an offset of i*4 bytes from the LPCG base address.

15.1.6 Functional description

At a high level, the DCSS consists of either three separate pipelines in HDR10 mode or two separate pipelines in Dolby Vision mode. These sources are composed to drive a single output display image.

The front end of the DCSS connects to DDR memory through an ADB400 slave interface with three decompression, DPR DMA channels, and three scalers. These componenent groups complete three separate channels for sourcing independent display buffers for display. Accesses for frame buffer data and control information is arbitrated by the bus interconnect component. There is also one write back channel and one read back channel, all clocked with the 800 MHz system bus clock. The display timing generator and the context loader work congruently to provide the overall DCSS control for updating the display between frame sequences. The pixel processing components (Dolby or HDR10) of the DCSS runs with a single display resolution and a single pixel clock. An HDMI 2.0 compliant controller and PHY complete the source solution for driving next generation HDR UHD displays with compatibility for current non-HDR HD displays.

The two operation modes, Dolby and HDR10, are mutually exclusive.

15.1.6.1 Operating Modes

15.1.6.1.1 Dolby Vision Mode Operation

In Dolby Vision mode, the video pipeline and the overlay pipeline get blended together, post processed and sent to the HDMI protocol controller. The HDMI output consists of a display window containing a video window and an overlay window. Both the video and overlay windows can be driven by the read back channel. Both the video and overlay windows can be full screen or smaller and offset inside the display window with the rest of the display window filled with the background color. The compositing of the video and overlay windows is controlled by the per pixel alpha channel. The overlay path creates an alpha based on the window priority and the graphics per pixel alpha. The diagram below shows a possible window configuration.

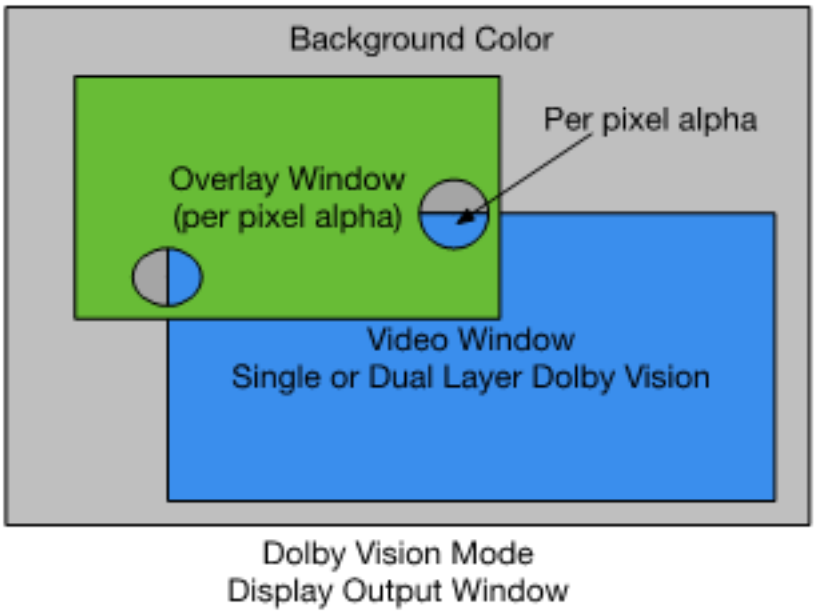

Figure 15-3. Dolby Processed Display

15.1.6.1.2 HDR10 Mode Operation

In HDR10 mode, the three inputs get merged or blended together, post processed and sent to the HDMI protocol controller. The HDMI output consists of a display window containing up to three input windows. Any of the three windows can by driven by the Readback channel. All three windows can be full screen or smaller and offset inside the display window with the rest of the display window filled with the background color. The compositing of the three windows is controlled by the per pixel alpha channel from channel 1. The alpha logic creates an alpha based on the window priority and the graphics per pixel alpha. The diagram below shows a possible window configuration. Note that window priority is fixed with channel 1 on top of channel 2 on top of channel 3. Only channel 1 can have a per pixel alpha.

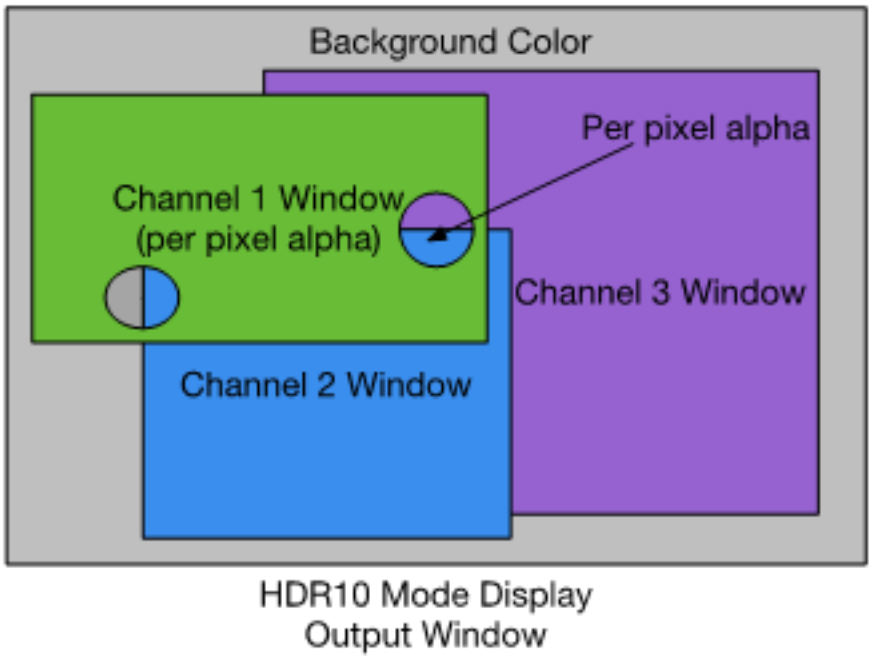

Figure 15-4. HDR10 Processed Display

15.1.6.2 Clocks

Clocks used in the DCSS are either sourced from the top level (see CCM) or the integrated HDMI PHY. The fundamental clock frequencies required to clock the DCSS are listed in the table below.

Table 15-2. DCSS Interrupt Mapping Table

Clock Domain	DCSS Clocked Components	Max Frequency
b_clk	NIC, DPR, RTRAM_CTRL, Scaler, etc	800MHz
rtr_clk	RTRAM_CTRL, DPR, Scaler. NOTE: the following condition must be met: b_clk/2 .lt. rtr_clk	400MHz
apb_clk	All peripheral PIO access interfaces. All APB and core clocks for the HDMI controller.	133MHz
ss_refclock	Reference clock for HDMI PLL. This reference source clock is optional since the refclk_pln pins are the primary source for the reference clock for the PHY.	27MHz
p_clk	This is driven by the phy_pma_pixel_clk_out port of the PHY	max 594MHz

Table 15-2. DCSS Interrupt Mapping Table

Clock Domain	DCSS Clocked Components	Max Frequency
	(in HDMI mode), or the top level pixel clock input (in MIPI mode). Dolby Vision, HDR10, HDMI_CTRL, SUBSAM	This clock is programmed to the correct frequency to drive the desired display resolution and refresh rate. Refer to the CEA861 display timing specification for HDMI compliant pixel clock frequencies.

15.1.6.3 Interrupts

There are many sources for interrupts within the DCSS. The IRQ_STEER module is used to collect interrupts in the DC. SW can read the IRQ_STEER status bits to determine which DC interrupt sources are active. The IRQ_STEER provides the first level resource to determine the interrupt source. Refer to the chapter related to the IRQ_STEER module for detailed operation related to interrupt steering.

15.1.6.3.1 DCSS Interrupt Outputs

The DCSS dcss_int_out[0] is driven by internal_irq logically ANDed with IRQSTEER_CH0_MINTDIS[0] register. The DCSS dcss_int_out[1] is driven by the internal_irq directly. This bit is logically equal to dcss_int_out[0], with the exception that it is not gated with the IRQSTEER_CH0_MINTDIS[0] register. The DCSS dcss_int_out[2] is not routed through the IRQ_STEER module, but is driven directly from the HDMI PHYs source_hpd_out signal. This is the HDMI hot plug detect signal.

15.1.6.3.2 DTG General Purpose Interrupt Allocation

There are 8 general purpose interrupt collected by the Display Timing Generator (DTG). Refer to the DTG Interrupt Generation section for a description of the general purpose interrupt generator. The table below indicates the DCSS level allocation of the 8 interrupts implemented in the DTG.

Table 15-3. DTG Interrupt Map

DTG IRQ Input	Signal Source to generate interrupt
0	Panic Channel 0 – This is the panic signal output from the RTRAM_CTRL for channel 0.
1	Panic Channel 1 – This is the panic signal output from the RTRAM_CTRL for channel 1.
2	Panic Channel 2 – This is the panic signal output from the RTRAM_CTRL for channel 2.
3-7	reserved

15.1.6.3.3 DCSS Interrupt Mapping

The mapping of interrupts into the IRQ_STEER are defined by the following table. Details for the interrupt functionality including status and mask can be obtained from description of the respective interrupt registers within the source modules.

Table 15-4. DCSS Interrupt Mapping Table

IRQ Steer Interrupt Number	Interrupt Source
0	dolby_video_core

15.2 DCSS Block Control (BLK_CTL)

15.2.1 Overview

The DC Block Control is the Display Controller Subsystem's general purpose control register block. The control registers contain various functionality including but not limited to:

- Async reset per clock domain
- Clock muxing control
- Async reset per clock domain
- HDMI source secure

15.3 Display Timing Generator (DTG)

15.3.1 Overview

The purpose of the Display Timing Generator (DTG) is to generate the display timing control signals for the display and the pixel data path in the pixel clk domain. The outputs from the DTG controls the pixel data path and front end components (scaler, DPR, CTX_LD).

15.3.1.1 Block Diagram

The following diagram gives a high-level overview of the configuration of the DTG.

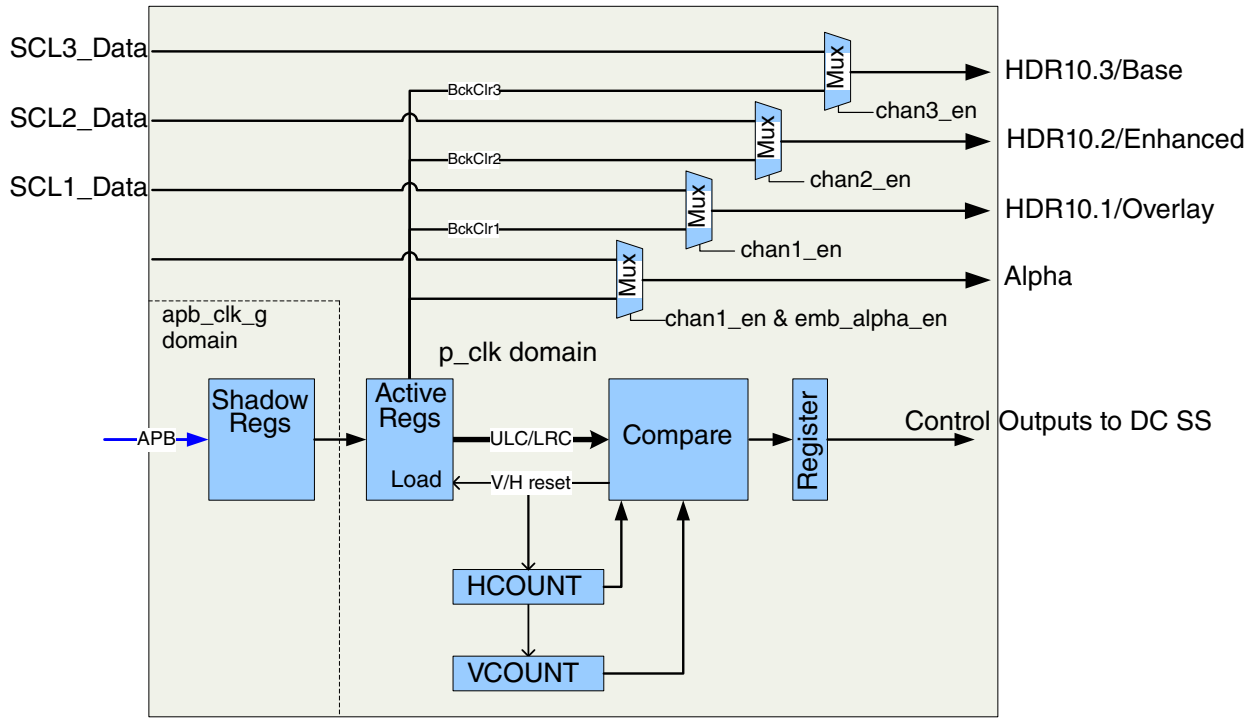

Figure 15-5. DTG block diagram

15.3.1.2 Features

The DTG contains the following components:

- Shadow Registers – These registers are loaded in advance of the next vertical retrace by system SW and used to load the active registers to setup for the next display trace at the vertical retrace time.
- Active Registers – These registers are loaded from the shadow registers in one clock in parallel. This occurs at the single p_clk edge where hcount = csr_dtg_lrc_x and vcount = csr_dtg_lrc_y.
- Hcount, vcount – Counters that determine the position in the display trace.
- Compare – Comparators that create active control signals for all DCSS components.
- Register – All control outputs are registered.
- Datapath – Muxes that select the scaler output data, or programmed background color based on whether the current H/Vcount are in the respective active regions.

Examples of control outputs from the DTG are:

- VActive_n, HActive, HSYNC – Note, these signals map to Dolby and HDR10 specific timing inputs. They are NOT equal to the traditional definition of display VSYNC/HSYNC/DE.

```
VActive_n = dolby_vsync_n
HActive = dolby_hsync
DE = dolby_de
```

- PS_EN[3,2,1] – Pixel Stream Enable, also referred to as VIDEO_ENABLE and OVERLAY_ENABLE. These active times are defined by the parameters *_ULC[X,Y]/*_LRC[X,Y], or the upper left and lower right display coordinates for the three pixel streams. These signals drive the bl_de, el_de, and de_in of the Dolby video and graphics pixel cores and the read_enable into the three scaler output FIFOs.
- CTX_LD__[DB|SB]_EN – Issue a control signal that indicates when a new display state can be loaded by the display context loader. There is one event for components with doubled buffered shadow registers, another with single buffered CSRs, since the timing events occur at different times in a single display trace.
- CONTROL[31:0] – Additional control signals that are used as the design evolves. These can be reduced at the final design release to match that actual implementation. Individual CSRs are used to determine when these signals are active within the display trace, and if they are horizontal or vertical control signals. Vertical means they are qualified by the horizontal count resetting to zero.

15.3.2 Functional description

15.3.2.1 DTG Timing Generator

The purpose of the DTG is to generate the display timing control signals for the display and the pixel data path in the p_clk domain. The DTG is fully synchronous to the p_clk domain except for the first set of double buffered CSR registers, also referred to as “shadow” registers. The shadow registers are synchronous to the apb_clk_s domain. The shadow registers are loaded into the active registers at the p_clk that defines the “origin” of the display. The active registers are clocked on p_clk and loaded when the shadow registers are not actively being updated. The outputs from the DTG control the pixel data path and front end components (scaler, DPR, CTX_LD). The “origin” of the display is defined as the p_clk cycle that causes the hcount and vcount to be set to zero. This occurs when the respective counters, hcount/vcount, reach their maximum programmed values and the p_clk results in hcount = vcount = 0x0. The origin of the display control is not arbitrarily defined, but must be the point at which the display enters the vertical front porch. This is the p_clk cycle that is just after the last pixel is sent to the display, or the lower right most pixel on the display. This origin is required to meet the proper

initialization of the display IP (Dolby and HDR10 components) AND to achieve synchronization with the output timing generator, or SUBSAM, that produces CEA861 HDMI compliant timing.

The Display Controller Subsystem (DCSS) does not support on-the-fly display resolution changes. Any display timing registers that effect the display resolution or refresh rate require the DCSS (and all components integrated) to be stopped, reset, and restarted with the correct pixel clock frequency and display parameters to drive the new resolution. One reason is that the SUBSAM (see subsequent descriptions) module doesn't implement double buffered display timing registers. Also, for a resolution update, the PLL, PHY, and clocking needs to be reinitialized. The double buffered registers that could be modified in the case of a display context change, and reloaded at retrace back to the origin, would be those that locate the three channels of display data within the active display region. In this case, the display resolution and timing is not changing, but the timing of the channels 1, 2, or 3, within the current display configuration, can change on-the-fly. This is one example of DTG registers that could change on-the-fly. Considering the transfer of the registers from shadows to active registers at retrace back to the origin, it is up to the application to determine which registers can be loaded using the double buffered scheme on-the-fly.

The CEA861 timing is generated at the end of the pixel data path in the SUBSAM module. The CEA861 timing is required to comply with the HDMI interface specification and provide the correct interface timing to the HDMI controller. The DTG timing is slightly different than the CEA861 timing. DTG produces the timing needed by Dolby and HDR10 pixel data path components, and the SUBSAM produces the CEA861 timing for HDMI controller and spec compliance. Refer to section Display Timing and Window Overlay for more information on display timing. A timing diagram that indicates the origin of the display is provided below. ALL timing parameters need to be programmed with the origin defined as the start of the vertical front porch AND the start of the horizontal front porch. The pixel data path IP (Dolby and HDR10) doesn't consider porches. There is only a blanking region, and a vertical active region (VActive). The vertical active region, VActive, is initiated when the VActive signal goes low. The vertical blanking region is initiated when the VActive signal goes high. The DTG and pixel data path logic needs to see the rising edge of the VActive signal as the first transition when the DTG is enabled. The reset state of the VActive signal is low. The low to high transition on VActive is the transition from the active display into the vertical front porch, and this event marks the origin (start) of the display trace.

In addition to timing and control, the DTG also implements the data path muxes for background color and alpha values.

NOTE

The timing of the VActive signal needs to be precise. No additional timing pulses during start up can exist since other components depend on a clean startup sequence.

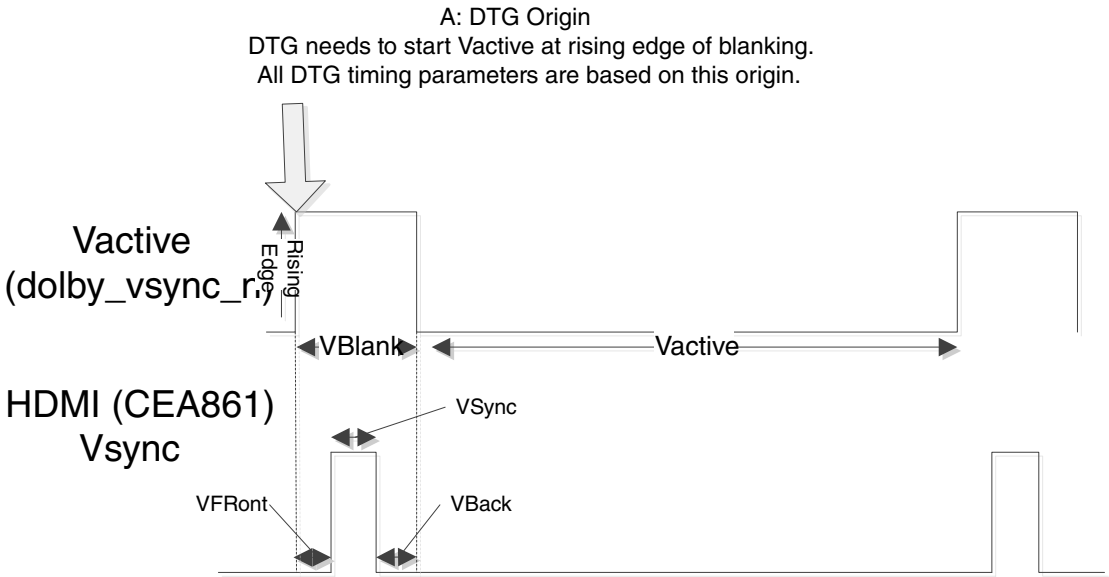

Figure 15-6. DTG Timing Diagram

15.3.2.2 DTG Window Overlay

The DTG generates the timing and control for the display and the pixel processing pipelines (Dolby/HDR10). Also, it generates timing for the CTX_LD to control when next state information is loaded to all DCSS components. An example of a display configuration is indicated as in the below diagram.

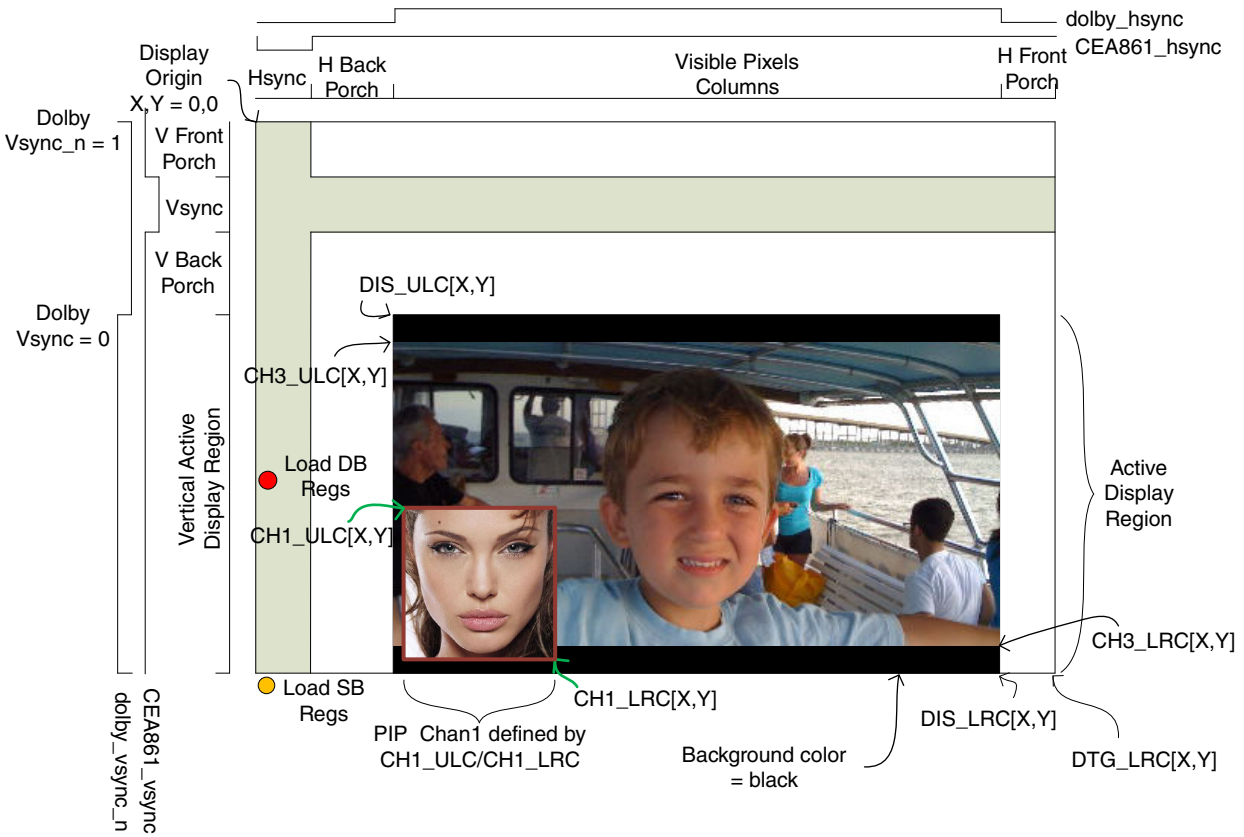

Figure 15-7. DTG Display Configuration

The DTG determines timing for the following events:

- When hcount and vcount counters are reset to zero, defined by =TC_DTG_LOWER_RIGHT_[X,Y], respectfully.
- When the active display region starts (Upper Left Coordinate or TC_DISPLAY_UPPER_LEFT_[X,Y]) and ends (Lower Right Coordinate or TC_DISPLAY_LOWER_RIGHT_[X,Y]).
- When Ch3/BL, starts/ends within the active display region defined by TC_CHANNEL_3_UPPER_LEFT_[X,Y]/ TC_CHANNEL_3_LOWER_RIGHT_[X,Y]. It is the same as the active display region in this example.
- When CH2/EL starts/ends indicated by TC_CHANNEL_2_UPPER_LEFT_[X,Y]/ TC_CHANNEL_2_LOWER_RIGHT_[X,Y]. This is the PIP window in this example.
- When the CH1/Overlay start/ends indicated by TC_CHANNEL_1_UPPER_LEFT_[X,Y]/ TC_CHANNEL_1_LOWER_RIGHT_[X,Y].
- When the context loader fetches register contents for double buffered (Dolby/DTG), indicated by the red dot, and single buffered (DPR/bus masters) components, indicated by the orange dot, in the DCSS.

The DTG output signals drive the Dolby Vision or HDR10 pixel processing IP and also drive the pixel_enables of the scaler output buffers. Also, the DTG drives the context loader enable with several event triggers during a single frame trace. This is required since the Dolby IP and DTG have double buffered registers that need to be preloaded during the active display time. Other processing components may not have double buffered registers (NXP IP), so these parameters need to be loaded during the vertical blanking time (not during active display time). The context loader bus masters the display state for the next display trace for the Dolby IP and NXP IP at programmable times determined by the DTG.

The display state sequence controlled by the DTG is:

1. At the Red Dot, Context Load DB Regs – Context load engine bus masters the double buffered registers in the Dolby IP and DTG. Must follow the sequence using the Metadata Copy, Start Bit, and Finish Bit (see Dolby IP specs).
2. VSYNC Active – Active CSR registers automatically loaded from shadow registers.
3. At the Orange Dot, Context Load SB Regs - Context load engine bus masters the register contents from DRAM to the single buffered IP control registers.
4. Prefetch/Process – the DPRs prefetch data and store rows of blocks into the RTRAM. The RTRAM_CTRL indicates when data is available to the scalers to begin processing. The rd_src engine also prefetches a buffer if enabled.
5. Display – When in the active display region, the PS_EN signals modulate when pixel data is transferred from the scaler output buffers and consumed by the Dolby pixel data path cores. HSYNC indicates an increment in each line.
6. Display Front Porch – goto #1.

15.3.2.2.1 HCount

The DTG uses a horizontal and vertical counter and the necessary parameters to maintain the sequence of the display. The horizontal counter (hcount) increments once every p_clk and reset back to zero when the hcount counter matches the TC_DTG_LOWER_RIGHT_[X] value in the active register set. The follow pseudo code is an example of when hcount resets to zero.

```
if (hcount == dtg_lrc_x) hcount <= 0;
else                     hcount <= hcount + 1;
```

15.3.2.2.2 VCount

The vertical counter (vcount) increments when the hcount counter resets to zero (hcount == TC_DTG_LOWER_RIGHT_[X]). The vertical counter resets to zero in the p_clk domain when hcount resets to zero and vcount matches the TC_DTG_LOWER_RIGHT_[Y] value in the active register set. The following pseudo code is an example of when the vcount resets to zero.

```
if ((hcount == TC_DTG_LOWER_RIGHT_X) &&
    (vcount == TC_DTG_LOWER_RIGHT_Y))    vcount <= 0;
else if (hcount == TC_DTG_LOWER_RIGHT_X) vcount <= vcount + 1;
```

A region in the display sequence that would actively process pixels for a channel is defined by the upper left and lower right coordinates, i.e. ULC/LRC. As an example, the following code would determine when to process pixels in the overlay channel.

```
if ((TC_CHANNEL_1_UPPER_LEFT_X <= hcount) &&
    (TC_CHANNEL_1_UPPER_LEFT_Y <= vcount) &&
    (TC_CHANNEL_1_LOWER_RIGHT_X >= hcount) &&
    (TC_CHANNEL_1_LOWER_RIGHT_Y >= vcount)) chan1_active <= 1'b1;
else                                chan1_active <= 1'b0;
```

The chan1_active (overlay is active in Dolby mode) signal would be used to read signals from scaler #1 output FIFO. It is typically active within the region defined by TC_DISPLAY_UPPER_LEFT_/TC_DISPLAY_LOWER_RIGHT_. Similar logic is used to create the timing for active processing of the other channels #2/3 , or video channels.

15.3.2.3 DTG Datapath

The DTG also implement the three pixel data path muxes for pixel data and back ground color. With the respective regions defined by ULC/LRC, pixel data is used to drive the pixel data path. Outside of these regions, the background color is forwarded to the pixel data path. The alpha MUX is also implemented in the DTG. The per pixel alpha value embedded in channel 1 is forwarded to the data path when channel 1 is active (or the TC_DEFAULT_OVERLAY_ALPHA is used when TC_CH1_PER_PEL_ALPHA_SEL = 0). The blender alpha is based on the per pixel graphics alpha:

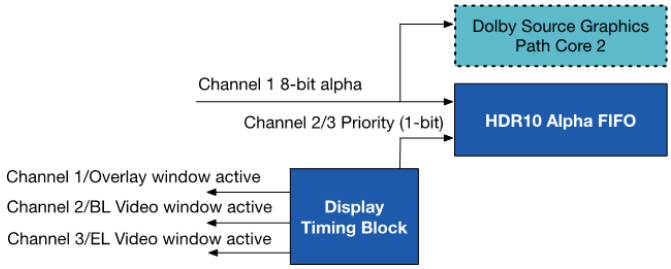

Figure 15-8. DTG Datapath Diagram

The Channel 2/3 Priority is 1 when Channel 2 is active and 0 when Channel 2 is inactive.

15.3.2.4 DTG Programming Example

The table below indicates the timing parameters for the Video Information Code (97, 107) defined for a progressive 4K TV at 60Hz.

Table 15-5. 4k TV at 60Hz Timing Parameters

Hactive	Vactive	Htotal	Hblank	Vtotal	Vblank	Pixel Freq
3840	2160	4400	560	2250	90	594
Hfront	**Hsync**	**Hback**	**Vfront**	**Vsync**	**Vback**	
176	88	296	8	10	72	

The DTG parameters for this display format are:

- TC_DTG_LOWER_RIGHT_X = 4400 – 1 = 4399; this is the Htotal from the table. Note the MINUS 1 value.
- TC_DTG_LOWER_RIGHT_Y = 2250 – 1 = 2249; this is the Vtotal from the table.
- TC_DISPLAY_UPPER_LEFT_X = 4400 – 3840 – 176 – 1 = 383; this is when the horizontal blanking ends, and active display region begins. dolby_hsync goes high at the p_clk when hcount == TC_DISPLAY_UPPER_LEFT_X
- TC_DISPLAY_UPPER_LEFT_Y = 89; this is when dolby_vsync_n goes low, and enters the active display region
- TC_DISPLAY_LOWER_RIGHT_X = 4400 – 176 – 1 = 4223; dolby_hsync goes low
- TC_DISPLAY_LOWER_RIGHT_Y = 2249; this is when dolby_vsync_n goes high, and enters vertical blanking

To extend the example to add a 64x64 pixel CH1 overlay with a 10 pixel offset into the active display area in both X and Y direction, the following CH1 parameters would be set:

- TC_CHANNEL_1_UPPER_LEFT_X = 4400 – 3840 – 176 – 1 + 10 = 559 + 10 = 393, or start of active display region (TC_CHANNEL_1_UPPER_LEFT_X) + 10

- TC_CHANNEL_1_UPPER_LEFT_Y = 90 – 1 + 10 = 89 + 10 = 99
- TC_CHANNEL_1_LOWER_RIGHT_X = 4400 – 3840 – 176 – 1 + 10 + 64 = 393 + 64 + 10 = 457 (TC_DISPLAY_LOWER_RIGHT_X + 64)
- TC_CHANNEL_1_LOWER_RIGHT_Y = 89 + 64 + 10 = 163

The timing to load SB registers starting with the second line (line #0, then line #1) in the vertical blanking region:

- TC_CNTXT_SB_Y = 0

And, to load double buffered registers in the active display region.

- TC_CNTXT_DB_Y = 199 //110 lines after the active display area begins

NOTE

The ATG in the SUBSAM must be programmed with compatible values that are consistent with the DTG values.

15.3.2.5 DTG Interlaced Video Timing Generator

The DTG supports interlaced timing generation. Interlaced timings comply to the definition of “General Interlaced” and “Special Interlaced” timing in the CEA861 specification. The timing diagram for the General Interlaced timing from the CEA861 spec is shown below.

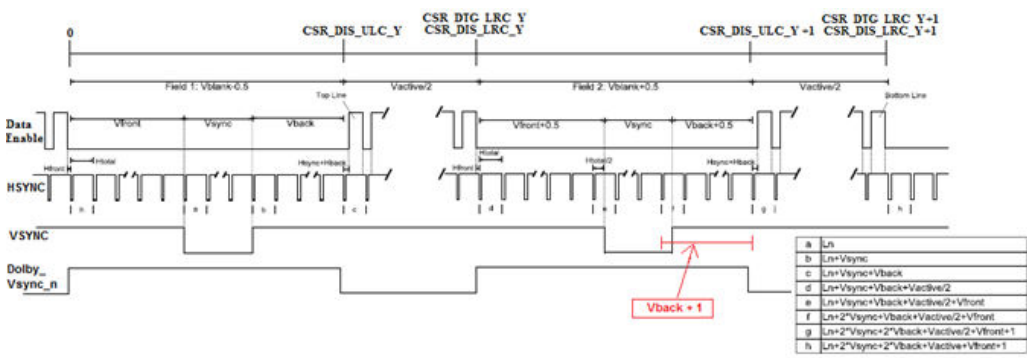

Figure 15-9. General Interlaced CEA861 Timing

The Dolby and HDR10 pixel processing engines do not use vertical front/back porches. The entire vertical blanking region is consider as one region.

```
Vblank = Vfront + Vsync + Vback
```

In interlaced mode, “Field 1” is the first field displayed, and “Field 2” is the second displayed, when the DTG is enabled. The DTG alternates between these fields indefinitely after the GO bit is set. The DTG doesn’t have separate timing parameters for the two fields, only one set of programming parameters is provided. There is an additional control bit to enable interlaced timing.

For Special Interlaced mode, there is no difference for the DTG between the fields.

For General Interlaced mode, Field 2 has an additional line added to the vertical blanking region (see Vback + 1 in the diagram above). The addition of the extra line is done automatically when the DTG interlaced mode is selected. The ATG in the SUBSAM module also needs to be programmed with the same General Interlaced mode when the extra line is needed. This is required to be sure the two timing generators are synced for both the odd and even fields in interlaced mode.

NOTE

Only the General Interlaced mode requires the DTG interlaced enable bit to the set. Special Interlaced mode does NOT need the interlaced mode to be set. Simply, the timing parameters need to be programmed considering there are half as many lines in the active display region, i.e. 540 lines for 1080i.

15.3.2.6 DTG Interrupt Generation

The DTG module can generate interrupts under the following conditions:

- There are four interrupts that are programmable which can generate an interrupt at a programmable XY coordinate
- Each of these are identical and independently programmable
- When the programmed coordinate (XY) is reached within the sweep of the display, the interrupt goes active. The X value is compared to the HCOUNT, and the Y value is compared to the VCOUNT. When both compares are equal, the interrupt status bit is set
- These timing based interrupts can be used for any purpose. Examples of interrupts include:
  - Notify when the display enters/exits the active display region
  - Notify when the Vsync goes active

The DTG also collects events, or signals, from other components in the system. The DTG supports up to 8 asynchronous event inputs that can be used as general DCSS level interrupts. The status and mask bits associated with these event sources are implemented within the DTG to generate DCSS interrupts. These 8 events, and using the status and mask registers, are collected and multiplexed down to a single interrupt output from the DTG module.

15.3.2.7 DTG Timing Standards

Refer to the CEA861-F for timing standards to drive displays at different resolutions. A summary of timings is in the following table.

Table 15-6. CEA861-F Timing Summary

Name	Resolution	Refresh	Pixel Clock	Hblank	Vblank	Aspect Ratio
2160p60	3840x2160	60.00	594.00	560	90	16:09
2160p59.94	3840x2160	59.94	593.41	560	90	16:09
2160p50	3840x2160	50.00	594.00	1440	90	16:09
2160p30	3840x2160	30.00	297.00	560	90	16:09
2160p29.97	3840x2160	29.97	296.70	560	90	16:09
2160p25	3840x2160	25.00	297.00	1440	90	16:09
2160p24	3840x2160	24.00	297.00	1660	90	16:09
2160p23.98	3840x2160	23.98	296.70	1660	90	16:09
1080p60	1920x1080	60.00	148.50	280	45	16:09

720p59.94	1280x720	59.94	74.18	370	30	16:09
720p50	1280x720	50.00	74.25	700	30	16:09
720p30	1280x720	30.00	74.25	2020	30	16:09
720p29.97	1280x720	29.97	74.18	2020	30	16:09
720p25	1280x720	25.00	74.25	2680	30	16:09
720p24	1280x720	24.00	74.25	2845	30	16:09
720p23.98	1280x720	23.98	74.18	2845	30	16:09
576p50	720x576	50.00	27.00	144	49	4:03
576p25	720x576	25.00	13.50	144	49	4:03
480p59.94	720x480	59.94	27.00	138	45	4:03
480p29.97	720x480	29.97	13.50	138	45	4:03

The display timing creates all control signals for the entire pixel data path and the output FIFOs for the scalers and the readback FIFOs. Some of the control signals that are used by the pixel data path are listed below:

- CHAN3_ACTIVE, CHAN2_ACTIVE – Indicates when pixels are fetched from the video scaler output FIFO. This signal, for either the base layer (bl_*) or enhancement layer (el_*), is logically equal to (~[bl|el]_vsync_n && [bl|el]_hsync && [bl|el]_de).
- CHAN1_ACTIVE – Indicates when pixels are fetched from the overlay scaler output FIFO. This signal is logically equal to (~vsync_n_in && hsync_in && de_in).

15.3.2.8 DTG Background Color

The YUV 3x10 bit and RGB 3x8 bit background colors are inserted at the inputs to the channel 1/2/3, or video and overlay, pipelines when CHAN1/2/3_ACTIVE are not asserted.

15.3.3 Memory Map and Registers

15.3.3.1 register descriptions

15.3.3.1.1 TIMING_CONTROL_AND_BLENDER Memory map

DTG base address: 2_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Timing Controller Control Register (TC_CONTROL_STATUS)	32	RW	0000_0000h

40h	DBY MODE blender control. (BLENDER_DBY_BDP)	32	RW	0000_0000h
44h	Backgound pixel color component sent to blender. Used when no valid pixels (BLENDER_BKRND_I_GRAPHICS)	32	RW	0000_0000h
48h	Backgound pixel color component sent to blender. Used when no valid pixels (BLENDER_BKRND_P_GRAPHICS)	32	RW	0000_0000h
4Ch	Backgound pixel color component sent to blender. Used when no valid pixels (BLENDER_BKRND_T_GRAPHICS)	32	RW	0000_0000h
50h	LINE1 interrupt control: Coordinate where line1 interrupt is asserted (TC_LINE1_INT_REG13)	32	RW	0000_0000h
54h	LINE2 interrupt control: Coordinate where line2 interrupt is asserted (TC_LINE2_INT_REG14)	32	RW	0000_0000h
58h	default alpha (TC_ALPHA_DEFAULT_REG15)	32	RW	0000_0000h
5Ch	Timing Controller interrupt status (TC_INTERRUPT_STATUS)	32	RO	0000_0000h
60h	Timing Controller interrupt control. (TC_INTRERRUPT_CONTROL_REG17)	32	RW	0000_0000h
64h	Channel_3 background pixel color. (TC_CH3_BKRND_REG18)	32	RW	0000_0000h
68h	Timing Controller interrupt masks (TC_INTRERRUPT_MASK)	32	RW	0000_0000h
6Ch	LINE3 interrupt control: Coordinate where line3 interrupt is asserted (TC_LINE3_INT_REG)	32	RW	0000_0000h
70h	LINE4 interrupt control: Coordinate where line4 interrupt is asserted (TC_LINE4_INT_REG)	32	RW	0000_0000h
74h	For DBY Mode: Controls the assertion and de-assertion DE signal (Overlay channel). (TC_OL_DE_CONTROL_REG)	32	RW	0000_0000h
78h	For DBY Mode: Controls the assertion and de-assertion DE signal (Base layer (BL) channel). (TC_BL_DE_CONTROL_REG)	32	RW	0000_0000h
7Ch	For DBY Mode: Controls the assertion and de-assertion DE signal (Enhancement layer (EL) channel). (TC_EL_DE_CONTROL_REG)	32	RW	0000_0000h

15.3.3.1.2 Timing Controller Control Register (TC_CONTROL_STATUS)

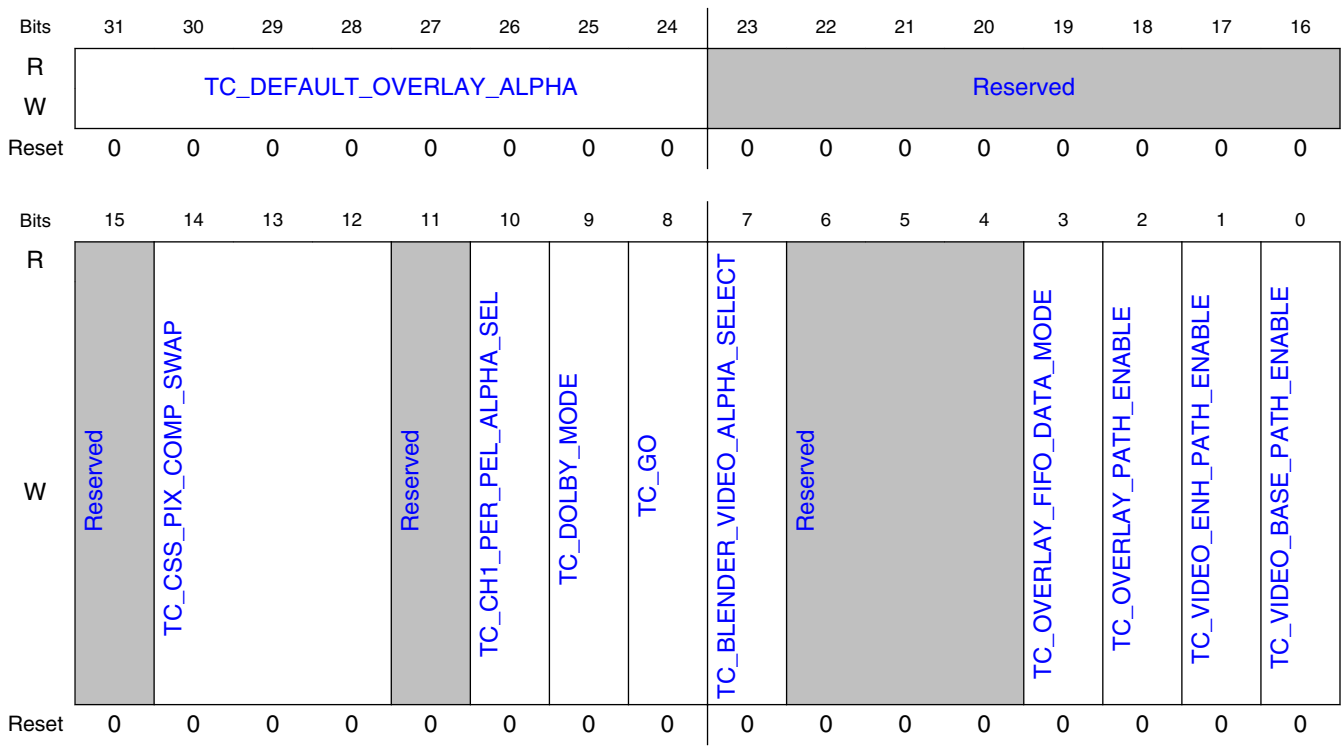
15.3.3.1.2.1 Offset

Register	Offset
TC_CONTROL_STATUS	0h

15.3.3.1.2.2 Function

Enables and controls the behaviour of timing controller and the three pixel channels in the display controller

15.3.3.1.2.3 Diagram



15.3.3.1.2.4 Fields

Field	Function
31-24 TC_DEFAULT_OVERLAY_ALPHA	Default alpha foreground used for the active regions where graphics channel does not provide an alpha value This is used when Graphics channel is ONLY RGB
23-15 —	Reserved.
14-12 TC_CSS_PIX_COMP_SWAP	Permutes the pixel conponent ordering into the chroma subsampler (CSS) block. 0: I P T 1: I T P 2: T I P 3: T P I 4: P I T 5: P T I

Table continues on the next page...

Field	Function
11 —	Reserved.
10 TC_CH1_PER_PEL_ALPHA_SEL	Enables per pixel alpha for channel1 (Overlay or Graphics) 0: use alpha from TC_DEFAULT_OVERLAY_ALPHA or foreground alpha 1: use alpha from channel1 Data stream and apply blending per pixel
9 TC_DOLBY_MODE	Enables Dolby mode. 0: HDR10 pixel processing is performed. Dolby processing disabled 1: Dolby Processing Enabled. Dolby timing control features enabled. Dolby Blending is enabled
8 TC_GO	Used to start and stop timing controller 0: timing controller inactive. No display control signal assertions (HSYNC = 0) 1: timing controller enabled. Display control processing is per the programming of the timing controller. HSYNC and VSYNC DE are running
7 TC_BLENDER_VIDEO_ALPHA_SELECT	alpha_valid 0: No alpha in the ch1 pixel so use default foreground alpha TC_DEFAULT_OVERLAY_ALPHA 1: there is an alpha in ch1 pixel
6-4 —	Reserved.
3 TC_OVERLAY_FIFO_DATA_MODE	Overlay fifo output data in yuv or RGB mode 0: YUV 1: RGB
2 TC_OVERLAY_PATH_ENABLE	Enable channel_1 (Dolby_mode:Overlay /HDR10: (GFX)) processing. 0: channel_1 disabled. Pixels cannot pass thru channel_1 1: channel_1 enabled
1 TC_VIDEO_ENH_PATH_ENABLE	Enable channel_2 (Dolby_mode:Enhancement channel) processing. 0: channel_2 disabled. Pixels cannot pass thru channel_2 1: channel_2 enabled
0 TC_VIDEO_BASE_PATH_ENABLE	Enable channel3 (Dolby_mode:Base Layer channel) processing. 0: channel_3 disabled. Pixels cannot pass thru channel_3 1: channel_3 enabled

15.3.3.1.3 DTG lower right corner locations (TC_DTG_REG1)

15.3.3.1.3.1 Offset

Register	Offset
TC_DTG_REG1	4h

15.3.3.1.3.2 Function

The X,Y cooridnates in this register specify the size of the raster table including blanking regions The upper left coordinate of this is (0,0)

15.3.3.1.3.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

28-16 TC_CHANNEL_2_LOWER_RIGHT_Y	lower right corner Y (vertical) coordinate of the channel_2 window

Table continues on the next page...

Field	Function
15-13 —	Reserved.
12-0 TC_CHANNEL_2_LOWER_RIGHT_X	lower rignt corner X (horizontal) coordinate of the channel_2 window

15.3.3.1.10 Channel 3 window Register: TOP Window Coordinates for channel_3 (TC_CH3_REG8)

15.3.3.1.10.1 Offset

Register	Offset
TC_CH3_REG8	20h

15.3.3.1.10.2 Function

The X,Y cooridnates in this register specify the size of the channel_3 window. The upper left coordinate of channel_3.

In HDR10 mode this is a video channel.

In DBY mode this is the Base Layer (BL)

15.3.3.1.10.3 Diagram

15.3.3.1.10.4 Fields

Field	Function
31-29	Reserved.

Table continues on the next page...

Field	Function
—	
28-16 TC_CHANNEL_3_UPPER_LEFT_Y	upper left corner Y (vertical) coordinate of the channel_3 window
15-13 —	Reserved.
12-0 TC_CHANNEL_3_UPPER_LEFT_X	upper left corner X (horizontal) coordinate of the channel_3 window

15.3.3.1.11 Channel_3 window Register: BOTTOM Window Coordinates for channel_3 pixel window (TC_CH3_REG9)

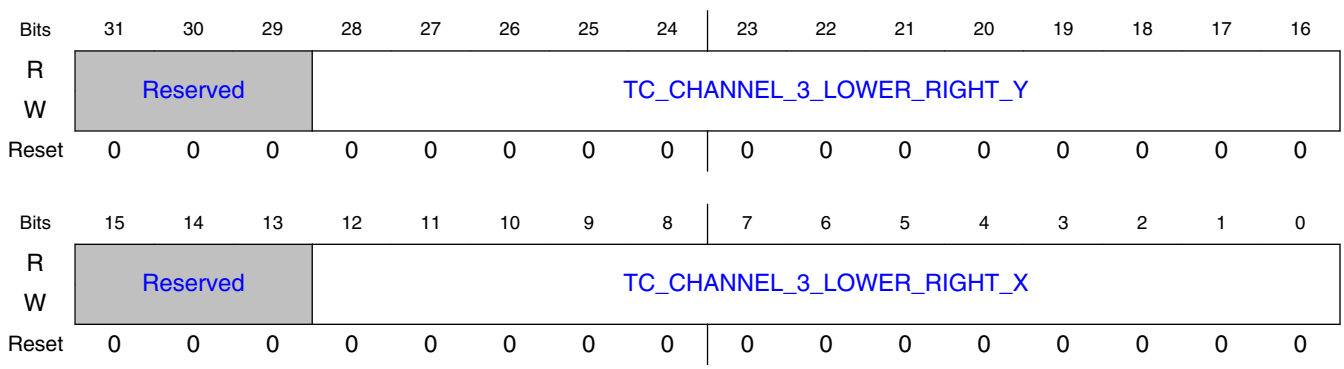
15.3.3.1.11.1 Offset

Register	Offset
TC_CH3_REG9	24h

15.3.3.1.11.2 Function

The X,Y cooridnates in this register specify the size of the channel_3 pixel window. Bottom Right

15.3.3.1.11.3 Diagram



15.3.3.1.11.4 Fields

Field	Function
31-29 —	Reserved.
28-16 TC_CHANNEL_3_LOWER_RIGHT_Y	lower right corner Y (vertical) coordinate of the channel_3 window
15-13 —	Reserved.
12-0 TC_CHANNEL_3_LOWER_RIGHT_X	lower rignt corner X (horizontal) coordinate of the channel_3 window

15.3.3.1.12 Context Loader Register: Coordinates in the raster table where the context loader is started. (TC_CTX_LD_REG10)

15.3.3.1.12.1 Offset

Register	Offset
TC_CTX_LD_REG10	28h

15.3.3.1.12.2 Function

Line Count in the raster table where the CTX_LD is triggered for loading context (some double buffered). The register field provides the line count that is compared with the VCOUNT counter value to generate the event for loading of Single Buffered or Double Buffered Context Timing Controller and Dolby context are double buffered. Rest of the blocks are single buffered

15.3.3.1.12.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

12-0 TC_LINE2_INT_X	X (horizontal) coordinate for line2 interrupt

15.3.3.1.23 default alpha (TC_ALPHA_DEFAULT_REG15)

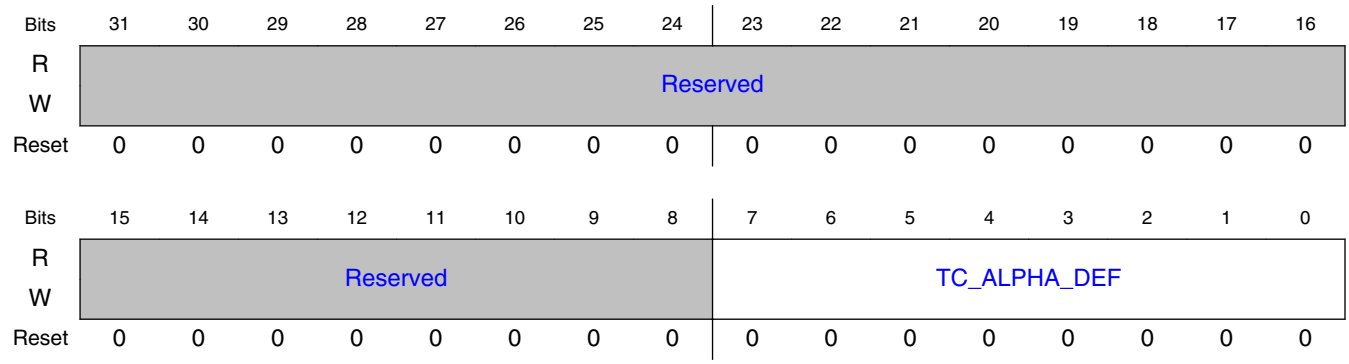
15.3.3.1.23.1 Offset

Register	Offset
TC_ALPHA_DEFAULT_REG15	58h

15.3.3.1.23.2 Function

This background alpha is applied when the per pixel alpha is not enabled

15.3.3.1.23.3 Diagram



15.3.3.1.23.4 Fields

Field	Function
31-8 —	Reserved.
7-0 TC_ALPHA_DEF	default background alpha value

15.3.3.1.24 Timing Controller interrupt status (TC_INTERRUPT_STATUS)

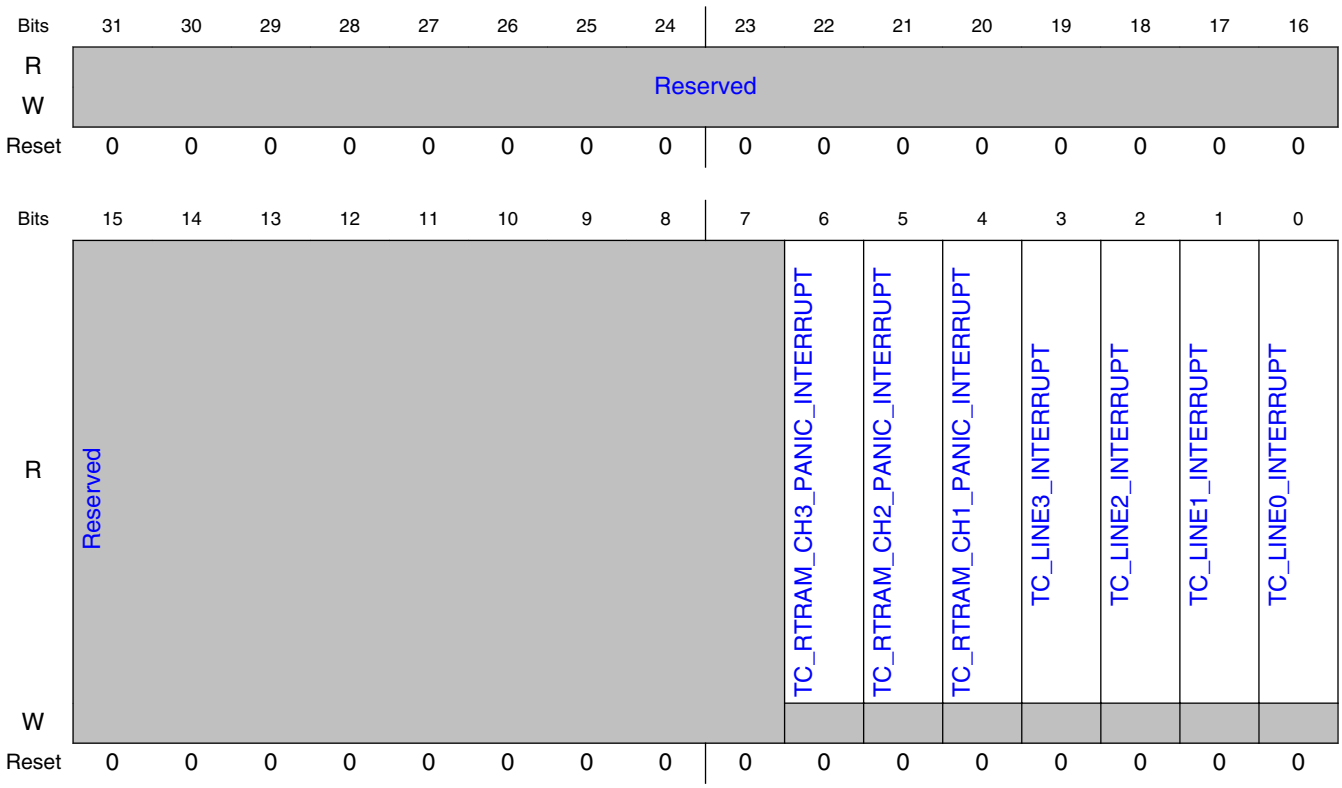
15.3.3.1.24.1 Offset

Register	Offset
TC_INTERRUPT_STATUS	5Ch

15.3.3.1.24.2 Function

This register has per interrupt status bits to indicate which interrupt(s) has occurred

15.3.3.1.24.3 Diagram



15.3.3.1.24.4 Fields

Field	Function
31-7 —	Reserved.
6 TC_RTRAM_CH3_PANIC_INTERRUPT	Panic interrupt is asserted by the scaler for channel3. Note: scaler doc may call this channel2 0: no interrupt 1: panic interrput has been asserted
5 TC_RTRAM_CH2_PANIC_INTERRUPT	Panic interrupt is asserted by the scaler for channel2. Note: scaler doc may call this channel1 0: no interrupt 1: panic interrput has been asserted
4 TC_RTRAM_CH1_PANIC_INTERRUPT	Panic interrupt is asserted by the scaler for channel1. Note: scaler doc may call this channel0 0: no interrupt 1: panic interrput has been asserted
3 TC_LINE3_INTERRUPT	LINE3 interrupt status. LINE3 interrupt can be programmed to occur at any coordinate. 0: no interrupt 1: LINE3 interrupt has been asserted
2	LINE2 interrupt status. LINE2 interrupt can be programmed to occur at any coordinate.

Table continues on the next page...

Field	Function
TC_LINE2_INTERRUPT	0: no interrupt 1: LINE2 interrupt has been asserted
1 TC_LINE1_INTERRUPT	LINE1 interrupt status. LINE1 interrupt can be programmed to occur at any coordinate. 0: no interrupt 1: LINE1 interrupt has been asserted
0 TC_LINE0_INTERRUPT	LINE0 interrupt status. LINE0 interrupt can be programmed to occur at any coordinate. 0: no interrupt 1: LINE0 interrupt has been asserted

15.3.3.1.25 Timing Controller interrupt control. (TC_INTRERRUPT_CONTROL_REG17)

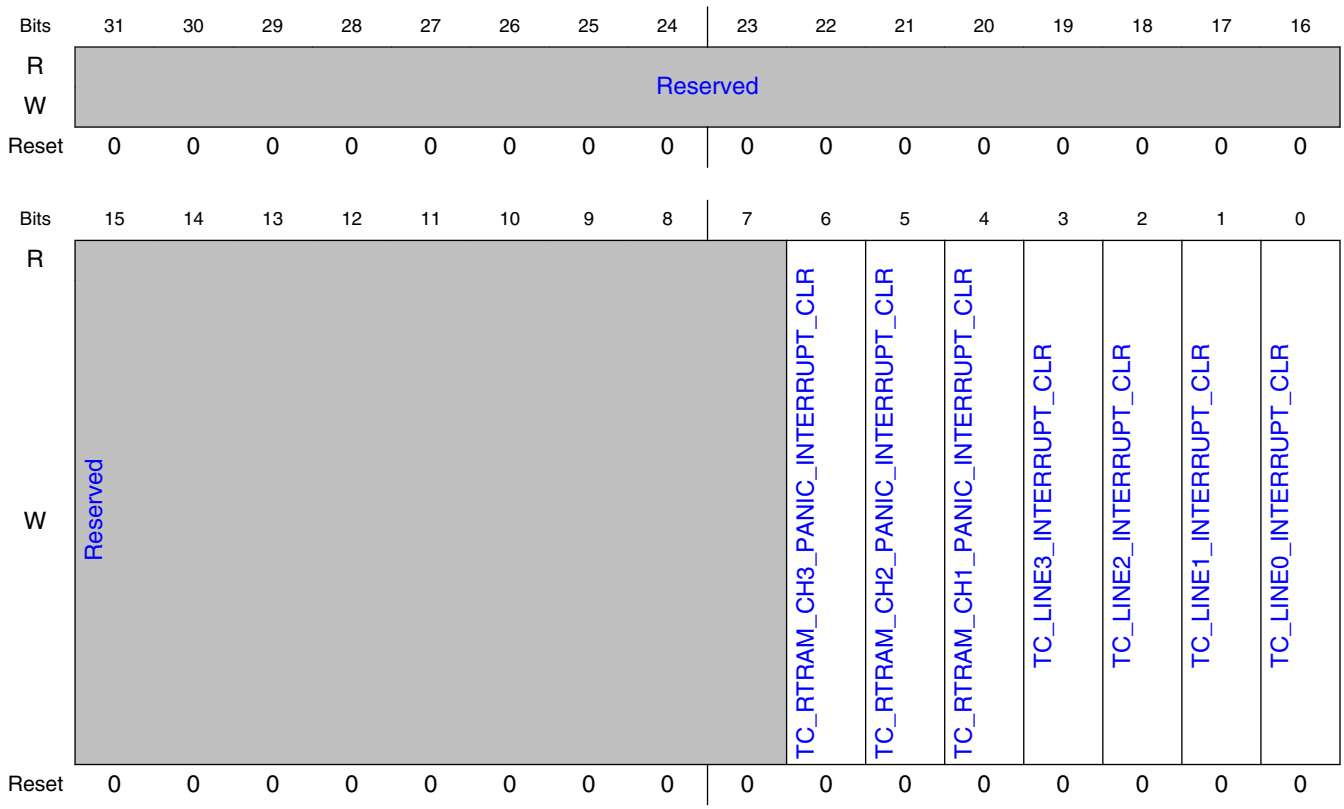
15.3.3.1.25.1 Offset

Register	Offset
TC_INTRERRUPT_CONTROL_REG17	60h

15.3.3.1.25.2 Function

This register has per interrupt control bits to clear interrupts in the TC_INTERRUPT_STATUS register

15.3.3.1.25.3 Diagram



15.3.3.1.25.4 Fields

Field	Function
31-7 —	Reserved.
6 TC_RTRAM_CH3_PANIC_INTERRUPT_CLR	Writing a 1 to this bit clears the respective interrupt in the TC_INTERRUPT_STATUS register. Channel 3 panic interrupt
5 TC_RTRAM_CH2_PANIC_INTERRUPT_CLR	Writing a 1 to this bit clears the respective interrupt in the TC_INTERRUPT_STATUS register. Channel 2 panic interrupt
4 TC_RTRAM_CH1_PANIC_INTERRUPT_CLR	Writing a 1 to this bit clears the respective interrupt in the TC_INTERRUPT_STATUS register. Channel 1 panic interrupt
3 TC_LINE3_INTERRUPT_CLR	Writing a 1 to this bit clears the respective interrupt in the TC_INTERRUPT_STATUS register.

Table continues on the next page...

Field	Function
2 TC_LINE2_INTERRUPT_CLR	Writing a 1 to this bit clears the respective interrupt in the TC_INTERRUPT_STATUS register.
1 TC_LINE1_INTERRUPT_CLR	Writing a 1 to this bit clears the respective interrupt in the TC_INTERRUPT_STATUS register.
0 TC_LINE0_INTERRUPT_CLR	Writing a 1 to this bit clears the respective interrupt in the TC_INTERRUPT_STATUS register.

15.3.3.1.26 Channel_3 background pixel color. (TC_CH3_BKRND_REG18)

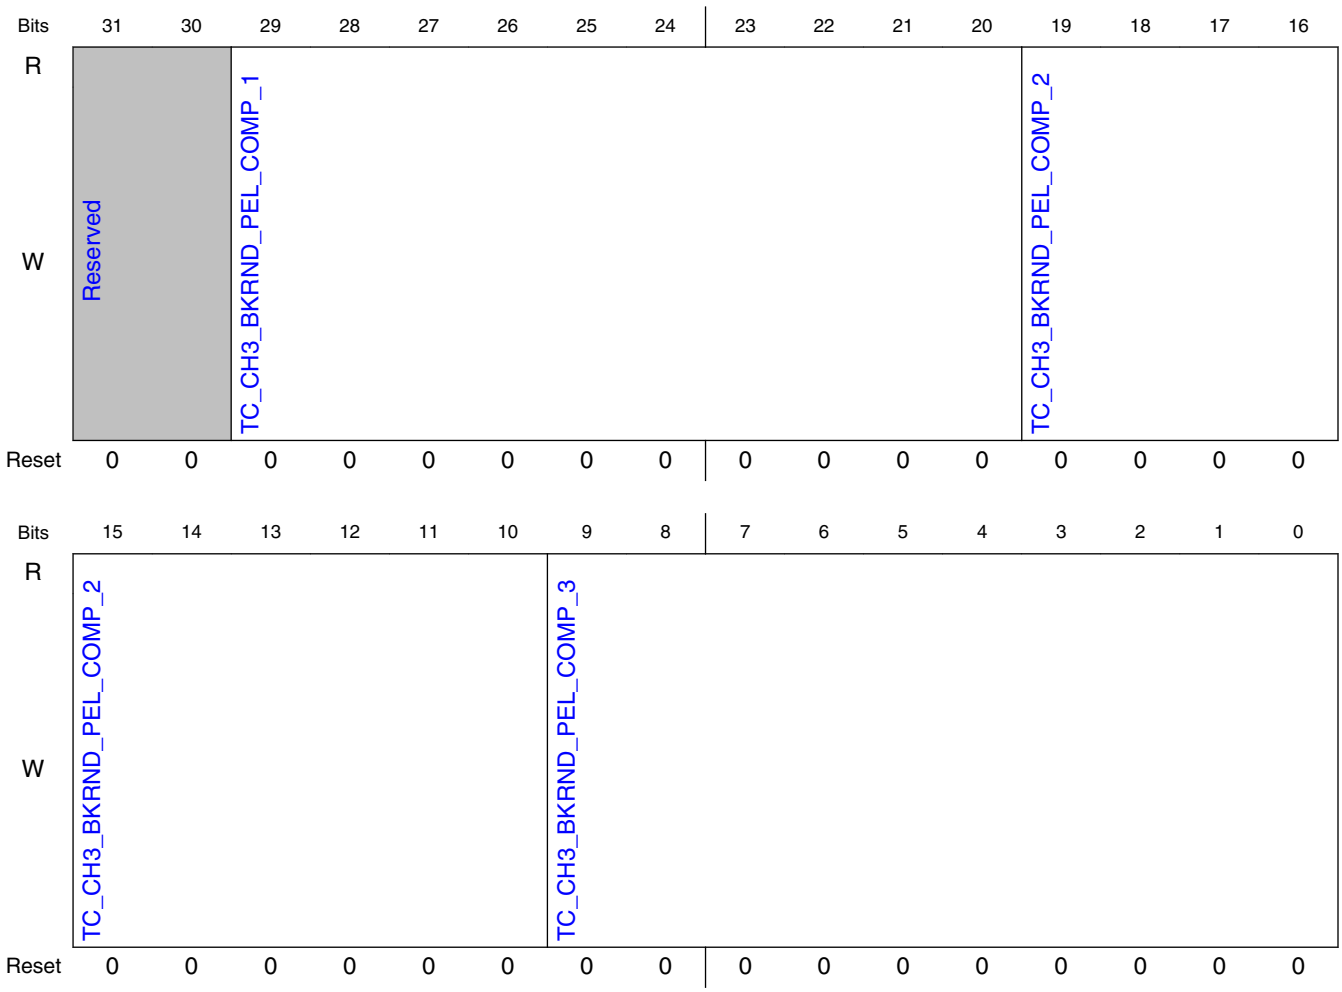
15.3.3.1.26.1 Offset

Register	Offset
TC_CH3_BKRND_REG18	64h

15.3.3.1.26.2 Function

Outside of the Channel_3 pixel window, This background color is put on channel_3. 10 bits per component. Color space depending on programming

15.3.3.1.26.3 Diagram



15.3.3.1.26.4 Fields

Field	Function
31-30 —	Reserved.
29-20 TC_CH3_BKRND_PEL_COMP_1	10-bit component (R or Y)

Field	Function
31-29 —	Reserved.
28-16 TC_LINE4_INT_Y	Y (vertical) coordinate for line4 interrupt
15-13 —	Reserved.
12-0 TC_LINE4_INT_X	X (horizontal) coordinate for line4 interrupt

15.3.3.1.30 For DBY Mode: Controls the assertion and de-assertion DE signal (Overlay channel). (TC_OL_DE_CONTROL_REG)

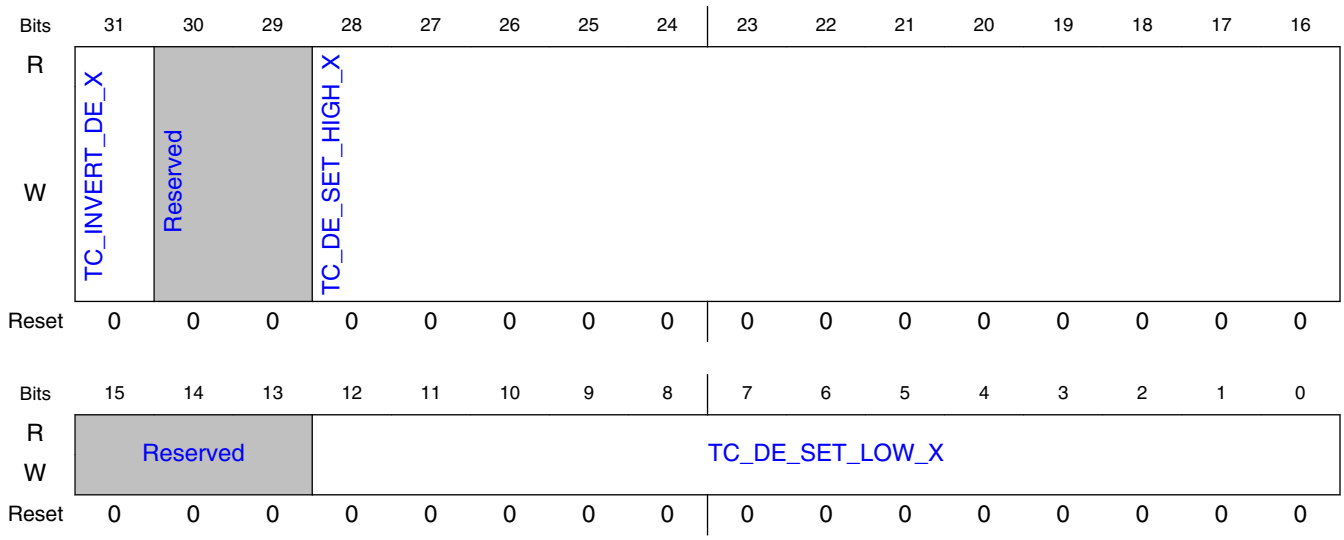
15.3.3.1.30.1 Offset

Register	Offset
TC_OL_DE_CONTROL_REG	74h

15.3.3.1.30.2 Function

This control register pertains to the DBY Overlay (OL) channel. The X cooridnates in this register specify where the DE signal is made 0 or 1 in a line.

15.3.3.1.30.3 Diagram



15.3.3.1.30.4 Fields

Field	Function
31 TC_INVERT_DE_X	0: DE signal is not inverted 1: DE signal is INVERTED
30-29 —	Reserved.
28-16 TC_DE_SET_HIGH_X	X (horizontal) coordinate Where DE control signal is set to 1 in a line.
15-13 —	Reserved.
12-0 TC_DE_SET_LOW_X	X (horizontal) coordinate Where DE control signal is set to 0 in a line.

15.3.3.1.31 For DBY Mode: Controls the assertion and de-assertion DE signal (Base layer (BL) channel). (TC_BL_DE_CONTROL_REG)

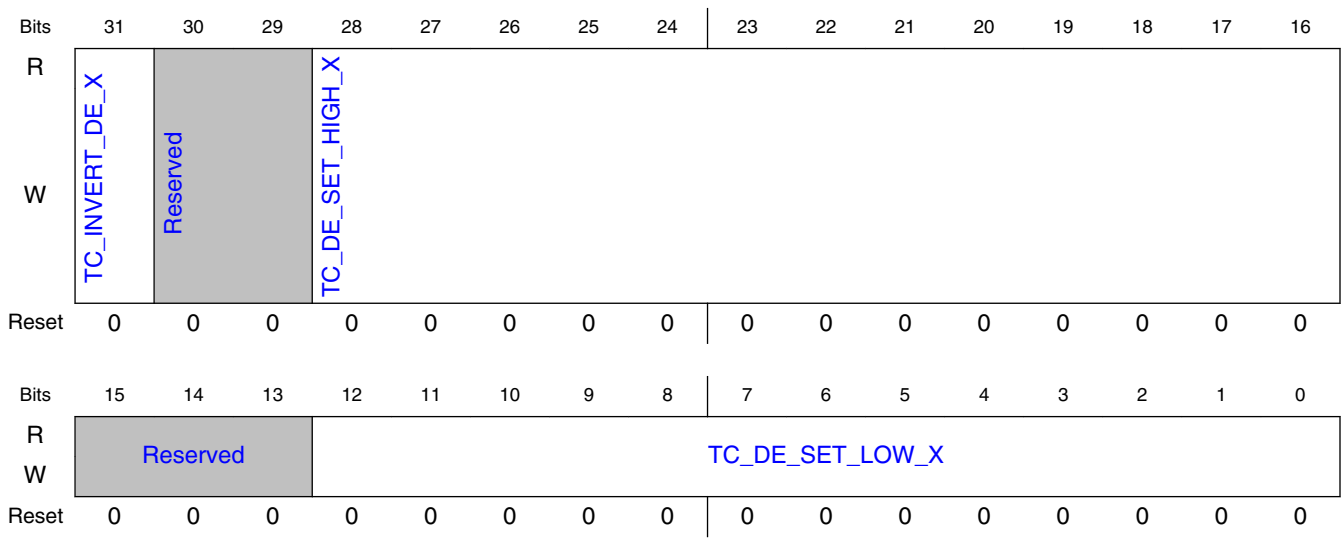
15.3.3.1.31.1 Offset

Register	Offset
TC_BL_DE_CONTROL_REG	78h

15.3.3.1.31.2 Function

This control register pertains to the DBY Base layer (BL) channel. The X cooridnates in this register specify where the DE signal is made 0 or 1 in a line.

15.3.3.1.31.3 Diagram



15.3.3.1.31.4 Fields

Field	Function
31 TC_INVERT_DE_X	0: DE signal is not inverted 1: DE signal is INVERTED
30-29 —	Reserved.
28-16 TC_DE_SET_HIGH_X	X (horizontal) coordinate Where DE control signal is set to 1 in a line.
15-13 —	Reserved.
12-0	X (horizontal) coordinate Where DE control signal is set to 0 in a line.

Field	Function
TC_DE_SET_LOW_X	

15.3.3.1.32 For DBY Mode: Controls the assertion and de-assertion DE signal (Enhancement layer (EL) channel). (TC_EL_DE_CONTROL_REG)

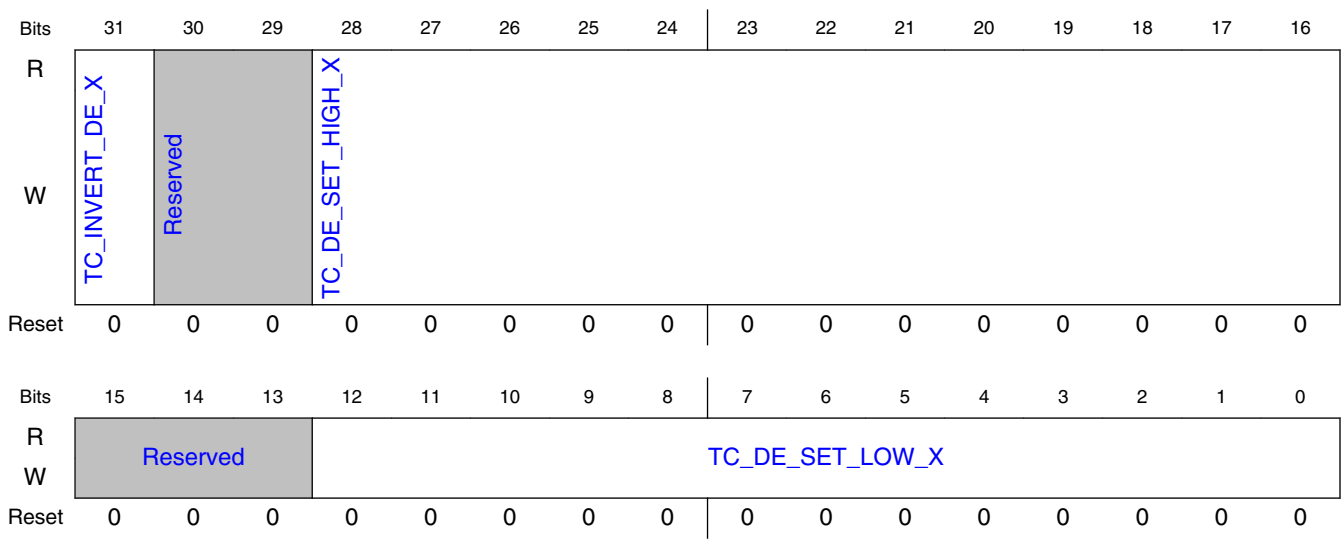
15.3.3.1.32.1 Offset

Register	Offset
TC_EL_DE_CONTROL_REG	7Ch

15.3.3.1.32.2 Function

This control register pertains to the DBY Enhancement layer (EL) channel. The X cooridnates in this register specify where the DE signal is made 0 or 1 in a line.

15.3.3.1.32.3 Diagram



15.3.3.1.32.4 Fields

Field	Function
31	0: DE signal is not inverted

Table continues on the next page...

Field	Function
TC_INVERT_DE_X	1: DE signal is INVERTED
30-29 —	Reserved.
28-16 TC_DE_SET_HIGH_X	X (horizontal) coordinate Where DE control signal is set to 1 in a line.
15-13 —	Reserved.
12-0 TC_DE_SET_LOW_X	X (horizontal) coordinate Where DE control signal is set to 0 in a line.

15.4 Context Load (CTX_LD)

15.4.1 Overview

The Context Loader (CTX_LD) module fetches and loads the next state of the display from system memory.

15.4.1.1 Block Diagram

The diagram below indicates the functional components and data flow in the CTX_LD module.

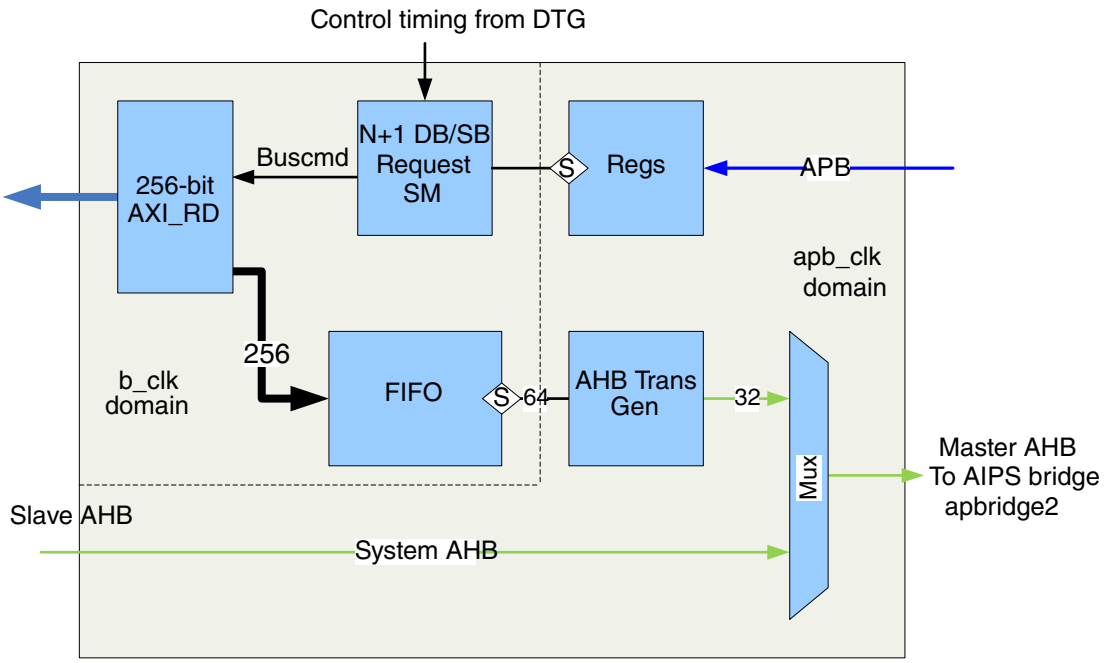


Figure 15-10. CTX_LD Block Diagram

- The request state machine issues transactions to fetch the register addr/data pairs from system memory (see System Memory Display State Format). It manages the FIFO to keep the register loading operation advancing until all the DB and SB registers are loaded.
- The loading sequence is described below in section Display State Loading Sequence. A likely size for the FIFO is 512 bytes. Each request to system memory by the state machine is half the size of the FIFO. When the FIFO is half full/empty, the SM requests another half FIFO size of addr/data pairs from system memory. This process proceeds until all the DB and SB registers are loaded.
- The AHB transaction generator creates the transactions needed to empty the FIFO and load DC registers contents.

15.4.2 Functional Description

Two events indicate when the next display context is loaded. The timing of the CTX_LD is controlled by the Display Timing Generator (DTG).

The first event, marked by the red dot in the DTG chapter's timing example (Display Timing and Window Overlay section), and also in the timing diagram in the section Timing Sequence, is for components that implement double buffered registers and require their next state to be loaded into shadow registers during the active display time. This interval is defined as the db_region, or double buffered region.

The second event, marked by the orange dot, occurs after the active display region for components that don't support double buffered registers and require the next state to be loaded during the vertical blanking time. This interval is defined as the sb_region, or single buffered region. The second region is subdivided into two regions. The first is high priority and critical from a timing perspective. The second includes all single buffered components that aren't critical from a timing perspective. These two sub regions are defined as sb_region.high_prioity and sb_region.low_priority.

The critical region should include loading component parameters that need to be issued first. As an example, the pixel prefetch components (DPR) would need to be programmed first and kicked to start their prefetch operation before the first scan line in the active display region. The DPR would not be enabled to start after the HDR10 LUTs are loaded, as an example. The idea is that low priority registers are being loaded in parallel with the DPR's prefetch operation. This provides the best opportunity to prefetch data BEFORE the first pixel is needed to drive the display when the active region begins

As stated before, the loading sequence has the following regions.

```
1. db_region; Region where all double buffered registers are loaded.
2. sb_region; Region where all single buffered registers are loaded.
   a. sb_region.high_priority - critical time to load single buffered
         components.
   b. sb_region.low_priority - time to load components not critical
         on timing.
```

The timing of db/sb regions are controlled and timed by the DTG, or respective display timing generator. These event trigger times are programmable based on vertical timing parameters in the DTG that go high for one scan line interval. The rising edge of these events cause the CTX_LD engine to fetch the next state parameters from DRAM.

The components that implement double buffered registers should transfer the shadow registers into the active registers when ctx_ld_sb_en goes active. This is the trigger used to start loading single buffered registers, and is used to allow the double buffered register components to start processing for the next frame. The idea is that the double buffered components should be enabled shortly after the active display region is complete, and the display enters the vertical front porch region. When the trigger is received by the double buffered component, then the component begins processing for trace N+1. The earliest possible event to enable the DB components is necessary to allow the most time to complete processing for trace N+1 before the active display area becomes active.

Components that implement single buffer registers receives their new values from the ctx_ld module after the ctx_ld_sb_en signal goes high. This is the event that indicates the CTX_LD fetches and loads the single buffered components in the display SS. Single buffered components starts processing using their last register write, or can also use the ctx_ld_sb_hp_kick output signal to "kick" their processing for trace N+1.

NOTE

It could be valid that the CTX_LD is NOT enabled to fetch the next state for N+1, i.e. there is no state change and the display system repeats the frame N+1 with the existing parameters already programmed. In this case, the CTX_LD still receives the ctx_ld_[sb|db]_en signal inputs and the CTX_LD does not issue DRAM accesses to load the parameters. The ctx_ld_sb_hp_kick_en and the ctx_ld_sb_lp_kick_en output strobes cycle low/high/low to indicate all modules should start processing using their existing parameters. Or, 0 registers were fetched in 0 time, and the process completes by issuing both ctx_ld_sb_hp_kick and ctx_ld_sb_lp_kick to “kick” all the SB components so processing can begin. The ctx_ld_sb_[hp|lp]_kick signal is asserted just after it receives the ctx_ld_sb_en input strobe if the CTX_LD register loading sequence was not enabled during trace N. This allows to restart the components with the previous state used in N.

Double buffered components use either vsync or the ctx_ld_sb_hp_kick signal to start processing for trace N+1.

Once the display state is completely loaded, both those that are doubled buffered and those that use a single buffering scheme, all components commence operation to refresh the display. Some of the next state parameters that are loaded by the CTX_LD engine are defined as, but not limited to, the following:

- The source buffer addresses, formats, and rotation parameters fetched by each DPR.
- The scale width, height, X/Y scaling factors and initial offsets, and coeffs for the scaling operation
- X,Y min/max extents for the three surfaces in the output display.
- WR_SCL and RD_SRC buffer addresses, pitch, and formats, if needed.
- Data flow configuration options (which scaler goes to DRAM if any).

The Context Loader Engine is also capable of loading the Dolby Vision tables or the HDR10 LUT entries from DDR. When the CTX_LD is done with the next state loading sequence, it returns to its idle state by auto clearing the ENABLE bit in the CTRL_STATUS register.

15.4.2.1 Timing Sequence

The timing diagram below indicates the sequence over the trace time N, in preparation for trace N+1. The DB load strobe starts the CTX_LD sequence. The first ctx_ld_db_en event that occurs AFTER the PIO write to set CTX_LD_CTRL[ENABLE] commences the register loading sequence for display trace N+1.

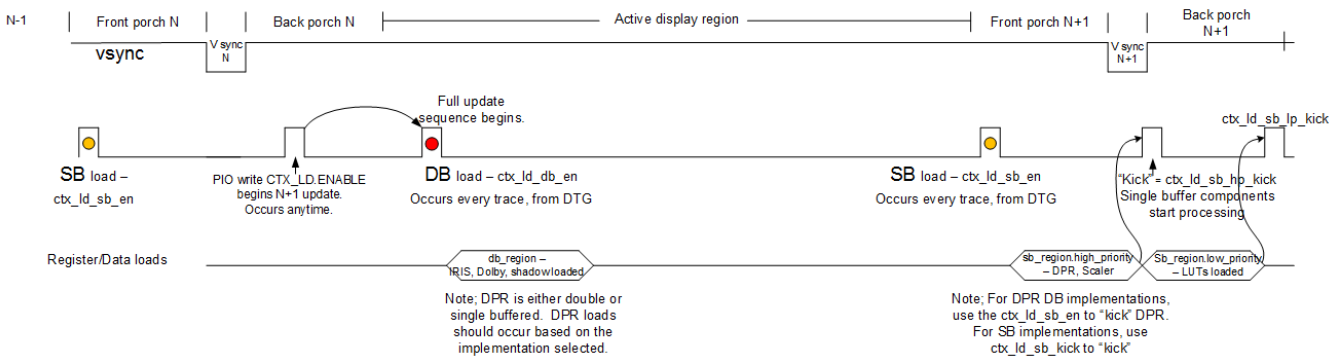

Figure 15-11. CTX_LD Timing Sequence

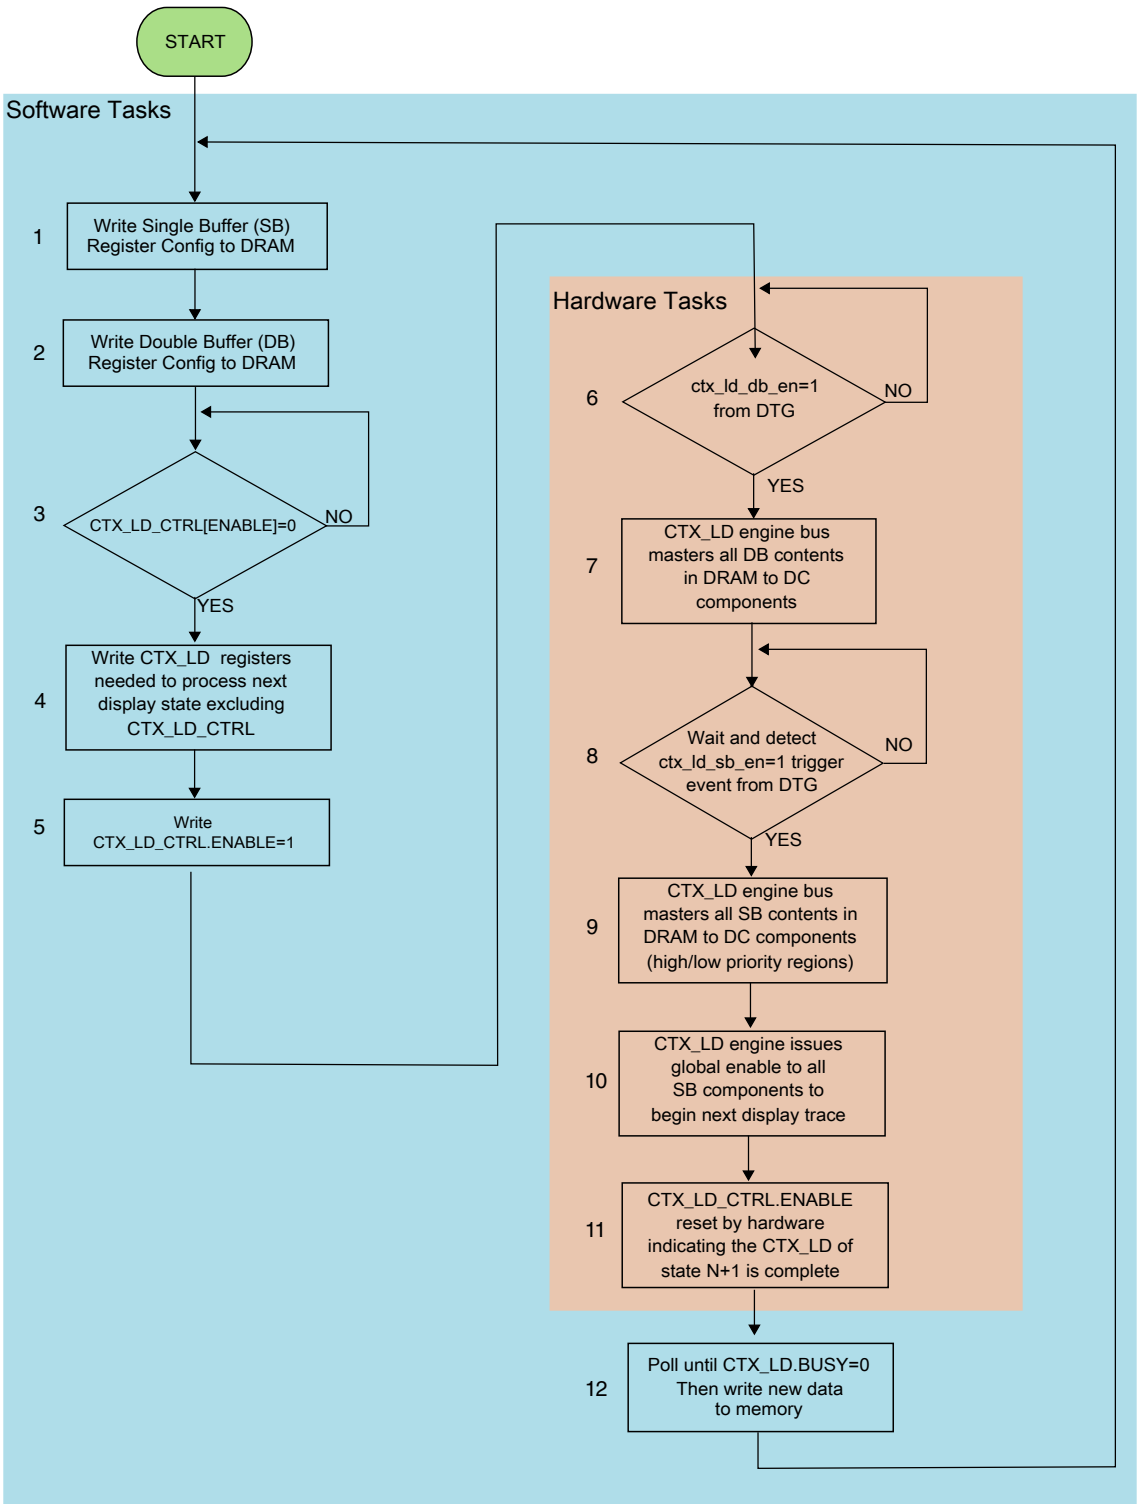
NOTE

If the PIO write to set the CTX_LD_CTRL[ENABLE] comes after the ctx_ld_db_en event AND before the ctx_ld_sb_en event, nothing occurs. The process to load DB and SB registers always starts at the ctx_ld_db_en event. So, DB registers are loaded first, and then the SB registers are loaded second to complete the full sequence.

15.4.2.2 Display State Loading Sequence

The sequence to properly load all registers for the next display state N+1 is shown below.



See detailed descriptions of these steps below for more information.

Figure 15-12. Display State Loading Sequence

NOTE: “SW” indicates an action taken by the software, and “HW” indicates action on behalf of the hardware.

1. SW: Write all single buffered register configurations in DRAM at address SB_BASE_ADDR. This should be a new address not used in the previous CTX_LD sequence.
2. SW: Write all double buffered register configurations in DRAM at address DB_BASE_ADDR. This should be a new address not used in the previous CTX_LD sequence.
3. SW: Read the CTX_LD_CTRL[ENABLE] = 0. This indicates the CTX_LD is idle and ready for the next state update.
   a. CTX_LD_CTRL[ENABLE] = 1, wait, goto #3
   b. CTX_LD_CTRL[ENABLE] = 0, goto #4
4. SW: Write all CTX_LD registers needed to process the next display state excluding CTX_LD_CTRL. CTX_LD_SB_HP_CNT cannot be 0 if CTX_LD_SB_LP_CNT != 0.
5. SW: Write the CTX_LD_CTRL[ENABLE] = 1. This bit can only be set by SW. Note, it is reset by HW when the CTX_LD engine is complete loading the entire next state. When the ENABLE bit is high, it indicates that
   a. The CTX_LD is ready to start the loading sequence when the ctx_ld_db_en input goes high.
   b. or CTX_LD is currently busy loading the state N+1.
6. HW: Wait and detect the ctx_ld_db_en trigger input event from the DTG. This occurs around the timing indicated by the red dot in the display timing diagram.
7. HW: The CTX_LD engine bus masters all double buffered register contents from DRAM to DC components.
8. HW: Wait and detect the ctx_ld_sb_en trigger event input from the DTG. Generally, this timing is indicated by the orange dot and is just after the completion of the active display region (start of vertical front porch).
9. HW: The ctx_ld engine bus masters all single buffered register contents from DRAM to DC components. Waits for the last transaction response via AHB. a. NOTE: During this interval, there are two regions to load registers divided into the high/low priority regions.
10. HW: The ctx_ld engine issues a global enable control signal to all single buffered components to begin processing for the next display trace after each of the high/low priority regions are complete. These control signals are the ctx_ld_sb_hp_kick and ctx_ld_sb_lp_kick. DC components that are considered high priority should use ctx_ld_sb_hp_kick signal to indicate when they should start processing. Likewise for low priority DC components.
11. The CTX_LD_CTRL[ENABLE] bit is reset by HW indicating the CTX_LD of state N+1 is complete.

12. Goto #1. When CTX_LD_CTRL[ENABLE] set by SW, it should not update the DRAM contents the CTX_LD uses to set the state for display trace N+1. SW should also refrain from writing CTX_LD registers that control the next context load for display trace N+1. If alternate buffers in DRAM are used for another display state, then they can be preloaded at a different address since the CTX_LD engine only uses the buffers pointed to by the base address registers. When the CTX_LD_CTRL[ENABLE] bit is low, SW can program CTX_LD registers and set CTX_LD_CTRL[ENABLE] to initiate the process again.

15.4.2.3 System Memory Display State Format

The format of the entries in DRAM used to load a register is indicated in the table below:

Table 15-7. 64-bit Address Offset and Data Pair in Memory

Address in DRAM	63:32 DC register address offset	31:0 DC register value
ctx_[db|sb]_base_addr	First reg offset to be loaded in DC	Respective first reg data value.
ctx_[db|sb]_base_addr + 8	Second reg offset to loaded in DC	Respective second reg value.
...	...	...
ctx_[db|sb]_base_addr + 8*count	CTX_[DB|SB]_COUNT reg offset in DC	Respective last reg value.

15.4.2.4 Arbitration

The MUX arbitrates between transactions from the AHB transaction generator and the system AHB bus. When the CTX_LD state machine is actively fetching register contents from system memory and loading registers in the DC, accesses from the slave AHB bus (the host) are arbitrated. This occurs during the time when the CTX_LD is loading DB or SB registers. So, if concurrent access is required by the CTX_LD engine AND the host (via AHB), then the accesses are arbitrated in an alternating sequence. If the host is attempting a burst, a single burst is consider as a single access. This access completes, and then the CTX_LD engine wins the right to initiate a single burst.

As a programmable option (NOT the default), the host AHB bus can be blocked while the CTX_LD engine is actively processing transactions. This is intended to allow the CTX_LD to completely load the register state without interruption. It is expected that blocking the host is not permitted for long intervals. This option is an intent to avoid programming issues while the CTX_LD and host are concurrently accessing registers. Another way to view this is that the CTX_LD always has priority over the slave AHB accesses via the host. The following CTX_LD operational states would stall the slave AHB bus.

- CTX_LD request state machine is active and generating requests.
- CTX_LD request state machine is done, but the transaction FIFO is not empty and still has transactions to complete to components within the DC.

NOTE

System software is responsible for guaranteeing the system AHB transactions and the CTX_LD transactions do not violate the programming and operation model of the DC SS. This is required regardless if the arbitration scheme, or the round robin scheme, is used for processing transactions from the two sources.

15.4.3 Memory Map and Registers

15.4.3.1 register descriptions

15.4.3.1.1 CTX_LD Memory map

ctx_ld base address: 2_3000h

Offset	Register	Width (In bits)	Access	Reset value

15.4.3.1.2.3 Fields

Field	Function
31-23 —	Reserved
22 AHB_ERR	AHB error Status bit to indicate when the internal AHB bus returns an error response. This reflects an error on the AHB bus output from the CTX_LD to the DCSS memory mapped components. This could occur when accessing a region that is not mapped. This status bit can be set ONLY for CTX_LD initiated transactions

Table continues on the next page...

Field	Function
	that receive an AHB error. System transactions that respond with an error are passed through, and the initiating master manages the error response at the source.
21 SB_PEND_DISP_ACTIVE	Single/active region overlap Status bit to indicate when the SB region is still actively loading registers to the display subsystem AND the display enters the active display time. This would indicate the SB registers are not loaded in time and the display trace could be corrupt. Unpredicatable behaviour could result if this occurs.
20 DB_PEND_SB_REC	Double/single region overlap Status bit to indicate when the DB region is still actively loading registers to the display subsystem AND a kick to load the SB region is received. This could indicate a timing or BW issue with loading the DB region in time before the SB region register loading should begin. Unpredicatable behaviour could result if this occurs.
19 SB_LP_COMP	Single buffer low priority region loading complete IRQ enable Status bit to indicate when the low priority SB region loading sequence is complete.
18 SB_HP_COMP	Single buffer high priority region loading complete Status bit to indicate when the high priority SB region loading sequence is complete.
17 DB_COMP	Double buffer region loading complete Status bit to indicate when the DB (double buffer) region loading sequence is complete.
16 RD_ERR	AXI read error Status bit to indicate when the AXI read bus returns a SLV_ERR or DEC_ERR. This could result in an illegal or unmapped address programmed into the base address registers.
15-9 —	Reserved
8 AHB_ERR_EN	AHB error IRQ enable Enable and interrupt when the internal AHB bus returns an error response. This reflects an error on the AHB bus output from the CTX_LD to the DCSS memory mapped components. This could occur when accessing a region that is not mapped.
7 SB_PEND_DISP_ACTIVE_EN	Single/active region overlap interrupt enable. Enable an interrupt when the SB region is still actively loading registers to the display subsystem AND the display enters the active display time. This would indicate the SB registers are not loaded in time and the display trace could be corrupt. Unpredicatable behaviour could result if this occurs.
6 DB_PEND_SB_REC_EN	Double/single region overlap interrupt enable Enable an interrupt when the DB region is still actively loading registers to the display subsystem AND a kick to load the SB region is received. This could indicate a timing or BW issue with loading the DB region in time before the SB region register loading should begin. Unpredicatable behaviour could result if this occurs.
5 SB_LP_COMP_EN	Single buffer low priority region loading complete IRQ enable Enable an interrupt when the low priority SB region loading sequence is complete.
4 SB_HP_COMP_EN	Single buffer high priority region loading complete IRQ enable Enable an interrupt when the high priority SB region loading sequence is complete.
3 DB_COMP_EN	Double buffer region loading complete IRQ enable Enable an interrupt when the DB (double buffer) region loading sequence is complete.
2 RD_ERR_EN	AXI read error IRQ enable

Table continues on the next page...

Field	Function
	Enable an interrupt when the AXI read bus returns a SLV_ERR or DEC_ERR. This could result in an illegal or unmapped address programmed into the base address registers.
1 ARB_SEL	Arbitration select This selects between always choosing the CTX_LD while it's active verses a round robin arbitration scheme of equal weight between the CTX_LD and the system register access bus. • 0 - Round robin arbitration at all times. • 1 - CTX_LD gets priority while it's active.
0 ENABLE	Enable/Busy Enable bit for the context loader. The context loader does not start the register loading sequence if this bit is not set. SW can set this bit only when it is logic 0 (never set this bit if it is already logic 1). The CTX_LD hardware resets this bit when the entire register loading sequence is complete. It is complete after the DB and SB regions are loaded and the CTX_LD state machine returns to the idle state to allow the next context loading sequence to be enabled.

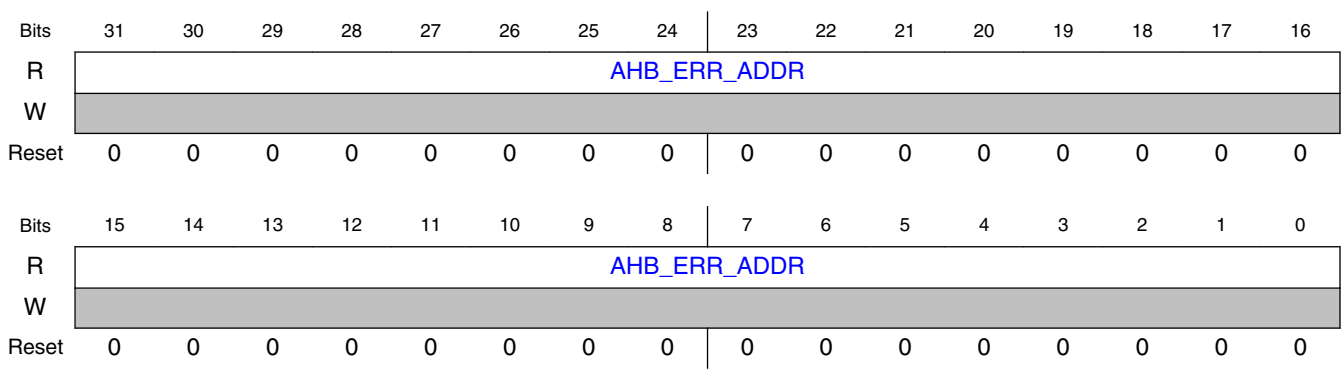
15-0 HP_COUNT	Single buffered high priority region fetch count Number of 64 bit high priority entries of single buffer registers to fetch and load.

15.4.3.1.10 AHB address with error response. (AHB_ERR_ADDR)

15.4.3.1.10.1 Offset

Register	Offset
AHB_ERR_ADDR	20h

15.4.3.1.10.2 Diagram



15.4.3.1.10.3 Fields

Field	Function
31-0 AHB_ERR_ADDR	AHB error address. Stores the address of the CTX_LD transaction that responded with an AHB error. A new address is stored only if ahb_error bit in ctrl_status is 0. If AHB_ERR is set, new address is not logged until the bit is cleared. This address is trapped only for CTX_LD initiated transactions when it is fetching the display state from memory. Error response for system transactions are not trapped and does NOT effect this register.

15.5 Graphics Decompression (DEC400D)

15.5.1 Overview

The DEC400D decompresses graphics data. The DEC400D decompresses the data on the fly, and the compressed format in DRAM is transparent to the Display Prefetch Resolve (DPR) block. The DPR is programmed as if the frame buffer is not compressed.

15.5.1.1 Block diagram

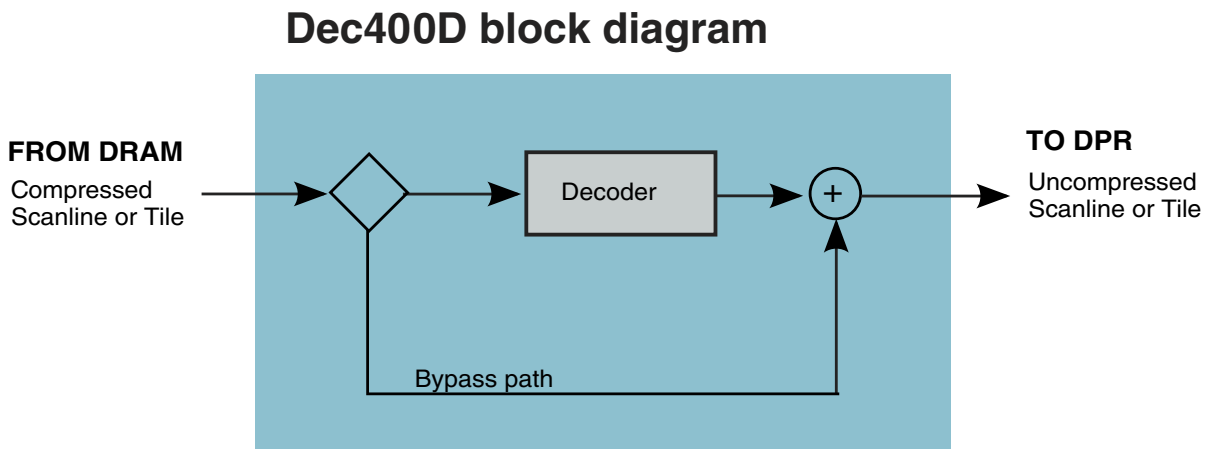


Figure 15-13. DEC400D block diagram

15.5.1.2 Features

The DEC400D includes the following host and memory features:

- 32-bit AHB Interface
- 128-bit width AXI data channel with dedicated pins for Pixel Engine and Memory
- 8-bit AXI ID, up to 16 read transactions supported for decompression
- 16-256 Byte AXI burst data range
- Supports interleaved return data
- Output arbitration, required to insure data output matches request
- Resource locks with CPU (Semaphore lock)

The DEC400D includes the following decode features:

- Up to 8/16 pixels per cycle decode for 32bpp with 128 bit AXI

- 2:1 to 3:1 average decompression ratio
- Pixel data organization support for Linear (scanline) or Tiled (4x4, 4x8, 8x4 and 8x8-XMajor)
- Bypass option controlled via software
- Full frame or partial screen update supported

15.5.2 Functional description

The following sections describe functional details of the DEC400D module.

15.5.2.1 Graphics compression/decompression

The DEC400D decompresses graphics data. The DPR issues AXI requests at a pixel size of 8x4 at 32bpp, or 128B per request, as an uncompressed AXI transaction. The DEC400D decompresses on the fly, and the compressed format in DRAM is transparent to the DPR. The DPR is programmed as if the frame buffer is not compressed.

Graphics buffer formats use the Z order super tile frame buffer format. A diagram depicting the tile format is shown below.

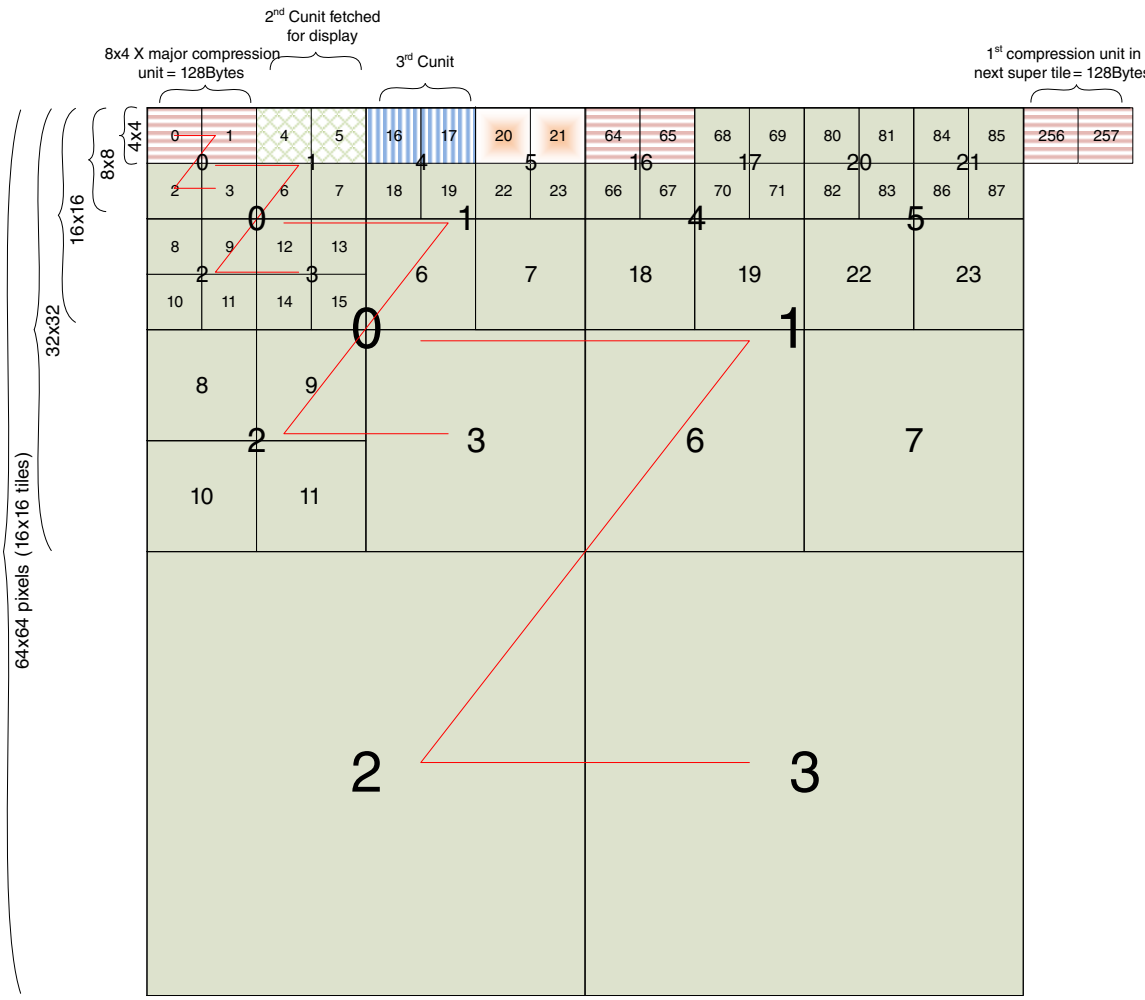

Figure 15-14. Graphics Tile Format

The DPR, or bus master that fetches data from DRAM uncompressed, is programmed to request 128B for each request. Each compression unit is 128B in the X major organization. The first compression unit in the diagram above is two 4x4 tiles labeled as 0,1, the second compression unit the DPR fetches contains the tiles labeled as 4,5. This fetch pattern continues left to right across the supertiled source buffer. The GPU compression scheme must compliment the DC's decompression scheme in that compressed units must be 8x4 pixel groups, which is 128B for two 4x4 tiles. The complete order of compression units the DPR fetches for GPU frames is:

- Bank 1 = cu(0,1), cu(4,5), cu(16,17), cu(20,21), cu(64,65), cu(68,69), cu(80,81), cu(84,85), cu(256,257), … continues to the programmed width of the buffer.
- Bank 2 = cu(2,3), cu(6,7), cu(18,19), …
- Bank 3 = cu(8,9), cu(12,13), cu(24,25), …

The equivalent address fetch pattern for the first row of CUs is:

- 0x0, 0x100, 0x400, 0x500, 0x1000, 0x1100, 0x1400, 0x1500, 0x4000, …

Each bank above is 4 lines high across the display. This data is stored locally in the RTRAM memory for subsequent use by the display controller for screen refresh (see DPR/RTRAM sections).

Note the Z order of 4x4 tiles, which extends to the next size of 8x8, 16x16, etc., to the super tile size that is 64x64 pixels. At a resolution above 64x64, the ordering of super tiles is raster ordered which extends for the entire frame size.

15.5.2.2 CU tile status

Each compression unit (CU) is two consecutive 4x4 tiles. The memory use before/after compression is depicted in the diagram below.

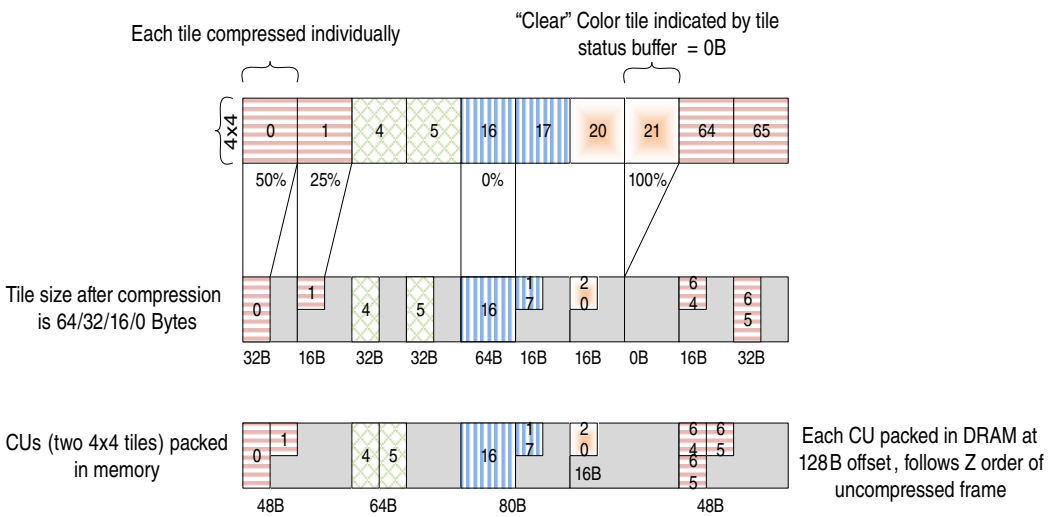

Figure 15-15. Memory use before/after compression

The uncompressed frame buffer is on the first row of tiles above, with each tile arranged as 4x4 pixels. The tiles are compressed to a reduced number of bytes, as in the second row. The compressed tiles are then packed into memory on a per CU basis (note the address order of CUs is still Z which is not depicted in the diagram). DRAM access to compressed tiles is on a per CU basis, and the AXI transaction size is determined by the tile status buffer entry for each CU. The CU data request could be from 16B – 128B on 16B increments. From an LPDDR4 32-bit implementation, 16/32/48/64B accesses are effectively 64B accesses. 80/96/112/128B accesses are effectively 128B accesses from the DRAM perspective.

15.5.3 Memory Map and register definition

This section includes the DEC400D module memory map and detailed descriptions of all registers.

15.5.3.1 DEC400D register descriptions

15.6 Decompression and Tile to Raster Conversion (DTRC)

15.6.1 Overview

The Decompression and Tile to Raster Conversion (DTRC) module decompresses content for video frames. It decompresses and resolves the tile data into linear scan lines.

The DTRC buffers a full 4K of raster lines in its local memory. This is required since the DPR fetches scan lines from the resolve memory attached to the DTRC.

15.6.2 Features

The DTRC includes the following functionality features:

- Input data format can be one of the following:
  - Compressed Hantro G2 reference frame buffer format
  - Uncompressed tile Hantro G2 reference frame buffer format
  - Uncompressed tile Hantro G1 reference frame buffer format
- Output data format is uncompressed YCbCr pixels on AXI bus
- Decompression for G2:
  - DTRC decompresses data in units of Coding Block Set Groups (CBSG)
  - DTRC decompression can be bypassed
- The DTRC converts G2/G1 tile format pixels into raster scan order pixels
- Picture size:
  - Minimum width of 144
  - Minimum height of 144
  - Maximum width of 4096
  - Maximum width of 4096
  - The width and height must be integer multiples of 8
- Maximum pixel sample rate is 4096 x 2304 at 60fps
- Output pixel scan order is normal whole picture raster scan
- Output picture crop:
  - Cropped picture origin (x,y) points to the top left corner of the cropped picture
  - Both x and y are even, and the unit is pixel
  - Cropped width is even and unit is pixel
  - Cropped height is even and unit is pixel
  - Minimum cropped picture size is 144 x 2
- Non-G2/G1 data read transactions directly pass through the DTRC
  - The transactions are distinguished by ARID or address
- Run-time hot reset triggered by software
  - G2/G1 data processing path is reset
  - Non-G2/G1 data path continues working
- Data prefetch and pre-decompression supported:
  - Prefetch between frames
  - Prefetch along with pixel scan order

15.6.3 Block diagram

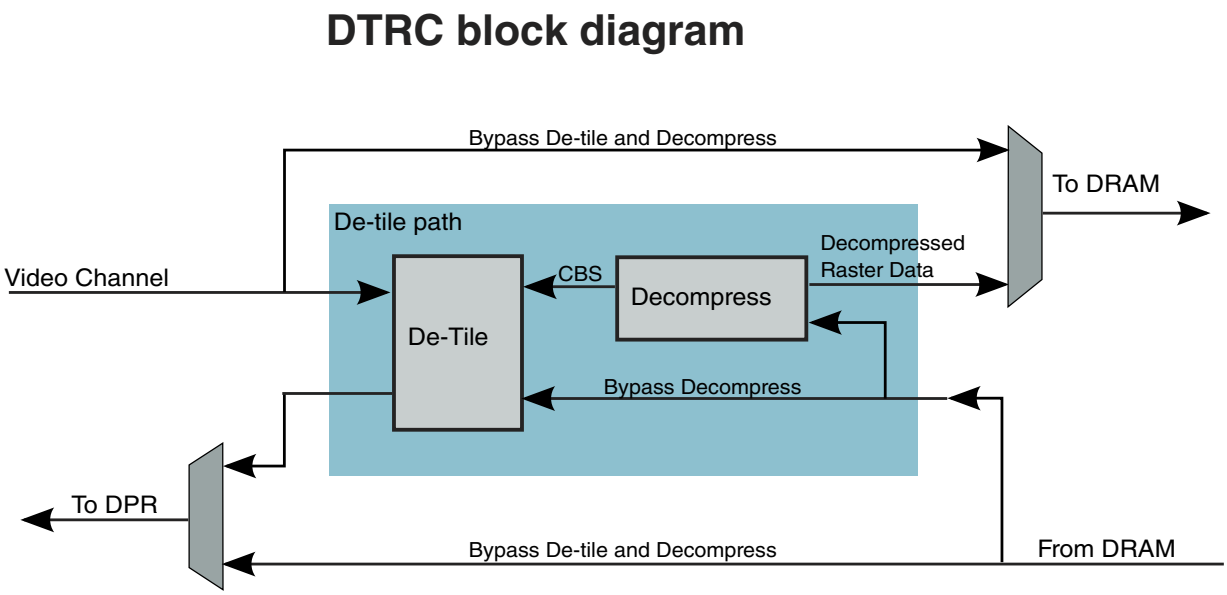

Figure 15-16. DTRC block diagram

15.6.4 Functional description

The following sections describe functional details of the DTRC module.

15.6.4.1 Video compression/decompression

Video decompression uses the DTRC module. This module decompresses CBSGs (Coding Block Set Groups) and store the resolved data in raster order in a local buffer exclusive to each DTRC instance. The DPR is programmed to fetch raster data, and the DTRC returns the scan line data to the DPRs.

The compression scheme used by the video engine is not Z ordered like in GPU frames. Instead, video frames are compressed using 8x8 pixel tiles (for Luma) as each compressed unit, and the compressed results are packed in memory. The 8x8 tiles are compressed in raster scan order from left to right, then top to bottom. The tile order of video frames is depicted in the following diagram.

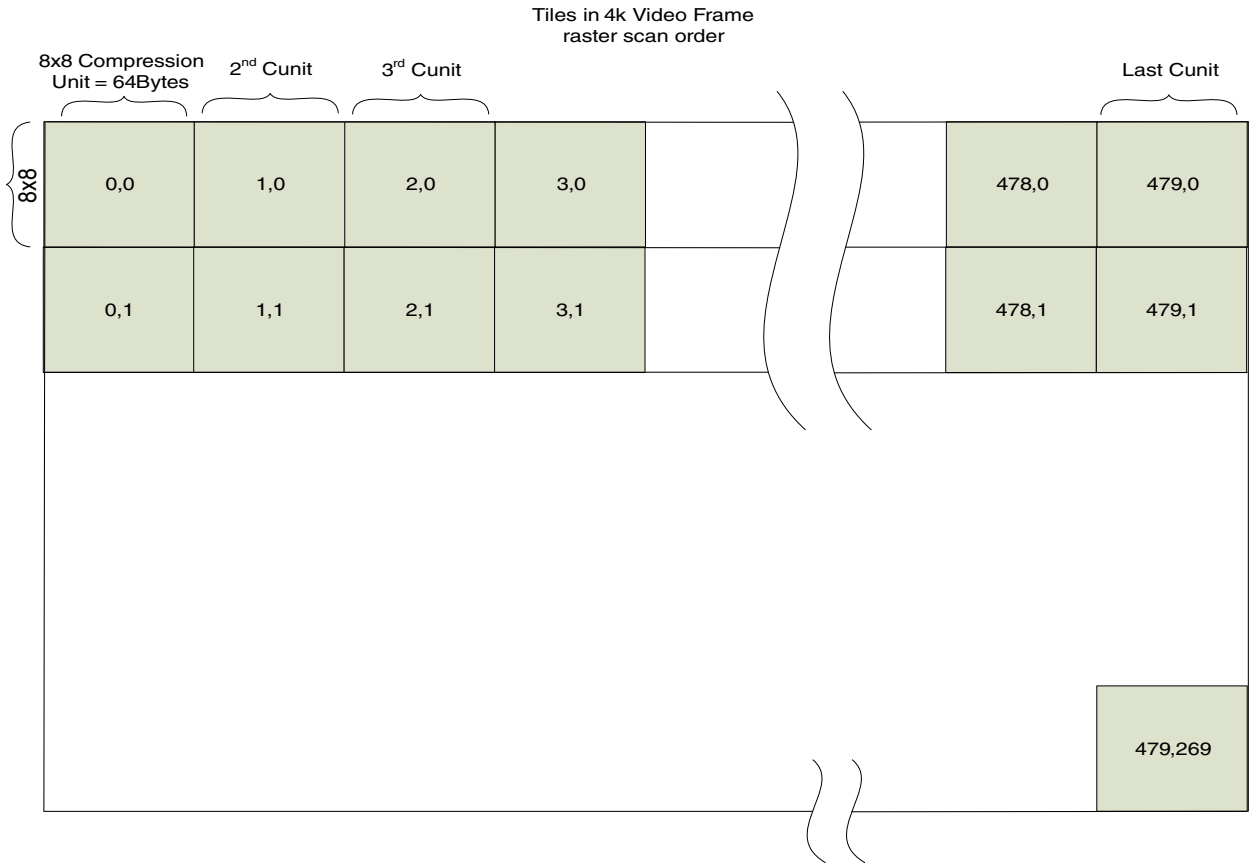

Figure 15-17. Video Frame Tile Order

NOTE

CbCr frame buffers are 8x4 compressed units, which are also 64B per compressed unit.

The video compression scheme is depicted in the diagram below.

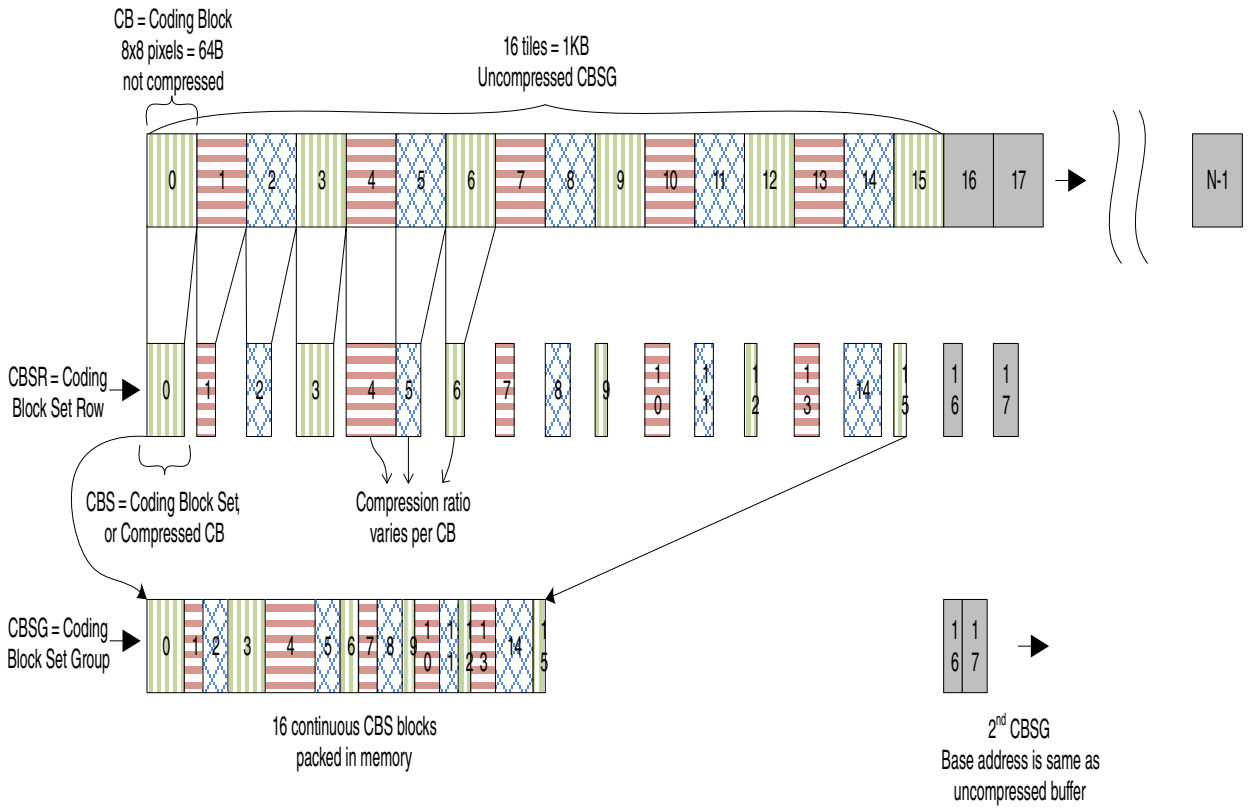

Figure 15-18. Video Compression Scheme

Each 8x8 tile (for Luma) is compressed separately as a single compressed unit, called a CBS unit. The compression ratio can be different for each unit. Then, 16 CBSs are packed in memory to form a CBSG. These 16 uncompressed tiles are 1KB, and when compressed and packed requires less than 1KB. In the example above, the compressed result for the 1st CBSG is about 50%, so the CBSG requires 512B in memory.

NOTE

The DTRC fetches compressed CBSGs, uncompress the units, and store them as raster scan lines in local memory attached to the DTRC. The DTRC then returns the data to the DPR in raster scan order. The DPR is programmed in raster scan mode, with a burst length of 4KB. This forces the DPR to fetch an entire scan line, and then move to the next scan line in the vertical direction. In this case, the DPR does not resolve tiles, but just process raster ordered scan lines.

15.6.4.2 DTRC scan line memory size

The maximum display is 3840 pixels. The scan line structure is 8 lines high for luma, and 4 lines high for chroma. Each pixel is 10-bit per component. The memory size is:

- Luma buffer = 3840 * 8 * 10/8 = 38400B
- Chroma buffer = 3840 * 4 * 10/8 = 19200B

This implementation supports 40960B for the luma buffer and 20480B for the chroma buffer to support 4096 horizontal displays. The total memory size is 61440B.

15.6.5 Programming considerations

The following sections describe software usage for the DTRC module.

15.6.5.1 Initial configuration

At the beginning to start the decompression of a video sequence, software needs to configure the following:

- Set DTRCINTEN register to enable/disable interrupt sources
- Set DTID2DDR register to configure AXI ID of DTRC generated transaction to fetch G2/G1 video data. If the default, AXI ID won't be used.
- Configure the mechanism to determine between G2/G1 and non-G2/G1 data
  - If ARID used to determine:
    - Set DTCTRL[30] to 0
    - Set DTCTRL[1:0] to select a mode of how to use IDs in ARIDR register
    - According to DTCTRL[1:0], set all of the four IDs in ARIDR. Duplicate if ID to be set is less than 4
  - If address used to determine:
    - Set DTCTRL[30] to 1
    - If all transactions are non-G2/G1 transactions, so that no meaningful address segment corresponding to G2/G1 video data, set all bit 0 of F0SYSSA, F0SYSEA, F0SUVSSA, F0SUVSEA, F1SYSSA, F1SYSEA, F1SUVSSA, F1SUVSEA to 1.

15.6.5.2 Picture-level configuration

There are two sets of picture level configuration registers corresponding to two back-to-back pictures, which allow seamless display between two pictures.

Software first looks at DTCTRL[31] to know which set of registers to program. After that, it sets addresses, picture size, vertical scan direction etc. into corresponding registers.

If ARADDR_S is used to tell G2/G1 and non-G2/G1 transactions, set luma and chroma video data address segment into F0SYSSA, F0SYSEA, F0SUVSSA, F0SUVSEA, or F1SYSSA, F1SYSEA, F1SUVSSA, F1SUVSEA.

After the whole set of configuration is done, set the F0DCTL[0] or F1DCTL[0] to 1.

In scenario that there is no G2/G1 transactions, set F0DCTL[0] or F1DCTL[0] to 0 and do not need to do any picture level configuration.

The DTRC internal state machine periodically performs the following action sequence:

1. (After an asynchronous reset) wait frame 0 bit 0 == 1’b1
2. Decompress frame
3. Wait frame 1 bit 0 == 1’b1
4. Decompress frame
5. Wait frame 0 bit 0 == 1’b1
6. Decompress frame
7. Wait frame 1 bit 0 == 1’b1
8. Decompress frame
9. ...

Although the switch of the two sets of picture configuration is predictable, it is recommended software always check the DTCTRL[31] to program picture settings.

15.6.5.3 Interrupts

If interrupt is enabled, DTRC raises the interrupt signal to high and sets the interrupt cause bit in FDINTR. Software should clean the interrupt after it finished the handling (such as program the next picture configurations).

15.6.5.4 Time out

To enable time out interrupt, software not only enables the interrupt but also enables the performance counter. Software calculates a reasonable maximum cycle count according to DTRC frequency and picture frame rate to set TOCR.

15.6.5.5 Hot reset

The video path of decompression and detile can be hot reset and do not influence the bypass non-G2/G1 transactions. To do the reset, the user needs to guarantee the following requirements:

NOTE

Requirement: The hot reset must be triggered when there is no outstanding G2/G1 video transactions remained at the DTRC AXI slave port.

The hot reset details are described below:

1. Software can write DTCTRL[2] by 1 to start a hot reset
2. A hot reset can start at any time in case the requirement described above is met
3. The reset action is hold a while after DTRC received the reset
4. When G2/G1 data related BUS transactions are clean, DTRC performs the reset
    a. The following external visible register bits are reset, and others are not reset
        1. F0DCTL[0]
        2. F1DCTL[1]
        3. DTCTRL[31]
        4. PFCR[31:0]
    b. Decompression and detile status is reset so that DTRC restarts from a new frame configured by the frame setting register group 0
    c. If DTRCINTEN[4] is 1, DTRC raises hot reset finish interrupt as well as set the interrupt bit DTRCINTR[4]
    d. DTRC clears DTCTRL[2] to 0
5. During the hot reset procedure, only bus error interrupt can be asserted, except for hot reset finish interrupt
6. During the hot reset procedure, the whole non-G2/G1 data path keeps working

15.6.6 Memory Map and register definition

This section includes the DTRC module memory map and detailed descriptions of all registers.

15.6.6.1 DTRC register descriptions

15.6.6.1.1 DTRC Memory map

DTRC_CHAN2 base address: 1_6000h

DTRC_CHAN3 base address: 1_7000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Luma video data start address (F0DYDSADDR)	32	RW	0000_0000h
4h	Chroma video data start address (F0DCDSADDR)	32	RW	0000_0000h
8h	Luma table data start address (F0DYTSADDR)	32	RW	0000_0000h
Ch	Chroma table data start address (F0DCTSADDR)	32	RW	0000_0000h

15.6.6.1.17.4 Fields

Field	Function
31-0 F1DCTSADDR	Chroma table data start address Start address for chroma table data saved in external memory. Unit is byte and 16-byte aligned.

15.6.6.1.18 Frame size (F1SIZE)

15.6.6.1.18.1 Offset

Register	Offset
F1SIZE	70h

15.6.6.1.18.2 Function

This register specifies frame width and frame height in units of 8.

15.6.6.1.18.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								F1HEIGHT							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								F1WIDTH							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

15.6.6.1.18.4 Fields

Field	Function
31-26 —	Reserved.
25-16 F1HEIGHT	Frame height Indicates frame height in units of 8 lines.
15-10 —	Reserved.
9-0 F1WIDTH	Frame width Indicates frame width in units of 8 pixels.

15.6.6.1.19 Luma data slave start address (F1SYSSA)

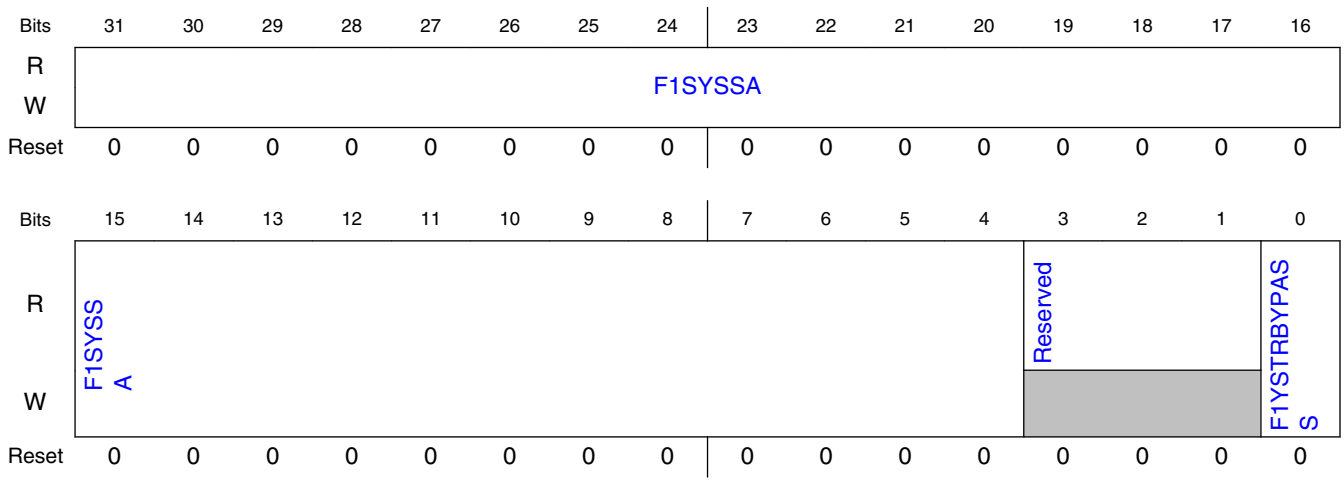
15.6.6.1.19.1 Offset

Register	Offset
F1SYSSA	74h

15.6.6.1.19.2 Function

This register specifies the start address range of the luma data associated to frame 0 and appears at ARADDR_S. Only used when G1/G2 transactions are told by ARADDR_S. It has nothing to do with F1DYDSADDR.

15.6.6.1.19.3 Diagram



15.6.6.1.19.4 Fields

Field	Function
31-4 F1SYSSA	Luma data slave start address Start of address space of slave interface luma data. This address should be 16-byte aligned and unit is 16 bytes, inclusive.
3-1 —	Reserved.
0 F1YSTRBYPASS	Luma Start Tile to Raster scan Bypass 0b - All ARADDR does NOT bypass the tile-to-rasterscan logic. 1b - All ARADDR bypasses the tile-to-rasterscan logic.

15.6.6.1.20 Luma data slave end address (F1SYSEA)

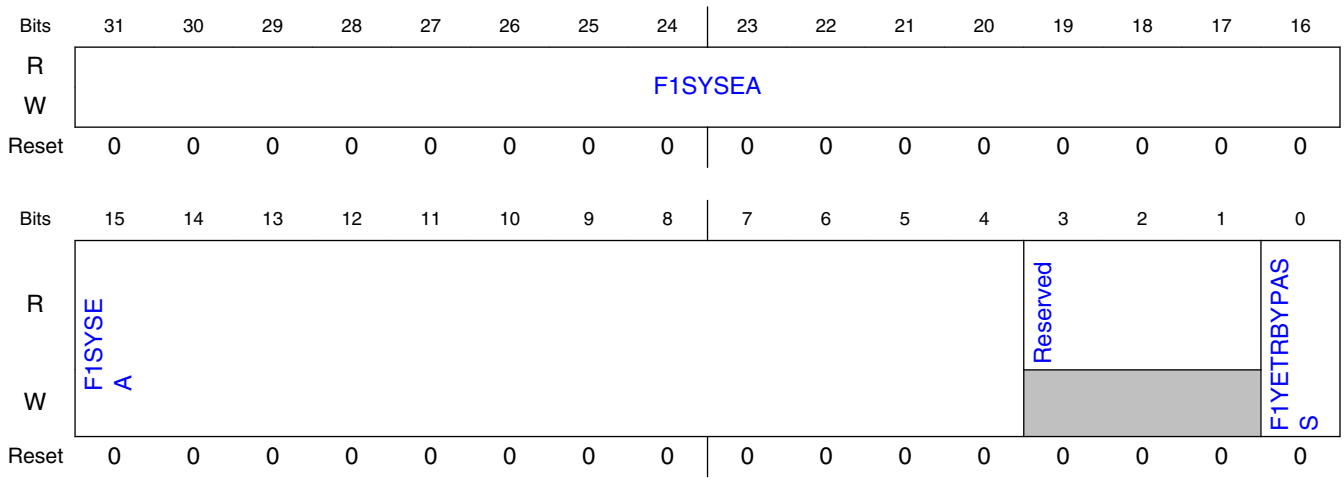
15.6.6.1.20.1 Offset

Register	Offset
F1SYSEA	78h

15.6.6.1.20.2 Function

This register specifies the end address space of luma data.

15.6.6.1.20.3 Diagram



15.6.6.1.20.4 Fields

Field	Function
31-4 F1SYSEA	Luma data slave end address End of address space of slave interface luma data. This address should be 16-byte aligned and unit is 16 bytes, exclusive.
3-1 —	Reserved.
0 F1YETRBYPASS	End Tile to Raster scan Bypass 0b - All ARADDR does NOT bypass the tile-to-rasterscan logic. 1b - All ARADDR bypasses the tile-to-rasterscan logic.

15.6.6.1.21 Chroma data slave start address (F1SUVSSA)

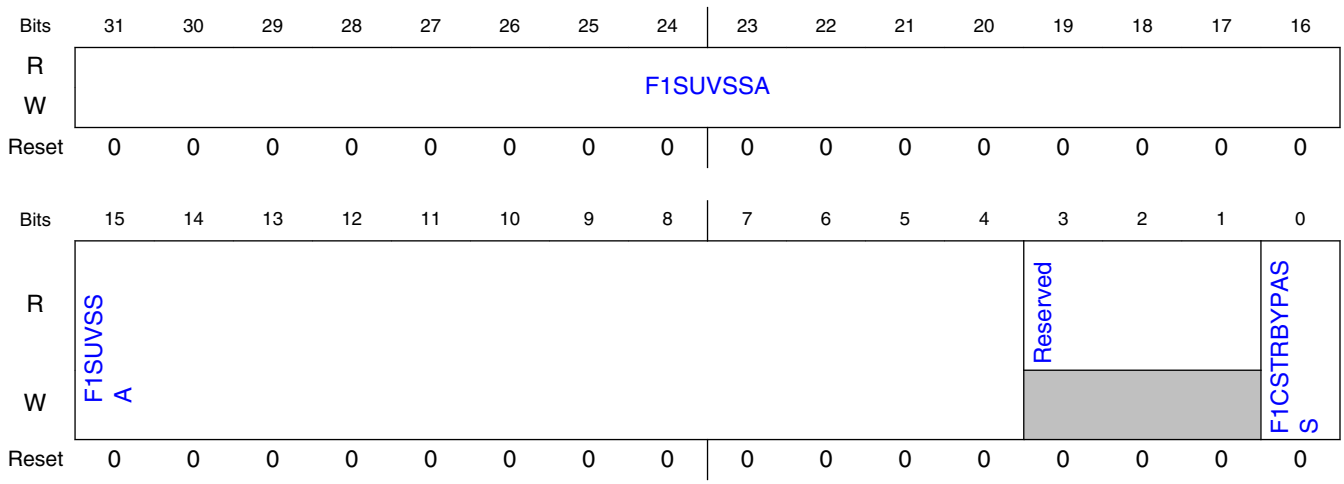
15.6.6.1.21.1 Offset

Register	Offset
F1SUVSSA	7Ch

15.6.6.1.21.2 Function

This register specifies the start address of the address range of the chroma data associated to frame 0 and appears at ARADDR_S. Only used when G2/G1 and non G2/G1 transactions are told by ARADDR_S. It has nothing to do with F1DCDSADDR.

15.6.6.1.21.3 Diagram



15.6.6.1.21.4 Fields

Field	Function
31-4 F1SUVSSA	Chroma data slave start address Start of address space of slave interface chroma data. This address should be 16-byte aligned and unit is 16 bytes, inclusive.
3-1 —	Reserved.
0 F1CSTRBYPASS	Chroma Start Tile to Raster scan Bypass 0b - All ARADDR does NOT bypass the tile-to-rasterscan logic. 1b - All ARADDR bypasses the tile-to-rasterscan logic.

15.6.6.1.22 Chroma data slave end address (F1SUVSEA)

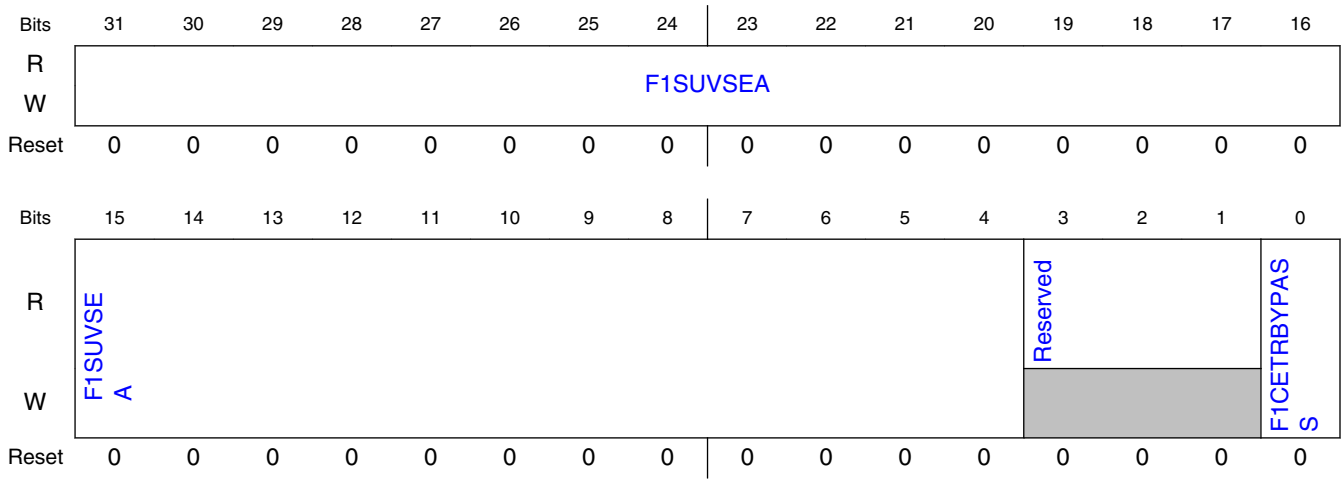
15.6.6.1.22.1 Offset

Register	Offset
F1SUVSEA	80h

15.6.6.1.22.2 Function

This register specifies the end address space of slave interface chroma data.

15.6.6.1.22.3 Diagram



15.6.6.1.22.4 Fields

Field	Function
31-4 F1SUVSEA	Chroma data slave end address End of address space of slave interface chroma data. This address should be 16-byte aligned and unit is 16 bytes, exclusive.
3-1 —	Reserved.
0 F1CETRBYPASS	End Tile to Raster scan Bypass 0b - All ARADDR does NOT bypass the tile-to-rasterscan logic. 1b - All ARADDR bypasses the tile-to-rasterscan logic.

15.6.6.1.23 Cropped picture origin (F1CROPORIG)

15.6.6.1.23.1 Offset

Register	Offset
F1CROPORIG	84h

15.6.6.1.23.2 Function

This register specifies the origin of the cropped picture.

15.6.6.1.23.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved			F1CROPORIGY												
W

R	Reserved			F1CROPORIGX												
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

15.6.6.1.23.4 Fields

Field	Function
31-29 —	Reserved.
28-16 F1CROPORIGY	Cropped picture y origin Indicates the y origin of the cropped picture in units of pixels. This number must be even. 0 points to the top left corner.
15-13 —	Reserved.
12-0 F1CROPORIGX	Cropped picture x origin Indicates the x origin of the cropped picture in units of pixels. This number must be even. 0 points to the top left corner.

15.6.6.1.24 Cropped picture size (F1CROPSIZE)

15.6.6.1.24.1 Offset

Register	Offset
F1CROPSIZE	88h

15.6.6.1.24.2 Function

This register specifies the size of the cropped picture.

15.6.6.1.24.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved			F1CROPHEIGHT												
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved			F1CROPWIDTH												
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

15.6.6.1.24.4 Fields

Field	Function
31-29 —	Reserved.
28-16 F1CROPHEIGHT	Cropped picture height Indicates the height of the cropped picture in units of pixels. This number must be even.
15-13 —	Reserved.
12-0 F1CROPWIDTH	Cropped picture width Indicates the width of the cropped picture in units of pixels. This number must be even.

15.6.6.1.25 Frame data control (F1DCTL)

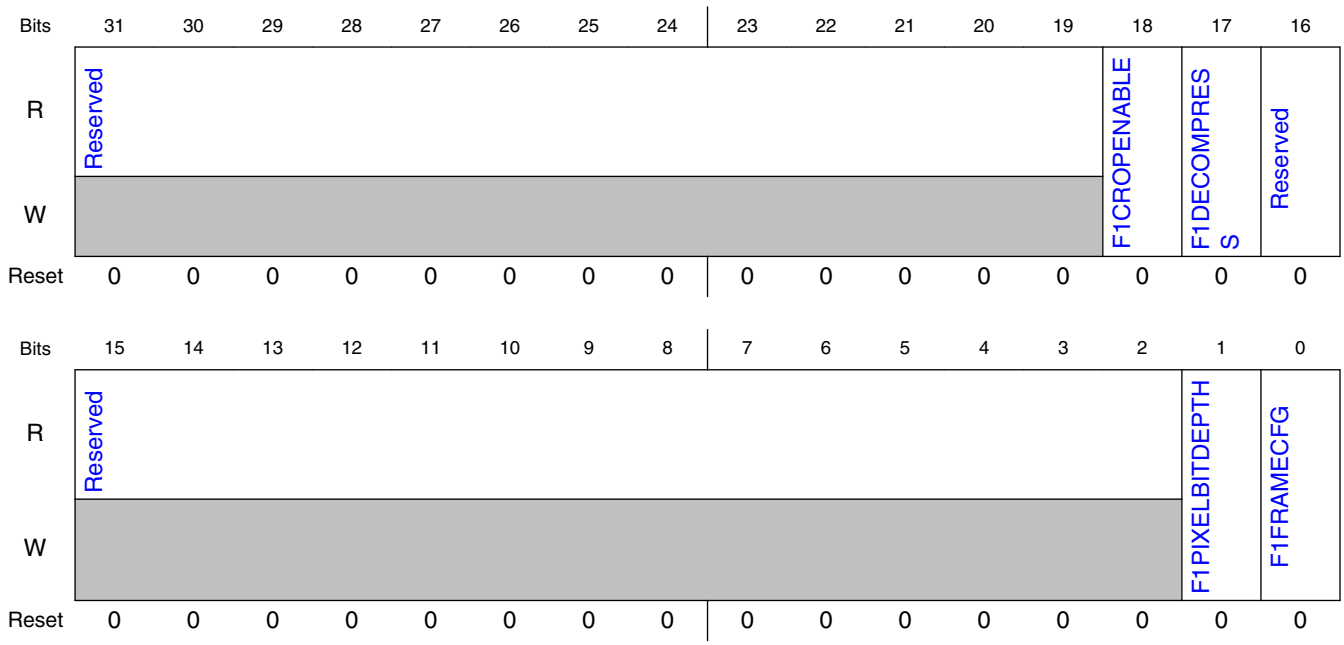
15.6.6.1.25.1 Offset

Register	Offset
F1DCTL	8Ch

15.6.6.1.25.2 Function

Hardware fetches data of Frame - first after reset.

15.6.6.1.25.3 Diagram



15.6.6.1.25.4 Fields

Field	Function
31-19 —	Reserved.
18 F1CROPENABLE	Cropped enable DTRC outputs the cropped picture data according to the settings of Frame0 Cropping Origin Register (F1CROPORIG) and Frame0 Cropping Size Register (F1CROPSIZE).
17 F1DECOMPRESS	Decompress bypass Indicates whether or not decompress is bypassed. For G1, this should always be set to 1. 0b - G2 reference frame is compressed. 1b - G2/G1 reference frame is not compressed.
16 —	Reserved.
15-2 —	Reserved.
1 F1PIXELBITDEPTH	Pixel bit depth Indicates pixel bit depth 0b - 10-bit pixel depth 1b - 8-bit pixel depth
0 F1FRAMECFG	Frame configuration ready Indicates whether or not the frame configuration is ready 0b - Frame 0 configuration is not ready.

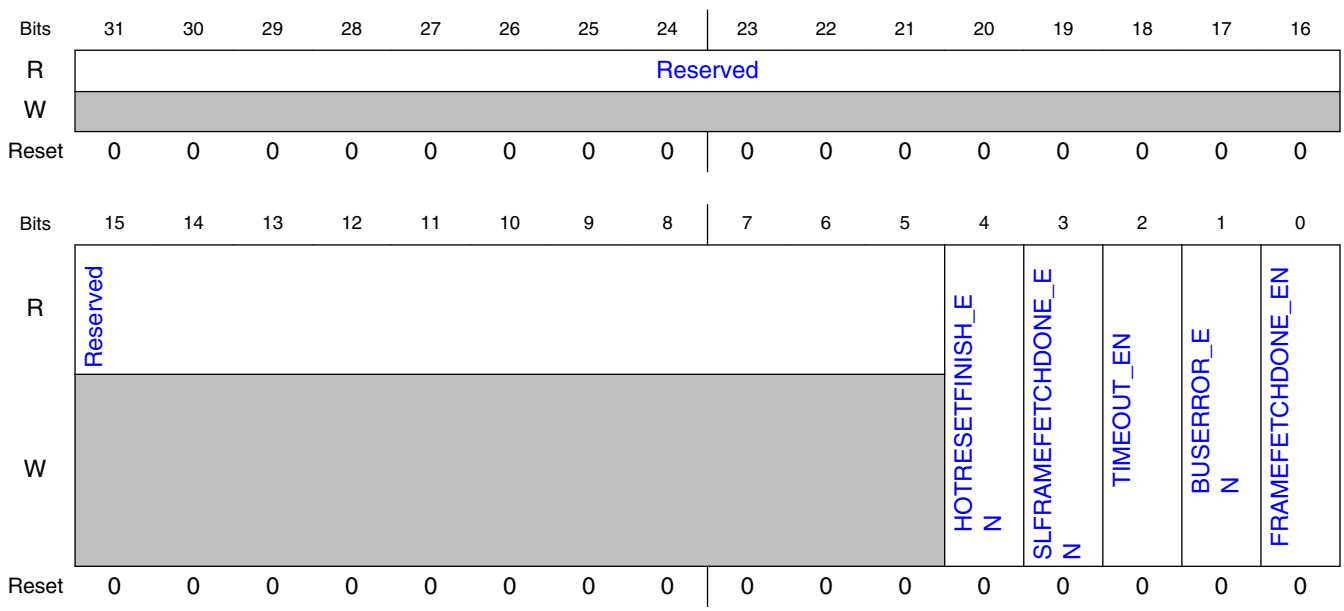
Field	Function
	1b - Frame 0 configuration is ready and decompress can start for the frame. All other configuration, such as main8/main10 are updated before setting this bit to 1. If there is no G1/G2 video transaction, set this bit to 0.

15.6.6.1.26 DTRC Interrupt enables (DTRCINTEN)

15.6.6.1.26.1 Offset

Register	Offset
DTRCINTEN	C0h

15.6.6.1.26.2 Diagram



15.6.6.1.26.3 Fields

Field	Function
31-5 —	Reserved.
4 HOTRESETFINISH_EN	Hot reset finish 0b - Hot reset finish disabled. 1b - Hot reset finish enabled.

Table continues on the next page...

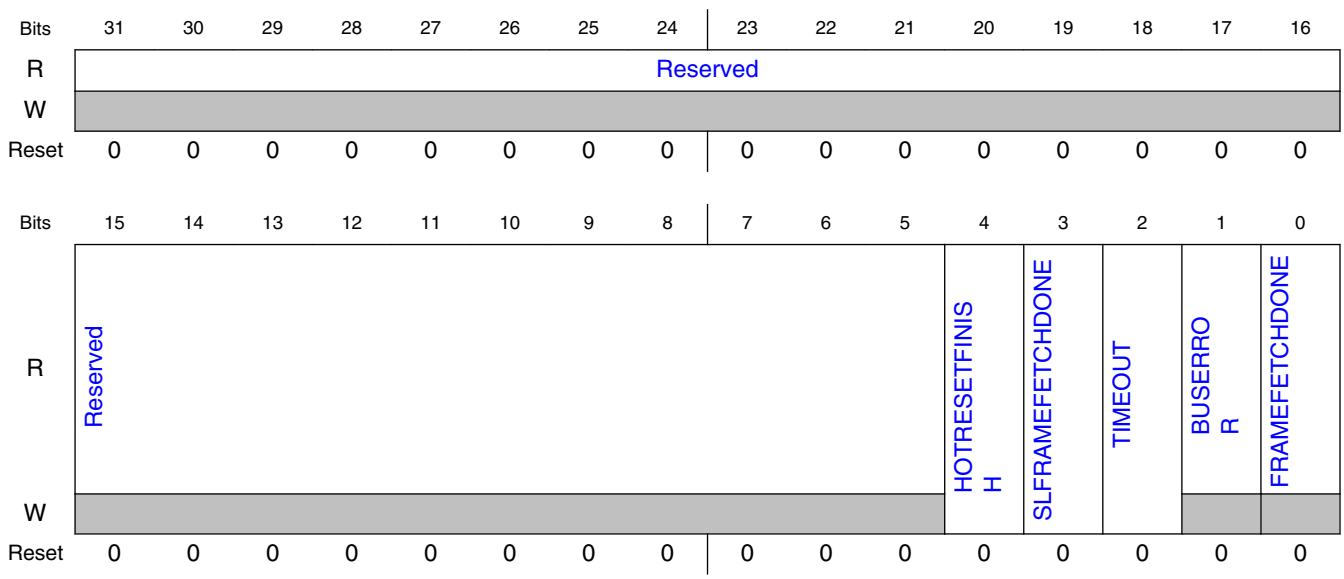
Field	Function
3 SLFRAMEFETCHDONE_EN	Slave frame fetch done 0b - Slave frame fetch done disabled. 1b - Slave frame fetch done enabled.
2 TIMEOUT_EN	Time out enable 0b - Time out disabled. 1b - Time out enabled.
1 BUSERROR_EN	Bus error interrupt enable 0b - Bus error interrupt disabled. 1b - Bus error interrupt enabled.
0 FRAMEFETCHDONE_EN	Frame fetch done interrupt enable 0b - Frame fetch done interrupt disabled. 1b - Frame fetch done interrupt enabled.

15.6.6.1.27 DTRC Interrupt Requests (FDINTR)

15.6.6.1.27.1 Offset

Register	Offset
FDINTR	C4h

15.6.6.1.27.2 Diagram



15.6.6.1.27.3 Fields

Field	Function
31-5 —	Reserved.
4 HOTRESETFINISH	Hot reset finish interrupt Write 1 clear.
3 SLFRAMEFETCHDONE	Slave frame fetch done interrupt Set by hardware when the down-stream IP finishes fetching the data of one frame from DTRC. Software usually ignore this interrupt. Write 1 clear.
2 TIMEOUT	Time out interrupt Set by hardware if the value of PFCR is larger than TOCR. It is cleared after software writes 1'b1.
1 BUSERROR	Bus error interrupt Set by hardware, and cleared after software writes 1'b1
0 FRAMEFETCHDONE	Frame fetch done interrupt Set by hardware and cleared after software writes 1'b1. Software watches this interrupt to configure frame parameters to DTRC.

15.6.6.1.28 DTRC Control (DTCTRL)

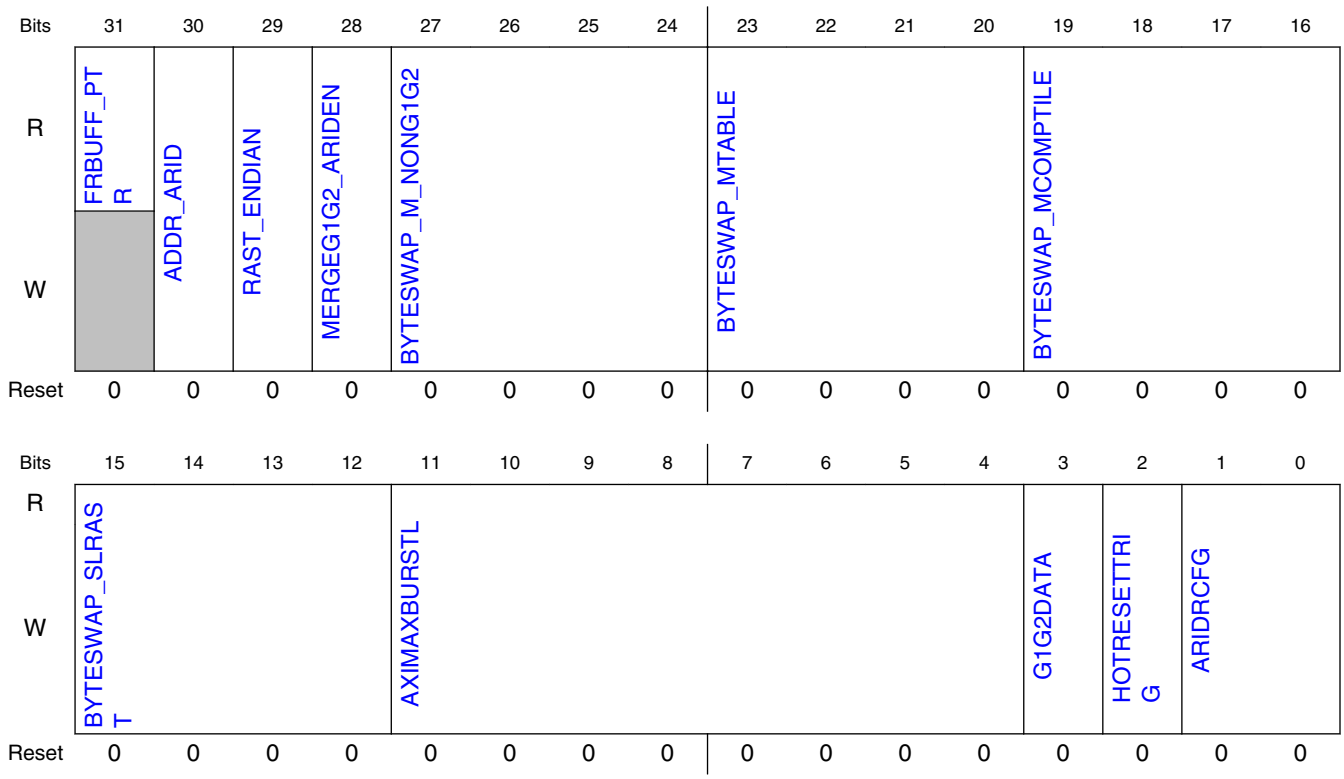
15.6.6.1.28.1 Offset

Register	Offset
DTCTRL	C8h

15.6.6.1.28.2 Function

This register specifies some global control information.

15.6.6.1.28.3 Diagram



15.6.6.1.28.4 Fields

Field	Function
31 FRBUFF_PTR	FRBUFF_PTR Frame buffer configure pointer, to indicate current pointer (Frme0 or Frame1) need to configure. 0b - Configure frame 0 registers. 1b - Configure frame 1 registers.
30 ADDR_ARID	ADDR_ARID Bypass tile-to-rasterscan by Address or AXI ID 0b - By ARID (See bit[1:0] of this register). 1b - By ARADDR
29 RAST_ENDIAN	Raster endian mode This bit indicates the endian mode of DTRC 10-bit raster scan output data. 0b - 10-bit output format is little-endian. Byte swap setting of DTCTRL[15:12] is used. 1b - 10-bit output format is big-endian. Byte swap setting of DTCTRL[15:12] is ignored.
28 MERGEG1G2_ARIDEN	Merge G2/G1 ARID enable 0b - G2/G1 transactions at AXI master interface use different id for table/chroma and data/luma according to DTID2DDR definition. 1b - All G2/G1 transactions at AXI master interface use the same id configured in DTID2DDR[15:8] Please note that DTID2DDR[15:8] and DTID2DDR[7:0] still need to be set the same way as when DTCTRL[28] is 0.
27-24	Byte swap mode for master interface non-G1/G2 data

Table continues on the next page...

Field	Function
BYTESWAP_M_NONG1G2	• bit 4: 8 bit swap • bit 5: 16 bit swap • bit 6: 32 bit swap • bit 7: 64 bit swap • 4'b0000: 0-1-2-3-4-5-6-7-8-9-10-11-12-13-14-15 (the original bit sequence) • 4'b0001: 1-0-3-2-5-4-7-6… • 4'b0010: 2-3-0-1-6-7-4-5… • 4'b0011:3-2-1-0-7-6-5-4… • 4'b0100: 4-5-6-7-0-1-2-3… • ... • 4'b0111: 7-6-5-4-3-2-1-0… • 4'b1000: 8-9-10-11-12-13-14-15-0-1-2-3-4-5-6-7… • ... • 4'b1111: 15-14-13-12-11-10-9-8-7-6-5-4-3-2-1-0

15-12 BYTESWAP_SLRAST	Byte swap mode for slave interface raster scan data • bit 4: 8 bit swap • bit 5: 16 bit swap • bit 6: 32 bit swap • bit 7: 64 bit swap • 4'b0000: 0-1-2-3-4-5-6-7-8-9-10-11-12-13-14-15 (the original bit sequence) • 4'b0001: 1-0-3-2-5-4-7-6…

Table continues on the next page...

Field	Function
	• 4'b0010: 2-3-0-1-6-7-4-5… • 4'b0011:3-2-1-0-7-6-5-4… • 4'b0100: 4-5-6-7-0-1-2-3… • ... • 4'b0111: 7-6-5-4-3-2-1-0… • 4'b1000: 8-9-10-11-12-13-14-15-0-1-2-3-4-5-6-7… • ... • 4'b1111: 15-14-13-12-11-10-9-8-7-6-5-4-3-2-1-0
11-4 AXIMAXBURSTL	Maximum burst length of AXI master port If maximum burst length feature is supported (see DTRCCONFIG[0]), DTRC sends the G1/G2 relating requests with ARLEN less than or equal to (the maximum burst length - 1).
3 G1G2DATA	G2 or G1 source data When this bit is set, F0DCTL[17] and F1DCTL[17] must be 1'b1. DTRC converts G1 tile data to raster scan data. 0b - The source data is G2 data. 1b - The source data is G1 tile data
2 HOTRESETTRIG	Hot reset trigger Software writes 1 to initiate a hot reset of video decompression and detile path. Hardware clears the bit to 0 after the reset finished.
1-0 ARIDRCFG	ARIDR configuration Specify ARIDR mode. 00b - All ARID is de-tiled. 01b - ARID in ARIDR is de-tiled, and others are bypass. NOTE: ARID[0] specify decode luma or chroma, so 4 ARIDs in ARIDR should include both of ARID[0] ==1 and ARID[0] ==0. 10b - ARID in ARIDR is bypass_de-tile, and others are de-tiled. 11b - Same as 2'b01.

15.6.6.1.29 ARIDR (ARIDR)

15.6.6.1.29.1 Offset

Register	Offset
ARIDR	CCh

15.6.6.1.29.2 Function

This register specifies ARID to use to fetch de-tile data or bypass de-tile data.

15.6.6.1.29.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ARID_TABLE								ARID_COMPR							
Reset	0	0	0	0	1	1	1	1	0	0	0	0	1	1	1	0

15.6.6.1.30.4 Fields

Field	Function
31-16 —	Reserved.
15-8 ARID_TABLE	ARID_TABLE If G2 frame is compressed, this is ARID of table fetching, from DTRC to external memory. If G2 frame is not compressed or G1 tile is the case, this is ARID of chroma data The value should be different from non-G2/G1 transaction ARID received from DTRC AXI slave port, and different from bits 7:0 of this register.
7-0 ARID_COMPR	ARID_COMPR If G2 frame is compressed, this is ARID of compressed data fetching, from DTRC to external memory. If G2 frame is not compressed or G1 tile is the case, this is ARID of luma data. The value should be different from non-G2/G1 transaction ARID received from DTRC AXI slave port, and different from bits 15:8 of this register.

15.6.6.1.31 DTRCCONFIG (DTRCCONFIG)

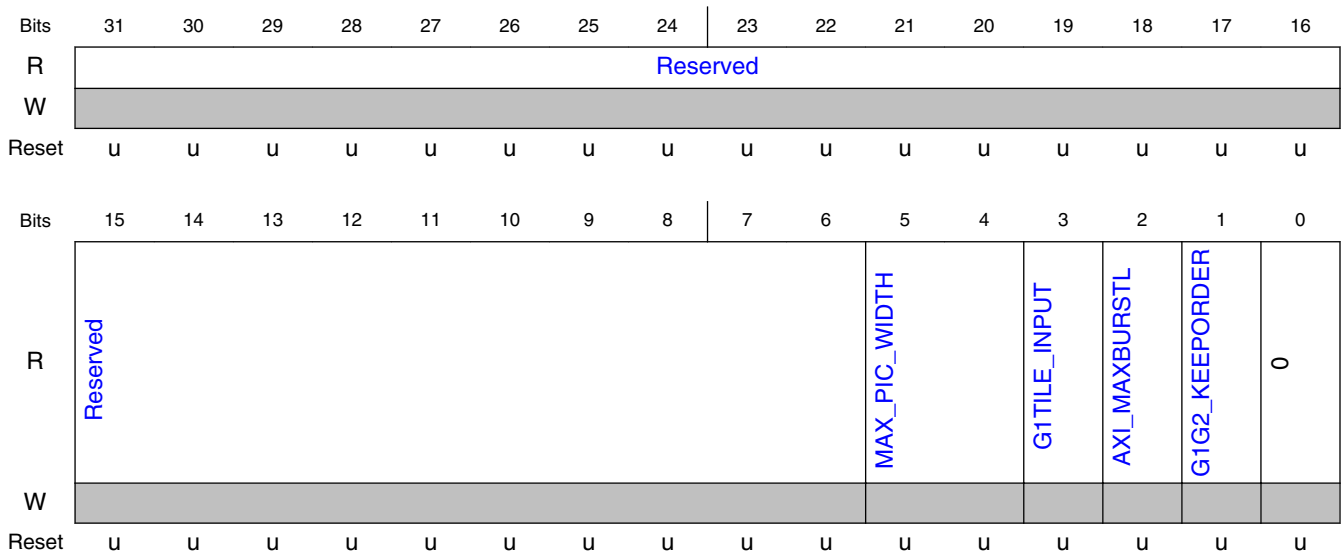
15.6.6.1.31.1 Offset

Register	Offset
DTRCCONFIG	D4h

15.6.6.1.31.2 Function

This register specifies ARID to use to fetch video data from DTRC to external memory.

15.6.6.1.31.3 Diagram



15.6.6.1.31.4 Fields

Field	Function
31-6 —	Reserved.
5-4 MAX_PIC_WIDTH	MAX_PIC_WIDTH Maximum supported picture width 00b - 4096 01b - 1920 10b - Reserved. 11b - Reserved.
3 G1TILE_INPUT	G1TILE_INPUT G1 tile input 0b - Not supported. 1b - Supported.
2 AXI_MAXBURSTL	AXI_MAXBURSTL Maximum burst length of AXI master port. 0b - Not supported. 1b - Supported. DTRC sends the G1/G2 relating requests with ARLEN <= (the maximum burst length - 1). The maximum burst length is set by DTCTRL[16:8].
1 G1G2_KEEPORDER	G1G2_KEEPORDER Keep the order between g1/g2 transactions and non-g1/g2 transactions at AXI slave interface. 0b - Not supported. DTRC sends out data transactions as soon as they are ready regardless of the address transactions order, The master connected to AXI slave interface must recognize the data transactions by the RID. 1b - Supported, DTRC ensure return read data from a sequence of read transactions in the same order in which it received the address.
0 —	Reserved.

15.6.6.1.32 DTRC Version (DTRCVERSION)

15.6.6.1.32.1 Offset

Register	Offset
DTRCVERSION	D8h

15.6.6.1.32.2 Function

This is a constant read-only register that contains encoded information about the hardware version.

15.6.6.1.32.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15.6.6.1.32.4 Fields

Field	Function
31-16 —	Reserved.
15-10 MAJOR	MAJOR Major version. • 0x00: Version before 0831, including 0831. Support G2 tile + G2 compressed + raster scan output • 0x01: Support G1 tile + G2 tile + G2 compressed + raster scan output. • All other values: Reserved.
9-4 MINOR	MINOR Minor version. Simply an update count (update at a release time) of a certain Major version. Count from 0.
3-0 CUST_VERSION	CUST_VERSION Customer Version.

15.6.6.1.33 Performance counter control (PFCTRL)

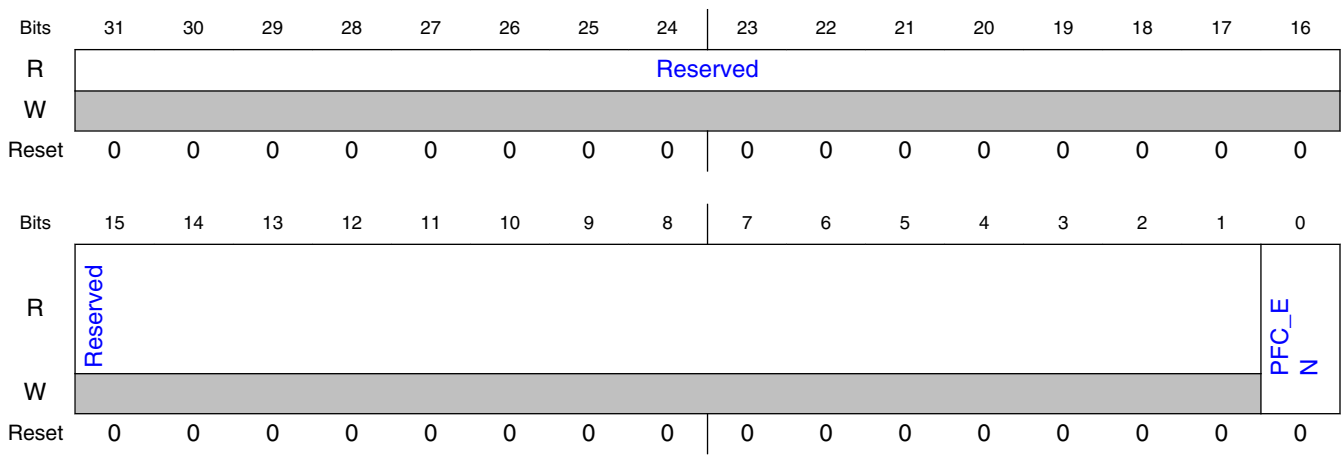
15.6.6.1.33.1 Offset

Register	Offset
PFCTRL	F0h

15.6.6.1.33.2 Function

This register enables or disables performance counter.

15.6.6.1.33.3 Diagram



15.6.6.1.33.4 Fields

Field	Function
31-1 —	Reserved.
0 PFC_EN	PFC_EN Performance Counter Enable. 0b - Performance Counter disabled. 1b - Performance Counter enabled.

15.6.6.1.34 Performance counter (PFCR)

15.6.6.1.34.1 Offset

Register	Offset
PFCR	F4h

15.6.6.1.34.2 Function

This is performance counter to count total clock cycle from DTRC begins to send out a frame and finishes sending out the frame.

This counter belongs to decompression clock domain, not APB clock domain. The software can read this counter after received slave frame fetch done interrupt.

15.6.6.1.34.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15.7 Display, Prefetch and Resolve (DPR)

15.7.1 Overview

Display prefetch resolve, or DPR, is the process of fetching display data before the display pipeline needs the data to drive pixels in the active display region. This data is transformed, or resolved, from a variety of tiled buffer formats into linear format.

In a system with many bus masters, arbitration and transaction reordering, significant delays in the response time of returned read data can occurr. Therefore, the prefetch process is required to issue transaction sequences which are processed with a high level of DRAM efficiency.

The resolve process is required to transform tile formatted frame buffers into linear buffers. Displays process data in linear scan line order. In the resolve process, local memory is used to store a small number of scan lines which the local display controller will source to refresh the panel. The DPR works with a double/triple bank memory structure. This memory structure is implemented in the RTRAM_CTRL and the banks are referred to as A, B, and optionally C. The DPR is configurable to work with either two or three banks, and each bank is either 4 or 8 lines high depending on the source frame buffer format. Zenverge VPU 2-Plane 420 source buffers use RTRAM banks that are 8 lines high. All other GPU, VP9 and VPU 1-Plane buffers use RTRAM banks that are 4 lines high.

15.7.1.1 Block Diagram

The following diagram gives a high-level overview of the configuration of the DPR.

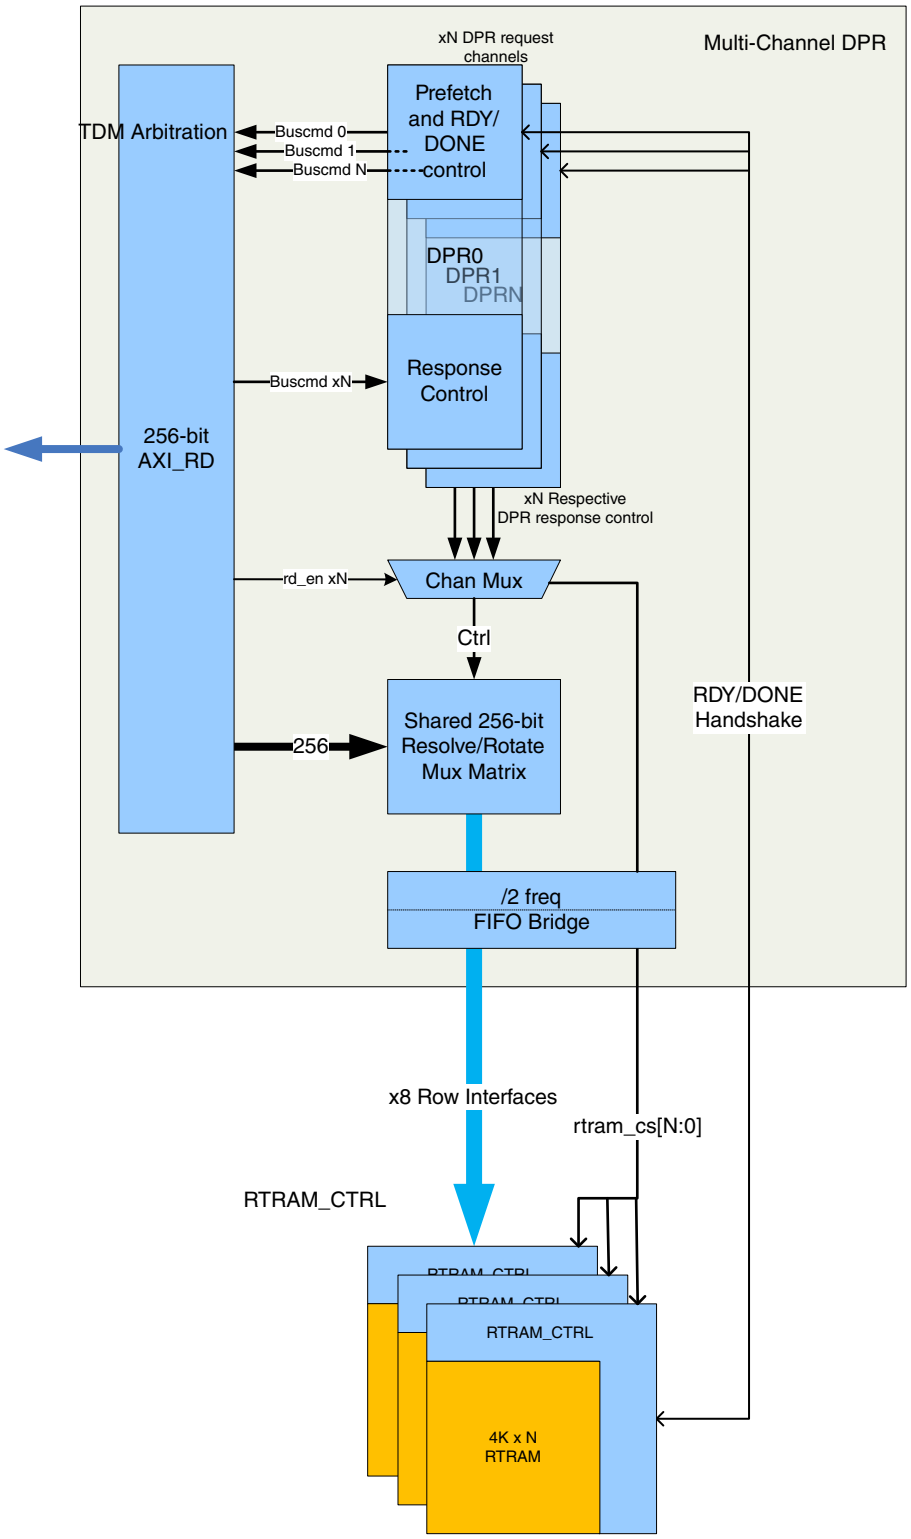

Figure 15-19. DPR block diagram

15.7.1.2 Features

The DPR module is capable of supporting the following features:

- Double/Triple (A,B and opt C) RTRAM buffers.
- Resolves and rotates at the bus width, 256-bit, without stalling the input bus.
- 32bpp ARGB pixel swapping
- 1-Plane YUV422 YUV pixel swapping
- 2-Plane 8bpp YUV420 UV pixel swapping
- RTRAM panic and stall underrun detection.

The supported prefetch and resolve modes are listed in the table below:

Mode	Linear or Tile	HFLIP	VFLIP	Rotation (0, 90, 180 or 270)	Lines per RTRAM Bank
GPU 32bpp xRGB	Linear	Yes	Yes	0 and 180 only	4
GPU 32bpp xRGB	X-Major Supertile and Standard tile	Yes	Yes	0, 90, 180 or 270	4
GPU 16bpp xRGB, 1-Plane YUV422	Linear	Yes	Yes	0 and 180 only	4
GPU 16bpp xRGB, 1-Plane YUV422	X-Major Supertile and Standard tile	Yes	Yes	0 and 180 only	4
VPU 8bpp 2-Plane YUV420	Linear	Yes	Yes	0 and 180 only	8
VPU 8bpp 2-Plane YUV420	Zenverge tile	Yes	Yes	0, 90, 180 or 270	8
VPU 10bpp 2-Plane YUV420	Linear	No	Yes	0 only	8
VPU 10bpp 2-Plane YUV420	Zenverge tile	No	Yes	0 only	8
VP9 8bpp 2-Plane YUV420	Linear	Yes	Yes	0 and 180 only	4
VP9 8bpp 2-Plane YUV420	Google tile	Yes	Yes	0 and 180 only	4
VP9 10bpp 2-Plane YUV420	Linear	No	Yes	0 only	4
VP9 10bpp 2-Plane YUV420	Google tile	No	Yes	0 only	4

For detailed GPU and VPU tile specifications, refer to the following application documents:

- Vivante.ArchNote.GPU.TileSpec-v2.0-20141003.pdf
- VPU_memory_tiling_v0.4.09092015.docx
- G-Series_2_v3_HW_Integration_Guide-2015-06-29.pdf

The following features are not supported:

- Progressive to interlaced conversion by dropping lines
- 3-plane YUV source buffers
- 2-plane to 1-plane conversion
- 90/270 rotation for all linear, all 16bpp and 10bpp 2-Plane YUV422 sources
- 10-bit packed input will be maintained as 10-bit packed output. The output will not unpack the compnents to 32/24/16-bit alignment.

15.7.1.3 DPR Signal Descriptions

Signal	Description	I/O
rtr_m_clk	RTMEM memory clock	I
rtr_aresetn	RTMEM async reset	I
dpr_apb_clk	APB Control register clock	I
dpr_b_clkg	APB Control register gated clock	I
dpr_apb_aresetn	APB async reset	I
dpr_b_clk	DPR system clock	I
dpr_b_clkg	DPR system gated clock	I
dpr_chip_resetn	DPR system async reset	I
dpr_b_clkg_en	DPR system gated clock enable	O
dpr_irq[3-1:0]	DPR_IRQ per dpr_ctrl block	O
tg2dpr_start_en[3-1:0]	Logic high enable from timing generator (during VSYNC), to restart DPR with current CSR settings	I
tg2dpr_shadow_load_en[3-1:0]	Logic high strobe from timing generator indicating load shadow registers to active registers on next start.	I
dpr_apb_sel[3-1:0]	APB Select	I
dpr_apb_enable	APB Enable	I
dpr_apb_addr[16-1:0]	APB Address	I
dpr_apb_write	APB Write=1, Read=0	I
dpr_apb_wdata[31:0]	APB Write Data	I
dpr_apb_rdata[31:0]	APB Read Data	O
dpr_apb_ready	APB Ready	O
dpr_apb_slverr	APB Slave Error	O
dpr_axi_ar	AXI Read Command Channel Bus	O
dpr_axi_arready	AXI Read Command Channel Ready	I
dpr_axi_r	AXI Read Data Channel Bus	I
dpr_axi_rready	AXI Read Data Channel Ready	O
rtr2dpr_abort_yrgb[(3*3)-1:0]	1=abort YRGB buffer being written to RTMEM bank	I
rtr2dpr_abort_uv[(3*3)-1:0]	1=abort UV buffer being written to RTMEM bank	I

Table continues on the next page...

Signal	Description	I/O
rtr2dpr_buf_done_yrgb[(3*3)-1:0]	YRGB buffer becomes available to prefetch	I
rtr2dpr_buf_done_uv[(3*3)-1:0]	UV buffer becomes available to prefetch	I
dpr2rtr_ch_done_yrgb[3-1:0]	DPR completed prefetch/resolve of the YRGB channel	O
dpr2rtr_ch_done_uv[3-1:0]	DPR completed prefetch/resolve of the UV channel	O
dpr2rtr_buf_rdy_yrgb[(3*3)-1:0]	DPR has completed filling current YRGB row of blocks in the RTRAM buffer	O
dpr2rtr_buf_rdy_uv[(3*3)-1:0]	DPR has completed filling current UV row of blocks in the RTRAM buffer	O
dpr2rtr_cs[3-1:0]	Chip select which RTMEM is being written	O
dpr2rtr_row_data[(64*8)-1:0]	RTMEM row data	O
dpr2rtr_row_uv_sel	2-Plane UV memory select	O
dpr2rtr_bank_addr[1:0]	memory bank address	O
dpr2rtr_row_addr[13:3]	memory row address	O
dpr2rtr_row_sel[2:0]	memory row select	0
dpr2rtr_csr_mode[(3*3)-1:0]	RTRAM Mode Control	O
dpr2rtr_csr_num_rows[3-1:0]	Number of RTRAM lines/buffer: 0=8 lines, 1=4 lines	O
dpr2rtr_csr_num_planes[3-1:0]	0=Enable 1-Plane, 1=Enable 2-Plane	O
dpr2rtr_csr_num_rows_active[3-1:0]	0=Row0-4 enabled. 1=Row0-6, all rows, enabled	O
dpr2rtr_csr_thres_high[(3*3)-1:0]	panic high water mark threshold	O
dpr2rtr_csr_thres_low[(3*3)-1:0]	panic low water mark threshold	O
dpr2rtr_csr_abort_sel[3-1:0]	0=Panic Select. 1=Abort Select	O
dpr2rtr_csr_vflip_en[3-1:0]	1=vflip enable, 0=not vertical flipped	O
ipt_scan_mode	scan mode enable	I
ipt_se_gatedclk	ICG gated clock test enable	I

15.7.2 Functional description

15.7.2.1 Clocking and Resets

15.7.2.1.1 Functional clocks

The DPR b_clk clock, RTRAM rtr_m_clk and APB apb_clk clock domains are all asynchronous. The following clocking restriction exists in the DPR: m_clk >= b_clk/2

15.7.2.1.2 Chip resets

There is a seperate asynchronous chip reset for each clock domain. The DPR implements reset synchronizers for each asynchronous reset, to deassert each reset synchronously.

15.7.2.2 DPR Sub-blocks

15.7.2.2.1 DPR Prefetch Control

This control engine is responsible for prefetching the source frame data. Request sizes are software programmable in a range from 64 bytes to 4k bytes. The prefetch engine is designed so the RTRAM buffer will always fill from left to right, top to bottom across the line regardless of the output image orientation.

15.7.2.2.2 DPR Response Control

The response control block is responsible for managing the DPR datapath resolve mux, horizontal flip, vertical flip and image rotation.

15.7.2.2.3 DPR Datapath

The DPR datapath block is a shared across all DPR channel response blocks because on any given clock cycle, pixels for only 1 DPR response channel will be returned by the system. The datapath implements pixel cross bar logic for tile resolve, horizontal flip, vertical flip and image rotation by 0, 90, 180 or 270 degrees.

15.7.3 Memory Map and Registers

15.7.3.1 register descriptions

15.7.3.1.2 System Control 0 (SYSTEM_CTRL0)

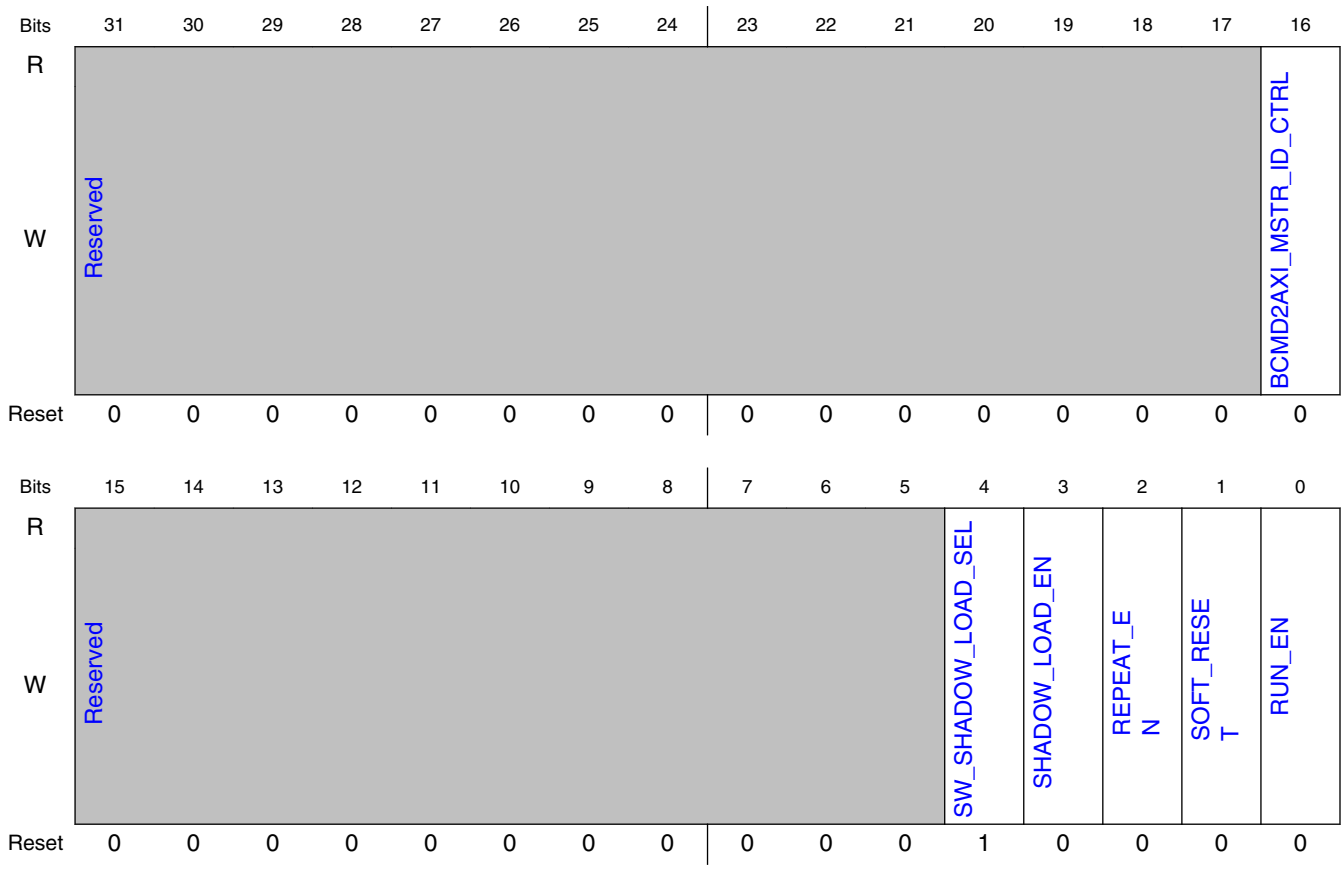
15.7.3.1.2.1 Offset

Register	Offset
SYSTEM_CTRL0	0h

15.7.3.1.2.2 Function

The System Control0 register contains register for DPR block level control functions.

15.7.3.1.2.3 Diagram



15.7.3.1.2.4 Fields

Field	Function
31-17 —	Reserved.
16 BCMD2AXI_MSTR_ID_CTRL	Buscmd To AXI Master ID Control 0x0 = All DPR buscmd master channels assigned a unique AXI ID 0x1 = All DPR buscmd master channels assigned the same AXI ID Note: If the DPR is configured to have > 1 DPR channel, then DPR channel 0, will control the BCMD2AXI_MSTR_ID_CTRL for all DPR Channels. DPR Channel 1-N's BCMD2AXI_MSTR_ID_CTRL will be reserved.
15-5 —	Reserved.
4 SW_SHADOW_LOAD_SEL	Software Shadow Load Select The SW_SHADOW_LOAD_SEL is used to select the shadow_load_en source.

Table continues on the next page...

Field	Function
	If set to 1, SYSTEM_CTRL0: SHADOW_LOAD_EN control register is used to allow update of the shadow control registers to the active control registers. If set to 0, Subystem hardware signal is used to allow update of the shadow control registers to the active control registers. SW_SHADOW_LOAD_SEL should be set to 1, for initial DPR control register load and RUN_EN enablement. SW_SHADOW_LOAD_SEL should only be set to 0, after SYSTEM_CTRL0: REPEAT_EN is enabled.
3 SHADOW_LOAD_EN	Shadow Load Enable The SHADOW_LOAD_EN bit is written to 1 by software after all control registers are written. If set to 1, shadowed control registers are updated to the active control registers on next REPEAT_EN or RUN_EN to start DPR processing of the next frame. If set to 0, shadowed control registers are not loaded into the active control registers. The previous active control register settings will be used to process the next frame. Hardware will automatically clear this bit, when the shadow registers are loaded to the active control regsisters.
2 REPEAT_EN	Repeat Enable Writing a 1 to this register will enable the timing generator to write the RUN_EN register on subsequent restarts using the current control register settings. The REPEAT_EN will not take effect until after the 1st frame has been processed with RUN_EN issued by software. The REPEAT_EN may remain enabled for as many concurrent frames as desired to be automatically restarted. When automatic restart should be disabled, software must clear the REPEAT_EN before the next available hardware restart command.
1 SOFT_RESET	Soft Reset This bit is not self-clearing software will need to write a: 0x0 = deassert soft reset 0x1 = assert soft reset Note: Channel 0 soft reset will reset the SYSTEM_CTRL0:BCMD2AXI_MSTR_ID_CTRL. This should only be done if all DPR Channels are done processing.
0 RUN_EN	Run Enable Writing a 1 to this register will start processing the next frame image. This register is self-clearing.

If set to 1, SYSTEM_CTRL0: SHADOW_LOAD_EN control register is used to allow update of the shadow control registers to the active control registers. If set to 0, Subystem hardware signal is used to allow update of the shadow control registers to the active control registers. SW_SHADOW_LOAD_SEL should be set to 1, for initial DPR control register load and RUN_EN enablement. SW_SHADOW_LOAD_SEL should only be set to 0, after SYSTEM_CTRL0: REPEAT_EN is enabled.
3 SHADOW_LOAD_EN	Shadow Load Enable The SHADOW_LOAD_EN bit is written to 1 by software after all control registers are written. If set to 1, shadowed control registers are updated to the active control registers on next REPEAT_EN or RUN_EN to start DPR processing of the next frame. If set to 0, shadowed control registers are not loaded into the active control registers. The previous active control register settings will be used to process the next frame. Hardware will automatically clear this bit, when the shadow registers are loaded to the active control regsisters.
2 REPEAT_EN	Repeat Enable Writing a 1 to this register will enable the timing generator to write the RUN_EN register on subsequent restarts using the current control register settings. The REPEAT_EN will not take effect until after the 1st frame has been processed with RUN_EN issued by software. The REPEAT_EN may remain enabled for as many concurrent frames as desired to be automatically restarted. When automatic restart should be disabled, software must clear the REPEAT_EN before the next available hardware restart command.
1 SOFT_RESET	Soft Reset This bit is not self-clearing software will need to write a: 0x0 = deassert soft reset 0x1 = assert soft reset Note: Channel 0 soft reset will reset the SYSTEM_CTRL0:BCMD2AXI_MSTR_ID_CTRL. This should only be done if all DPR Channels are done processing.
0 RUN_EN	Run Enable

Field	Function
	Writing a 1 to this register will start processing the next frame image. This register is self-clearing.

15.7.3.1.6 Interrupt Mask (IRQ_MASK)

15.7.3.1.6.1 Offset

Register	Offset
IRQ_MASK	20h

15.7.3.1.6.2 Function

The IRQ_MASK control register contains interrupt mask control register bits.
Writing a 1 to the IRQ_MASK control register will mask off the interrupt.

15.7.3.1.6.3 Diagram

This error indicates the following: • pixel data will be loaded incorrectly into the RTRAM • The error is (most likely) due to incorrect programming of the NUM_X_PIX_WIDE value not being evenly divisible by 64-bytes.
5 DPR2RTR_UV_FIFO_OVFL	DPR to RTRAM UV Fifo Overflow Non-Masked IRQ Non-masked interrupt status of the DPR2RTR_UV Fifo Overflow interrupt. When this IRQ is set, the DPR2RTR Fifo Overflowed writing 2PYUV420 UV data.
4 DPR2RTR_YRGB_FIFO_OVFL	DPR to RTRAM YRGB Fifo Overflow Non-Masked IRQ Non-masked interrupt status of the DPR2RTR_YRGB Fifo Overflow interrupt. When this is set, the DPR2RTR Fifo Overflowed writing YRGB data.
3 IRQ_AXI_READ_ERROR	AXI Read Error Non-Masked IRQ Non-masked interrupt status of the AXI Read Error interrupt. When this IRQ is set, the AXI Read Master received a bus transaction error code.
2 IRQ_DPR_SHADOW_LOADED_NMSTAT	DPR Shadow Loaded Non-Masked IRQ Non-masked interrupt status of the DPR_SHADOW_LOADED interrupt. When this IRQ IS set, the dpr_ctrl shadow control registers have been loaded into the active control registers.
1 IRQ_DPR_RUN	DPR Run Non-Masked IRQ Non-masked interrupt status of the DPR_RUN interrupt. When this IRQ IS set, the dpr_ctrl RUN_EN has been asserted in the control registrer clock domain. All control registers are considered active at this time.
0 IRQ_DPR_CTRL_DONE	DPR Control Done Non-Masked IRQ Non-masked interrupt status of the DPR_CTRL_DONE interrupt. When this IRQ is set, the dpr_ctrl_prefetch and dpr_ctrl_response blocks are done processing the current frame.

15.7.3.1.30.4 Fields

Field	Function
31-16 CROP_ULC_X	Starting Coordinate of Cropped Image X (1-Plane or 2-Plane Luma) Due to the tile geometry in VPU and Super-Tile formats, a simple address offset cannot be used to crop an image (in all cases). In these modes, the CROP_ULC_X and CROP_ULC_Y coordinate pair will be used to specify an offset to begin fetching pixels within an image. In addition, the NUM_X_PIX_WIDE and NUM_Y_PIX_HIGH will indicate when to stop fetching pixels. Note, these coordinate pairs (CROP_ULC_X,CROP_ULC_Y) and (NUM_X_PIX_WIDE,NUM_Y_PIX_HIGH) must be aligned to block boundaries for proper functionality. The following table illustrates coordinate restrictions for the tile types of interest (Note, the same restrictions apply to (NUM_X_PIX_WIDE,NUM_Y_PIX_HIGH)): |---|---|---| | Tile Type |X Alignment |Y Alignment | |---|---|---| | GPU 32bpp (X-Major Super-tile) |CROP_ULC_X[1:0] = 0 |CROP_ULC_Y[1:0] = 0 | | GPU 16bpp xRGB,1-Plane YUV422 |CROP_ULC_X[2:0] = 0 |CROP_ULC_Y[2:0] = 0 | | VPU 8bpp 2-Plane YUV420 |CROP_ULC_X[3:0] = 0 |CROP_ULC_Y[3:0] = 0 | | VP9 8bpp 2-Plane YUV420 |CROP_ULC_X[3:0] = 0 |CROP_ULC_Y[3:0] = 0 | | VP9 10bpp 2-Plane YUV420 |CROP_ULC_X[2:0] = 0 |CROP_ULC_Y[2:0] = 0 |

Table continues on the next page...

Field	Function
	|------------------------------|--------------------|--------------------|

15-0
NUM_X_PIX_WIDE
	Number of Pixels Wide in X-direction
	
	The number of input frame pixels to fetch in the x-axis direction.
	In non-linear (raster) tile mode, the starting pixel must be at the start of a tile boundary. Partial tile fetch is not allowed.
	
	The NUM_X_PIX_WIDE must be sized so the prefetch is evenly divisible by 64 bytes. If the NUM_X_PIX_WIDE is not evenly divisible by 64 bytes, then an offset must be applied.
	To calculate if NUM_X_PIX_WIDE is divisible by 64 bytes:
	
	First determine the number of pix_x pixels divisible in 64 bytes, based on MODE_CTRL0: PIX_SIZE and TILE_TYPE settings:
	num_pix_x_in_64byte = (((PIX_SIZE==2) && (TILE_TYPE==0)) ? 16 : // GPU 32bpp linear tile must be divisible by 16 pixels in x-direction
	((PIX_SIZE==2) && ((TILE_TYPE==1) || (TILE_TYPE==2))) ? 4 : // GPU 32bpp standard and/or super tile must be divisible by 4 pixels in x-direction
	((PIX_SIZE==1) && (TILE_TYPE==0)) ? 32 : // GPU 16bpp linear tile must be divisible by 32 pixels in x-direction. VPU 10bpp VP9-10 UV linear tile must be divisible by 32 pixels in x-direction
	((PIX_SIZE==1) && ((TILE_TYPE==1) || (TILE_TYPE==2) || (TILE_TYPE==4))) ? 8 : // GPU 16bpp standard and/or super tile must be divisible by 8 pixels in x-direction. VPU 10bpp VP9-10 UV tile must be divisible by 8 pixels in x-direction
	((PIX_SIZE==0) && (TILE_TYPE==0)) ? 64 : // VPU 8bpp VP9 UV linear tile must be divisible by 64 pixels in x-direction
	((PIX_SIZE==0) && (TILE_TYPE==4)) ? 16 : // VPU 8bpp VP9 UV tile must be divisible by 16 pixels in x-direction
	((PIX_SIZE==0) && (TILE_TYPE==3)) ? 8 : // VPU 8bpp Luma zenverge tile must be divisible by 8 pixels in x-direction
	
	8); // default case shouldn't be hit
	
	Second calculate the modulus of the NUM_X_PIX_WIDE by dpr_num_pix_x_in_64byte
	Note: for 10bpp source frame, NUM_X_PIX_WIDE must first be multiplied by 1.25 to account for MODE_CTRL0: PIX_SIZE=8bpp operation.
	pix_x_div_64byte_mod = NUM_X_PIX_WIDE % num_pix_x_in_64byte
	
	Third calculate the number of offset pixels
	pix_x_offset = (pix_x_div_64byte_mod == 0) ? 0 : (num_pix_x_in_64byte - pix_x_div_64byte_mod)
	
	Fourth add pix_x_offset to NUM_X_PIX_WIDE. This is the value written to the NUM_X_PIX_WIDE control registers.
	NUM_X_PIX_WIDE = NUM_X_PIX_WIDE + pix_x_offset
	
	Note1: If FRAME_1P_CTRL0:MAX_BYTES_PREQ > 64 bytes AND FRAME_CTRL0:HFLIP_EN=1, then the prefetch calculation above must be evenly divisible by 128 bytes instead of 64 bytes.

15.7.3.1.31 Frame 1-Plane Pix X Control (FRAME_1P_PIX_X_CTRL_SET)

15-0
NUM_X_PIX_WIDE
	Number of Pixels Wide in X-direction
	
	The number of input frame pixels to fetch in the x-axis direction.
	In non-linear (raster) tile mode, the starting pixel must be at the start of a tile boundary. Partial tile fetch is not allowed.
	
	The NUM_X_PIX_WIDE must be sized so the prefetch is evenly divisible by 64 bytes. If the NUM_X_PIX_WIDE is not evenly divisible by 64 bytes, then an offset must be applied.
	To calculate if NUM_X_PIX_WIDE is divisible by 64 bytes:
	
	First determine the number of pix_x pixels divisible in 64 bytes, based on MODE_CTRL0: PIX_SIZE and TILE_TYPE settings:
	num_pix_x_in_64byte = (((PIX_SIZE==2) && (TILE_TYPE==0)) ? 16 : // GPU 32bpp linear tile must be divisible by 16 pixels in x-direction
	((PIX_SIZE==2) && ((TILE_TYPE==1) || (TILE_TYPE==2))) ? 4 : // GPU 32bpp standard and/or super tile must be divisible by 4 pixels in x-direction
	((PIX_SIZE==1) && (TILE_TYPE==0)) ? 32 : // GPU 16bpp linear tile must be divisible by 32 pixels in x-direction. VPU 10bpp VP9-10 UV linear tile must be divisible by 32 pixels in x-direction
	((PIX_SIZE==1) && ((TILE_TYPE==1) || (TILE_TYPE==2) || (TILE_TYPE==4))) ? 8 : // GPU 16bpp standard and/or super tile must be divisible by 8 pixels in x-direction. VPU 10bpp VP9-10 UV tile must be divisible by 8 pixels in x-direction
	((PIX_SIZE==0) && (TILE_TYPE==0)) ? 64 : // VPU 8bpp VP9 UV linear tile must be divisible by 64 pixels in x-direction
	((PIX_SIZE==0) && (TILE_TYPE==4)) ? 16 : // VPU 8bpp VP9 UV tile must be divisible by 16 pixels in x-direction
	((PIX_SIZE==0) && (TILE_TYPE==3)) ? 8 : // VPU 8bpp Luma zenverge tile must be divisible by 8 pixels in x-direction
	
	8); // default case shouldn't be hit
	
	Second calculate the modulus of the NUM_X_PIX_WIDE by dpr_num_pix_x_in_64byte
	Note: for 10bpp source frame, NUM_X_PIX_WIDE must first be multiplied by 1.25 to account for MODE_CTRL0: PIX_SIZE=8bpp operation.
	pix_x_div_64byte_mod = NUM_X_PIX_WIDE % num_pix_x_in_64byte
	
	Third calculate the number of offset pixels
	pix_x_offset = (pix_x_div_64byte_mod == 0) ? 0 : (num_pix_x_in_64byte - pix_x_div_64byte_mod)
	
	Fourth add pix_x_offset to NUM_X_PIX_WIDE. This is the value written to the NUM_X_PIX_WIDE control registers.
	NUM_X_PIX_WIDE = NUM_X_PIX_WIDE + pix_x_offset
	
	Note1: If FRAME_1P_CTRL0:MAX_BYTES_PREQ > 64 bytes AND FRAME_CTRL0:HFLIP_EN=1, then the prefetch calculation above must be evenly divisible by 128 bytes instead of 64 bytes.

	The number of input frame pixels to fetch in the x-axis direction.
	In non-linear (raster) tile mode, the starting pixel must be at the start of a tile boundary. Partial tile fetch is not allowed.
	
	The NUM_X_PIX_WIDE must be sized so the prefetch is evenly divisible by 64 bytes. If the NUM_X_PIX_WIDE is not evenly divisible by 64 bytes, then an offset must be applied.
	To calculate if NUM_X_PIX_WIDE is divisible by 64 bytes:
	
	First determine the number of pix_x pixels divisible in 64 bytes, based on MODE_CTRL0: PIX_SIZE and TILE_TYPE settings:
	num_pix_x_in_64byte = (((PIX_SIZE==2) && (TILE_TYPE==0)) ? 16 : // GPU 32bpp linear tile must be divisible by 16 pixels in x-direction
	((PIX_SIZE==2) && ((TILE_TYPE==1) || (TILE_TYPE==2))) ? 4 : // GPU 32bpp standard and/or super tile must be divisible by 4 pixels in x-direction
	((PIX_SIZE==1) && (TILE_TYPE==0)) ? 32 : // GPU 16bpp linear tile must be divisible by 32 pixels in x-direction. VPU 10bpp VP9-10 UV linear tile must be divisible by 32 pixels in x-direction
	((PIX_SIZE==1) && ((TILE_TYPE==1) || (TILE_TYPE==2) || (TILE_TYPE==4))) ? 8 : // GPU 16bpp standard and/or super tile must be divisible by 8 pixels in x-direction. VPU 10bpp VP9-10 UV tile must be divisible by 8 pixels in x-direction
	((PIX_SIZE==0) && (TILE_TYPE==0)) ? 64 : // VPU 8bpp VP9 UV linear tile must be divisible by 64 pixels in x-direction
	((PIX_SIZE==0) && (TILE_TYPE==4)) ? 16 : // VPU 8bpp VP9 UV tile must be divisible by 16 pixels in x-direction
	((PIX_SIZE==0) && (TILE_TYPE==3)) ? 8 : // VPU 8bpp Luma zenverge tile must be divisible by 8 pixels in x-direction
	
	8); // default case shouldn't be hit
	
	Second calculate the modulus of the NUM_X_PIX_WIDE by dpr_num_pix_x_in_64byte
	Note: for 10bpp source frame, NUM_X_PIX_WIDE must first be multiplied by 1.25 to account for MODE_CTRL0: PIX_SIZE=8bpp operation.
	pix_x_div_64byte_mod = NUM_X_PIX_WIDE % num_pix_x_in_64byte
	
	Third calculate the number of offset pixels
	pix_x_offset = (pix_x_div_64byte_mod == 0) ? 0 : (num_pix_x_in_64byte - pix_x_div_64byte_mod)
	
	Fourth add pix_x_offset to NUM_X_PIX_WIDE. This is the value written to the NUM_X_PIX_WIDE control registers.
	NUM_X_PIX_WIDE = NUM_X_PIX_WIDE + pix_x_offset
	
	Note1: If FRAME_1P_CTRL0:MAX_BYTES_PREQ > 64 bytes AND

Field	Function
	FRAME_CTRL0:HFLIP_EN=1, then the prefetch calculation above must be evenly divisible by 128 bytes instead of 64 bytes.

15.7.3.1.38.4 Fields

Field	Function
31-0 BASE_ADDR	Base Address The base address for 1-Plane and 2-Plane Luma. The base address is a source frame buffer offset to the non-rotated, non-hflip, non-vflip output image. This will correspond to the output image's pix_x=0, pix_y=0 position. If any non-linear GPU tile or VPU tile is being processed, then the base

Field	Function

	address must start at pixel 0 of the tile boundary.
	
	Under certain conditions, a offset must be applied to the BASE_ADDR pix_x=0, pix_y=0 position.
	
	1. The DPR will perform an internal hflip AND the pix_x_offset calculation doesn't equal 0 as described in FRAME_1P_PIX_X_CTRL: NUM_X_PIX_WIDE.
	2. The DPR will perform an internal vflip AND the pix_y_offset calculation doesn't equal 0 as described in FRAME_1P_PIX_Y_CTRL: NUM_Y_PIX_HIGH.
	
	Steps to apply an offset to the BASE_ADDR:
	
	First determine if the DPR will perform an internal hflip or vflip base on FRAME_CTRL0: ROT_FLIP_ORDER_EN, ROT_ENC, VFLIP_EN and HFLIP_EN.
	int_hflip = (((ROT_ENC==0) && ((~VFLIP_EN && HFLIP_EN) || (VFLIP_EN && HFLIP_EN))) || // rot_enc = 0 deg cases.
	((ROT_ENC==2) && ((VFLIP_EN && ~HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN))) || // rot_enc = 180 deg cases.
	((ROT_ENC==1) && ((~VFLIP_EN && HFLIP_EN) || (VFLIP_EN && HFLIP_EN)) && (ROT_FLIP_ORDER_EN==0)) || // rot_enc = 90 deg cases if rotation before v/hflip_en
	((ROT_ENC==1) && ((VFLIP_EN && ~HFLIP_EN) || (VFLIP_EN && HFLIP_EN)) && (ROT_FLIP_ORDER_EN==1)) || // rot_enc = 90 deg cases if rotation after v/hflip_en
	((ROT_ENC==3) && ((VFLIP_EN && ~HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN)) && (ROT_FLIP_ORDER_EN==0)) || // rot_enc = 270 deg cases if rotation before v/hflip_en
	((ROT_ENC==3) && ((~VFLIP_EN && HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN)) && (ROT_FLIP_ORDER_EN==1))); // rot_enc = 270 deg cases if rotation after v/hflip_en
	
	int_vflip = (((ROT_ENC==0) && ((VFLIP_EN && ~HFLIP_EN) || (VFLIP_EN && HFLIP_EN))) || // rot_enc = 0 deg cases.
	((ROT_ENC==2) && ((~VFLIP_EN && HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN))) || // rot_enc = 180 deg cases.
	((ROT_ENC==1) && ((VFLIP_EN && ~HFLIP_EN) || (VFLIP_EN && HFLIP_EN)) && (ROT_FLIP_ORDER_EN==0)) || // rot_enc = 90 deg cases if rotation before v/hflip_en
	((ROT_ENC==1) && ((~VFLIP_EN && HFLIP_EN) || (VFLIP_EN && HFLIP_EN)) && (ROT_FLIP_ORDER_EN==1)) || // rot_enc = 90 deg cases if rotation after v/hflip_en

15.7.3.1.39.4 Fields

Field	Function
31-0 BASE_ADDR	Base Address The base address for 1-Plane and 2-Plane Luma. The base address is a source frame buffer offset to the non-rotated, non-hflip, non-vflip output image. This will correspond to the output image's pix_x=0, pix_y=0 position. If any non-linear GPU tile or VPU tile is being processed, then the base address must start at pixel 0 of the tile boundary. Under certain conditions, a offset must be applied to the BASE_ADDR pix_x=0, pix_y=0 position. 1. The DPR will perform an internal hflip AND the pix_x_offset calculation doesn't equal 0 as described in FRAME_1P_PIX_X_CTRL: NUM_X_PIX_WIDE.

Field	Function

	2. The DPR will perform an internal vflip AND the pix_y_offset calculation doesn't equal 0 as described in FRAME_1P_PIX_Y_CTRL: NUM_Y_PIX_HIGH.
	
	Steps to apply an offset to the BASE_ADDR:
	
	First determine if the DPR will perform an internal hflip or vflip base on FRAME_CTRL0: ROT_FLIP_ORDER_EN, ROT_ENC, VFLIP_EN and HFLIP_EN.
	int_hflip = (((ROT_ENC==0) && ((~VFLIP_EN && HFLIP_EN) || (VFLIP_EN && HFLIP_EN))) || // rot_enc = 0 deg cases.
	((ROT_ENC==2) && ((VFLIP_EN && ~HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN))) || // rot_enc = 180 deg cases.
	((ROT_ENC==1) && ((~VFLIP_EN && HFLIP_EN) || (VFLIP_EN && HFLIP_EN)) && (ROT_FLIP_ORDER_EN==0)) || // rot_enc = 90 deg cases if rotation before v/hflip_en
	((ROT_ENC==1) && ((VFLIP_EN && ~HFLIP_EN) || (VFLIP_EN && HFLIP_EN)) && (ROT_FLIP_ORDER_EN==1)) || // rot_enc = 90 deg cases if rotation after v/hflip_en
	((ROT_ENC==3) && ((VFLIP_EN && ~HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN)) && (ROT_FLIP_ORDER_EN==0)) || // rot_enc = 270 deg cases if rotation before v/hflip_en
	((ROT_ENC==3) && ((~VFLIP_EN && HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN)) && (ROT_FLIP_ORDER_EN==1))); // rot_enc = 270 deg cases if rotation after v/hflip_en
	
	int_vflip = (((ROT_ENC==0) && ((VFLIP_EN && ~HFLIP_EN) || (VFLIP_EN && HFLIP_EN))) || // rot_enc = 0 deg cases.
	((ROT_ENC==2) && ((~VFLIP_EN && HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN))) || // rot_enc = 180 deg cases.
	((ROT_ENC==1) && ((VFLIP_EN && ~HFLIP_EN) || (VFLIP_EN && HFLIP_EN)) && (ROT_FLIP_ORDER_EN==0)) || // rot_enc = 90 deg cases if rotation before v/hflip_en
	((ROT_ENC==1) && ((~VFLIP_EN && HFLIP_EN) || (VFLIP_EN && HFLIP_EN)) && (ROT_FLIP_ORDER_EN==1)) || // rot_enc = 90 deg cases if rotation after v/hflip_en
	((ROT_ENC==3) && ((~VFLIP_EN && HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN)) && (ROT_FLIP_ORDER_EN==0)) || // rot_enc = 270 deg cases if rotation before v/hflip_en
	((ROT_ENC==3) && ((VFLIP_EN && ~HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN)) && (ROT_FLIP_ORDER_EN==1))); // rot_enc = 270 deg cases if rotation after v/hflip_en
	
	Second calculate the number of pix_x_byte_offset based on the pix_x_offset calculation described in FRAME_1P_PIX_X_CTRL: NUM_X_PIX_WIDE, and the MODE_CTRL0: PIX_SIZE.
	pix_x_byte_offset = int_hflip_en ? (pix_x_offset << PIX_SIZE) : 0;
	
	Third calculate the number of pix_y_byte_offset based on the pix_y_offset calculation described in FRAME_1P_PIX_Y_CTRL: NUM_Y_PIX_HIGH, and the FRAME_CTRL0: PITCH.
	pix_y_byte_offset = int_vflip_en ? (PITCH * pix_y_offset) : 0;
	
	Fourth apply the following pix_x_byte_offset and pix_y_byte_offset to the BASE_ADDR. This is the value which should be written to BASE_ADDR.
	BASE_ADDR = (BASE_ADDR - pix_y_byte_offset) - pix_x_byte_offset;

Field	Function
31-16 CROP_ULC_X	Starting Coordinate of Cropped Image X (2-Plane UV) Due to the tile geometry in VPU and Super-Tile formats, a simple address offset cannot be used to crop an image (in all cases). In these modes, the CROP_ULC_X and CROP_ULC_Y coordinate pair will be used to specify an offset to begin fetching pixels within an image. In addition, the NUM_X_PIX_WIDE and NUM_Y_PIX_HIGH will indicate when to stop fetching pixels. Note, these coordinate pairs (CROP_ULC_X,CROP_ULC_Y) and (NUM_X_PIX_WIDE,NUM_Y_PIX_HIGH) must be aligned to block boundaries for proper functionality. The following table illustrates coordinate restrictions for the tile types of interest (Note, the same restrictions apply to (NUM_X_PIX_WIDE,NUM_Y_PIX_HIGH)): |---|---|---| | Tile Type |X Alignment |Y Alignment | |---|---|---| | GPU 32bpp (X-Major Super-tile) |CROP_ULC_X[1:0] = 0 |CROP_ULC_Y[1:0] = 0 | | GPU 16bpp xRGB,1-Plane YUV422 |CROP_ULC_X[2:0] = 0 |CROP_ULC_Y[2:0] = 0 | | VPU 8bpp 2-Plane YUV420 |CROP_ULC_X[3:0] = 0 |CROP_ULC_Y[3:0] = 0 | | VP9 8bpp 2-Plane YUV420 |CROP_ULC_X[3:0] = 0 |CROP_ULC_Y[3:0] = 0 | | VP9 10bpp 2-Plane YUV420 |CROP_ULC_X[2:0] = 0 |CROP_ULC_Y[2:0] = 0 |

Table continues on the next page...

Field	Function
	|------------------------------|--------------------|--------------------|
15-0 NUM_X_PIX_WIDE	Number of Pixels Wide in X-direction The number of input frame pixels to fetch in the x-axis direction. Note: To simplify the logic conversion from pixels to bytes, the U and V components will be calculated as seperate pixels instead of UV as a combined pixel. As and example, in 2PYUV420, the U component will be treated as a 8-bit pixel and the V component as a 2nd 8-bit pixel instead of a single 16-bit pixel. In non-linear (raster) tile mode, the starting pixel must be at the start of a tile boundary. Partial tile fetch is not allowed. The NUM_X_PIX_WIDE must be sized so the prefetch is evenly divisible by 64 bytes. If the NUM_X_PIX_WIDE is not evenly divisible by 64 bytes, then an offset must be applied. To calculate if NUM_X_PIX_WIDE is divisible by 64 bytes: First determine the number of pix_x pixels divisible in 64 bytes, based on MODE_CTRL0: PIX_SIZE and TILE_TYPE settings: num_pix_x_in_64byte = (((PIX_SIZE==1) && (TILE_TYPE==0)) ? 32 : // VPU 10bpp VP9-10 UV linear tile must be divisible by 32 pixels in x-direction ((PIX_SIZE==1) && (TILE_TYPE==4)) ? 8 : // VPU 10bpp VP9-10 UV tile must be divisible by 8 pixels in x-direction ((PIX_SIZE==0) && (TILE_TYPE==0)) ? 64 : // VPU 8bpp VP9 UV linear tile must be divisible by 64 pixels in x-direction ((PIX_SIZE==0) && (TILE_TYPE==4)) ? 16 : // VPU 8bpp VP9 UV tile must be divisible by 16 pixels in x-direction ((PIX_SIZE==0) && (TILE_TYPE==3)) ? 8 : // VPU 8bpp 2PYUV420 UV zenverge tile must be divisible by 8 pixels in x-direction 8); // default case shouldn't be hit Second calculate the modulus of the NUM_X_PIX_WIDE by dpr_num_pix_x_in_64byte Note: for 2PYUV420 10bpp source frame, NUM_X_PIX_WIDE must first be multiplied by 1.25 to account for MODE_CTRL0: PIX_SIZE=8bpp operation. pix_x_div_64byte_mod = NUM_X_PIX_WIDE % num_pix_x_in_64byte Third calculate the number of offset pixels pix_x_offset = (pix_x_div_64byte_mod == 0) ? 0 : (num_pix_x_in_64byte - pix_x_div_64byte_mod) Fourth add pix_x_offset to NUM_X_PIX_WIDE. This is the value written to the NUM_X_PIX_WIDE control registers. NUM_X_PIX_WIDE = NUM_X_PIX_WIDE + pix_x_offset Note1: If FRAME_2P_CTRL0:MAX_BYTES_PREQ > 64 bytes AND FRAME_CTRL0:HFLIP_EN=1, then the prefetch calculation above must be evenly divisible by 128 bytes instead of 64 bytes.

15.7.3.1.47.4 Fields

Field	Function
31-16 CROP_ULC_X	Starting Coordinate of Cropped Image X (2-Plane UV) Due to the tile geometry in VPU and Super-Tile formats, a simple address offset cannot be used to crop an image (in all cases). In these modes, the CROP_ULC_X and CROP_ULC_Y coordinate pair will be used to specify an offset to begin fetching pixels within an image. In addition, the NUM_X_PIX_WIDE and NUM_Y_PIX_HIGH will indicate when to stop fetching pixels. Note, these coordinate pairs (CROP_ULC_X,CROP_ULC_Y) and (NUM_X_PIX_WIDE,NUM_Y_PIX_HIGH) must be aligned to block boundaries for proper functionality. The following table illustrates coordinate restrictions for the tile types of interest (Note, the same restrictions apply to (NUM_X_PIX_WIDE,NUM_Y_PIX_HIGH)): |---|---|---| | Tile Type |X Alignment |Y Alignment | |---|---|---| | GPU 32bpp (X-Major Super-tile) |CROP_ULC_X[1:0] = 0 |CROP_ULC_Y[1:0] = 0 | | GPU 16bpp xRGB,1-Plane YUV422 |CROP_ULC_X[2:0] = 0 |CROP_ULC_Y[2:0] = 0 | | VPU 8bpp 2-Plane YUV420 |CROP_ULC_X[3:0] = 0 |CROP_ULC_Y[3:0] = 0 |

Table continues on the next page...

Field	Function
	| VP9 8bpp 2-Plane YUV420 |CROP_ULC_X[3:0] = 0 |CROP_ULC_Y[3:0] = 0 | | VP9 10bpp 2-Plane YUV420 |CROP_ULC_X[2:0] = 0 |CROP_ULC_Y[2:0] = 0 | |---|---|---|
15-0 NUM_X_PIX_WIDE	Number of Pixels Wide in X-direction The number of input frame pixels to fetch in the x-axis direction. Note: To simplify the logic conversion from pixels to bytes, the U and V components will be calculated as seperate pixels instead of UV as a combined pixel. As and example, in 2PYUV420, the U component will be treated as a 8-bit pixel and the V component as a 2nd 8-bit pixel instead of a single 16-bit pixel. In non-linear (raster) tile mode, the starting pixel must be at the start of a tile boundary. Partial tile fetch is not allowed. The NUM_X_PIX_WIDE must be sized so the prefetch is evenly divisible by 64 bytes. If the NUM_X_PIX_WIDE is not evenly divisible by 64 bytes, then an offset must be applied. To calculate if NUM_X_PIX_WIDE is divisible by 64 bytes: First determine the number of pix_x pixels divisible in 64 bytes, based on MODE_CTRL0: PIX_SIZE and TILE_TYPE settings: num_pix_x_in_64byte = (((PIX_SIZE==1) && (TILE_TYPE==0)) ? 32 : // VPU 10bpp VP9-10 UV linear tile must be divisible by 32 pixels in x-direction ((PIX_SIZE==1) && (TILE_TYPE==4)) ? 8 : // VPU 10bpp VP9-10 UV tile must be divisible by 8 pixels in x-direction ((PIX_SIZE==0) && (TILE_TYPE==0)) ? 64 : // VPU 8bpp VP9 UV linear tile must be divisible by 64 pixels in x-direction ((PIX_SIZE==0) && (TILE_TYPE==4)) ? 16 : // VPU 8bpp VP9 UV tile must be divisible by 16 pixels in x-direction ((PIX_SIZE==0) && (TILE_TYPE==3)) ? 8 : // VPU 8bpp 2PYUV420 UV zenverge tile must be divisible by 8 pixels in x-direction 8); // default case shouldn't be hit Second calculate the modulus of the NUM_X_PIX_WIDE by dpr_num_pix_x_in_64byte Note: for 2PYUV420 10bpp source frame, NUM_X_PIX_WIDE must first be multiplied by 1.25 to account for MODE_CTRL0: PIX_SIZE=8bpp operation. pix_x_div_64byte_mod = NUM_X_PIX_WIDE % num_pix_x_in_64byte Third calculate the number of offset pixels pix_x_offset = (pix_x_div_64byte_mod == 0) ? 0 : (num_pix_x_in_64byte - pix_x_div_64byte_mod) Fourth add pix_x_offset to NUM_X_PIX_WIDE. This is the value written to the NUM_X_PIX_WIDE control registers. NUM_X_PIX_WIDE = NUM_X_PIX_WIDE + pix_x_offset Note1: If FRAME_2P_CTRL0:MAX_BYTES_PREQ > 64 bytes AND FRAME_CTRL0:HFLIP_EN=1, then the prefetch calculation above must be evenly divisible by 128 bytes instead of 64 bytes.

Field	Function
31-16 CROP_ULC_Y	Starting Coordinate of Cropped Image Y (2-Plane UV) Due to the tile geometry in VPU and Super-Tile formats, a simple address offset cannot be used to crop an image (in all cases). In these modes, the CROP_ULC_X and CROP_ULC_Y coordinate pair will be used to specify an offset to begin fetching pixels within an image. In addition, the NUM_X_PIX_WIDE and NUM_Y_PIX_HIGH will indicate when to stop fetching

Table continues on the next page...

Field	Function
	pixels. Note, these coordinate pairs (CROP_ULC_X,CROP_ULC_Y) and (NUM_X_PIX_WIDE,NUM_Y_PIX_HIGH) must be aligned to block boundaries for proper functionality. The following table illustrates coordinate restrictions for the tile types of interest (Note, the same restrictions apply to (NUM_X_PIX_WIDE,NUM_Y_PIX_HIGH)): |---|---|---| | Tile Type |X Alignment |Y Alignment | |---|---|---| | GPU 32bpp (X-Major Super-tile)|CROP_ULC_X[1:0] = 0 |CROP_ULC_Y[1:0] = 0 | | GPU 16bpp xRGB,1-Plane YUV422 |CROP_ULC_X[2:0] = 0 |CROP_ULC_Y[2:0] = 0 | | VPU 8bpp 2-Plane YUV420 |CROP_ULC_X[3:0] = 0 |CROP_ULC_Y[3:0] = 0 | | VP9 8bpp 2-Plane YUV420 |CROP_ULC_X[3:0] = 0 |CROP_ULC_Y[3:0] = 0 | | VP9 10bpp 2-Plane YUV420 |CROP_ULC_X[2:0] = 0 |CROP_ULC_Y[2:0] = 0 | |---|---|---|

15-0
NUM_Y_PIX_HIGH
	Number of Pixels High in Y-direction
	
	The number of input frame pixels to fetch in the y-axis direction.
	In non-linear (raster) t mode, the number of pixels must be sized for a full tile block boundary. Partial tile fetch is not allowed.
	
	The NUM_Y_PIX_HIGH value must be evenly divisible by the number of rows programmed in MODE_CTRL0: RTR_4LINE_BUF_EN.
	First determine the number of rows in the buffer
	num_rows_buf = (RTR_4LINE_BUF_EN==0) ? 8 : 4;
	
	Second calculate the modulus of NUM_Y_PIX_HIGH by the num_rows_buf
	Note: The NUM_Y_PIX_HIGH UV height is 1/2 height of Luma from FRAME_1P_PIX_Y_CTRL:NUM_Y_PIX_HIGH before luma height offset was calculated
	pix_y_mod = NUM_Y_PIX_HIGH % num_rows_buf;
	
	Third calculate the number of rows to offset
	pix_y_offset = (pix_y_mod==0) ? 0 : (num_rows_buf - pix_y_mod);
	
	Fourth add pix_y_offset to NUM_Y_PIX_HIGH. This is the value written to the NUM_Y_PIX_HIGH control registers.
	NUM_Y_PIX_HIGH = NUM_Y_PIX_HIGH + pix_y_offset;

15.7.3.1.54.4 Fields

Field	Function
31-0 BASE_ADDR	Base Address The base address for 2-Plane Chroma. The base address is an input frame offset to the non-rotated, non-hflip, non-vflip output image. This will correspond to the output image's pix_x=0,

Field	Function

	pix_y=0 position.
	If any non-linear GPU tile or VPU tile is being processed, then the base address must start at pixel 0 of the tile boundary.
	
	Under certain conditions, a offset must be applied to the BASE_ADDR pix_x=0, pix_y=0 position.
	
	1. The DPR will perform an internal hflip AND the pix_x_offset calculation doesn't equal 0 as described in FRAME_2P_PIX_X_CTRL: NUM_X_PIX_WIDE.
	2. The DPR will perform an internal vflip AND the pix_y_offset calculation doesn't equal 0 as described in FRAME_2P_PIX_Y_CTRL: NUM_Y_PIX_HIGH.
	
	Steps to apply an offset to the BASE_ADDR:
	
	First determine if the DPR will perform an internal hflip or vflip base on FRAME_CTRL0: ROT_FLIP_ORDER_EN, ROT_ENC, VFLIP_EN and HFLIP_EN.
	int_hflip = (((ROT_ENC==0) && ((~VFLIP_EN && HFLIP_EN) || (VFLIP_EN && HFLIP_EN))) || // rot_enc = 0 deg cases.
	((ROT_ENC==2) && ((VFLIP_EN && ~HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN))) || // rot_enc = 180 deg cases.
	((ROT_ENC==1) && ((~VFLIP_EN && HFLIP_EN) || (VFLIP_EN && HFLIP_EN)) && (ROT_FLIP_ORDER_EN==0)) || // rot_enc = 90 deg cases if rotation before v/hflip_en
	((ROT_ENC==1) && ((VFLIP_EN && ~HFLIP_EN) || (VFLIP_EN && HFLIP_EN)) && (ROT_FLIP_ORDER_EN==1)) || // rot_enc = 90 deg cases if rotation after v/hflip_en
	((ROT_ENC==3) && ((VFLIP_EN && ~HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN)) && (ROT_FLIP_ORDER_EN==0)) || // rot_enc = 270 deg cases if rotation before v/hflip_en
	((ROT_ENC==3) && ((~VFLIP_EN && HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN)) && (ROT_FLIP_ORDER_EN==1)) ; // rot_enc = 270 deg cases if rotation after v/hflip_en
	
	int_vflip = (((ROT_ENC==0) && ((VFLIP_EN && ~HFLIP_EN) || (VFLIP_EN && HFLIP_EN))) || // rot_enc = 0 deg cases.
	((ROT_ENC==2) && ((~VFLIP_EN && HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN))) || // rot_enc = 180 deg cases.
	((ROT_ENC==1) && ((VFLIP_EN && ~HFLIP_EN) || (VFLIP_EN && HFLIP_EN)) && (ROT_FLIP_ORDER_EN==0)) || // rot_enc = 90 deg cases if rotation before v/hflip_en
	((ROT_ENC==1) && ((~VFLIP_EN && HFLIP_EN) || (VFLIP_EN && HFLIP_EN)) && (ROT_FLIP_ORDER_EN==1)) || // rot_enc = 90 deg cases if rotation after v/hflip_en
	((ROT_ENC==3) && ((~VFLIP_EN && HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN)) && (ROT_FLIP_ORDER_EN==0)) || // rot_enc = 270 deg cases if rotation before v/hflip_en
	((ROT_ENC==3) && ((VFLIP_EN && ~HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN)) && (ROT_FLIP_ORDER_EN==1)) ; // rot_enc = 270 deg cases if rotation after v/hflip_en
	
	Second calculate the number of pix_x_byte_offset based on the pix_x_offset calculation described in FRAME_2P_PIX_X_CTRL: NUM_X_PIX_WIDE, and the MODE_CTRL0: PIX_SIZE.
	pix_x_byte_offset = int_hflip_en ? (pix_x_offset << PIX_SIZE) : 0;
	
	Third calculate the number of pix_y_byte_offset based on the pix_y_offset calculation described in FRAME_2P_PIX_Y_CTRL: NUM_Y_PIX_HIGH, and the FRAME_CTRL0: PITCH.
	pix_y_byte_offset = int_vflip_en ? (PITCH * pix_y_offset) : 0;
	
	Fourth apply the following pix_x_byte_offset and pix_y_byte_offset to the

Field	Function
	BASE_ADDR. This is the value which should be written to BASE_ADDR. Note: the pix_y_byte_offset is divided by 2 because the 2-Plane YUV420 UV height is 1/2 the pix_y_byte_offset calculated for the 2-Plane YUV420 Luma in FRAME_1P_PIX_Y_CTRL: NUM_Y_PIX_HIGH. BASE_ADDR = (BASE_ADDR - (pix_y_byte_offset >> 1)) - pix_x_byte_offset;

	Under certain conditions, a offset must be applied to the BASE_ADDR pix_x=0, pix_y=0 position.
	
	1. The DPR will perform an internal hflip AND the pix_x_offset calculation doesn't equal 0 as described in FRAME_2P_PIX_X_CTRL: NUM_X_PIX_WIDE.
	2. The DPR will perform an internal vflip AND the pix_y_offset calculation doesn't equal 0 as described in FRAME_2P_PIX_Y_CTRL: NUM_Y_PIX_HIGH.
	
	Steps to apply an offset to the BASE_ADDR:
	
	First determine if the DPR will perform an internal hflip or vflip base on FRAME_CTRL0: ROT_FLIP_ORDER_EN, ROT_ENC, VFLIP_EN and HFLIP_EN.
	int_hflip = (((ROT_ENC==0) && ((~VFLIP_EN && HFLIP_EN) || (VFLIP_EN && HFLIP_EN))) || // rot_enc = 0 deg cases.
	((ROT_ENC==2) && ((VFLIP_EN && ~HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN))) || // rot_enc = 180 deg cases.
	((ROT_ENC==1) && ((~VFLIP_EN && HFLIP_EN) || (VFLIP_EN && HFLIP_EN)) && (ROT_FLIP_ORDER_EN==0)) || // rot_enc = 90 deg cases if rotation before v/hflip_en
	((ROT_ENC==1) && ((VFLIP_EN && ~HFLIP_EN) || (VFLIP_EN && HFLIP_EN)) && (ROT_FLIP_ORDER_EN==1)) || // rot_enc = 90 deg cases if rotation after v/hflip_en
	((ROT_ENC==3) && ((VFLIP_EN && ~HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN)) && (ROT_FLIP_ORDER_EN==0)) || // rot_enc = 270 deg cases if rotation before v/hflip_en
	((ROT_ENC==3) && ((~VFLIP_EN && HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN)) && (ROT_FLIP_ORDER_EN==1)) ; // rot_enc = 270 deg cases if rotation after v/hflip_en
	
	int_vflip = (((ROT_ENC==0) && ((VFLIP_EN && ~HFLIP_EN) || (VFLIP_EN && HFLIP_EN))) || // rot_enc = 0 deg cases.
	((ROT_ENC==2) && ((~VFLIP_EN && HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN))) || // rot_enc = 180 deg cases.
	((ROT_ENC==1) && ((VFLIP_EN && ~HFLIP_EN) || (VFLIP_EN && HFLIP_EN)) && (ROT_FLIP_ORDER_EN==0)) || // rot_enc = 90 deg cases if rotation before v/hflip_en
	((ROT_ENC==1) && ((~VFLIP_EN && HFLIP_EN) || (VFLIP_EN && HFLIP_EN)) && (ROT_FLIP_ORDER_EN==1)) || // rot_enc = 90 deg cases if rotation after v/hflip_en
	((ROT_ENC==3) && ((~VFLIP_EN && HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN)) && (ROT_FLIP_ORDER_EN==0)) || // rot_enc = 270 deg cases if rotation before v/hflip_en
	((ROT_ENC==3) && ((VFLIP_EN && ~HFLIP_EN) || (~VFLIP_EN && ~HFLIP_EN)) && (ROT_FLIP_ORDER_EN==1)) ; // rot_enc = 270 deg cases if rotation after v/hflip_en
	
	Second calculate the number of pix_x_byte_offset based on the pix_x_offset calculation described in FRAME_2P_PIX_X_CTRL: NUM_X_PIX_WIDE, and the MODE_CTRL0: PIX_SIZE.
	pix_x_byte_offset = int_hflip_en ? (pix_x_offset << PIX_SIZE) : 0;
	
	Third calculate the number of pix_y_byte_offset based on the pix_y_offset calculation described in FRAME_2P_PIX_Y_CTRL: NUM_Y_PIX_HIGH, and the FRAME_CTRL0: PITCH.
	pix_y_byte_offset = int_vflip_en ? (PITCH * pix_y_offset) : 0;
	
	Fourth apply the following pix_x_byte_offset and pix_y_byte_offset to the

Field	Function
	BASE_ADDR. This is the value which should be written to BASE_ADDR. Note: the pix_y_byte_offset is divided by 2 because the 2-Plane YUV420 UV height is 1/2 the pix_y_byte_offset calculated for the 2-Plane YUV420 Luma in FRAME_1P_PIX_Y_CTRL: NUM_Y_PIX_HIGH. BASE_ADDR = (BASE_ADDR - (pix_y_byte_offset >> 1)) - pix_x_byte_offset;

15.8 Scaler (MED_DC_SCALE)

15.8.1 Overview

The Scaler's purpose is to resize images for display. Content can be delivered to the application at a resolution that different than the display resolution. Or, images may be reduced in size for PIP viewing. The scaler can resize the images to the required resolution for display. There are three scalers within the DCSS design, one dedicated to each of the three display channels.

15.8.1.1 Block Diagram

The diagram below illustrates the micro architecture of the RTRAM_CTRL, Scaling engine, and scaler output buffer. The example depicts an RTRAM_CTRL 12 row GPU configuration. The VPU configuration uses the same RAMs logically configured as 24 rows with 8 rows per buffer. It is intended that the Scaler, in conjunction with the RTRAM_CTRL, is a cohesive functional unit to resize images on the fly to the display.

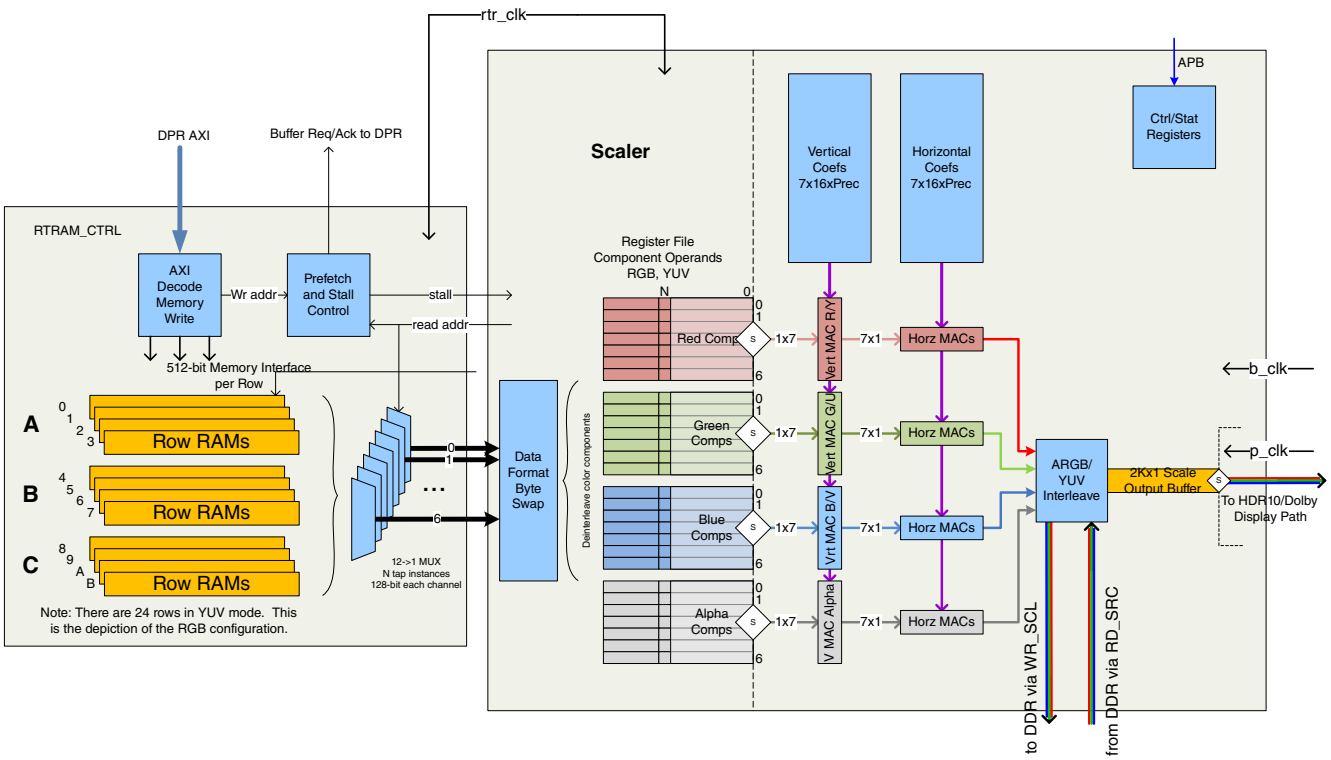

Figure 15-20. Block Diagram

The fundamental components within the Scaler design are as follows:

- Separate vertical and horizontal 7x1 MACs for independent image resizing.
- Separate vertical and horizontal coefficient memories for independent luma/chroma scaling.
- Data formatting and byte swapping to support pixel formats and data endianness.
- Color component FIFOS that contain pixel data used in the resizing of images. These FIFOs bridge between the rtr_clk and b_clk domains.
- Configuration registers to control the scaling configuration.
- Scaler output pixel FIFO to provide elasticity to meet the peak consumption rates of the pixel data path and display. This FIFO bridges between the b_clk and p_clk domains.

The Scaler takes in a block of 7 rows for video and 5 rows for graphics pipe and 128-bit wide data to process the current row. The input pixels go through vertical filtering first and horizontal filtering next to arrive at 1 output pixel. The input is fetched based on the size of the tap filter used. For the edges where the neighbor pixels aren't present, the boundary pixels are replicated. The scaling operation takes place in the raster format i.e. top-left to bottom right till the desired output size is obtained.

Based on the tap filter used (7 or 5), the input rows are filtered vertically giving out 1 pixel per cycle. These vertically filtered pixels are passed on to the horizontal pixels. Once the first 4 vertically filtered pixels are available, the horizontal filter kicks in and generates a scaled pixel output. Subsequently the horizontal tap filter is applied in sliding window manner as the vertical filter keeps giving out vertical filtered pixels till the end of the row. This gives out a row of scaled data and the same is continued till the end of the picture (based on the destination height).

For upscaling >= 1, this results in the output performance of one pixel per clock since there are fewer pixels used at the source to scale images up. For downscaling, the scaling ratio limits the output pixel rate. With a down scale ratio = 1/R, the scaler produces an output pixel per R clock cycles.

The output pixels generated are either sent to the pixel pipe directly or to the DDR through Write Scale interface. If the channel is programmed to send out the data to the memory using the write scale path, it should be programmed to use the data from the DDR via the RD_SRC block to send the data to the pixel pipe. The output format can be either YUV444, YUV422 or ARGB based on the configuration. Only the first channel has the capacity to send out 38 bit output (including 8 bit Alpha component). The output of the scaler is always 10bit. In case of YUV422 each cycle contains only 2 components, i.e. Y0U0, Y1V0 etc.

15.8.1.2 Features

- Upscaling (up to 1:8).
- Downscaling (up to 7:1 for video channels, up to 5:1 for graphics channels). The down scale ratio, 1/R, determines the rate at which the scaler produces output pixels. One pixel for every R cycles determines the down scaler performance.
- Alternate option for the Scaler to write data directly to the DRAM via the WR_SCL bus master interface.
- Alternate option for the Scaler Output FIFO to receive data directly from the DRAM via the RD_SRC bus master interface.
- 13-bit fractional accumulator to approximate fractional scaling ratios.
- Support 8/10-bits per component.
- Inputs formats supported, 8-bit components converted to 10-bit for processing.

  - 1; A8R8G8B8
  - 2; A8Y8U8V8
  - 3; A2R10G10B10
  - 4; A2Y10U10V10
  - 5; Y8U8Y8V8
  - 6; U8Y8V8Y8
  - 7; Y8_U8V8, 2-plane
  - 8; Y10_U10V10, 2-plane
- Output pixel format is 10-bit YUV422/444 (video) and ARGB-8:10:10:10 (graphics)
- 7-tap(video) and 5-tap(graphics) 16-phase FIR filtering
- Software programmable 12 bit filter coefficients in 2s complement
- Independent X/Y cropping

15.8.1.3 Scaler Use Cases

The horizontal and vertical scalers are used to resize source buffers for the following cases:

1. Downscaling for a lower resolution display or for PIP video with a maximum downscale of 7 to 1. The largest allowed 4K PIP window width is 2048 (determined by the scaler output FIFO size in pixels).
2. Upscaling to match the resolution of the display including upscaling HD graphics to 4K graphics with a maximum upscale of 1 to 8.

When the output resolution is UHD, and a UHD source is scaled down to cover less than the entire display, the largest sized PIP within the UHD output window is a HD PIP within the UHD display. This is limited by two factors:

- The Scaler Output FIFO is 2K pixels
- The rate of input into the scaling engine is 1 pixel per clock. So, it takes two clocks to derive one output pixel when scaling down by 2.

The FIFO allows the scaler to pre-compute pixels and store them for when the PIP window is active. This removes any issues with the scaler's performance to produce 1/R (R=scale ratio) pixels per clock. Or, the 2K pixel FIFO has a 2K PIP line worth of data for immediate consumption by the pixel pipeline for PIP display.

Cropping on the Left, Top, Right or Bottom boundaries to project only the area of interest in the incoming video

15.8.2 Functional Description

15.8.2.1 RTRAM Scaler Interface

RTRAM Interface

Scaler gets pixel data from RTRAM in raster format. The request is based on row number and address and RTRAM returns 7 rows of 128bits of data from the requested address and requested data. The row address is always a modulus of the total rows in the bank. If RTRAM operates in 4 lines per bank mode, the total rows is 12 (3 banks in RTRAM), if RTRAM operates in 8 lines per bank, the total rows is 24. For example, a request from ROW 38 and address 0 translates to row_address of 14 in 8 lines per bank mode and row_address of 2 in 4 lines per bank mode. RTRAM responds to the request from Scaler through ack signal. Scaler extends the request till the ack is received. The data from RTRAM is valid 1 cycle after the ack is received. The interface operates at 400MHz clock. In case of 2 plane mode operation i.e YUV420 semi planar, RTRAM has separate request bus to request for Y plane and UV plane. But the data bus is shared. There can be only 1 request at a time.

RTRAM Pixel Data

The data from the RTRAM is arranged in the following format:

1. 32 bpp A8R8G8B8/A8Y8U8V8 - 8bit input
2. 32 bpp A2R10G10B10/A2Y10U10V10 - 10 bit input
3. 16 bpp YUV 422 8 bit
4. 8 bpp Y/UV (2 planes) 420 - 8 bit input
5. 10 bpp Y/UV (2 planes) 420 - 10 bit input

Scaler supports swapping of the components based on the input pixel arrangement. Incase of 32bpp, the pixels can be in the format of ARGB, ARBG, AGBR, RGBA, BRGA etc. The input data is modified to match the scaler processing to form ARGB as the pixel arrangement. Incase of 16bpp, the data can be of the format Y0U0,Y1V0 or U0Y0,V0Y1 etc. Scaler swaps the data internally. All the pixels are in the little endian format from the RTRAM i.e. Pixel15..Pixel0. Scaler swaps it internally to convert to big endian format (pixel0..pixel15)

Incase of 32bpp (ARGB or AYUV), a 5 tap filter is used. RTRAM returns only 5 rows of valid data per request from Scaler. The rows6 and rows7 are not used by Scaler.

Once Scaler is done processing the rows of a bank, bank_done signal is asserted so that RTRAM can fill the next rows in the bank. rtram_vsync_reset is asserted after all the rows of the picture are processed.

15.8.2.2 Scaler Horizontal and Vertical Operation

The scaler, based on the current X,Y position within the source image, operates on the 7x7 matrix of source pixels to produce a single output pixel. Note that for ARGB scaling, a 5x5 matrix of source pixels is used to produce a single output pixel.

For example, for 1:1 scaling, each source pixel is mapped to a destination pixel. For 7:1 downscale, only 1 out of 7 source pixels is mapped to a destination pixel. For 1:4 upscale, the same source group of 7 source pixels is used 4 times at the output but with different filter coefficients. Note that an output buffer is required to support the case of downscaling to manage the rate of BW at the source. In effect, the output buffer allows for the scaling process to spread the input peak BW over the width of the entire display, not just the region that we are displaying, which may not be at the resolution of the display. Of concern are the downscaling cases, fetching large amounts of data, and displaying that data in small regions of the display.

The scaling hardware relies on software to configure the following parameters for the horizontal and vertical scalers:

- 26 bit (13 int, 13 frac) Fractional pixel start
- 17 bit (4 int, 13 frac) Fractional pixel increment (max value is 8)
- 12 bit (12 int) Filter coefficients

The fractional pixel start corresponds to the starting bias, or the first source pixel position to be selected. The start location acts as a top and left crop value since all output pixels before the start location are dropped. The fractional pixel increment gives the scale ratio, or the number of source pixels to ‘skip’ for each output pixel. The fractional pixel start location consists of an integer and fractional part. The integer component is used to skip a selected number of pixels, usually the desired offset into a row of tiles in the X or Y direction. For a 4K image and a 13-bit fractional component, a maximum error of .5 pixel is achieved with a ratio of 4095/4094. The pixel increment is 17-bit in width made up of 4 integer and 13 fractional bits. This is limited to a maximum downscale value of 7 to 1 for video, or 5 to 1 for graphics that matches the filter width so that no pixels are dropped (except pixels outside the crop region). To limit the size of the polyphase filter table, 16 phases are used between source pixels. The phase accumulator keeps accumulating the pixel position based on the pixel_increment. Based on the phase index which is bit [12:9] of the phase accumulated, the pixel position to apply the 7 tap filter is arrived at.

The scaling method is output centric. The input pixels are filtered vertically first and then horizontally. A running output pixel location is maintained using the phase accumulator. Based on the location of the pixel, the corresponding pixels are chosen from the vertically filtered samples. The filter window slides across the vertically filtered samples to generate the row of pixels, and then the process is repeated until the end of the picture.

15.8.2.3 Scaler Filter

For each color component (R/Y, G/U, B/V, A), the scaler computes an output pixel value as a weighted average of 7 (5 for RGBA) source pixel values. The weights, or coefficients, are programmed by software. To produce output pixels of acceptable quality, the selected source pixel's neighbors must figure in the output pixel generation, instead of simply dropping them. It is the job of the filter to include the neighbors in generating the final output pixel value. For each component (R/Y, G/U, B/V, A), the design implements a 7-tap filter (5-tap filter for RGBA), i.e. the selected source pixel, plus its 3 neighboring pixels to either side. Each of the 7 pixels is given a different weight with the coefficients programmed by software. The output pixel is the sum-of-products of the 7 pixels multiplied by the corresponding coefficients. Scaling is performed in the vertical orientation first, followed by the horizontal orientation to determine each final output pixel value.

Polyphase Filter

The source pixel is selected by the accumulated phase from the scaler, rounded up to the next integer. In this way, there is no difference between 2 'real' source pixels with the same integer but different fractional components. To account for the fractional phase difference, a polyphase filter is implemented. The 4-bit fraction allows for 16 phases between 2 integer positions. Instead of using the same set of coefficients for all, each phase is configured with its own coefficient set of 7 coefficients for each component (YUV or 5-tap RGBA), one for each tap. While the current phase's integer component selects the source pixel (and its neighbors), the fractional component selects the coefficient set to operate over the source pixels. As shown in the diagram above, the index into the coefficient table is the accumulated phase's fractional component. The index into the source pixel array is the accumulated phase's integer component.

Boundary Conditions

If a source pixel is less than 3 pixels from the edge, there are an insufficient number of neighboring pixels. In this case, the value of the edge pixel is simply repeated, i.e. the 'missing' neighbors assume the value of the edge pixels.

Filter Operation

The output buffer is sized to handle the worst case downscale case allowed which is the largest width PIP or graphics window of 2048 from 4096 (2 to 1) requiring a buffer that is 2Kx32 bits to support the following output pixel formats:

1. 38 bit RGBA 8 bit Alpha, 10bit pixels per component for RGB.
2. 20 bit YUV 422 10 bit
3. 30 bit YUV 444 10 bit

The Alpha output from the scaler is always 8-bit. For the color components its always 10bit output.

Note that for downscaling 3 to 1, the peak bandwidth goes up by a factor of 3 (but not 9 due to the output buffer).

The scaler output buffer is the data structure used to cross the asynchronous boundary between the b_clk and p_clk domains. This allows the scaler to run at the rate of the system bus interface with no asynchronous boundary crossing.

Scaler Output Buffer with Status Interrupts

The scaler output buffer has a mechanism to detect when underflow could occur. There are three levels of state that determine how full or empty the fifo is at any time. These states are listed and ordered in levels of severity if these states are reached.

- Underflow - a buffer underflow has occurred. This is the most severe state, as the pointers into the write and read interfaces of the buffer may not recover.
- Near Empty - Also known as low threshold. The number of valid pixels in the buffer is less than or equal to this programmable threshold.
- Almost Full – Also known as high threshold. The number of valid pixels in the buffer is less than or equal to this programmable threshold.

The states are described here.

Underflow – The buffer was read while empty. An interrupt is generated and SW restarts the display.

Low Threshold – This is a SW programmable threshold, between 1 and 2048, of pixels that are valid in the FIFO. This value of valid pixels can be reached when the scaler is not able to produce pixels at the rate of consumption by the pixel data path. The SW programmable register that sets this value should be less than or equal to the high threshold.

High Threshold – This is a SW programmable threshold, between 1 and 2048, of pixels that are valid in the FIFO. This is a high threshold of pixels in the buffer and should be set to a value equal or greater than the low threshold.

All states reached can generate an interrupt so that SW can respond by changing system priorities and restarting the display if needed.

15.8.3.1.2 Scale Control Register (SCALE_CTRL)

15.8.3.1.2.1 Offset

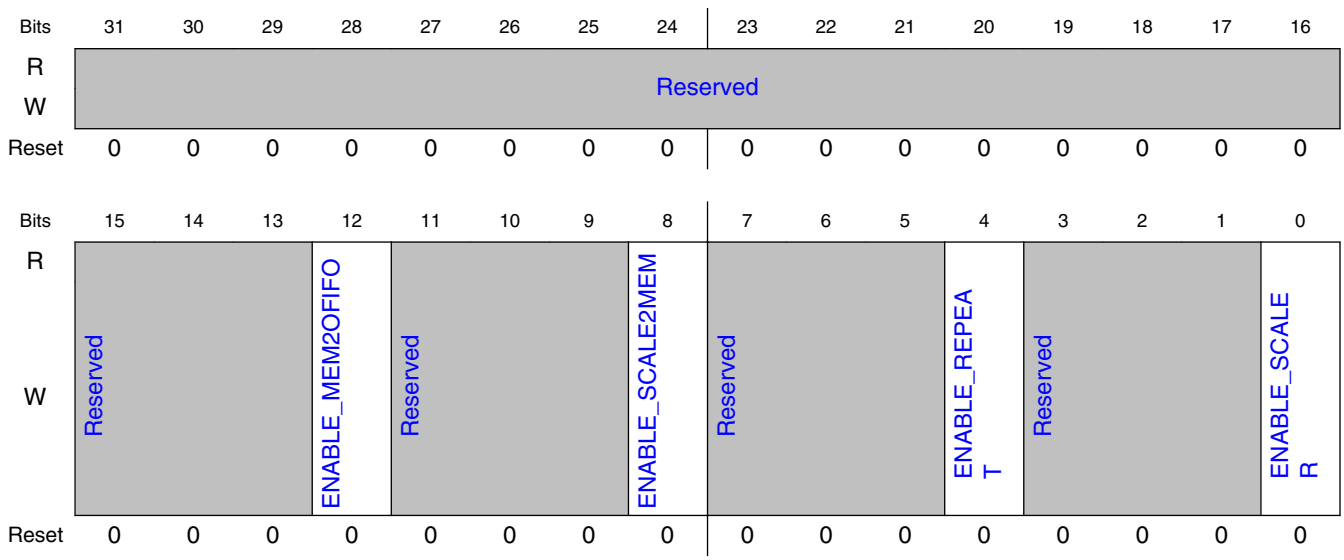
Register	Offset
SCALE_CTRL	0h

15.8.3.1.2.2 Function

This register is the main control register for the scaler.

Note: the bit fields ENABLE_MEM2OFIFO and ENABLE_SCALE2MEM MUST be programmed to the same state, both 1'b0 or both 1'b1.

15.8.3.1.2.3 Diagram



15.8.3.1.2.4 Fields

Field	Function
31-13 —	Reserved.
12 ENABLE_MEM2OFIFO	This bit enables the path from external memory to drive the data into the scale output FIFO. This option is used when the RD_SRC module is enabled to fetch data directly from the memory and bypassing decompression, DPR, and scaling is desired. 0: disabled, scaler drives the data directly into the scale output FIFO. 1: enabled, external pixel interface input bus is used to drive data into the scale output FIFO.
11-9 —	Reserved.

Table continues on the next page...

Field	Function
8 ENABLE_SCALE2MEM	This bit enables the path from the scaler output back to the system memory. This option is used when the WR_SCL module is enabled to write data out to memory. It is intended this path is used when significant down scaling is required to manage peak bandwidth requirements. 0: disabled, the scaler drives data directly into the scale output FIFO. 1: enabled, the scaler drives data out on the pixel data bus to the WR_SCL module.
7-5 —	Reserved.
4 ENABLE_REPEAT	This bit enables the scaler to restart processing a frame buffer without receiving a SW "kick" event using the ENABLE_SCALER control bit. There is a HW event that can start the scaler to process a frame buffer when the ENABLE_REPEAT is high. This event usually occurs after the current active display region is complete. 0: disabled, the scaler will not repeat the processing when the HW repeat event occurs. 1: enabled, the scaler will repeat with the existing programming when the HW "kick" occurs.
3-1 —	Reserved.
0 ENABLE_SCALER	This bit, when set to logic 1, will cause the scaler to begin processing a frame buffer based on all current programmable settings. This bit is cleared after a few cycles, once the start is latched by the HW. If ENABLE_REPEAT is not set to 1, after every frame, this bit has to be programmed to restart the scaler for the next frame. SW can set this bit during the processing of the current frame, but the other parameters shouldn't be changed during frame processing. For predictable results, set ENABLE_SCALER (along with all other programmable parameters) after the scaler is done with processing the current frame. The CTX_LD engine is the best way to determine when to load and enable the scaler considering the tight timing relationship with display retrace. 0: disabled, 1: enabled, the scaler will start processing the frame based on the programmable settings.

15.8.3.1.3 Scale Output FIFO Control Register (SCALE_OFIFO_CTRL)

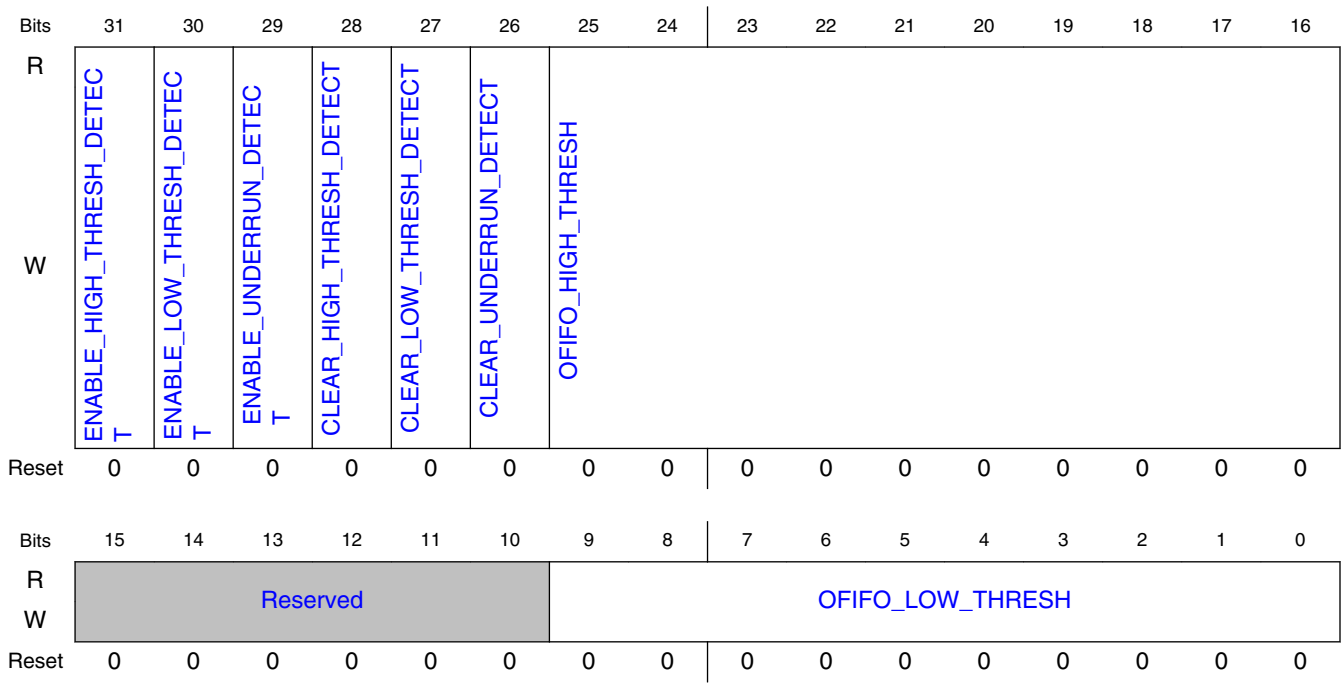
15.8.3.1.3.1 Offset

Register	Offset
SCALE_OFIFO_CTRL	4h

15.8.3.1.3.2 Function

This register controls when the output FIFO will generate an interrupt based on how many pixels are valid within the FIFO and the programmable thresholds.

15.8.3.1.3.3 Diagram



15.8.3.1.3.4 Fields

Field	Function
31 ENABLE_HIGH_THRESH_DETECT	This bit will control if the high threshold detection of the output FIFO can generate an interrupt. 0: disabled, no interrupt will be generated. 1: enabled, interrupt will occur if the high threshold is reached.
30 ENABLE_LOW_THRESH_DETECT	This bit will control if the low threshold detection of the output FIFO can generate an interrupt. 0: disabled, no interrupt will be generated. 1: enabled, interrupt will occur if the low threshold is reached.
29 ENABLE_UNDERRUN_DETECT	This bit will control if the underrun on the output FIFO can generate an interrupt. 0: disabled, no interrupt will be generated. 1: enabled, interrupt will occur if the low threshold is reached.
28 CLEAR_HIGH_THRESH_DETECT	This bit clears the high threshold detect interrupt. 0: disabled, no action. 1: enabled, clear the high threshold reached interrupt.
27 CLEAR_LOW_THRESH_DETECT	This bit clears the low threshold detect interrupt 0: disabled, no action. 1: enabled, clear the low threshold detect interrupt.
26	This bit clears the underrun detected interrupt. 0: disabled, no action.

Table continues on the next page...

Field	Function
CLEAR_UNDERRUN_DETECT	1: enabled, underrun detected interrupt is cleared.
25-16 OFIFO_HIGH_THRESH	This value is used to detect when the output FIFO has a number of pixels that are valid that first exceeds this value, and then decrements to a value equal to the value programmed in this register. Note: This value should be greater than the value programmed into OFIFO_LOW_THRESH.
15-10 —	Reserved.
9-0 OFIFO_LOW_THRESH	This value is used to detect when the output FIFO has a number of pixels that are valid that first exceeds this value, and then decrements to a value equal to the value programmed in this register. Note: This value should be less than the value programmed into OFIFO_HIGH_THRESH.

15.8.3.1.4 Scale Source Data Control Register (SCALE_SRC_DATA_CTRL)

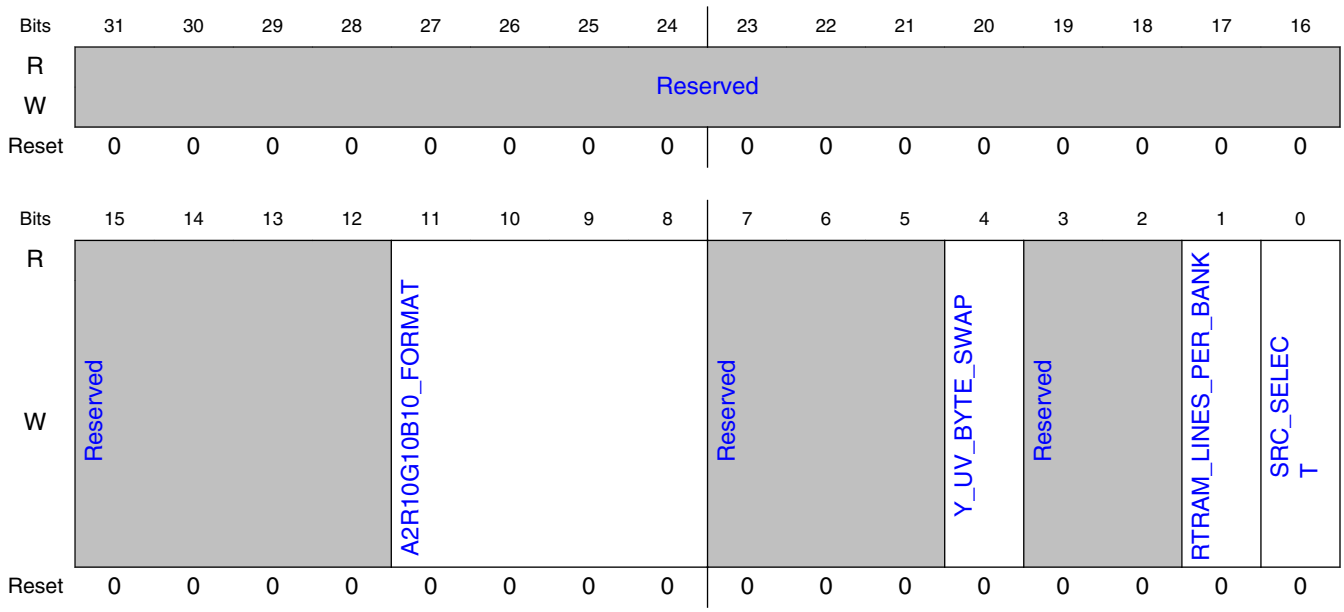
15.8.3.1.4.1 Offset

Register	Offset
SCALE_SRC_DATA_CTRL	8h

15.8.3.1.4.2 Function

This register control aspects related to data formats in the scaler. It also controls HW resources that are used based on the different modes that are programmed.

15.8.3.1.4.3 Diagram



15.8.3.1.4.4 Fields

Field	Function
31-12 —	Reserved.
11-8 A2R10G10B10_FORMAT	This field represents the data arrangement in the memory in case 10 RGB mode. 0: ARGB is the format in 32bit data. A[31:30], R[29:20], G[19:10], B[9:0] 1: ARBG is the format in 32bit data. A[31:30], R[29:20], B[19:10], G[9:0] 2: AGRB is the format in 32bit data. A[31:30], G[29:20], R[19:10], B[9:0] 3: AGBR is the format in 32bit data. A[31:30], R[29:20], B[19:10], R[9:0] 4: ABRG is the format in 32bit data. R[31:22], G[21:12], B[11: 2], A[1:0] 7: RBGA is the format in 32bit data. R[31:22], B[21:12], G[11: 2], A[1:0] 8: GRBA is the format in 32bit data. G[31:22], R[21:12], B[11: 2], A[1:0] 9: GBRA is the format in 32bit data. G[31:22], B[21:12], R[11: 2], A[1:0] 10: BRGA is the format in 32bit data. B[31:22], R[21:12], G[11: 2], A[1:0] 11: BGRA is the format in 32bit data. B[31:22], G[21:12], R[11: 2], A[1:0]
7-5 —	Reserved.
4 Y_UV_BYTE_SWAP	This bit will control the swapping of alternate bytes in the incoming data word. 0: disabled, no byte steering. 1: enabled, each pair of bytes is swapped. This option can be used to achieve UYVY -> YUYV swapping of bytes.
3-2 —	Reserved.

Table continues on the next page...

Field	Function
1 RTRAM_LINES_PER_BANK	This field determines the number of lines that are used in each bank of the RTRAM_CTRL module. This should match the respective setting of lines per bank in the DPR. 0: RTRAM has 4 lines per bank. 1: RTRAM has 8 lines per bank.
0 SRC_SELECT	This bit controls whether the source is Video format(YUV) or Graphics(RGB). AYUV444 operates similar to ARGB, hence the SRC_SELECT bit has to be set to 0. However to work around a HW bug in YUV444 to YUV422, the bit has to be programmed to 0. The below are the scenarios and the corresponding programming ARGB input: SRC_SELECT should be set to 0 AYUV444 input to YUV444 output: SRC_SELECT should be set to 1 AYUV444 input to YUV422 output: SRC_SELECT should be set to 0 AYUV422 input to Any output: SRC_SELECT should be set to 1 AYUV420 input to Any output: SRC_SELECT should be set to 1 In particular, it determines if the chroma coefficients, start value, and increment value in HW are used. If the input source is an RGB format, the Luma coefficients, start, and increment values are used, and the chroma parameters are ignored (programming not needed). If the input source is any YUV format, both the Luma and Chroma parameters need to be programmed. Programming of the Luma/Chroma parameters start/inc need to be congruent and consistent with the input format. For example: YUV444: requires Luma/Chroma start/inc values to be identical. YUV422/YUV420: horizontal/vertical Chroma start/inc values are independent of Luma values The values in this register define the source format as: 0: Input source has ARGB or AYUV444 components. 1: Input source has YUV components.

15.8.3.1.5 Scale Bit Depth Control Register (SCALE_BIT_DEPTH)

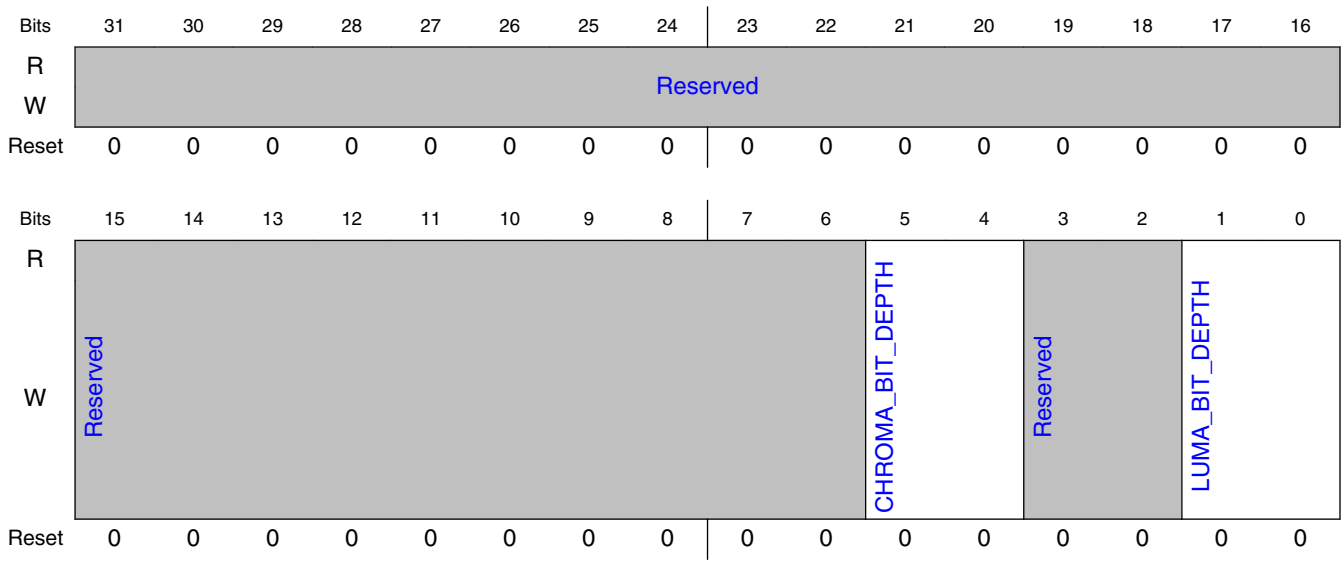
15.8.3.1.5.1 Offset

Register	Offset
SCALE_BIT_DEPTH	Ch

15.8.3.1.5.2 Function

This register determines the component bit depth of the source frame buffer.

15.8.3.1.5.3 Diagram



15.8.3.1.5.4 Fields

Field	Function
31-6 —	Reserved.
5-4 CHROMA_BIT_DEPTH	These bits determine the bit depth of the alternate component (UV 2-plane) processing. 0: 8-bit. 2: 10-bit. other: reserved Both Chroma and Luma bit depths MUST be programmed with the same value.
3-2 —	Reserved.
1-0 LUMA_BIT_DEPTH	These bits determine the bit depth of the primary component (Y, RGB) processing. 0: 8-bit. 2: 10-bit. other: reserved Both Chroma and Luma bit depths MUST be programmed with the same value.

15.8.3.1.6 Scale Source Format Control Register (SCALE_SRC_FORMAT)

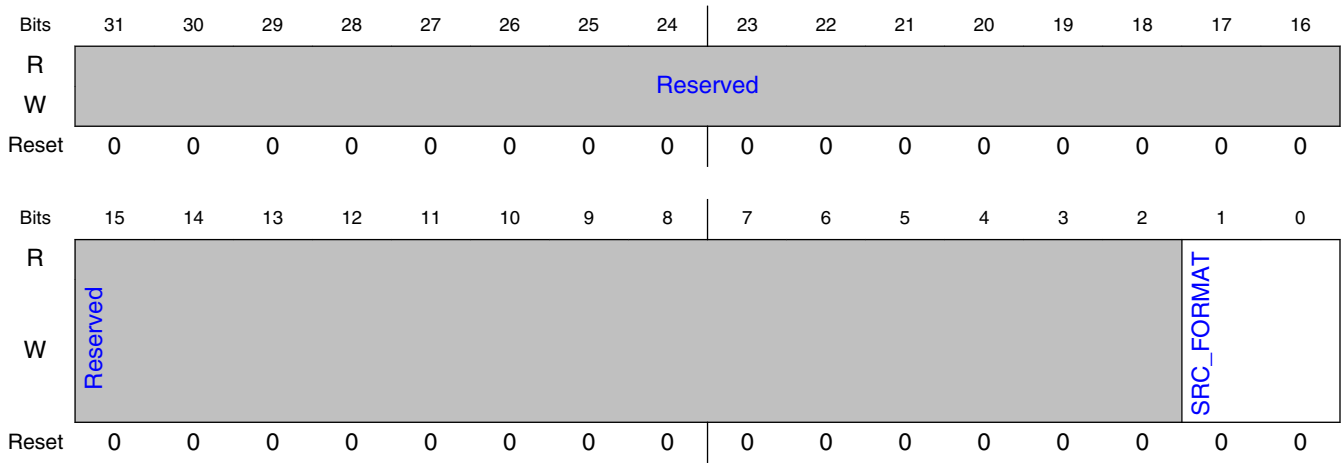
15.8.3.1.6.1 Offset

Register	Offset
SCALE_SRC_FORMAT	10h

15.8.3.1.6.2 Function

This register controls the format of the source frame buffer.

15.8.3.1.6.3 Diagram



15.8.3.1.6.4 Fields

Field	Function
31-2 —	Reserved.
1-0 SRC_FORMAT	These bits define the input buffer format. 0: YUV420 (2-plane chroma sub-sampled V/H). 1: YUV422 (1-plane chroma sub-sampled H). 2: ARGB8888/YUV444 (1-plane full color). Other: Reserved. This parameter needs to be congruent with the SRC_SELECT programming.

15.8.3.1.7 Scale Destination Format Control Register (SCALE_DST_FORMAT)

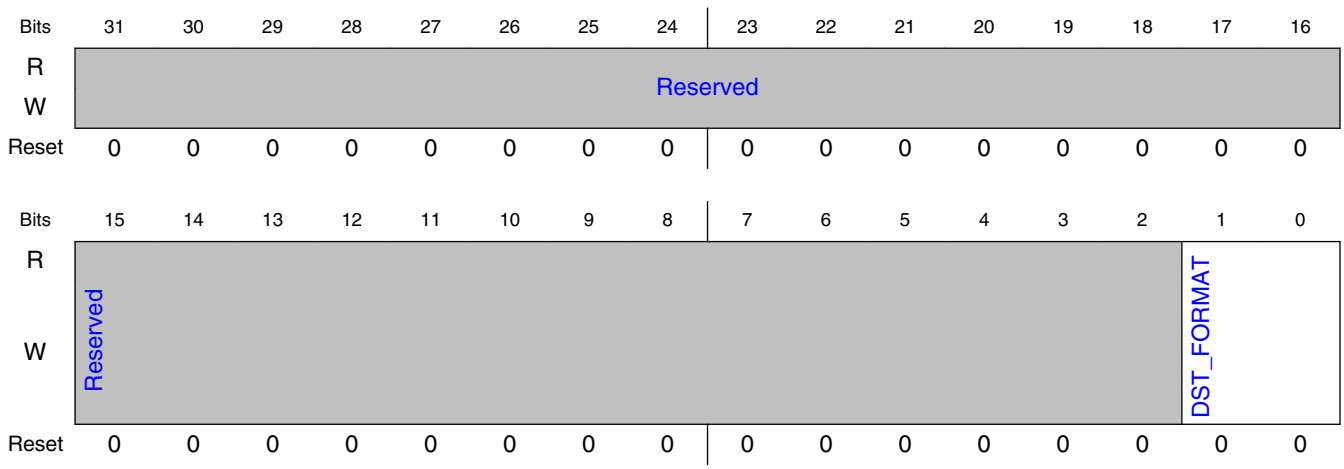
15.8.3.1.7.1 Offset

Register	Offset
SCALE_DST_FORMAT	14h

15.8.3.1.7.2 Function

This register controls the format of the scaler output.

15.8.3.1.7.3 Diagram



15.8.3.1.7.4 Fields

Field	Function
31-2 —	Reserved.
1-0 DST_FORMAT	These bits define the scaler output format. 1: YUV422. 2: RGB888/YUV444. Other: Reserved.

15.8.3.1.8 Scale Source Luma Resolution Register (SCALE_SRC_LUMA_RES)

15.8.3.1.8.1 Offset

Register	Offset
SCALE_SRC_LUMA_RES	18h

15.8.3.1.8.2 Function

This register defines the resolution of the source image. The source image resolution needs to be congruent with the resolution programmed in the DPR to guarantee that all data prefetched by the DPR is consumed by the scaler engine. If the resolution programmed into the DPR is not congruent, scaler and DCSS operation will be unpredictable. This restriction pertains to all source buffers formats, either raster or tiled, and with any RTRAM bank size configuration, either 4 or 8 lines per bank.

15.8.3.1.8.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved				HEIGHT

15.8.3.1.8.4 Fields

Field	Function
31-28 —	Reserved.
27-16 HEIGHT	This field defines the height of the source image in pixels minus 1. Incase of cropping, the height should be programmed removing the bottom lines to be cropped. The top lines cropped will be conveyed through vs_luma_start programming. Programmed height = Actual_height - bottom_crop - 1.
15-12 —	Reserved.
11-0 WIDTH	This field defines the width of the source image in pixels minus 1. Incase of cropping, the width should be programmed removing the right pixels to be cropped. The left pixels to be cropped will be conveyed through hs_luma_start programming. programmed width = actual_width - right_crop - 1.

15.8.3.1.9 Scale Source Chroma Resolution Register (SCALE_SRC_CHROMA_RES)

15.8.3.1.9.1 Offset

Register	Offset
SCALE_SRC_CHROMA_RES	1Ch

15.8.3.1.9.2 Function

This register defines the resolution of the source image. The value of the chroma resolution is dependent on the resolution of the source image programmed in the SCALE_SRC_LUMA_RES register, since the luma and chroma scaling channels are separate. The programming restrictions are described below.

ARGB8888/YUV444: SCALE_SRC_CHROMA_RES = SCALE_SRC_LUMA_RES, SCALE_SRC_FORMAT.SRC_FORMAT = 444
YUV422: SCALE_SRC_CHROMA_RES.BUFFER_WIDTH = SCALE_SRC_LUMA_RES.BUFFER_WIDTH/2, SCALE_SRC_CHROMA_RES.BUFFER_HEIGHT = SCALE_SRC_LUMA_RES.BUFFER_HEIGHT, SCALE_SRC_FORMAT.SRC_FORMAT = 422
YUV420: SCALE_SRC_CHROMA_RES.BUFFER_WIDTH = SCALE_SRC_LUMA_RES.BUFFER_WIDTH/2, SCALE_SRC_CHROMA_RES.BUFFER_HEIGHT = SCALE_SRC_LUMA_RES.BUFFER_HEIGHT/2, SCALE_SRC_FORMAT.SRC_FORMAT = 420

15.8.3.1.9.3 Diagram

Field	Function
31-28 —	Reserved.
27-16 HEIGHT	This field defines the height of the source image in pixels minus 1. Incase of cropping, the height should be programmed removing the bottom lines to be cropped. The top lines cropped will be conveyed through vs_chroma_start programming. Programmed height = Actual_height - bottom_crop - 1.
15-12 —	Reserved.
11-0 WIDTH	This field defines the width of the source image in pixels minus 1. Incase of cropping, the width should be programmed removing the right pixels to be cropped. The left pixels to be cropped will be conveyed through hs_chroma_start programming. programmed width = actual_width - right_crop - 1.

15.8.3.1.10 Scale Destination Luma Resolution Register (SCALE_DST_LUMA_RES)

15.8.3.1.10.1 Offset

Register	Offset
SCALE_DST_LUMA_RES	20h

15.8.3.1.10.2 Function

This register defines the resolution of the scaled result, or destination image. The destination image resolution needs to be congruent with the source image resolution and the scaling factors applied. For example, if the source image is scaled down by a factor of 2, the destination resolution needs to be set to exactly half of the resolution of the source image. Fractional scaling ratios, cropping, and initial offsets into the source image all need to be congruent with the source and destination resolution values.

15.8.3.1.10.3 Diagram

15.8.3.1.12 Scale Vertical Luma Start Register (SCALE_V_LUMA_START)

15.8.3.1.12.1 Offset

Register	Offset
SCALE_V_LUMA_START	48h

15.8.3.1.12.2 Function

This register contains the initial vertical pixel start, or offset, into the image that is fetched by the prefetch engine. Essentially it is used to discard pixels (integer component) and provide and initial phase (fractional component) into the image in RTRAM. Fundamentally, the images loaded into the RTRAM from the DPR are aligned to 64 byte addresses. This register is used for cropping the top rows from the source image. To achieve better DRAM efficiency, DPR should be used to not fetch the unwanted lines in the top of the picture. The remaining rows i.e. the rows that cannot be dropped by DPR can be cropped in Scaler. There is no limit on the number of lines that can be cropped in

the Scaler. If it crosses the bank boundary, Scaler gives out bank done without reading the bank data and this continues till the actual row is needed. If a few lines from the top are cropped, the source image pixels beyond the crop boundary aren't considered for scaling. Its treated as if they are outside the picture

15.8.3.1.12.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Function
31-20 —	Reserved.
19-0 V_INC	Vertical increment value used for scaling the image. This register is programmed with the following format: ####.#_####_####_####. The maximum value that can be programmed into this register is 0xE000, for a maximum scale down ratio of 1/7. Other programming examples could be: 0x1000, scale up by 2. 0x0800, scale up by 4. 0x6000, scale down by 3. 0x0AAB, scale up by 3, digital approximation of 1/3.

15.8.3.1.14 Scale Horizontal Luma Start Register (SCALE_H_LUMA_STARTRT)

15.8.3.1.14.1 Offset

Register	Offset
SCALE_H_LUMA_STARTRT	50h

15.8.3.1.14.2 Function

This register contains the initial horizontal pixel start, or offset, into the image that is fetched by the prefetch engine. Essentially it is used to disgard pixels (integer component) and provide and initial phase (fractional component) into the image in RTRAM. Fundamentally, the images loaded into the RTRAM from the DPR are aligned to 64 byte addresses. This is essential to achieve DRAM efficiency.

The integer component of this register is used to skip input pixels in the horizontal direction.

This register may use a fractional component to establish an initial horizontal phase offset.

15.8.3.1.14.3 Diagram

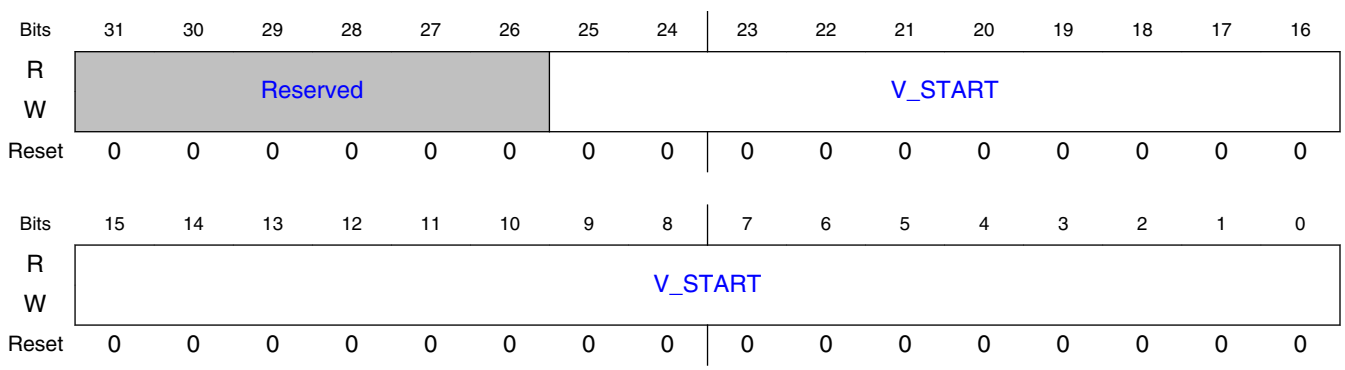
15.8.3.1.16.1 Offset

Register	Offset
SCALE_V_CHROMA_START	58h

15.8.3.1.16.2 Function

This register contains the initial vertical pixel start, or offset, into the image that is fetched by the prefetch engine. Essentially it is used to discard pixels (integer component) and provide and initial phase (fractional component) into the image in RTRAM. Fundamentally, the images loaded into the RTRAM from the DPR are aligned to 64 byte addresses. This register is used for cropping the top rows from the source image. To achieve better DRAM efficiency, DPR should be used to not fetch the unwanted lines in the top of the picture. The remaining rows i.e. the rows that cannot be dropped by DPR can be cropped in Scaler. There is no limit on the number of lines that can be cropped in the Scaler. If it crosses the bank boundary, Scaler gives out bank done without reading the bank data and this continues till the actual row is needed. If a few lines from the top are cropped, the source image pixels beyond the crop boundary aren't considered for scaling. Its treated as if they are outside the picture

15.8.3.1.16.3 Diagram



15.8.3.1.16.4 Fields

Field	Function
31-26 —	Reserved.
25-0 V_START	This register contains 13 integer and 13 fractional bits to define the vertical offset into the start of the prefetched image. It is a continuous 16 bit value with the following format ###.#_####_####_####.

15.8.3.1.17 Scale Vertical Chroma Increment Register (SCALE_V_CHROMA_INC)

15.8.3.1.17.1 Offset

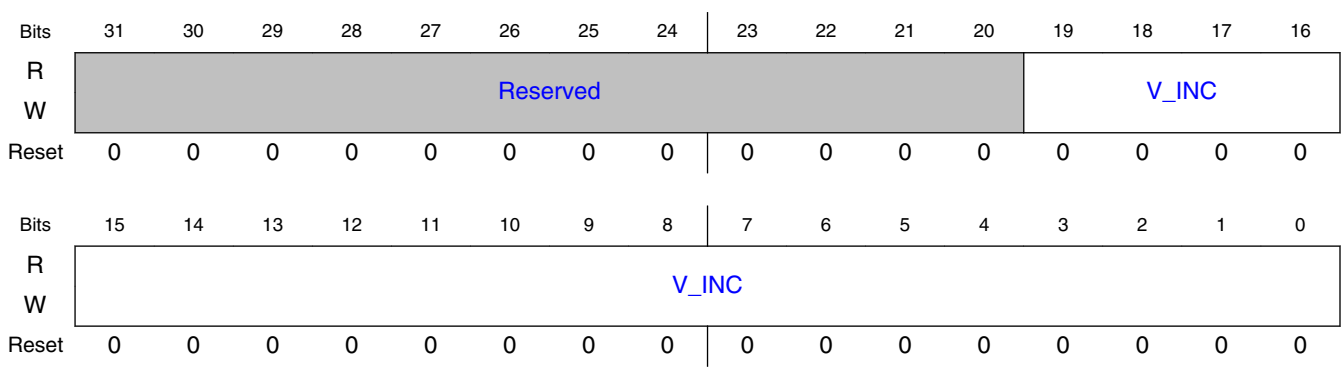
Register	Offset
SCALE_V_CHROMA_INC	5Ch

15.8.3.1.17.2 Function

This register contains the increment which is used to define the scaling ratio. The upper 4 bits is the integer component of the step value. The lowest 13 bits is the fractional component. The value programmed in this register is dependent on the value in the SCALE_V_LUMA_INC register AND the buffer format.

ARGB8888, YUV 1-plane: SCALE_V_CHROMA_INC = SCALE_V_LUMA_INC

15.8.3.1.17.3 Diagram



15.8.3.1.17.4 Fields

Field	Function
31-20 —	Reserved.
19-0 V_INC	Vertical increment value used for scaling the image. This register is programmed with the following format: ###.#_####_####_####. The maximum value that can be programmed into this register is 0xE000, for a maximum scale down ratio of 1/7. Other programming examples could be:

Field	Function
	0x1000, scale up by 2. 0x0800, scale up by 4. 0x6000, scale down by 3. 0x0AAB, scale up by 3, digital approximation of 1/3.

15.8.3.1.18 Scale Horizontal Chroma Start Register (SCALE_H_CHROMA_START)

15.8.3.1.18.1 Offset

Register	Offset
SCALE_H_CHROMA_START	60h

15.8.3.1.18.2 Function

This register contains the initial horizontal pixel start, or offset, into the image that is fetched by the prefetch engine. Essentially it is used to disgard pixels (integer component) and provide and initial phase (fractional component) into the image in RTRAM. Fundamentally, the images loaded into the RTRAM from the DPR are aligned to 64 byte addresses. This is essential to achieve DRAM efficiency.

The integer component of this register is used to skip input pixels in the horizontal direction.

If SW requires a high integer start value, change the base address of the source image in the DPR so that the undesired data is NOT prefetched.

This register may use a fractional component to establish an initial horizontal phase offset.

15.8.3.1.18.3 Diagram

15.8.3.1.18.4 Fields

Field	Function
31-26 —	Reserved.
25-0 H_START	This register contains 13 integer and 13 fractional bits to define the horizontal offset into the start of the prefetched image. It is a continuous 19 bit value with the following format ##_####.#_####_####_####. The start can be negative but greater than -1

15.8.3.1.19 Scale Horizontal Chroma Increment Register (SCALE_H_CHROMA_INC)

15.8.3.1.19.1 Offset

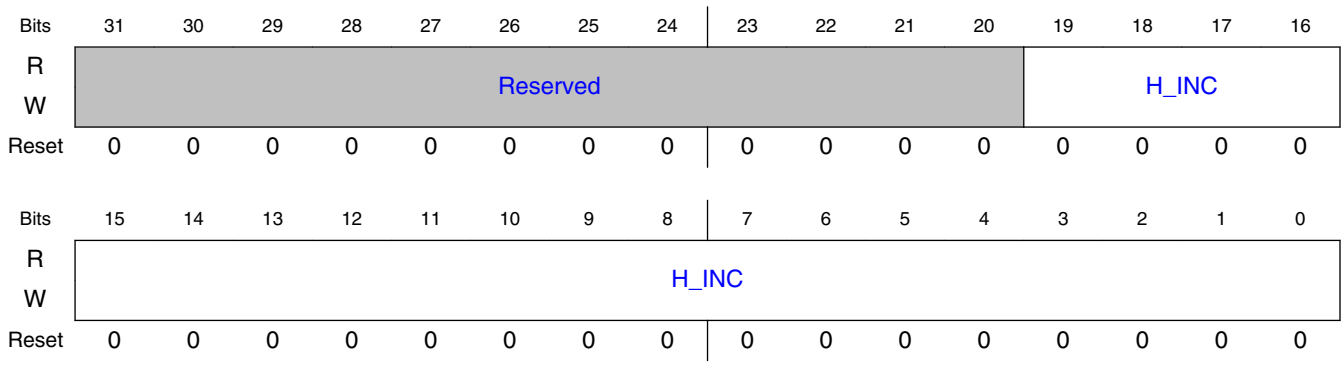
Register	Offset
SCALE_H_CHROMA_INC	64h

15.8.3.1.19.2 Function

This register contains the increment which is used to define the scaling ratio. The upper 4 bits is the integer component of the step value. The lowest 13 bits is the fractional component. The value programmed in this register is dependent on the value in the SCALE_H_LUMA_INC register AND the buffer format.

ARGB8888, YUV444: SCALE_H_CHROMA_INC = SCALE_H_LUMA_INC

15.8.3.1.19.3 Diagram



15.8.3.1.19.4 Fields

Field	Function
31-20 —	Reserved.
19-0 H_INC	Horizontal increment value used for scaling the image. This register is programmed with the following format: ###.#_####_####_####. The maximum value that can be programmed into this register is 0xE000, for a maximum scale down ratio of 1/7. Other programming examples could be: 0x1000, scale up by 2. 0x0800, scale up by 4. 0x6000, scale down by 3. 0x0AAB, scale up by 3, digital approximation of 1/3.

15.8.3.1.20 Scale Coefficient Memory Array (SCALE_COEF_ARRAY)

15.8.3.1.20.1 Offset

Register	Offset
SCALE_COEF_ARRAY	80h

15.8.3.1.20.2 Function

This register is not implemented in HW. This is place holder to document the address range used to program the scaling coefficients. The coefficients are defined as c(P,T) where P(0-15) are the possible 16 phases, and T(0-6) are the possible 7 coefficient taps per phase. The base address of all coefficient RAMs starts at 0x80. The entire range of addresses for coefficient access ends with address 0x3BF. Each coefficient is 12-bits.

Note, there are 12-bits per coefficent, and 7 taps, for a total of 12*7=84-bits. There are 3 memories to store the coefficients, and these memories have a word width of 28-bits. So, the coefficients are loaded 28-bits per PIO write. Since the coefficient bit width and memory word width are not evenly divisable, some coefficients will cross a memory word boundary. This is described below.

Vertical/Horizontal coefficients are accessed according to the following memory mapped layout.

ADDRESS	DESCRIPTION
0x80-0xBC	Vert/Luma, increment through 16-phases, tap 0, 1, and the high 4-bits of tap 2
0xC0-0xFF	Vert/Luma, increment through 16-phases, tap 2 low 8-bits, tap 3, and the high 8-bits of tap 4
0x100-0x13F	Vert/Luma, increment through 16-phases, tap 4 low 4-bits, tap 5, 6
0x140-0x17F	Horz/Luma, increment through 16-phases, taps 0, 1, and the high 4-bits of tap 2
0x180-0x1BF	Horz/Luma, increment through 16-phases, taps 2, 3, 4, as above
0x1C0-0x1FF	Horz/Luma, increment through 16-phases, taps 4, 5, 6, as above
0x200-0x23F	Vert/Chroma, increment through 16-phases, taps 0, 1, 2, as above
0x240-0x27F	Vert/Chroma, increment through 16-phases, taps 2, 3, 4, as above
0x280-0x2BF	Vert/Chroma, increment through 16-phases, taps 4, 5, 6, as above
0x300-0x33F	Horz/Chroma, increment through 16-phases, taps 0, 1, 2, as above
0x340-0x37F	Horz/Chroma, increment through 16-phases, taps 2, 3, 4, as above
0x380-0x3BF	Horz/Chroma, increment through 16-phases, taps 4, 5, 6, as above

```
As an example, the first few writes starting at address 0x80, 0x84, ..., would be:
# Adr = 0x80; Write phase 0, taps 0, 1, and the high 4-bits of tap 2.
# Adr = 0x84; Write phase 1, taps 0, 1, and the high 4-bits of tap 2.
...
# Adr = 0xBC; Write phase 15, taps 0, 1, and the high 4-bits of tap 2.
# Adr = 0xC0; Write phase 0, the low 8-bits of tap 2, tap 3, and the high 8-bits of tap 4.
WRITE(0x80, {4'b0, c(0,0),      c(0,1),  c(0,2)[11:8]})
WRITE(0x84, {4'b0, c(1,0),      c(1,1),  c(1,2)[11:8]})
...
WRITE(0xBC, {4'b0, c(15,0),     c(15,1), c(15,2)[11:8]})
WRITE(0xC0, {4'b0, c(0,2)[7:0], c(0,3),  c(0,4)[11:4]})
...
```

Using two dimensional arrays for vertical/horizontal and luma/chroma "c[v|h][l|c][P,T]" to store 12-bit coefficients, defined as c[15:0][6:0][11:0], the following code could be used to load the coefficient memories with the desired coefficient values.

```
for (i=0, i.lt.16, i=i+1) (
   WRT(0x80+(4*i) ,{cvl(i,0)[11:0], cvl(i,1)[11:0], cvl(i,2)[11:8]});
   WRT(0xC0+(4*i) ,{cvl(i,2)[7:0],  cvl(i,3)[11:0], cvl(i,4)[11:4]});
   WRT(0x100+(4*i),{cvl(i,4)[3:0],  cvl(i,5)[11:0], cvl(i,6)[11:0]});
   WRT(0x140+(4*i),{chl(i,0)[11:0], chl(i,1)[11:0], chl(i,2)[11:8]});
   WRT(0x180+(4*i),{chl(i,2)[7:0],  chl(i,3)[11:0], chl(i,4)[11:4]});
   WRT(0x1C0+(4*i),{chl(i,4)[3:0],  chl(i,5)[11:0], chl(i,6)[11:0]});
   WRT(0x200+(4*i),{cvc(i,0)[11:0], cvc(i,1)[11:0], cvc(i,2)[11:8]});
   WRT(0x240+(4*i),{cvc(i,2)[7:0],  cvc(i,3)[11:0], cvc(i,4)[11:4]});
   WRT(0x280+(4*i),{cvc(i,4)[3:0],  cvc(i,5)[11:0], cvc(i,6)[11:0]});
```

```
WRT(0x300+(4*i),{chc(i,0)[11:0], chc(i,1)[11:0], chc(i,2)[11:8]});
WRT(0x340+(4*i),{chc(i,2)[7:0],  chc(i,3)[11:0], chc(i,4)[11:4]});
WRT(0x380+(4*i),{chc(i,4)[3:0],  chc(i,5)[11:0], chc(i,6)[11:0]});
)

15.9 Look Up Table Load (LUT_LD)

15.9.1 Overview

The Look Up Table Load module (LUT_LD) provides the interface between the DMA interface of the Dolby IP and the AXI bus transactions to system RAM. This interface orchestrates the fetch of the tone curve LUT and the G2L LUT data from system RAM. Both the Dolby video and graphics pixel data pipelines require this LUT data. The LUT_LD engine will serve as the interface for both the video and graphics IP. Essentially, the LUT_LD will fetch the LUT data for the video interface first, followed by the LUT data for the graphics pipeline second. This module will not provide an asynchronous domain crossing between clock domains.

NOTE: More information on the DMA interface and LUT data processing can be obtained from the Dolby IP specs.

15.9.1.1 Block Diagram

The following diagram indicates the microarchitecture of the LUT_LD module.

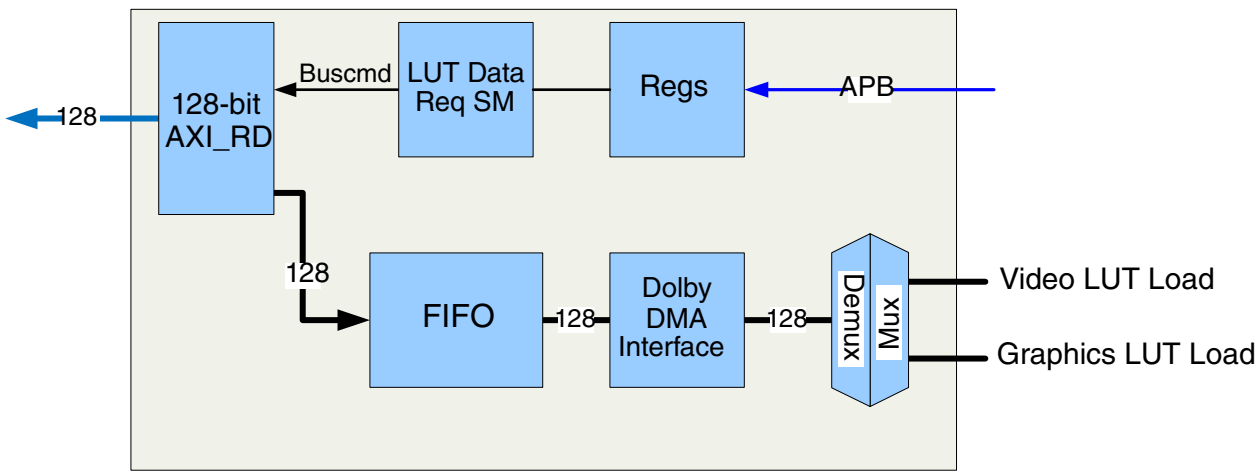

Figure 15-21. LUT_LD Block Diagram

15.9.1.2 Features

The LUT_LD integrates the following functional components:

- AXI_RD buscmd/AXI interface module at 128-bit bus width.
- LUT Data Request State Machine
- CSR registers to define the base address of the 10KB of LUT data.
- 512B FIFO.
- Dolby DMA interface SM

The amount of data to be fetched is defined in the Dolby IP specs. The video tone curve = 4KB and the G2L = 1KB.

Since both the video and graphics pixel pipelines require the same amount of LUT data (5KB), the LUT_LD engine serves the video pipeline first (5KB), followed by the graphics pipeline (5KB). Each Dolby pixel processing component needs 5KB of data to complete the LUT loading process. In all, 10KB is transferred over the two Dolby IP DMA interfaces (5KB each).

The FIFO is implemented to manage system memory latency and throughput.

The LUT_LD engine begins fetching LUT data from system memory when the CNTL_STATUS.ENABLE bit is set. The load sequence runs once and does not repeat every display trace. If the previous data needs to be fetched in subsequent display traces, the LUT_LD engine needs to be enabled for the loading sequence to commence.

15.10 HDR10 Image Processing (MED_HDR10)

15.10.1 Overview

In HDR10 mode, the three inputs get merged or blended together, post processed and sent to the HDMI protocol controller. The HDMI output consists of a display window containing up to three input windows. Any of the three windows can by driven by the Readback channel. All three windows can be full screen or smaller and offset inside the display window with the rest of the display window filled with the background color. The compositing of the three windows is controlled by the per pixel alpha channel from channel 1. The alpha logic creates an alpha based on the window priority and the graphics

per pixel alpha. The diagram below shows a possible window configuration. Note that window priority is fixed with channel 1 on top of channel 2 on top of channel 3. Only channel 1 can have a per pixel alpha.

Figure 15-22. HDR10 Processed Display

15.10.1.1 Features

In HDR10 mode, all three pixel processing pipelines are identical.

Each HDR10 pixel processing input pipeline supports:
- 10-bit per component input
- Color space conversion
- LUT gamma correction per component

HDR10 Output Pipeline The HDR10 pixel processing output pipeline supports:
- Linear to non-linear conversion per component
- Color space conversion
- 10-bit per component RGB/YUV444

15.10.2 Functional description

15.10.2.1 HDR10 Input Path

15.10.3.1.5.1 Offset

Register	Offset
HDR_PIPE1_CSCA_CONTROL_REG	3000h

15.10.3.1.5.2 Function

Controls the Color-Space-Converter-A (CSCA) in pipe1. This CSCA takes in 10-bit pixel components (component 0, component 1, component 2). A per-component offset (called pre-offset) is added to the pixel. After the pre-offset operation the pixel components are clipped. MAX_RANGE of PRE_CLIP is [-512, 1023]. A 3x3 matrix multiply (constant coefficiens H(x,y)) is performed on the pixel to take to a different color space. After this matrix multiply, a 28 bit signed offset (post-offset) is added to the normalized result of

the matrix multiply. After the post-offset operation the results are clipped. MAX_RANGE of POST_CLIP is [0,1023] Output of this CSCA are 10 bit per component pixels. After CSCA the pixels are fed into a LUT. Pipe1 is also called channel1.

15.10.3.1.35.1 Offset

Register	Offset
HDR_PIPE1_LUT_CONTROL_REG	3080h

15.10.3.1.35.2 Function

Controls the Look-Up-Table in pipe1. Control of LUT is PER PIXEL not per component. LUT has 1024 14-bit, per component, entries. LUT maybe used for conversion from non-linear (gamma corrected) to linear pixels. LUT maybe used for conversion from linear to non linear pixels (gamma corrected). LUT can contain 14-bit fixed point or 14-bit floating point pixel value. Floating point format has 9 bit unsigned mantissa with hidden bit and 5 bit, unsigned, biased exponent. {exp[4:0], mantissa[8:0]} => 1.mantissa[8:0] * 2^(exp-1) When using floating piont numbers, in this LUT, these are used in HDR OUTPUT PIPE for HDR non-linear operation and must bypass Color Space Converter B (CSCB). Pipe1 is also called channel1.

15.10.3.1.36.1 Offset

Register	Offset
HDR_PIPE1_CSCB_CONTROL_REG	3800h

15.10.3.1.36.2 Function

Controls the Color-Space-Converter-B (CSCB) in pipe1. This CSCB takes in 14-bit pixel components (component 0, component 1, component 2). A per-component offset (called pre-offset) is added to the pixel. After the pre-offset operation the pixel components are clipped. MAX_RANGE of PRE_CLIP is [-512, 1023]. A 3x3 matrix multiply (constant coefficiens H(x,y)) is performed on the pixel to take to a different color space. After this matrix multiply, a 28 bit signed offset (post-offset) is added to the normalized result of the matrix multiply. After the post-offset operation the results are clipped. MAX_RANGE of POST_CLIP is [0,1023] Output of this CSCA are 28 bit per component pixels. After CSCB the pixels are fed into the Blender. Pipe1 is also called channel1.

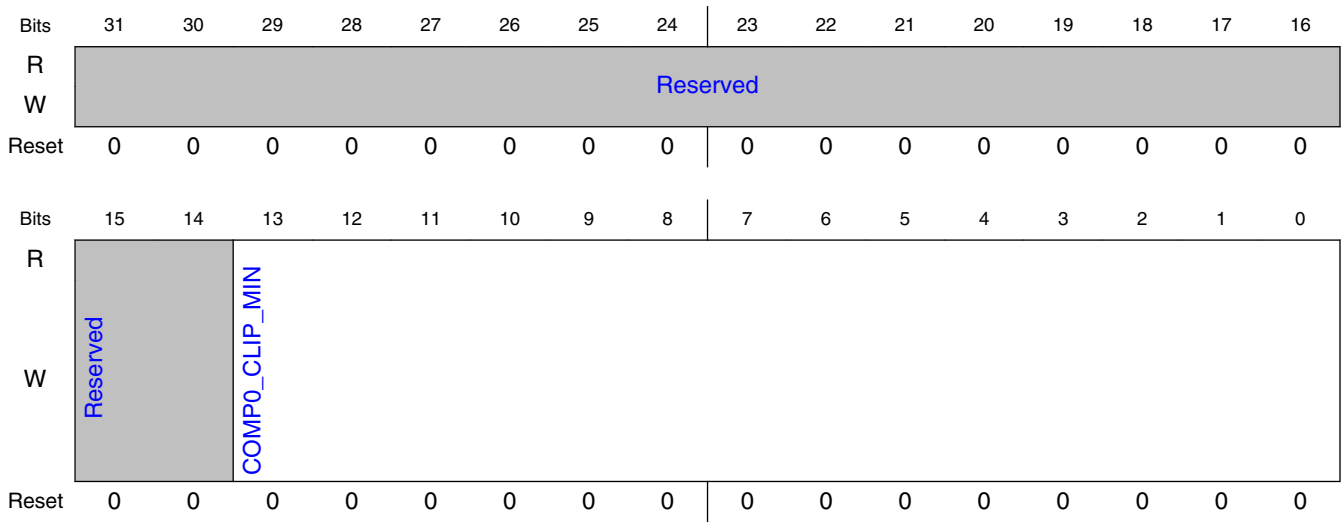
15.10.3.1.49.1 Offset

Register	Offset
HDR_PIPE1_CSCB_IO_MIN_0	3834h

15.10.3.1.49.2 Function

After the pre-increment, The result is clipped. This 14-bit signed value is the minimum value of pixel component after the pre-increment. So the minimun range is [-8192 , 8191]. Pipe1 is also called channel1.

15.10.3.1.49.3 Diagram



15.10.3.1.49.4 Fields

Field	Function
31-14 —	Reserved.
13-0 COMP0_CLIP_MIN	This 14-bit signed value is the minimum value of pixel component after the pre-increment.

15.10.3.1.50 Pipe1 Colorspace Converter B (CSCB) component 1 clip min. (HDR_PIPE1_CSCB_IO_MIN_1)

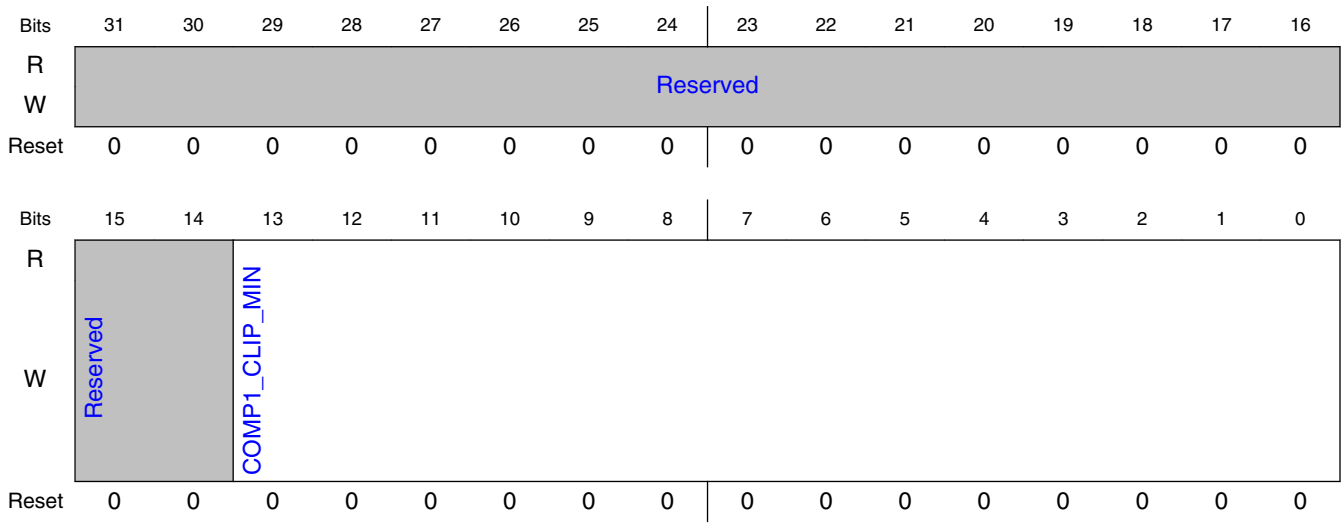
15.10.3.1.50.1 Offset

Register	Offset
HDR_PIPE1_CSCB_IO_MIN_1	3838h

15.10.3.1.50.2 Function

After the pre-increment, The result is clipped. This 14-bit signed value is the minimum value of pixel component after the pre-increment. So the minimun range is [-8192 , 8191]. Pipe1 is also called channel1.

15.10.3.1.50.3 Diagram



15.10.3.1.50.4 Fields

Field	Function
31-14 —	Reserved.
13-0 COMP1_CLIP_MIN	This 14-bit signed value is the minimum value of pixel component after the pre-increment.

15.10.3.1.51 Pipe1 Colorspace Converter B (CSCB) component 2 clip min. (HDR_PIPE1_CSCB_IO_MIN_2)

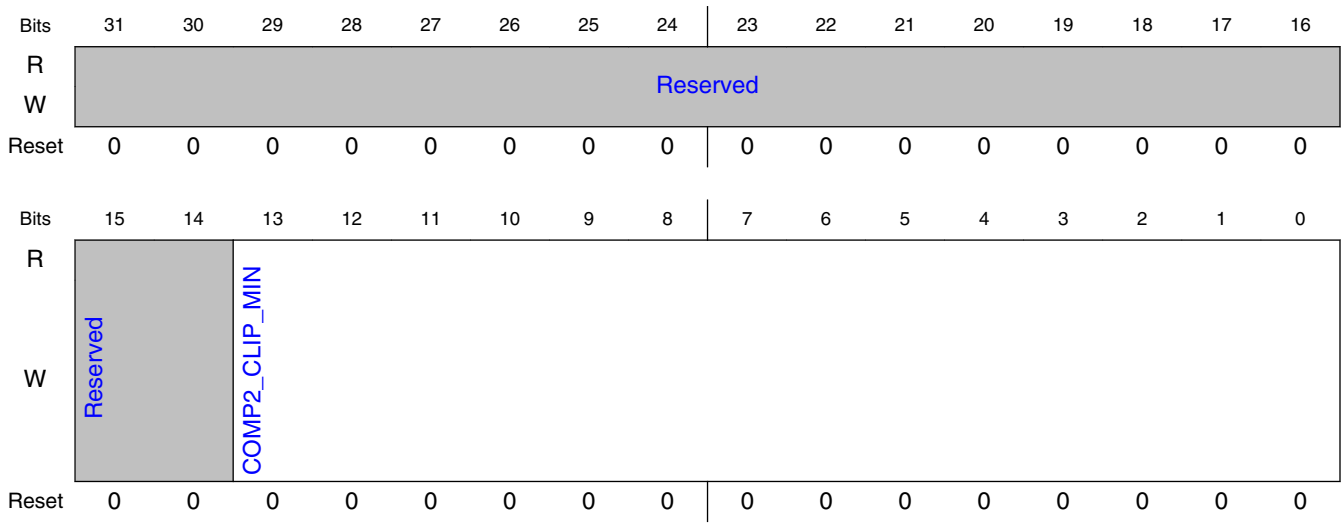
15.10.3.1.51.1 Offset

Register	Offset
HDR_PIPE1_CSCB_IO_MIN_2	383Ch

15.10.3.1.51.2 Function

After the pre-increment, The result is clipped. This 14-bit signed value is the minimum value of pixel component after the pre-increment. So the minimun range is [-8192 , 1891]. Pipe1 is also called channel1.

15.10.3.1.51.3 Diagram



15.10.3.1.51.4 Fields

Field	Function
31-14 —	Reserved.
13-0 COMP2_CLIP_MIN	This 10-bit signed value is the minimum value of pixel component after the pre-increment.

15.10.3.1.52 Pipe1 Colorspace Converter B (CSCB) component 0 clip max value. (HDR_PIPE1_CSCB_IO_MAX_0)

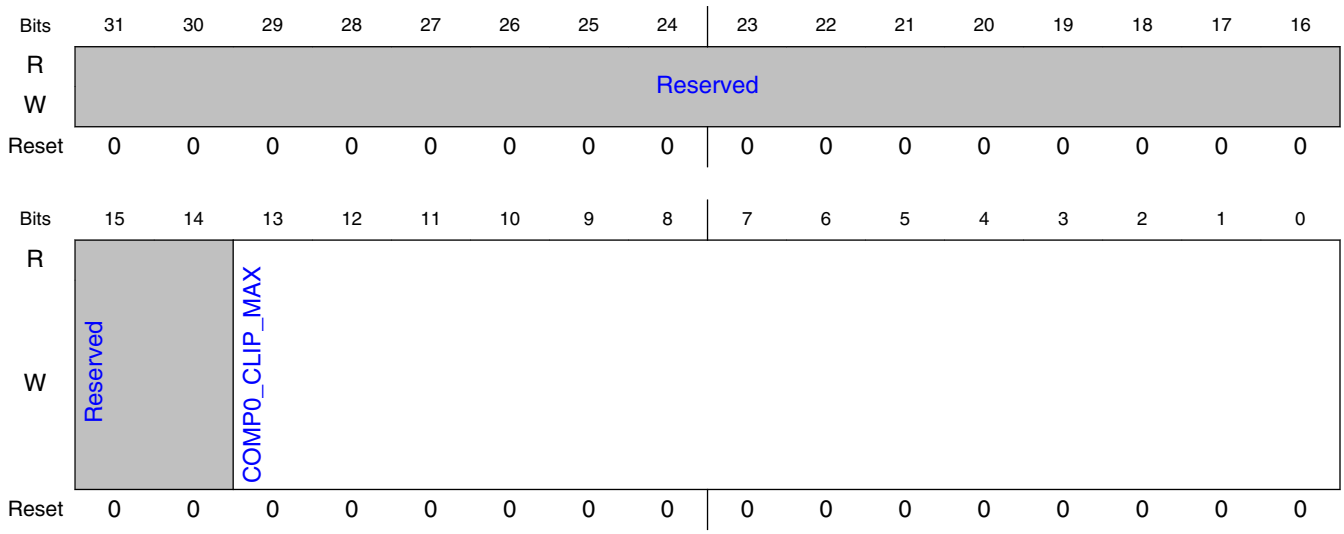
15.10.3.1.52.1 Offset

Register	Offset
HDR_PIPE1_CSCB_IO_MAX_0	3840h

15.10.3.1.52.2 Function

After the pre-increment, The result is clipped. This 14-bit unsigned value is the maximum value of pixel component after the pre-increment. So the maximum range is [0, 16383]. Pipe1 is also called channel1.

15.10.3.1.52.3 Diagram



15.10.3.1.52.4 Fields

Field	Function
31-14 —	Reserved.
13-0 COMP0_CLIP_MAX	This 14-bit unsigned value is the maximun value of pixel component after the pre-increment.

15.10.3.1.53 Pipe1 Colorspace Converter B (CSCB) component 1 clip max value. (HDR_PIPE1_CSCB_IO_MAX_1)

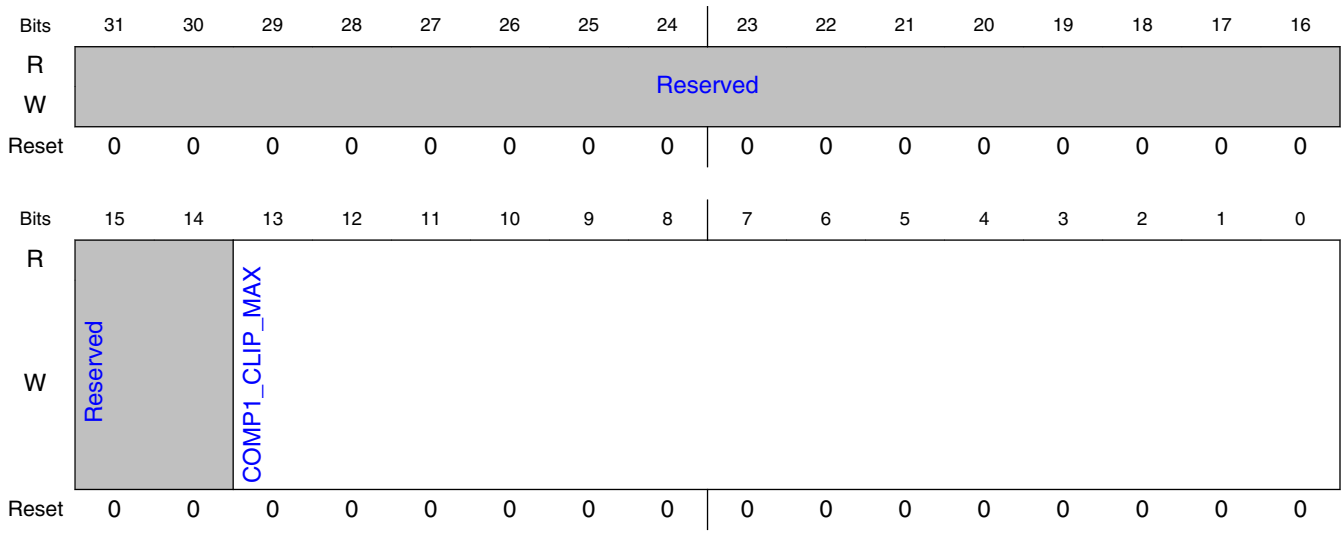
15.10.3.1.53.1 Offset

Register	Offset
HDR_PIPE1_CSCB_IO_MAX_1	3844h

15.10.3.1.53.2 Function

After the pre-increment, The result is clipped. This 14-bit unsigned value is the maximum value of pixel component after the pre-increment. So the maximum range is [0,16383]. Pipe1 is also called channel1.

15.10.3.1.53.3 Diagram



15.10.3.1.53.4 Fields

Field	Function
31-14 —	Reserved.
13-0 COMP1_CLIP_MAX	This 14-bit unsigned value is the maximun value of pixel component after the pre-increment.

15.10.3.1.70.1 Offset

Register	Offset
HDR_PIPE2_CSCA_CONTROL_REG	7000h

15.10.3.1.70.2 Function

Controls the Color-Space-Converter-A (CSCA) in pipe1. This CSCA takes in 10-bit pixel components (component 0, component 1, component 2). A per-component offset (called pre-offset) is added to the pixel. After the pre-offset operation the pixel components are clipped. MAX_RANGE of PRE_CLIP is [-512, 1023]. A 3x3 matrix multiply (constant coefficiens H(x,y)) is performed on the pixel to take to a different color space. After this matrix multiply, a 28 bit signed offset (post-offset) is added to the normalized result of

the matrix multiply. After the post-offset operation the results are clipped. MAX_RANGE of POST_CLIP is [0,1023] Output of this CSCA are 10 bit per component pixels. After CSCA the pixels are fed into a LUT. Pipe1 is also called channel1.

15.10.3.1.100.1 Offset

Register	Offset
HDR_PIPE2_LUT_CONTROL_REG	7080h

15.10.3.1.100.2 Function

Controls the Look-Up-Table in pipe1. Control of LUT is PER PIXEL not per component. LUT has 1024 14-bit, per component, entries. LUT maybe used for conversion from non-linear (gamma corrected) to linear pixels. LUT maybe used for conversion from linear to non linear pixels (gamma corrected). LUT can contain 14-bit fixed point or 14-bit floating point pixel value. Floating point format has 9 bit unsigned mantissa with hidden bit and 5 bit, unsigned, biased exponent. {exp[4:0], mantissa[8:0]} => 1.mantissa[8:0] * 2^(exp-1) When using floating piont numbers, in this LUT, these are used in HDR OUTPUT PIPE for HDR non-linear operation and must bypass Color Space Converter B (CSCB). Pipe1 is also called channel1.

15.10.3.1.101.1 Offset

Register	Offset
HDR_PIPE2_CSCB_CONTROL_REG	7800h

15.10.3.1.101.2 Function

Controls the Color-Space-Converter-B (CSCB) in pipe1. This CSCB takes in 14-bit pixel components (component 0, component 1, component 2). A per-component offset (called pre-offset) is added to the pixel. After the pre-offset operation the pixel components are clipped. MAX_RANGE of PRE_CLIP is [-512, 1023]. A 3x3 matrix multiply (constant coefficiens H(x,y)) is performed on the pixel to take to a different color space. After this matrix multiply, a 28 bit signed offset (post-offset) is added to the normalized result of the matrix multiply. After the post-offset operation the results are clipped. MAX_RANGE of POST_CLIP is [0,1023] Output of this CSCA are 28 bit per component pixels. After CSCB the pixels are fed into the Blender. Pipe1 is also called channel1.

15.10.3.1.135 Pipe1 Colorspace Converter A control. (HDR_PIPE3_CSCA_CONTROL_REG)

15.10.3.1.135.1 Offset

Register	Offset
HDR_PIPE3_CSCA_CONTROL_REG	B000h

15.10.3.1.135.2 Function

Controls the Color-Space-Converter-A (CSCA) in pipe1. This CSCA takes in 10-bit pixel components (component 0, component 1, component 2). A per-component offset (called pre-offset) is added to the pixel. After the pre-offset operation the pixel components are clipped. MAX_RANGE of PRE_CLIP is [-512, 1023]. A 3x3 matrix multiply (constant coefficiens H(x,y)) is performed on the pixel to take to a different color space. After this matrix multiply, a 28 bit signed offset (post-offset) is added to the normalized result of

the matrix multiply. After the post-offset operation the results are clipped. MAX_RANGE of POST_CLIP is [0,1023] Output of this CSCA are 10 bit per component pixels. After CSCA the pixels are fed into a LUT. Pipe1 is also called channel1.

15.10.3.1.165.1 Offset

Register	Offset
HDR_PIPE3_LUT_CONTROL_REG	B080h

15.10.3.1.165.2 Function

Controls the Look-Up-Table in pipe1. Control of LUT is PER PIXEL not per component. LUT has 1024 14-bit, per component, entries. LUT maybe used for conversion from non-linear (gamma corrected) to linear pixels. LUT maybe used for conversion from linear to non linear pixels (gamma corrected). LUT can contain 14-bit fixed point or 14-bit floating point pixel value. Floating point format has 9 bit unsigned mantissa with hidden bit and 5 bit, unsigned, biased exponent. {exp[4:0], mantissa[8:0]} => 1.mantissa[8:0] * 2^(exp-1) When using floating piont numbers, in this LUT, these are used in HDR OUTPUT PIPE for HDR non-linear operation and must bypass Color Space Converter B (CSCB). Pipe1 is also called channel1.

15.10.3.1.166.1 Offset

Register	Offset
HDR_PIPE3_CSCB_CONTROL_REG	B800h

15.10.3.1.166.2 Function

Controls the Color-Space-Converter-B (CSCB) in pipe1. This CSCB takes in 14-bit pixel components (component 0, component 1, component 2). A per-component offset (called pre-offset) is added to the pixel. After the pre-offset operation the pixel components are clipped. MAX_RANGE of PRE_CLIP is [-512, 1023]. A 3x3 matrix multiply (constant coefficiens H(x,y)) is performed on the pixel to take to a different color space. After this matrix multiply, a 28 bit signed offset (post-offset) is added to the normalized result of the matrix multiply. After the post-offset operation the results are clipped. MAX_RANGE of POST_CLIP is [0,1023] Output of this CSCA are 28 bit per component pixels. After CSCB the pixels are fed into the Blender. Pipe1 is also called channel1.

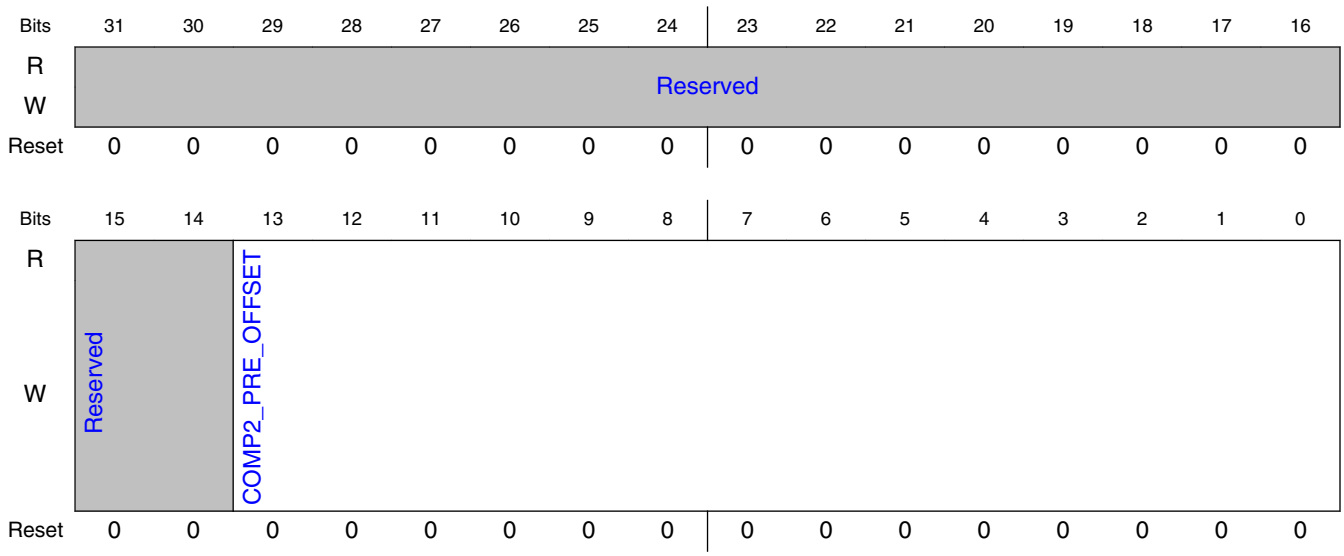
HDR_PIPE3_CSCB_IO_2	B830h

15.10.3.1.178.2 Function

A signed 14-bit offset is added to component 2 (B,Cr) before matrix multiply Pipe1 is also called channel1.

15.10.3.1.178.3 Diagram



15.10.3.1.178.4 Fields

Field	Function
31-14 —	Reserved.
13-0 COMP2_PRE_OFFSET	Before the color space conversion matrix multiply, This offset is added to component 2 of the pixel

15.10.3.1.179 Pipe1 Colorspace Converter B (CSCB) component 0 clip min. (HDR_PIPE3_CSCB_IO_MIN_0)

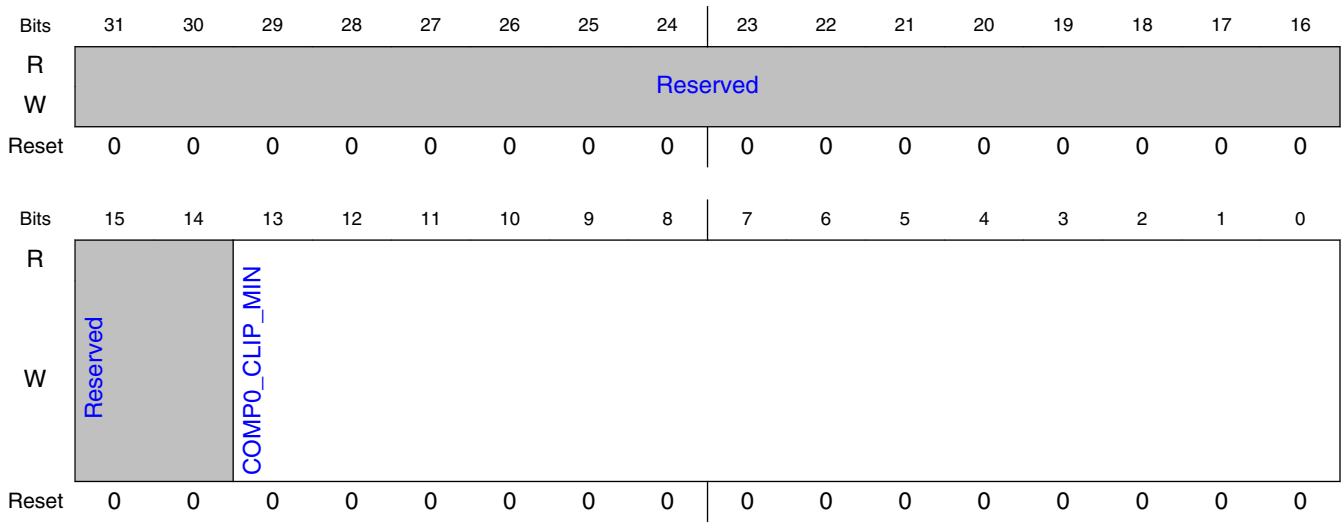
15.10.3.1.179.1 Offset

Register	Offset
HDR_PIPE3_CSCB_IO_MIN_0	B834h

15.10.3.1.179.2 Function

After the pre-increment, The result is clipped. This 14-bit signed value is the minimum value of pixel component after the pre-increment. So the minimun range is [-8192 , 8191]. Pipe1 is also called channel1.

15.10.3.1.179.3 Diagram



15.10.3.1.179.4 Fields

Field	Function
31-14 —	Reserved.
13-0 COMP0_CLIP_MIN	This 14-bit signed value is the minimum value of pixel component after the pre-increment.

15.10.3.1.180 Pipe1 Colorspace Converter B (CSCB) component 1 clip min. (HDR_PIPE3_CSCB_IO_MIN_1)

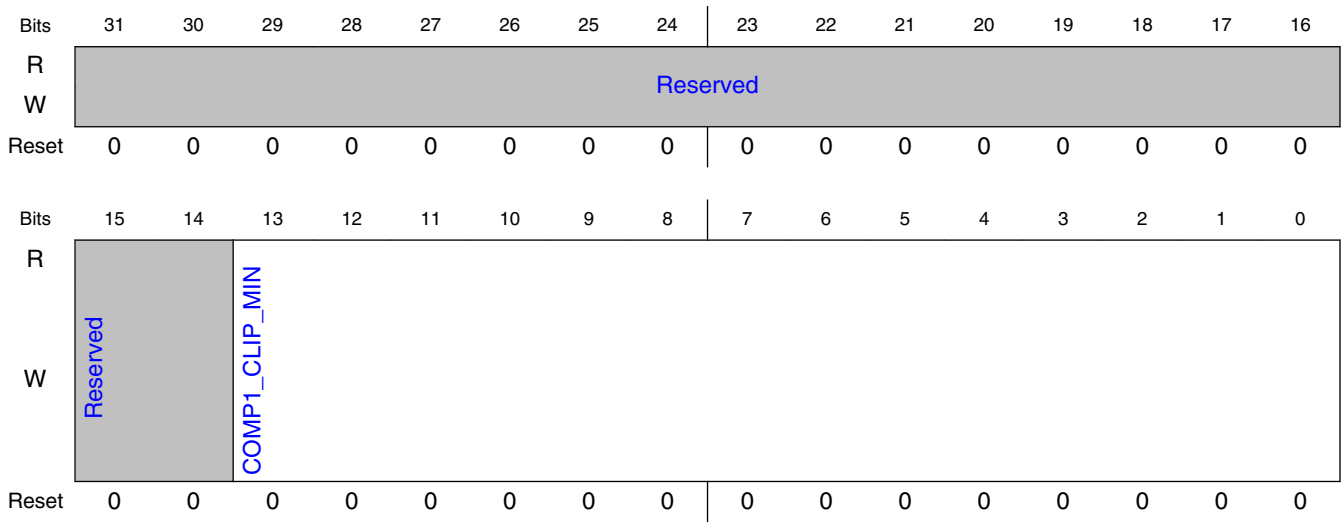
15.10.3.1.180.1 Offset

Register	Offset
HDR_PIPE3_CSCB_IO_MIN_1	B838h

15.10.3.1.180.2 Function

After the pre-increment, The result is clipped. This 14-bit signed value is the minimum value of pixel component after the pre-increment. So the minimun range is [-8192 , 8191]. Pipe1 is also called channel1.

15.10.3.1.180.3 Diagram



15.10.3.1.180.4 Fields

Field	Function
31-14 —	Reserved.
13-0 COMP1_CLIP_MIN	This 14-bit signed value is the minimum value of pixel component after the pre-increment.

15.10.3.1.181 Pipe1 Colorspace Converter B (CSCB) component 2 clip min. (HDR_PIPE3_CSCB_IO_MIN_2)

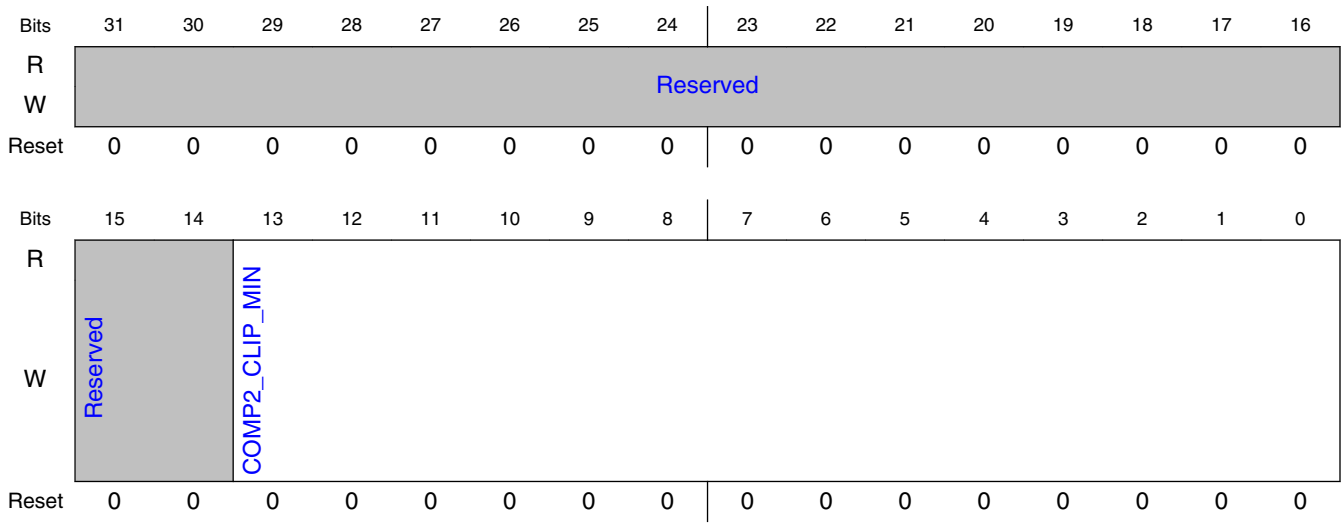
15.10.3.1.181.1 Offset

Register	Offset
HDR_PIPE3_CSCB_IO_MIN_2	B83Ch

15.10.3.1.181.2 Function

After the pre-increment, The result is clipped. This 14-bit signed value is the minimum value of pixel component after the pre-increment. So the minimun range is [-8192 , 1891]. Pipe1 is also called channel1.

15.10.3.1.181.3 Diagram



15.10.3.1.181.4 Fields

Field	Function
31-14 —	Reserved.
13-0 COMP2_CLIP_MIN	This 10-bit signed value is the minimum value of pixel component after the pre-increment.

15.10.3.1.182 Pipe1 Colorspace Converter B (CSCB) component 0 clip max value. (HDR_PIPE3_CSCB_IO_MAX_0)

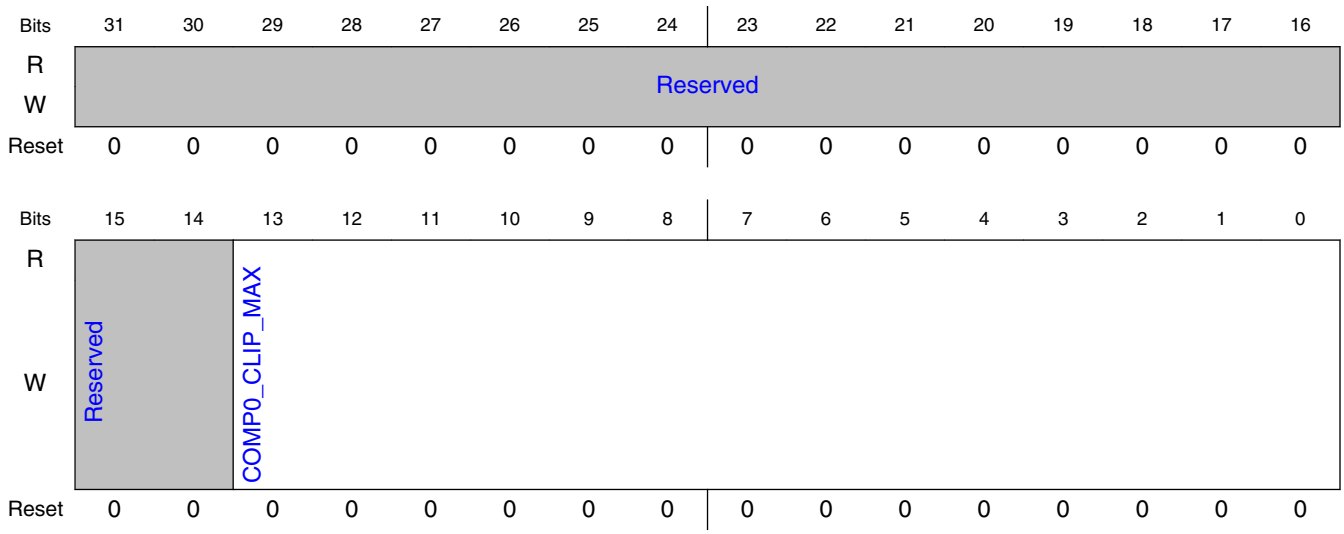
15.10.3.1.182.1 Offset

Register	Offset
HDR_PIPE3_CSCB_IO_MAX_0	B840h

15.10.3.1.182.2 Function

After the pre-increment, The result is clipped. This 14-bit unsigned value is the maximum value of pixel component after the pre-increment. So the maximum range is [0, 16383]. Pipe1 is also called channel1.

15.10.3.1.182.3 Diagram



15.10.3.1.182.4 Fields

Field	Function
31-14 —	Reserved.
13-0 COMP0_CLIP_MAX	This 14-bit unsigned value is the maximun value of pixel component after the pre-increment.

15.10.3.1.183 Pipe1 Colorspace Converter B (CSCB) component 1 clip max value. (HDR_PIPE3_CSCB_IO_MAX_1)

15.10.3.1.183.1 Offset

Register	Offset
HDR_PIPE3_CSCB_IO_MAX_1	B844h

15.10.3.1.183.2 Function

After the pre-increment, The result is clipped. This 14-bit unsigned value is the maximum value of pixel component after the pre-increment. So the maximum range is [0,16383]. Pipe1 is also called channel1.

15.10.3.1.183.3 Diagram

15.10.3.1.200 HDR output stage Colorspace Converter (CSCO) control. (HDR_OPIPE_CSC_CONTROL_REG)

15.10.3.1.200.1 Offset

Register	Offset
HDR_OPIPE_CSC_CONTROL_REG	F000h

15.10.3.1.200.2 Function

Controls the Color-Space-Converter (CSC) in HDR output stage. This CSCO takes in 10-bit pixel components (component 0, component 1, component 2). A per-component offset (called pre-offset) is added to the pixel. After the pre-offset operation the pixel components are clipped. MAX_RANGE of PRE_CLIP is [-512, 1023]. A 3x3 matrix multiply (constant coefficiens H(x,y)) is performed on the pixel to take to a different color space. After this matrix multiply, a 28 bit signed offset (post-offset) is added to the normalized result of the matrix multiply. After the post-offset operation the results are clipped. MAX_RANGE of POST_CLIP is [0,1023] Output of this CSCO are 10 bit per component pixels. After CSCO the pixels are fed to the Chroma Subsampler.

Field	Function
31-10 —	Reserved.
9-0 COMP1_CLIP_MIN	This 10-bit signed value is the minimum value of pixel component after the pre-increment.

15.10.3.1.215 HDR OUPTU pipe Colorspace Converter (CSCO) component 2 clip min. (HDR_OPIPE_CSC_MIN_2)

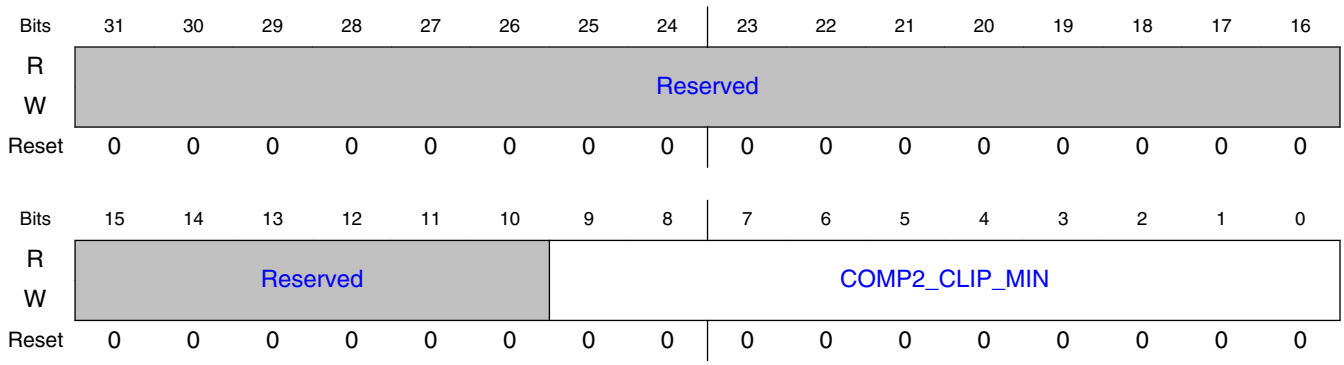
15.10.3.1.215.1 Offset

Register	Offset
HDR_OPIPE_CSC_MIN_2	F03Ch

15.10.3.1.215.2 Function

After the pre-increment, The result is clipped. This 10-bit signed value is the minimum value of pixel component after the pre-increment. So the minimun range is [-512,511].

15.10.3.1.215.3 Diagram



15.10.3.1.215.4 Fields

Field	Function
31-10 —	Reserved.
9-0 COMP2_CLIP_MIN	This 10-bit signed value is the minimum value of pixel component after the pre-increment.

15.10.3.1.216 HDR OUPTUT pipe Colorspace Converter O (CSC) component 0 clip max value. (HDR_OPIPE_CSC_MAX_0)

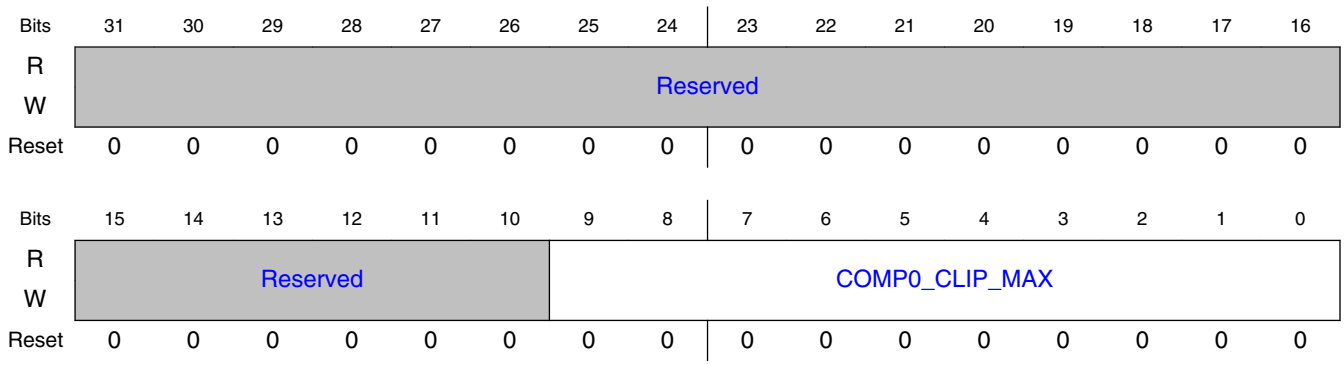
15.10.3.1.216.1 Offset

Register	Offset
HDR_OPIPE_CSC_MAX_0	F040h

15.10.3.1.216.2 Function

After the pre-increment, The result is clipped. This 10-bit unsigned value is the maximum value of pixel component after the pre-increment. So the maximum range is [0,1023].

15.10.3.1.216.3 Diagram



15.10.3.1.216.4 Fields

Field	Function
31-10 —	Reserved.
9-0 COMP0_CLIP_MAX	This 10-bit unsigned value is the maximun value of pixel component after the pre-increment.

15.10.3.1.217 HDR OUTPUT pipe Colorspace Converter (CSCO) component 1 clip max value. (HDR_OPIPE_CSC_MAX_1)

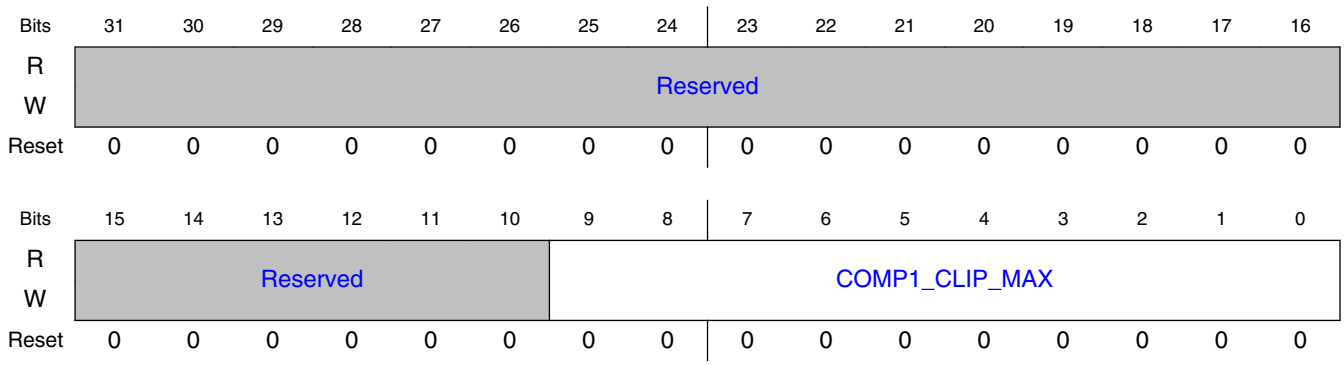
15.10.3.1.217.1 Offset

Register	Offset
HDR_OPIPE_CSC_MAX_1	F044h

15.10.3.1.217.2 Function

After the pre-increment, The result is clipped. This 10-bit unsigned value is the maximum value of pixel component after the pre-increment. So the maximum range is [0,1023].

15.10.3.1.217.3 Diagram



15.10.3.1.217.4 Fields

Field	Function
31-10 —	Reserved.
9-0 COMP1_CLIP_MAX	This 10-bit unsigned value is the maximun value of pixel component after the pre-increment.

15.10.3.1.218 HDR OUTPUT pipe Colorspace Converter (CSCO) component 2 clip max value. (HDR_OPIPE_CSC_MAX_2)

15.10.3.1.218.1 Offset

Register	Offset
HDR_OPIPE_CSC_MAX_2	F048h

15.10.3.1.218.2 Function

After the pre-increment, The result is clipped. This 10-bit unsigned value is the maximum value of pixel component after the pre-increment. So the maximum range is [0,1023].

15.11 Color Sub-Sampler (SUBSAM)

15.11.1 Overview

The Color Sub-Sampler, or SUBSAM, is used to reduce the resolution of chroma samples for display that require YCbCr422/420 formats. Based on the HDMI2.0 specification, YCbCr420 is required for 4K displays at a 60Hz rate. There are three primary modes of operation: YCbCr444, the SUBSAM is in bypass. YCbCr422 conversions, a 3-tap horizontal linear filter is applied to the incoming pixel stream. YCbCr420, a 3x3 tap filter is used for sub-sampling. One Y line buffer and two of each Cb and Cr line buffers are used to facilitate the vertical scaling function. The chroma line buffers store the horizontally scaled result.

15.11.1.1 Block Diagram

The following diagram gives a high-level overview of the configuration of the SUBSAM.

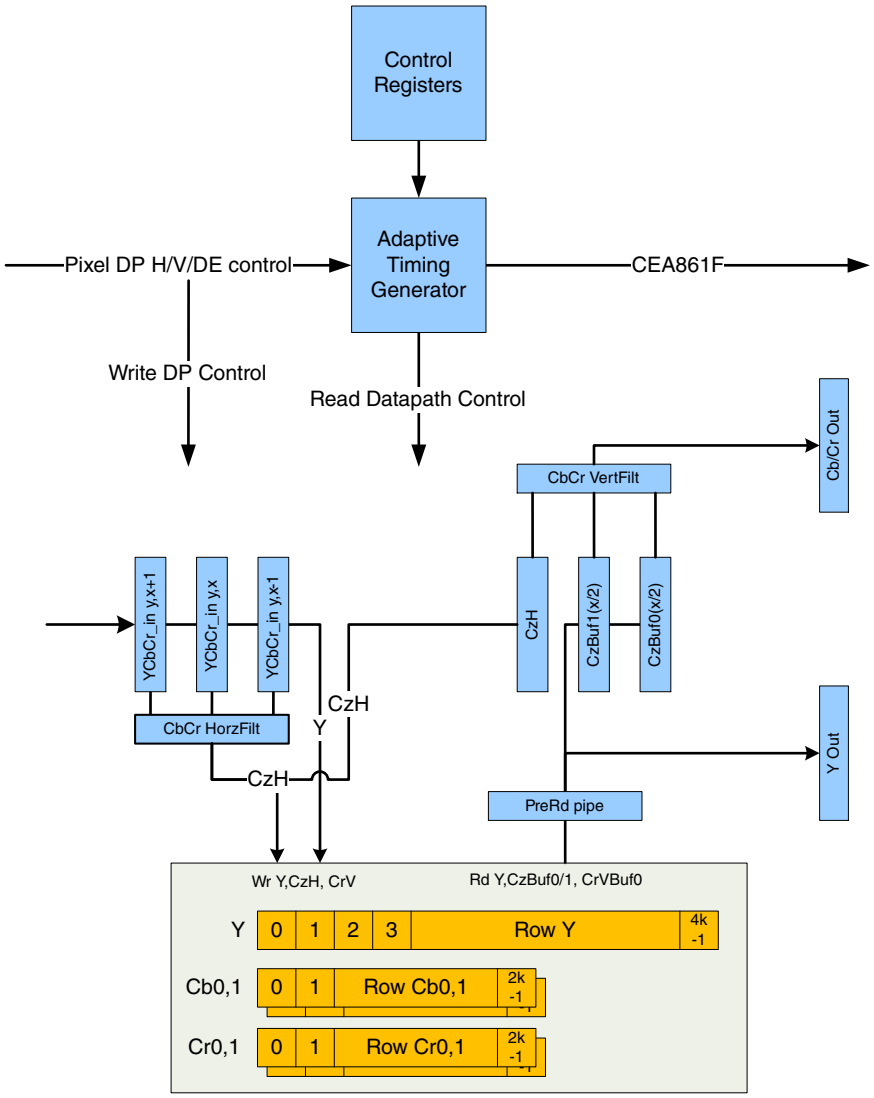

Figure 15-23. Color Subsampler Block Diagram

15.11.1.2 Features

From the block diagram above, the operands for the horizontal chroma subsampler, or CzH, are stored in shift registers. These registers are CbCr_in[x+1,x,x-1]. The results of the CzH are used to feed the vertical 3 tap filter and stored in line memories for subsequent vertical scaling. Line storage is used to store horizontally scaled chroma values and to store luma components. These components are sourced with one line of delay to feed the vertical scaling function. Luma values are stored unscaled, since luma is not subsampled.

These memories are single ported. The design pipelines the write and read data so that the same location is not accessed on the same clock. The preread function reads data out of the row rams so that reads lead locations that are written. Only 420 subsample mode uses

the memories due to the vertical scale requirement. 422 does not use the memories and the CzH is fed directly out of the subsample module aligned with the respective Y components.

15.11.2 Functional description

15.11.2.1 Sub-Sample Adaptive Timing Generator

The adaptive timing generator (ATG) uses the timing of the pixel data path signals to generate the timing of the CEA861F timing that is output to the HDMI controller. The timing is regenerated in the SUBSAM module, and the timing is completely programmable. Only the input pixdp_vsync is used to initiate the timing sequence at the SUBSAM output. When pixdp_vsync goes active (low to high transition), the SUBSAM resets its own H/V counters (h_count and v_count). The SUBSAM timing generator then walks across the entire display based on the programmable timing parameters defined in the SUBSAM PIO registers. It is expected the SUBSAM ATG timing parameters are consistent with the DTG timing parameters. As an example, the same LRC_X and LRC_Y values are programmed so that the display cycle time generated in the DTG is equivalent to the timing in the SUBSAM.

The display control is sequenced using the h_count/v_count counters. h_count is incremented on every clock, and is reset when it is equal to CSR_SS_DISPLAY.LRC_X. v_count is incremented, or reset, on the clock when h_count is reset to zero. The h_count value and respective comparators walks the display from left to right. The v_count value and vertical comparators walks the display timing from top to bottom. When the lower right corner (LRC) is reach, the timing generator resets back to the upper left corner (ULC) and begins to refresh the display again. This cycle continues indefinitely until the SUBSAM is disabled.

15.11.2.2 ATG Timing Details

Out of reset, the ATG timing sequence begins after receiving an initial positive edge of pixdp_vsync. This initial positive edge indicates the DTG is entering the vertical front porch. In order to synchronize the ATG HDMI output timing with the DTG pixel data path input timing, the ATG must also begin timing to enter the vertical front porch. This concept can be illustrated in the image below, and the timing begins when pixdp_vsync (also named dolby_vsync_n) transitions from low to high. Note the timing of pixdp_vsync is not the same as hdmi_vsync.

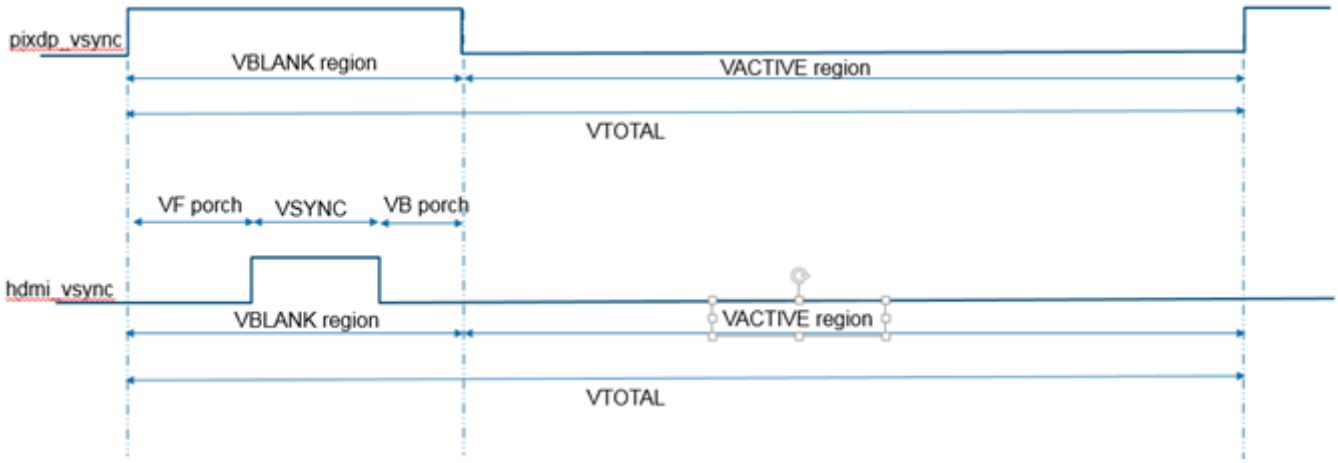

Figure 15-24. Initial VSYNC Timing

The following image illustrates the addition of pixdp_hsync and hdmi_de timing. Note the HDMI DE timing is based on the pixdp_hsync timing. This is based on how the pixel data path defines the timing of HSYNC and DE, which is not standard, and different then HDMI CEA861 timing standard.

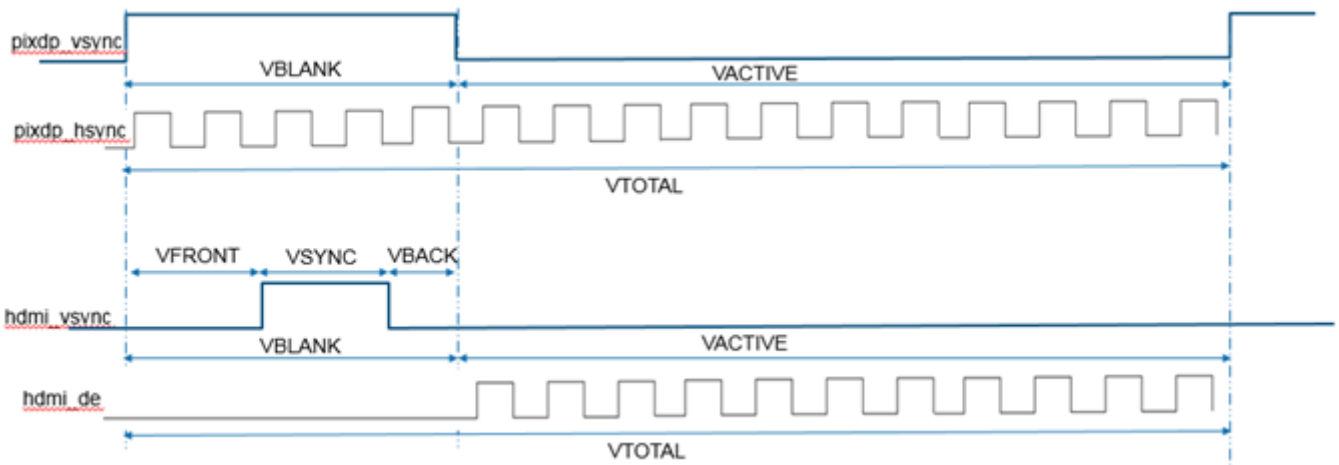

Figure 15-25. Initial VSYNC Timing with HSYNC and DE

The following provides an equivalence between standard HDMI timing and the ATG programming model. A waveform representation of CEA-861F timing is provided to illustrate which waveform sections correspond to which programming parameters. Typical HDMI timing parameters can be extracted from the following image:

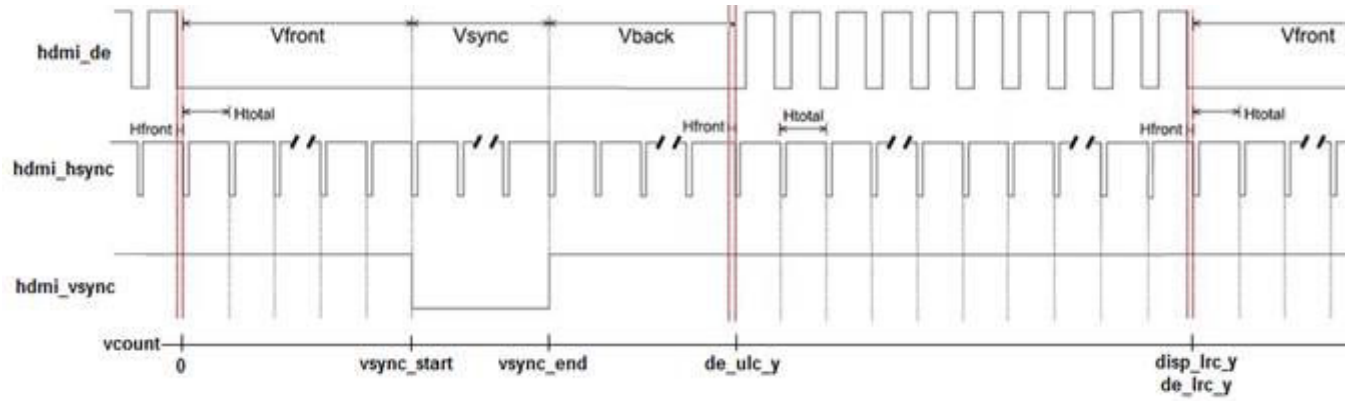

Figure 15-26. Typical HDMI Timing Parameters

- VFront = vsync_start + 1 (duration of VFront porch)
- VSync = vsync_end - vsync_start
- VBack = de_ulc_y - 1 - vsync_end
- VActive = disp_lrc_y - de_ulc_y - 1
- VTotal = disp_lrc_y + 1 = de_lrc_y + 1
- disp_lrc_y = de_lrc_y

In addition to the vertical programming guidelines shown in the image above, a set of horizontal programming guidelines should also be followed.

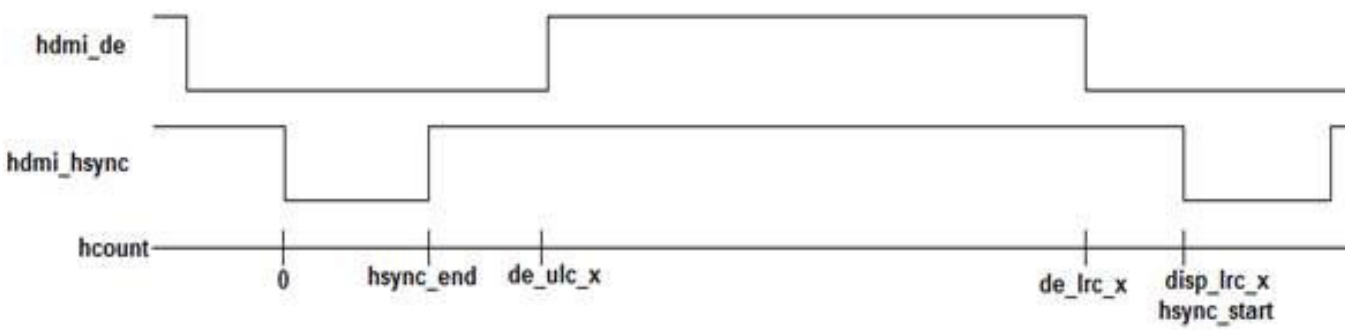

Figure 15-27. Typical HDMI horizontal timing parameters

Typical HDMI timing parameters can be extracted from the horizontal image above:

- HSync = hsync_end + 1
- HBack = de_ulc_x - hsync_end
- HActive = de_lrc_x - de_ulc_x
- HFront = disp_lrc_x - de_lrc_x
- HTotal = disp_lrc_x + 1 = hsync_start + 1
- disp_lrc_x = hsync_start

A table represetation of the programming example above is provided here:

Table 15-8. Subsampler Timing Registers

Subsampler Register	Register Setting
SS_DISPLAY[LRC_X]	Htotal - 1
SS_DISPLAY[LRC_Y]	Vtotal - 1
SS_HSYNC[START]	SS_DISPLAY[LRC_X]
SS_HSYNC[END]	Hsync - 1
SS_VSYNC[START]	Vfront - 1
SS_VSYNC[END]	Vsync + SS_VSYNC[START]
SS_DE_ULC[ULC_X]	Hback + SS_HSYNC[END]
SS_DE_ULC[ULC_Y]	Vback + SS_VSYNC[END] + 1
SS_DE_LRC[LRC_X]	Hactive + SS_DE_ULC[ULC_X]
SS_DE_LRC[LRC_Y]	SS_DISPLAY[LRC_Y]

15.11.2.3 SUBSAM Programming Example

The table below indicates the timing parameters for the Video Information Code (97, 107) defined for a progressive 4K TV at 60Hz.

Table 15-9. Video Information Code (97,107)

Hactive	Vactive	Htotal	Hblank	Vtotal	Vblank
3840	2160	4400	560	2250	90
Hfront	Hsync	Hback	Vfront	Vsync	Vback
176	88	296	8	10	72

The following programming example illustrates the practical use of the programming parameters derived in the ATG Timing Details section above. The SUBSAM parameters for this display format are:

- SS_DISPLAY[LRC_X] = Htotal - 1 = 4400 - 1 = 4399
- SS_DISPLAY[LRC_Y] = Vtotal - 1 = 2250 - 1 = 2249
- SS_HSYNC[START] = SS_DISPLAY[LRC_X] = 4399
- SS_HSYNC[END] = Hsync - 1 = 88 - 1 = 87
- SS_DE_ULC[ULC_X] = Hback + SS_HSYNC[END] = 296 + 87 = 383
- SS_DE_LRC[LRC_X] = Hactive + SS_DE_ULC[ULC_X] = 3840 + 383 = 4223
- SS_VSYNC[START] = Vfront - 1 = 8 - 1 = 7
- SS_VSYNC[END] = Vsync + SS_VSYNC[START] = 10 + 7 = 17
- SS_DE_ULC[ULC_Y] = Vback + SS_VSYNC[END] + 1 = 72 + 17 + 1 = 90
- SS_DE_LRC[LRC_Y] = SS_DISPLAY[LRC_Y] = 2249

Note that this example works for all subsampling modes (444, 422, and 420). To select between modes, the register field SS_MODE[PIPE_MODE] should be programmed. Each mode requires a different amount of processing latency. This latency is abstracted from the programming model and is accounted for in hardware based on the selection of SS_MODE[PIPE_MODE].

15.11.2.4 Sub-Sample Frame Sequence

The following table indicates the sequence of 420 subsampling over the first 6 lines of output. There is a nested looping structure iterating over Y and X pixel positions. The inner loop is iterating over the possible X values of the display.

The table represents what is done on each pixel clock cycle. Basically, x=0,1,…4K-1, then x resets to zero and the line increments. The first 7 lines of input processing is display, not the entire display of course. For 420, the Y loop repeats every two lines. The sequence reads as follows:

First horizontal iteration:

1. Pixel 0,0 is received, x=0
2. Hflit, CzH = H((x-1,x,x_1), or H(-1,0,1) on the first line. Both CbH and CrH are computed.
3. Vflit, ignored, since there is no vertical scaling when the first scan line is received.
4. No output, there is no output when the first input line is received, as we don’t have enough chroma data for the vertical filtering operation.
5. Store the Luma value in Ybuf(0) at address 0.
6. Store the CbH value in CbBuff[0](0)
7. No storage to CbBuf[1]
8. Store CrBuf[0](0)
9. No storage to CrBuff[1]

Second horizontal iteration. Note for entires where x/2 are not integers, then the operation is not performed.

1. At this point, x in incremented to 1 and the operation in the rist row repeat. The pixel position is now (1,0). Note all operations from 1-9 occur in the same clock cycle in a pipelined fashion in HW.
2. Hfilt is ignored, since x is odd, and the horizontal filter is valid only when x is even.
3. Again, ignored for the first input line.
4. ….

This loop continues until we reach the end of the scan line. This is determined when the logical DE goes low. The logical DE is a logic combination of Vsync, Hsync, and DE inputs from the pixel data path. Logical DE is active as follows:

- logical_de = ~pixdp_vsync && pixdp_hsync && pixdp_de

When all of the pixel are processed in the horizontal direction, processing increments to the next line, or all possible values of x for (x,1) for line 1.

Input Pixel YCbCr444(x,y) x = 0,1,… 3839	Hfilt (CzH) z = {b,r} x = even	Vfilt (CzV) z = {b,r}	Output Pixel 420	Ybuf(x)	CbBuf(0) (x/2)	CbBuf(1) (x/2)	CrBuf(0) (x/2)	CrBuf(1) (x/2)
1	2	3	4	5	6	7	8	9
(x,0)	CzH(x,0) = H(Cz(x-1, 0), Cz(x, 0), Cz(x +1,0))		none	Yin(x,0)	CbH(x,0)		CrH(x,0)	
(x,1)	CzH(x,1) = H(Cz(x-1, 1), Cz(x, 1), Cz(x +1,1))	CzV = V(bg_z, CzBuf(0) (x/2), CzH(x,1))	Ybuf(x), CbV	Yin(x,1)		CbH(x,1)	CrV(x,0)	CrH(x,1)
(x,2)	CzH(x,2) = H(Cz(x-1, 2), Cz(x, 2), Cz(x +1,2))	none	Ybuf(x), CrBuf(0) (x/2)	Yin(x,2)	CbH(x,2)		CrH(x,2)	
(x,3)	CzH(x,3) = H(Cz(x-1, 3),	CzV = V(CzBuf(1)(x/2), CzBuf(0)	Ybuf(x), CbV	Yin(x,3)		CbH(x,3)	CrV(x,2)	CrH(x,3)

Table continues on the next page...

Input Pixel YCbCr444(x,y) x = 0,1,… 3839	Hfilt (CzH) z = {b,r} x = even	Vfilt (CzV) z = {b,r}	Output Pixel 420	Ybuf(x)	CbBuf(0) (x/2)	CbBuf(1) (x/2)	CrBuf(0) (x/2)	CrBuf(1) (x/2)
	Cz(x, 3), Cz(x +1,3))	(x/2), CzH(x,3))						
(x,4)	CzH(x,4) = H(Cz(x-1, 4), Cz(x, 4), Cz(x +1,4))	none	Ybuf(x), CrBuf(0) (x/2)	Yin(x,4)	CbH(x,4)		CrH(x,4)	
(x,5)	CzH(x,5) = H(Cz(x-1, 5), Cz(x, 5), Cz(x +1,5))	CzV = V(CzBuf(1)(x/2), CzBuf(0) (x/2), CzH(x,5))	Ybuf(x), CbV	Yin(x,5)		CbH(x,5)	CrV(x,4)	CrH(x,5)
(x,6)	CzH(x,6) = H(Cz(x-1, 6), Cz(x, 6), Cz(x +1,6))	none	Ybuf(x), CrBuf(0) (x/2)	Yin(x,6)	CbH(x,6)		CrH(x,6)	

15.11.2.5 Sub-Sample Filter

For 422 conversions, the memory is bypassed, since the scaled result is a horizontal linear filter. Line storage is not needed in this case. For 420, line memory is needed to perform the 3 tap vertical filter.

The conversion for 422 is as follows:

```
        Cx = ( Hcoef0*Cx(x-1) + Hcoef1*Cx(x) + Hcoef2*Cx(x+1) + RoundX ) / NormX  // Where
Cx = Cb|Cr
```

Note: Output chroma values are computed at pixel positions where x is even. So, 0, 2, 4, etc are positions where pixel values are generated and output to the pixel data path.

The conversion for 420 is as follows:

```
      Cz = (
             Vcoef0 * (Hcoef0*Cz(x-1)(y-1) + Hcoef1*Cz(x)(y-1) + Hcoef2*Cz(x+1)(y-1) ) +
             Vcoef1 * (Hcoef0*Cz(x-1)(y) + Hcoef1*Cz(x)(y) + Hcoef2*Cz(x+1)(y) )       +
             Vcoef2 * (Hcoef0*Cz(x-1)(y+1) + Hcoef1*Cz(x)(y+1) + Hcoef2*Cz(x+1)(y+1) ) +
             RoundY
           ) / NormY
```

Note: x,y => can only take even values in the calculation.

There is also a programmable clipping function applied in the sub_sample module. The final Cz output value is:

```
         Cz_out = clip(Cz, minCzvalue, maxCzvalue)
```

The filter equations above use variable substitutions above for readability. To equate the variables to register settings, the following conversions should be used:

Hcoef0 = SS_COEFF[HORIZ_C]

Hcoef1 = SS_COEFF[HORIZ_B]

Hcoef2 = SS_COEFF[HORIZ_A]

If (SS_COEFF[HORIZ_NORM] = 0) RoundX = 0; NormX = 1;

else if (SS_COEFF[HORIZ_NORM] < 5) RoundX = 2^(NORM); NormX = 2^(NORM +1);

else RoundX = 2^(5); NormX = 2^(5+1);

Vcoef0 = SS_COEFF[VERT_C]

Vcoef1 = SS_COEFF[VERT_B]

Vcoef2 = SS_COEFF[VERT_A]

If (SS_COEFF[VERT_NORM] = 0) RoundY = 0; NormY = 1;

else if (SS_COEFF[VERT_NORM] < 5) RoundY = 2^(SS_COEFF[VERT_NORM]); NormY = 2^(SS_COEFF[VERT_NORM]+1);

else RoundY = 2^(5); NormY = 2^(5+1);

Register	Offset
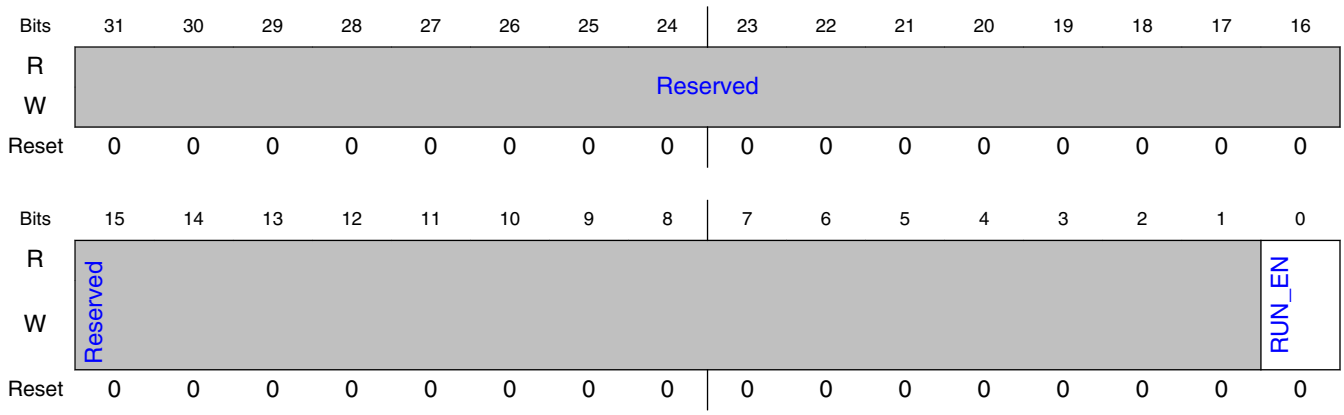
SS_SYS_CTRL_SET	4h

15.11.3.1.3.2 Function

The ss_sys_ctrl register contains all top level system control fields.

15.11.3.1.3.3 Diagram



15.11.3.1.3.4 Fields

Field	Function
31-1 —	Reserved
0 RUN_EN	Software sets this bit to indicate when the subsam module is ready to be enabled. Setting this bit from 1 to 0 causes a software reset.

15.11.3.1.4 (SS_SYS_CTRL_CLR)

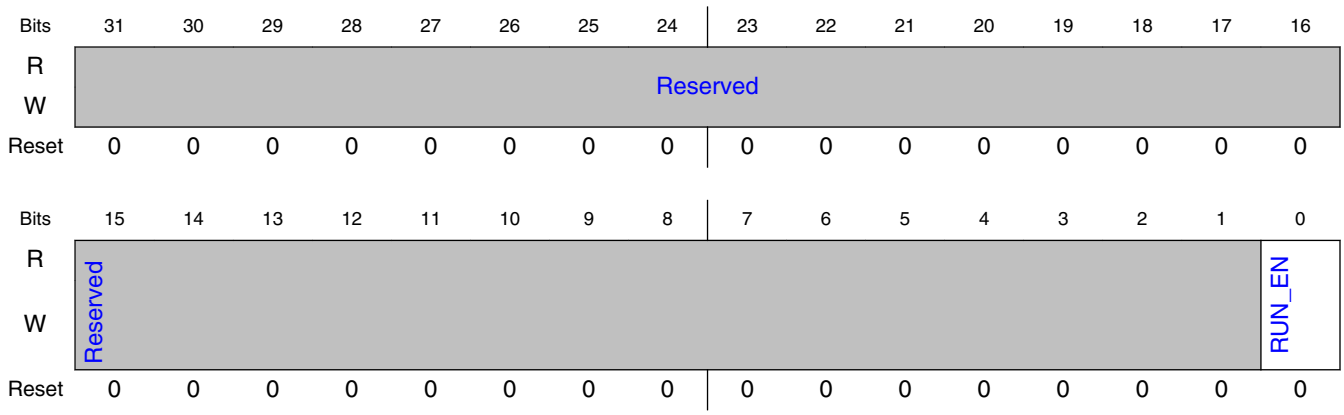
15.11.3.1.4.1 Offset

Register	Offset
SS_SYS_CTRL_CLR	8h

15.11.3.1.4.2 Function

The ss_sys_ctrl register contains all top level system control fields.

15.11.3.1.4.3 Diagram



15.11.3.1.4.4 Fields

Field	Function
31-1 —	Reserved
0 RUN_EN	Software sets this bit to indicate when the subsam module is ready to be enabled. Setting this bit from 1 to 0 causes a software reset.

15.11.3.1.5 (SS_SYS_CTRL_TOG)

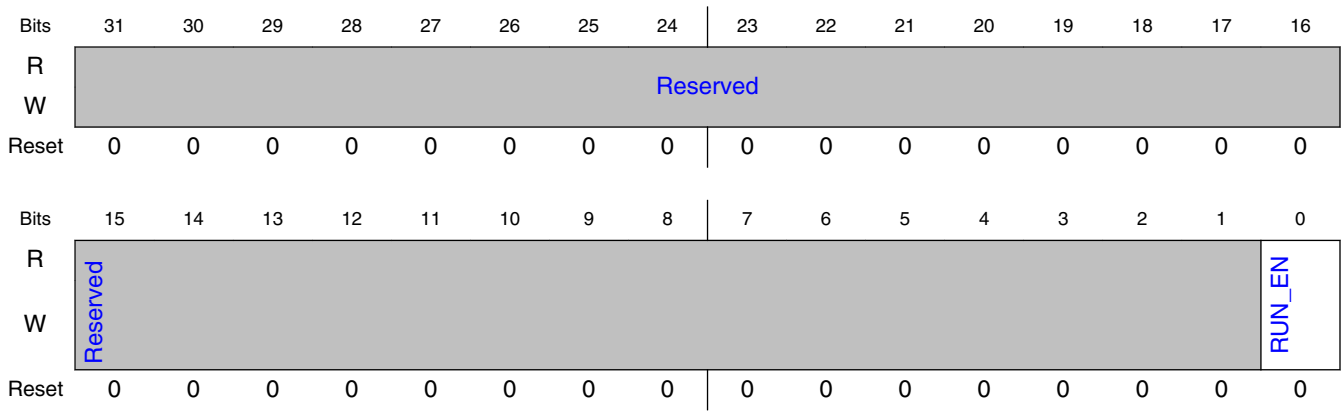
15.11.3.1.5.1 Offset

Register	Offset
SS_SYS_CTRL_TOG	Ch

15.11.3.1.5.2 Function

The ss_sys_ctrl register contains all top level system control fields.

15.11.3.1.5.3 Diagram



15.11.3.1.5.4 Fields

Field	Function
31-1 —	Reserved
0 RUN_EN	Software sets this bit to indicate when the subsam module is ready to be enabled. Setting this bit from 1 to 0 causes a software reset.

15.11.3.1.6 (SS_DISPLAY)

15.11.3.1.6.1 Offset

Register	Offset
SS_DISPLAY	10h

15.11.3.1.6.2 Function

```
The csr_ss_display register defines the entire size of the display timing window.
  SS_DISPLAY_LRX_Y = VACTIVE+VBLANK-1
  SS_DISPLAY_LRC_X = HACTIVE+HBLANK-1
```

15.11.3.1.6.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved			LRC_Y												
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved			LRC_X												
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

15.11.3.1.6.4 Fields

Field	Function
31-29 —	Reserved
28-16 LRC_Y	Holds the lower right corner y coordinate. The vertical count reg should conditionally reset to zero when it reaches this value and v_count = DTG_LRC_Y
15-13 —	Reserved
12-0 LRC_X	Holds the lower right corner x coordinate. The horizontal count reg should reset to zero when it reaches this value.

15.11.3.1.7 (SS_DISPLAY_SET)

15.11.3.1.7.1 Offset

Register	Offset
SS_DISPLAY_SET	14h

15.11.3.1.7.2 Function

```
The csr_ss_display register defines the entire size of the display timing window.
  SS_DISPLAY_LRX_Y = VACTIVE+VBLANK-1
  SS_DISPLAY_LRC_X = HACTIVE+HBLANK-1
```

15.11.3.1.7.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15.11.3.1.9.4 Fields

Field	Function
31-29 —	Reserved
28-16 LRC_Y	Holds the lower right corner y coordinate. The vertical count reg should conditionally reset to zero when it reaches this value and v_count = DTG_LRC_Y
15-13 —	Reserved
12-0 LRC_X	Holds the lower right corner x coordinate. The horizontal count reg should reset to zero when it reaches this value.

15.11.3.1.10 (SS_HSYNC)

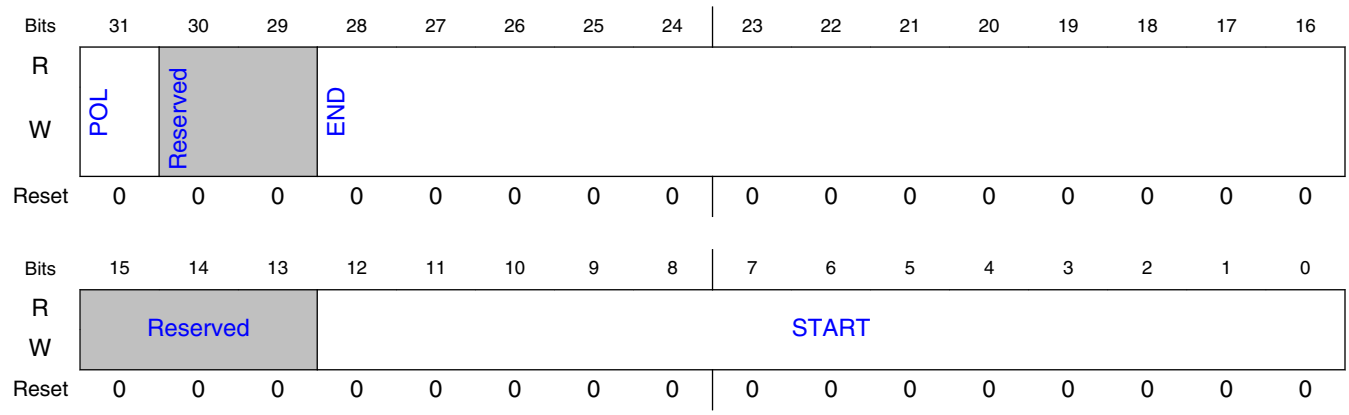
15.11.3.1.10.1 Offset

Register	Offset
SS_HSYNC	20h

15.11.3.1.10.2 Function

Defines when horizontal sync signal goes high/low.
There are two X coordinates defined in this register.
Horizontal sync width determined by END - START.

15.11.3.1.10.3 Diagram



15.11.3.1.10.4 Fields

Field	Function
31 POL	Polarity of sync signal. 0 == active low ; 1 == active_high
30-29 —	Reserved
28-16 END	horizontal sync is de-asserted when horizontal count == END
15-13 —	Reserved
12-0 START	horizontal sync is asserted when horizontal count == START

15.11.3.1.11 (SS_HSYNC_SET)

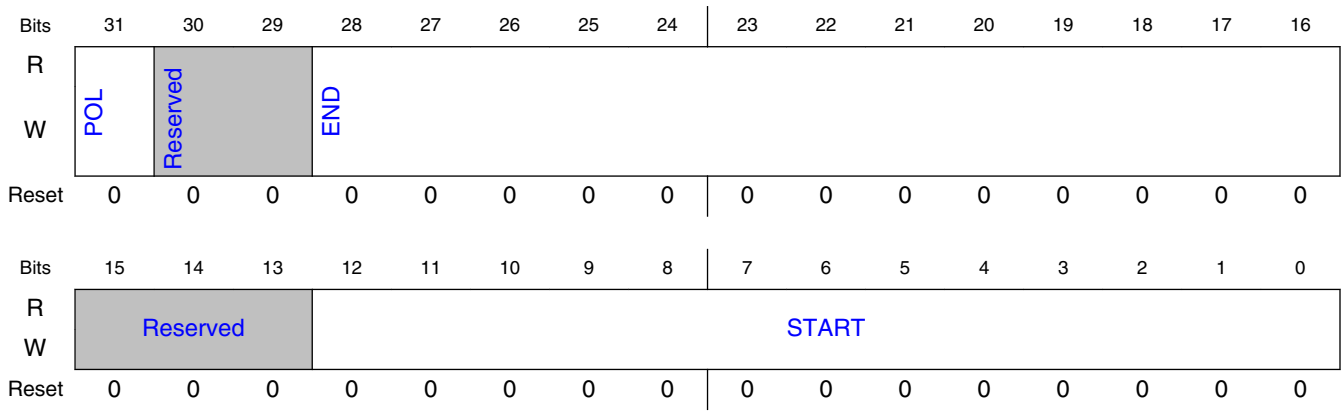
15.11.3.1.11.1 Offset

Register	Offset
SS_HSYNC_SET	24h

15.11.3.1.11.2 Function

```
Defines when horizontal sync signal goes high/low.
There are two X coordinates defined in this register.
Horizontal sync width determined by END - START.
```

15.11.3.1.11.3 Diagram



15.11.3.1.11.4 Fields

Field	Function
31 POL	Polarity of sync signal. 0 == active low ; 1 == active_high
30-29 —	Reserved
28-16 END	horizontal sync is de-asserted when horizontal count == END
15-13 —	Reserved
12-0 START	horizontal sync is asserted when horizontal count == START

15.11.3.1.12 (SS_HSYNC_CLR)

15.11.3.1.12.1 Offset

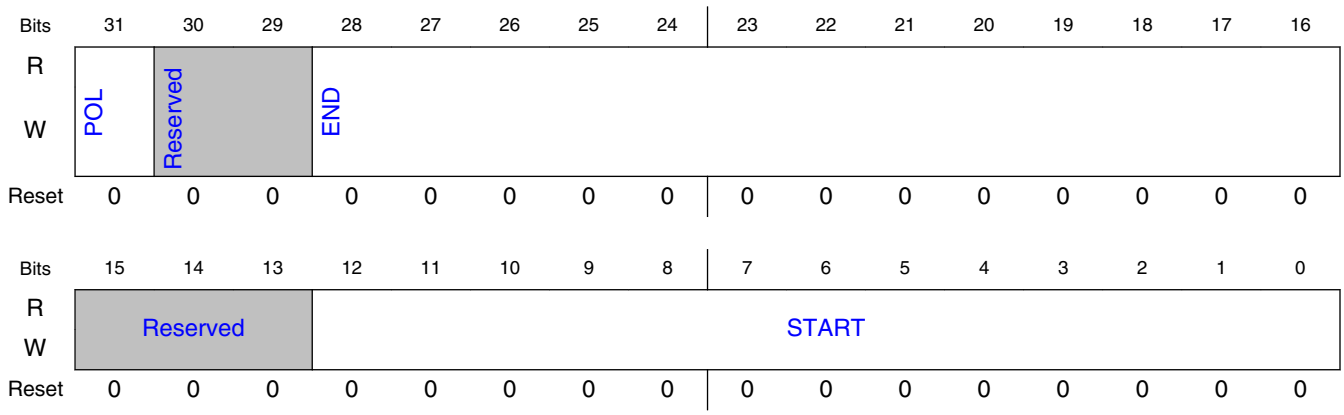
Register	Offset
SS_HSYNC_CLR	28h

15.11.3.1.12.2 Function

Defines when horizontal sync signal goes high/low.

```
There are two X coordinates defined in this register.
Horizontal sync width determined by END - START.
```

15.11.3.1.12.3 Diagram



15.11.3.1.12.4 Fields

Field	Function
31 POL	Polarity of sync signal. 0 == active low ; 1 == active_high
30-29 —	Reserved
28-16 END	horizontal sync is de-asserted when horizontal count == END
15-13 —	Reserved
12-0 START	horizontal sync is asserted when horizontal count == START

15.11.3.1.13 (SS_HSYNC_TOG)

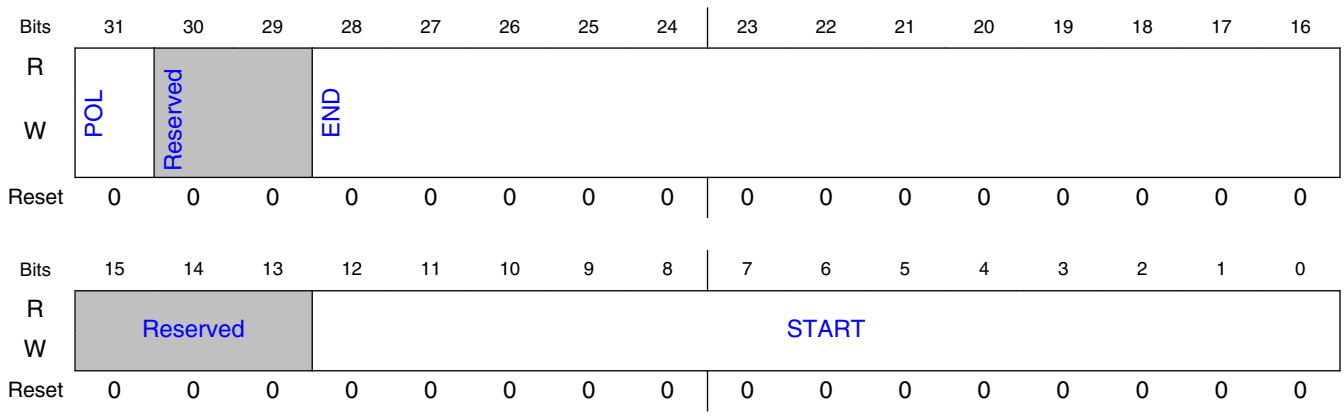
15.11.3.1.13.1 Offset

Register	Offset
SS_HSYNC_TOG	2Ch

15.11.3.1.13.2 Function

```
Defines when horizontal sync signal goes high/low.
There are two X coordinates defined in this register.
Horizontal sync width determined by END - START.
```

15.11.3.1.13.3 Diagram



15.11.3.1.13.4 Fields

Field	Function
31 POL	Polarity of sync signal. 0 == active low ; 1 == active_high
30-29 —	Reserved
28-16 END	horizontal sync is de-asserted when horizontal count == END
15-13 —	Reserved
12-0 START	horizontal sync is asserted when horizontal count == START

15.11.3.1.14 (SS_VSYNC)

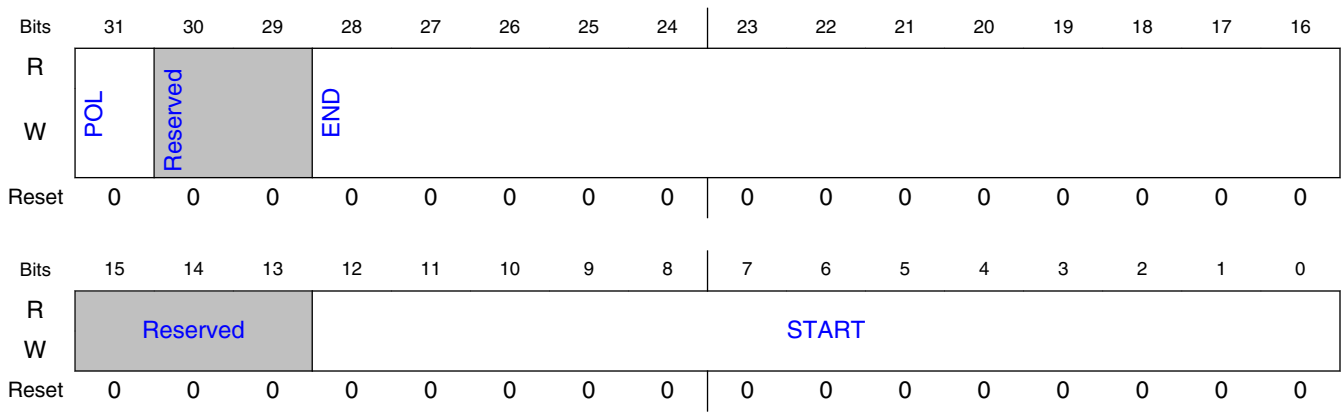
15.11.3.1.14.1 Offset

Register	Offset
SS_VSYNC	30h

15.11.3.1.14.2 Function

```
Defines Y coordinate when vertical sync signal goes high/low.
Horizontal sync width determined by END - START.
```

15.11.3.1.14.3 Diagram



15.11.3.1.14.4 Fields

Field	Function
31 POL	Polarity of sync signal. 0 == active low ; 1 == active_high
30-29 —	Reserved
28-16 END	When v_count = END h_count = CSR_SS_LRC_X vsync goes inactive
15-13 —	Reserved
12-0 START	When v_count = START and h_count = CSR_SS_LRC_X then vsync goes active

15.11.3.1.15 (SS_VSYNC_SET)

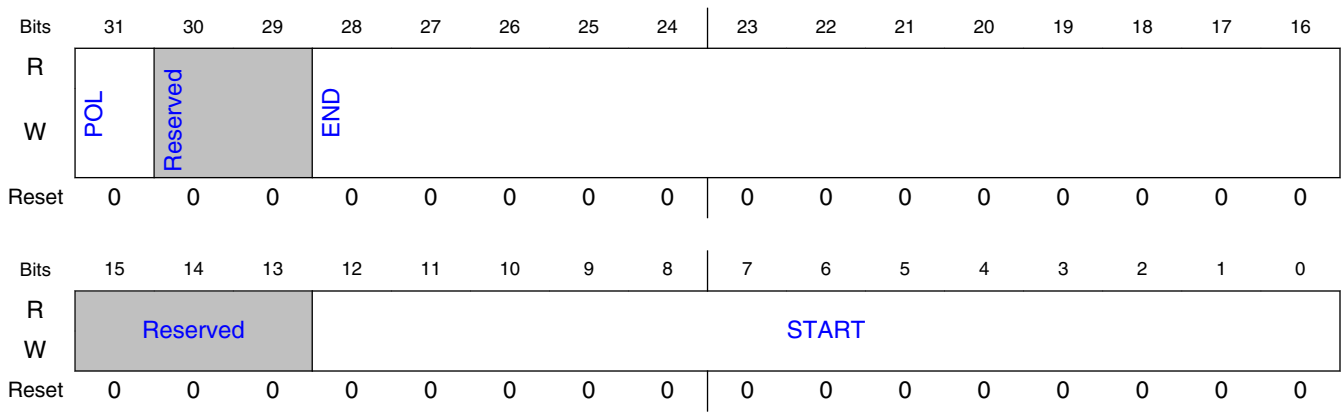
15.11.3.1.15.1 Offset

Register	Offset
SS_VSYNC_SET	34h

15.11.3.1.15.2 Function

```
Defines Y coordinate when vertical sync signal goes high/low.
Horizontal sync width determined by END - START.
```

15.11.3.1.15.3 Diagram



15.11.3.1.15.4 Fields

Field	Function
31 POL	Polarity of sync signal. 0 == active low ; 1 == active_high
30-29 —	Reserved
28-16 END	When v_count = END h_count = CSR_SS_LRC_X vsync goes inactive
15-13 —	Reserved
12-0 START	When v_count = START and h_count = CSR_SS_LRC_X then vsync goes active

15.11.3.1.16 (SS_VSYNC_CLR)

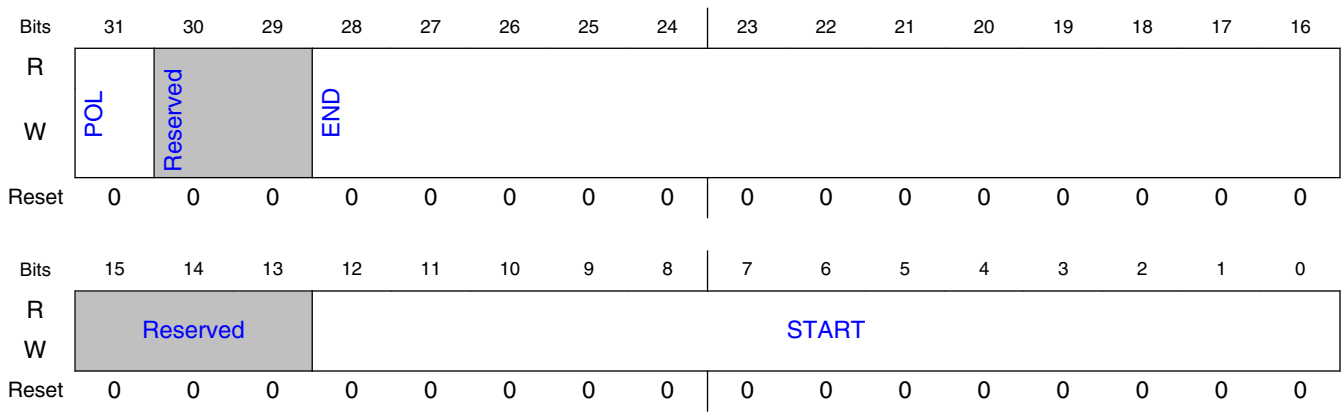
15.11.3.1.16.1 Offset

Register	Offset
SS_VSYNC_CLR	38h

15.11.3.1.16.2 Function

```
Defines Y coordinate when vertical sync signal goes high/low.
Horizontal sync width determined by END - START.
```

15.11.3.1.16.3 Diagram



15.11.3.1.16.4 Fields

Field	Function

15.11.3.1.30 (SS_COEFF)

15.11.3.1.30.1 Offset

Register	Offset
SS_COEFF	70h

15.11.3.1.30.2 Function

```
Holds coefficients for both vertical + horizontal filters.
Three coefficients used for 3 tap fir filter.
HORIZ_A, HORIZ_B, HORIZ_C is used for horizontal filter coefficients.
VERT_A, VERT_B, VERT_C is used for vertical filter coefficients.
In addition, the horizontal and vertical filters have a normalization factor called
HORIZ_NORM and VERT_NORM respectively.
A general formula for these filters is:
   pixel_out = (A*pixel[x+1]+B*pixel[x]+C*pixel[x-1]+Round)/Normalize
The values Round and Normalize are selected based on the values of HORIZ_NORM and VERT_NORM.
The mapping can be described by the following equations:
   if (NORM = 0)       Round = 0; Normalize = 1;
   else if (NORM < 5)  Round = 2^(NORM); Normalize = 2^(NORM+1);
   else                Round = 2^(5); Normalize = 2^(5+1);
```

15.11.3.1.30.4 Fields

Field	Function
31 —	Reserved
30-28	Sets the 3 bit vertical filter normalization factor.

Table continues on the next page...

Field	Function
VERT_NORM	
27-24 VERT_C	Sets the 4 bit vertical C coefficient.
23-20 VERT_B	Sets the 4 bit vertical B coefficient.
19-16 VERT_A	Sets the 4 bit vertical A coefficient.
15 —	Reserved
14-12 HORIZ_NORM	Sets the 3 bit horizontal filter normalization factor.
11-8 HORIZ_C	Sets the 4 bit horizontal C coefficient.
7-4 HORIZ_B	Sets the 4 bit horizontal B coefficient.
3-0 HORIZ_A	Sets the 4 bit horizontal A coefficient.

15.11.3.1.31 (SS_COEFF_SET)

15.11.3.1.31.1 Offset

Register	Offset
SS_COEFF_SET	74h

15.11.3.1.31.2 Function

```
Holds coefficients for both vertical + horizontal filters.
Three coefficients used for 3 tap fir filter.
HORIZ_A, HORIZ_B, HORIZ_C is used for horizontal filter coefficients.
VERT_A, VERT_B, VERT_C is used for vertical filter coefficients.
In addition, the horizontal and vertical filters have a normalization factor called
HORIZ_NORM and VERT_NORM respectively.
A general formula for these filters is:
   pixel_out = (A*pixel[x+1]+B*pixel[x]+C*pixel[x-1]+Round)/Normalize
The values Round and Normalize are selected based on the values of HORIZ_NORM and VERT_NORM.
The mapping can be described by the following equations:
   if (NORM = 0)      Round = 0; Normalize = 1;
   else if (NORM < 5) Round = 2^(NORM); Normalize = 2^(NORM+1);
   else               Round = 2^(5); Normalize = 2^(5+1);
```

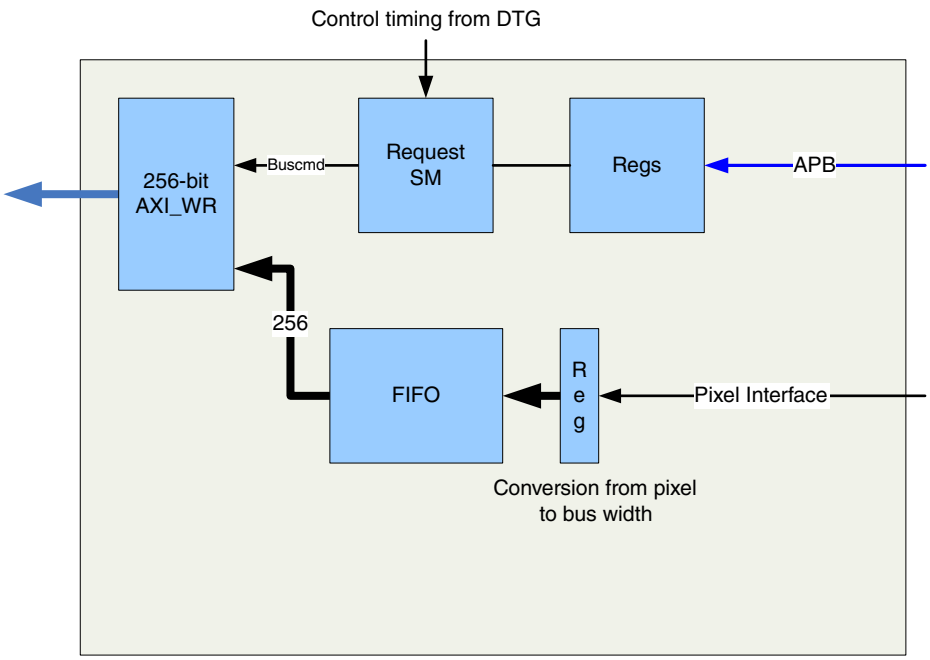
15.12 Write Scale (WR_SCL)

15.12.1 Overview

The Write Scale engine (WR_SCL) can be used to send pixel data from the scaler to DDR. This path to external memory would be used when significant downscaling factors are selected due to large bandwidth requirements on the source image within smaller regions of the display output. The WR_SCL module accepts valid pixels from the scaling engine and packs them into an output FIFO to manage bursts of data out onto the AXI interface to external memory.

15.12.1.1 Block Diagram

The diagram indicating the functional components in the WR_SCL module is below.



15.12.1.2 Features

The WR_SCL module is a bus master engine that accepts pixels from the scaler and generates packets of requests over the AXI interface.

The components in the WR_SCL are highlighted here:

- Req_SM: State machine to generate the sequence of transactions to write a buffer to system memory.
- Regs: All configuration registers used to store the WR_SCL configuration.
- AXI_WR: The buscmd to AXI interface convertor used in many AXI based designs.
- FIFO: used to store a sample set of data to be written to system memory.
- Up sample Reg: Register used to convert from pixel bus width to bus width.

15.12.2 Functional Description

It is expected that several parameters provides the configuration options to achieve buffer sizes and access patterns that maximizes DDR efficiency and design size. There are hardware and software parameters for the design as defined below.

WR_SCL SW parameters are:

- AXI transaction size (64B up to 512B per burst) is programmable.
- Buffer threshold: defines how much data needs to be in the FIFO before issuing a burst of system memory requests. When the number of bytes is greater than this value, the necessary AXI requests to transfer the data are issued
- Burst frequency: how often the wr_scale engine issues a sequence of AXI requests
- Buffer base address
- Line stride in bytes

15.12.2.1 WR_SCL Output Pixel Formatting

There are a variety of input to output format conversions that are available in the WR_SCL. The input is always 10-bit per component with an 8-bit alpha. Consumers of the data could be 8-bit or 10-bit, so the option to convert the output to 8-bit can be selected. Also, the consumer may not use an alpha value, so it can be truncated. The output pixel format should be influenced by the final consumer of pixels. It is up to SW to determine which to use. The idea is that data that is not needed at the consumer can be removed to save memory bandwidth.

The input pixel_data[37:0] to output conversions are programmed in the BPP field of the CSR_WR_SCL_CTRL register. The input to output conversion of the pixels is defined for each mode as below. Note that P0 is the first pixel received on the pixel_data[37:0] input bus, P1 is the second, etc.

BPP = 0x0: 40bpp, Full pass through of all 38-bits appended with 2’b00 for each pixel. Appending 2’b00 is intended to created byte alignment. The pixels in bold wrap on the 128-bit boundary.

This pattern repeats.

```
1st pixel_out[127:0] = {P3[7:0],
                        2'b00,P2[37:0],
                        2'b00,P1[37:0],
                        2'b00,P0[37:0]};

2nd pixel_out[127:0] = {P6[15:0],
                        2'b00,P5[37:0],
```

```
                          2'b00,P4[37:0],
                          2'b00,P3[37:8]};

3rd pixel_out[127:0] = {P9[23:0],
                          2'b00,P8[37:0],
                          2'b00,P7[37:0],
                          2'b00,P6[37:16]};

4th pixel_out[127:0] = {P12[31:0],
                          2'b00,P11[37:0],
                          2'b00,P10[37:0],
                          2'b00,P9[37:24]};
```

BPP = 0x1: 32bpp, ARGB8888/AYUV8888

The lowest two bits for each color component are dropped. Alpha is on the high order byte.

```
Pixel_out[127:0] = { P3[37:30,29:22,19:12,9:2],
                     P2[37:30,29:22,19:12,9:2],
                     P1[37:30,29:22,19:12,9:2],
                     P0[37:30,29:22,19:12,9:2]}
```

BPP = 0x2: 32bpp, RGB/YUV 10-bit per component

All 10-bits of each component are used. The 2 highest bits of alpha are passed.

```
Pixel_out[127:0] = { P3[37:36,29:20,19:10,9:0],
                     P2[37:36,29:20,19:10,9:0],
                     P1[37:36,29:20,19:10,9:0],
                     P0[37:36,29:20,19:10,9:0]}
```

BPP = 0x3: 24bpp, YUV422 10-bit per component

Y (pixel_data[29:20]) with alternate U/V (pixel_data[19:10]). The 20-bit pixel is concatenated with 4-bit Alpha.

```
1st pixel_out[127:0] = { P5[17:10],
                         P4[37:34],P4[29:10],
                         P3[37:34],P3[29:10],
                         P2[37:34],P2[29:10],
                         P1[37:34],P1[29:10],
                         P0[37:34],P0[29:10] }

2nd pixel_out[127:0] = { P10[25:10],
                         P9[37:34],P9[29:10],
                         P8[37:34],P8[29:10],
                         P7[37:34],P7[29:10],
                         P6[37:34],P6[29:10],
                         P5[37:34],P5[29:18] }

3rd pixel_out[127:0] = { P15[37:34],P15[27:10],
                         P14[37:34],P14[29:10],
                         P13[37:34],P13[29:10],
                         P12[37:34],P12[29:10],
                         P11[37:34],P11[29:10],
                         P10[37:34],P10[29:26] }
```

This pattern repeats.

BPP = 0x4: 16bpp, YUV422 8-bit per component

The lowest two bits for each color component are dropped. Pixel_data[9:0] is dropped and not used in YUV422 mode. No alpha is used.

Pixel_out[127:0] = { P7[29:22,19:12], P6, …, P3, P2[29:22,19:12], P1[29:22,19:12], P0[29:22,19:12] }

15.12.2.2 WR_SCL Interrupt

The WR_SCL module can generate interrupts under the following conditions.

- AXI SLVERR or DECERR is received.
- Frame processing complete. The last pixel coincident with pixel_v_sync is written to system memory.

15.12.3.1.2.3 Fields

Field	Function
31 WR_ERR	Indicates a write error on the axi interface.
30 WR_ERR_EN	Write error IRQ enable If set, it allows WR_ERR to create an irq whenever there is an error responsde to a write request.
29 FRAME_COMP	Indicates the current frame being processed has finished.
28 FRAME_COMP_EN	Write error IRQ enable If set, it allows FRAME_COMP to create an irq whenever processing a frame finishes.
27-25 —	Reserved
24-18 FIFO_SIZE	Size of FIFO in design This is the fifo size in the HW. This can be used to program the appropriate P_SIZE. P_SIZE should ideally be 1/2 the FIFO size. • 7'h0F - 512B • 7'h1F - 1KB • 7'h3F - 2KB • 7'h7F - 4KB
17-10 P_FREQ	Payload frequency P_FREQ*8 is the number of clocks between payload requests. A value of 0 does not limit the frequency of the payload requests. Instead, the payload is written as frequently as data is available.
9-7	Payload Size

Table continues on the next page...

Field	Function
P_SIZE	Holds the payload size. This is used with the T_SIZE to calculate the number of transactions required per request. PSIZE and TSIZE are co-related and should be programmed as PSIZE >= TSIZE. • 000 -> 64B • 001 -> 128B • 010 -> 256B • 011 -> 512B • 100 -> 1KB • 101 -> 2KB • 110 -> 4KB • 111 -> Reserved
6-5 T_SIZE	Transaction Size Holds the transaction size / request. Transaction size determines how many AXI transactions a payload should be divided into.T_SIZE is related to P_SIZE and needs to be programmed as PSIZE >= TSIZE • 00 -> 64B • 01 -> 128B • 10 -> 256B • 11 -> 512B
4-2 BPP	Bits per pixel Holds the number of bits / pixel format interface on the output. • 0 -> 38 bpp, 38 bit components are unpacked • 1 -> 32 bpp, 8-bit to 10-bit upconversion • 2 -> 32 bpp, 10-bit output, alpha(37:30) tied to 0x0 • 3 -> 20 bpp, 10-bit YUV422. pixel_data[37:30]/pixel_data[9:0] tied to 0x0 • 4 -> 16 bpp, 8-bit component, YUV422
1 REPEAT	Repeat feature Repeat bit for the write_scalar. When set, write scalar does not lower the BUSY bit after each frame and processes the new frame of data with the same address, bpp, p_size and t_size values as the previous frame. If you do not expect a new frame, reset this signal before the current frame finishes. Once the frame finishes, and the design sees this bit set, it resets address to the programmed value and wait for new pixels. If you do not expect any more pixels, the only way to recover from this is through a reset.
0 ENABLE	Enable / Busy Enable bit for the write_scalar. When set, the wr_scalar waits for pixels and write them to memory as per the address and transfer sizes programmed in the control register. This bit is reset by HW when it has completed the frame write. If the REPEAT bit is set, this bit is not cleared as the WR_SCL resets it's pointers and waits for new pixels to be written to the same address in memory.

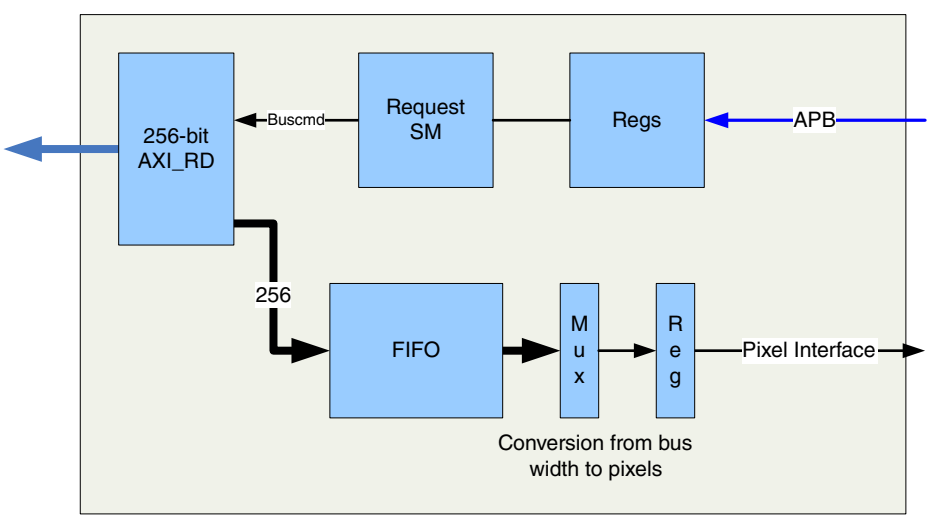
15.13 Read Surface (RD_SRC)

15.13.1 Overview

The Read Surface (RD_SRC) engine is a bus master that reads pixels from system memory and drive pixels out to the scale output buffer. The scale output buffer (1 of 3 not used for storing the scaled result) is reused as a read latency elasticity buffer. Minimal storage is needed in the RD_SRC module to store returned read data since the scale output buffer is repurposed as a pixel elasticity buffer. The RD_SRC engine supports raster scan source buffers. There is no support for tiled based buffers.

15.13.1.1 Block Diagram

The diagram indicating the functional components in the RD_SRC module is below.



The components are listed here:

- Req_SM: State machine to generate the sequence of transactions to read a buffer from system memory.
- Regs: All configuration registers used to store the RD_SRC configuration.
- AXI_RD: The buscmd to AXI interface convertor used in many AXI based designs. This instance is shared with the CTX_LD module.
- FIFO: used to store a sample set of data to be read from system memory.
- Down Sample Mux/Reg: Multiplexor used to down size from the bus width to a pixel interface to the scale output buffer.

The software parameters are:

- AXI transaction size (64B up to 512B per request) is programmable.
- Buffer threshold determines how empty the input data FIFO should be to trigger a sequence of read transactions from the system. When the number of available bytes is greater than this value, the necessary AXI requests to fill this buffer are issued.
- Buffer base address.
- Line stride in bytes.
- Source buffer format, either ARGB8888 (32bpp), or YUV422 1-plane (16bpp).
- Width, or number of pixels to fetch and write to the scale output buffer in a horizontal scan line.
- Height, number of lines in the source buffer.

15.13.2 Functional Description

The RD_SRC engine fetches and forwards only the pixels needed to drive the display. The granularity of the source buffer, in X and Y, forwarded to the display pipeline has no limits. Any width and height can be fetched and forwarded to the scale output buffer. Also, in YUV422 mode, the programmed width should be divisible by 2.

The RD_SRC has two events that can enable it to issue requests to fetch data for the next display trace.

1. SW can write the BUSY bit to 1’b1.
2. The rd_src_kick_enable signal input can go low to high.

The RD_SRC is disabled when the csr_rd_src_width AND csr_rd_src_height = 0x0. When these two registers are 0x0, both events that enable the RD_SRC are ignored. Also, if the RD_SRC is already enabled and processing a frame, any of the two events that are used to start processing would be ignored.

15.13.2.1 Input to Output Pixel Formatting

The pixel_data[37:0] output bus to the Scaler engine is normalized as 10-bit per color component, with an 8-bit alpha. Refer to section 4.21.1 Pixel Component Order for the standard on how to convert 8-bit to 10-bit color components when required depending on the format selected.

Input pixels from the system can be in 8/10-bit format, may contain an alpha value, or may have sub-sampled chroma components. The BPP field of the CSR_RD_SRC_CTRL register defines what the input format is. The definition of this field matches the respective control field in the WR_SCL module. Essentially, the RD_SRC reverses the pixel formatting process and send a full 38-bits back to the Scaler engine. The definition of this data format is defined as

```
Pixel_data[37:30] = Alpha
Pixel_data[29:20] = R/Y
Pixel_data[19:10] = G/U, or UV alternating in YUV422 modes
Pixel_data[9:0] = B/V
```

The output pixel modes are defined as:

- **BPP = 0x0: 40bpp**, Full pass through of all 38-bits with the appended 2'b00 bits dropped.
  - 1st pixel_data = [37:0],
  - 2nd pixel_data = [77:40], etc.
- **BPP = 0x1: 32bpp**, ARGB8888/AYUV8888
- 32bpp expanded to the full 38-bit vector. Refer to the standards section 4.21.2 Pixel Component Width Conversion to determine how to expand 8-bit components up to 10-bit.
- 1st pixel_data = {[31:24],[23:16],[23:22],[15:8],[15:14],[7:0],[7:6]} //ARGB: 8:10:10:10
- **BPP = 0x2: 32bpp**, RGB/YUV 10-bit per component
- All 10-bits of each component are passed to the output. The alpha is expanded from 2-bits to 8-bit.
- 1st pixel_data = {{4{[31:30]}},[29:20],[19:10],[9:0]} //Alpha expanded, component pass-through
- **BPP = 0x3: 24bpp**, YUV422 10-bit per component
- The full Y and alternating UV components are passed through as 10-bit. Bits 9:0 are driven as 10'b0. The 4-bit alpha is converted based on the standard conversion described in section 4.21.2 Pixel Component Width Conversion.
- 1st pixel_data = {{2{[23:20]}},[19:10],[9:0],10'b0} //Alpha expanded 4 to 8, Y and UV pass-through
- **BPP = 0x4: 16bpp**, YUV422 8-bit per component
- The Y and alternating UV components are expanded from 8 to 10 bits. Bits [9:0] and [37:30] are driven as 0x0.
- 1st pixel_data = {8'b0,[15:7],[15:14],[7:0],[7:6],10'b0} //Alpha = 0,

15.13.2.2 Interrupt

The RD_SRC module can generate interrupts under the following conditions.

- AXI SLVERR or DECERR is received.
- Frame processing complete. The last pixel coincident with pixel_v_sync is written to the scaler output FIFO.

15.13.3 Memory Map and Registers

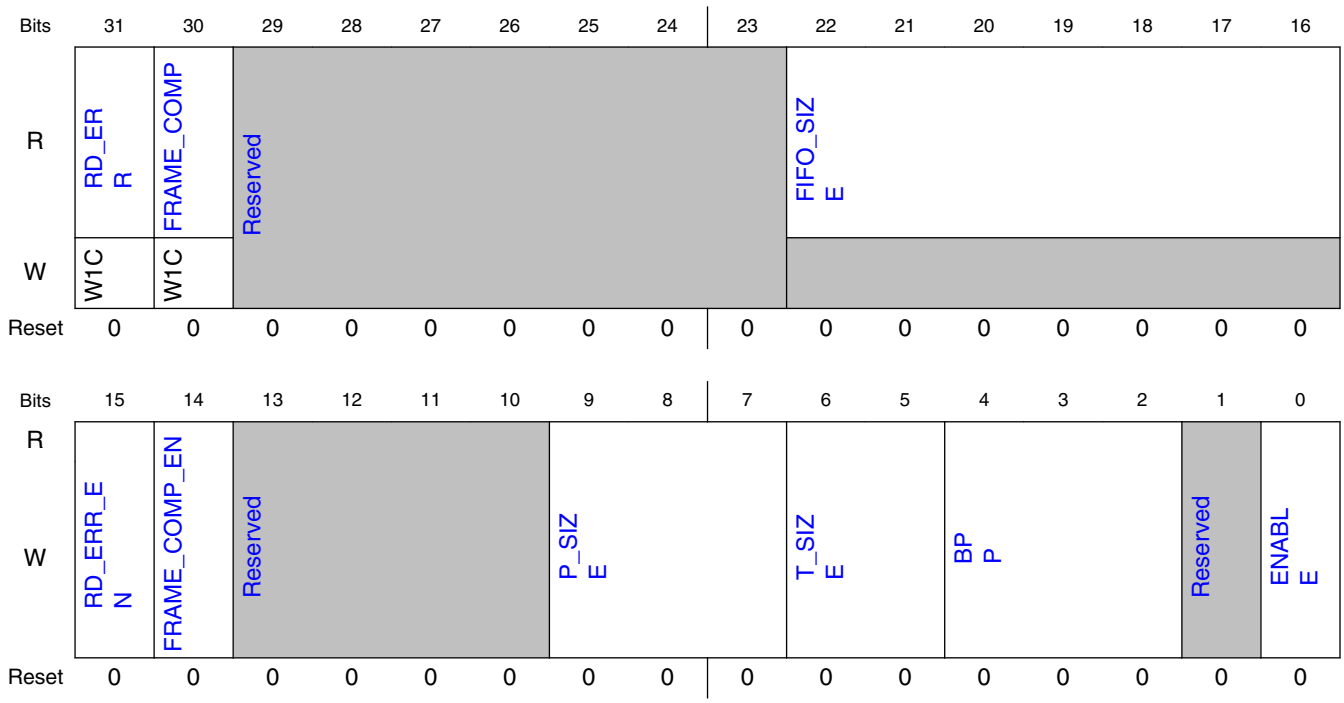
15.13.3.1.2.2 Diagram



15.13.3.1.2.3 Fields

Field	Function
31 RD_ERR	AXI Read Error Status bit that indicates an AXI read response terminates with a SLV_ERR or DEC_ERR.
30 FRAME_COMP	Frame processing complete Status bit that indicates the current frame processing is complete. This is set even if the height and width are 0. If the respective interrupt enable bit is set, an interrupt is generated.
29-23 —	Reserved
22-16 FIFO_SIZE	FIFO size This is the fifo size implemented in the HW. The P_SIZE should never be set to a value higher than this value in bytes. • 7'h0F - 512B • 7'h1F - 1KB • 7'h3F - 2KB • 7'h7F - 4KB
15 RD_ERR_EN	AXI Read Error IRQ enable Enable an interrupt when the AXI read response completes with a SLV_ERR or DEC_ERR.
14 FRAME_COMP _EN	Frame complete IRQ enable Enable an interrupt when the read surface engine is finished processing a frame.
13-10	Reserved

Table continues on the next page...

Field	Function
—	
9-7 P_SIZE	Payload size (P_SIZE) Holds the payload size per AXI burst sequence. The P_SIZE should never be programmed to be less than T_SIZE. If the T_SIZE and P_SIZE are both set to 64B, there is a high frequency of 64B requests issued to DRAM. If the P_SIZE is 256B, the requests are issued when there is 256B of space empty in the RD_SRC FIFO. The requests are issued 1/4 as frequently as when the P_SIZE is 64B. With a P_SIZE=256 and T_SIZE=128, two 128B transactions are issued to fullfill the 256B P_SIZE selection. The P_SIZE and T_SIZE should be set to optimize for DRAM efficiency. P_SIZE = T_SIZE = 256B is a good choice to start, but other settings could provide more optimal performance. • 000 -> 64B • 001 -> 128B • 010 -> 256B • 011 -> 512B • others -> Reserved FIXME this should be based on the BUFF_SZ parameter setting.
6-5 T_SIZE	Transaction Size (T_SIZE) Holds the AXI system bus transaction size per request in bytes. This should always be programmed in conjunction with P_SIZE where P_SIZE >= T_SIZE. • 00 -> 64B • 01 -> 128B • 10 -> 256B • 11 -> 512B
4-2 BPP	Bits per pixel Holds the number of bits/pixel format interface on the input. These settings are intended to reverse the operation of the respective settings in the WR_SCL engine. • 0 -> 40 bpp, 38 bit components are unpacked • 1 -> 32 bpp, 8-bit to 10-bit upconversion • 2 -> 32 bpp, 10-bit output, alpha(37:30) tied to 0x0 • 3 -> 24 bpp, 10-bit YUV422. pixel_data[37:30]/pixel_data[9:0] tied to 0x0 • 4 -> 16 bpp, 8-bit component, YUV422
1 —	Reserved
0 ENABLE	Read surface enable. Enable bit for read surface bus master. When this bit is set, AND the width and height are both not zero, the RD_SRC engine begins to fetch buffer based on existing programming.

15-0 HEIGHT	Height Height, in pixels, of the source frame buffer. This is the number of scan lines written to the output buffer pixel interface per frame.

15.14 Interrupt Request Steering (IRQ_STEER)

15.14.1 Introduction

The irq_steer module redirects/steers the incoming interrupts to output interrupts of a selected/designated channel as specified by a set of configuration registers.

15.14.1.1 Block diagram

The figure below shows a high-level diagram of the irq_steer module.

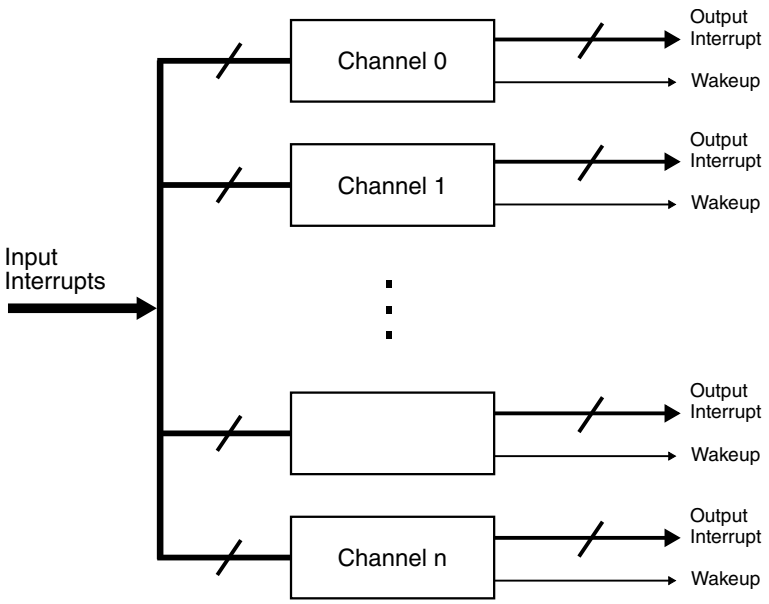

Figure 15-28. irq_steer block diagram

The figure below shows the high-level operation of one channel of the irq_steer module.

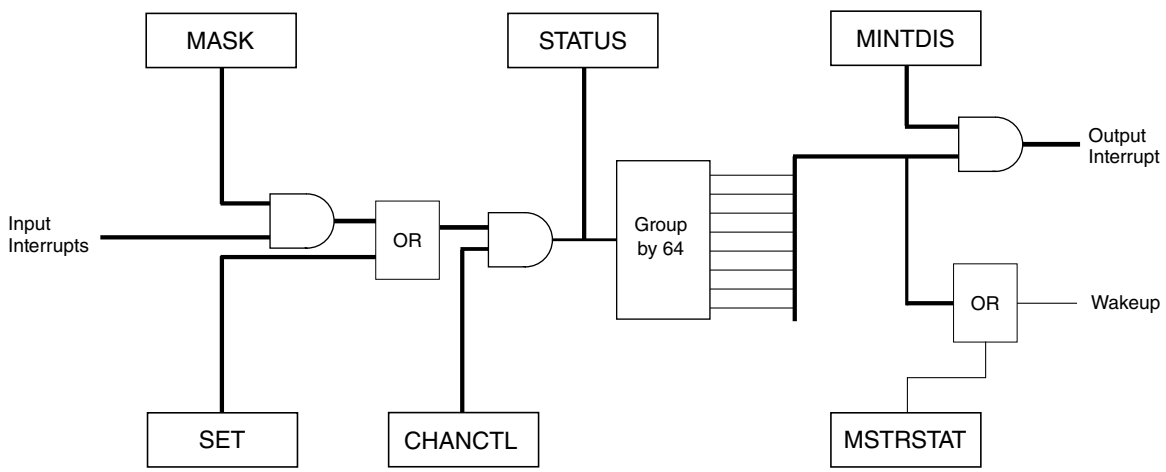

Figure 15-29. irq_steer channel block diagram

15.14.1.2 Features

This irq_steer module supports:

- 5 IRQ channels
- 512 interrupts per channel

15.14.2 Functional description

The irq_steer module allows the user to steer 512 interrupts into one of 5 channels.

15.14.3 Memory Map / Register Definition

This section describes the registers that are implemented for one channel. One channel in this module supports up to 512 interrupts per channel. Each channel has its own set of registers consisting of:

- One CHANnCTL register
- 16 CHn_MASK registers
- 16 CHn_SET registers
- 16 CHn_STATUS registers
- One CHn_MINTDIS register
- One CHn_MSTRSTAT register

This module supports 5 channels. Therefore, there are sets of 5 these registers. Each set of registers will have its own base offset, which must be added to the relative offset shown here.

The following table shows the correlation between an interrupt and its register and bit offset for the CHn_MASK, CHn_SET, and CHn_STATUS registers.

Table 15-10. Interrupt Mapping (incomplete)

Chapter 16
Low Speed Communication and Interconnects

16.1 I2C Controller (I2C)

16.1.1 Overview

This chapter describes block-level operation and programming of I2C. The chapter is intended for a block-driver software developer. To understand how the block is integrated at the SoC level, a system software developer should see discussions of the block in the appropriate SoC-level chapter(s).

References: This document assumes an understanding of the following document:

- *The I2C Bus Specification*, Version 2.1, by Philips Semiconductor

The Inter IC (I2C) provides functionality of a standard I2C slave and master. The I2C is designed to be compatible with the standard NXP I2C bus protocol.

NOTE

Four independent I2C channels are available.

I2C is a two-wire, bidirectional serial bus that provides a simple, efficient method of data exchange, minimizing the interconnection between devices. This bus is suitable for applications requiring occasional communications over a short distance between many devices. The flexible I2C standard allows additional devices to be connected to the bus for expansion and system development. See the connection diagram in the figure below.

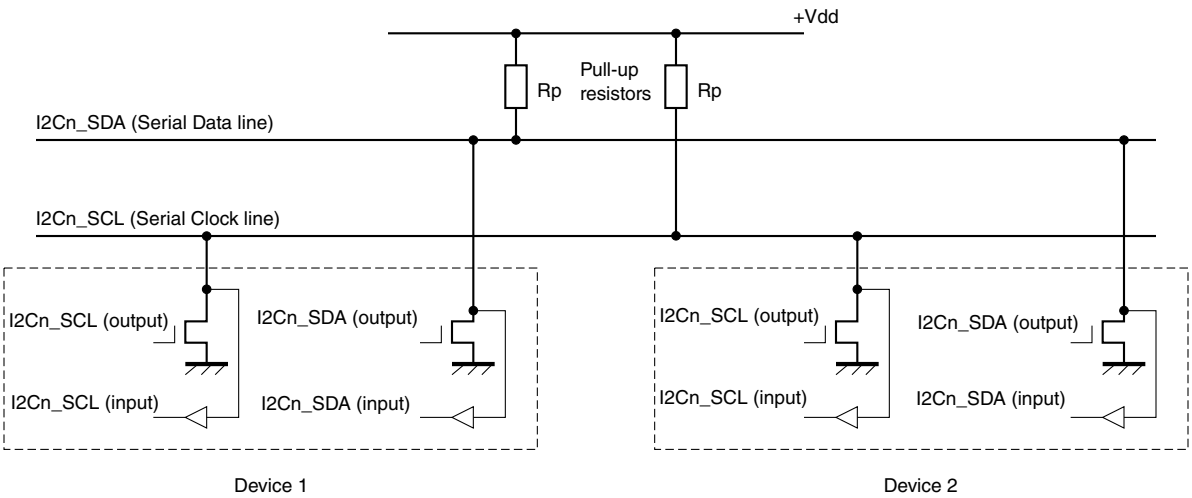

Figure 16-1. Connection of devices to I2C bus

The I2C interface speed is dependent on the I2C bus loading and timing characteristics. For pin requirement details, see *The I2C Bus Specification*. The I2C system is a true multimaster bus including arbitration and collision detection that prevents data corruption if multiple devices attempt to control the bus simultaneously. This feature supports complex applications with multiprocessor control and can be used for rapid testing and alignment of end products through external connections to an assembly-line computer. The figure below shows the block diagram of I2C.

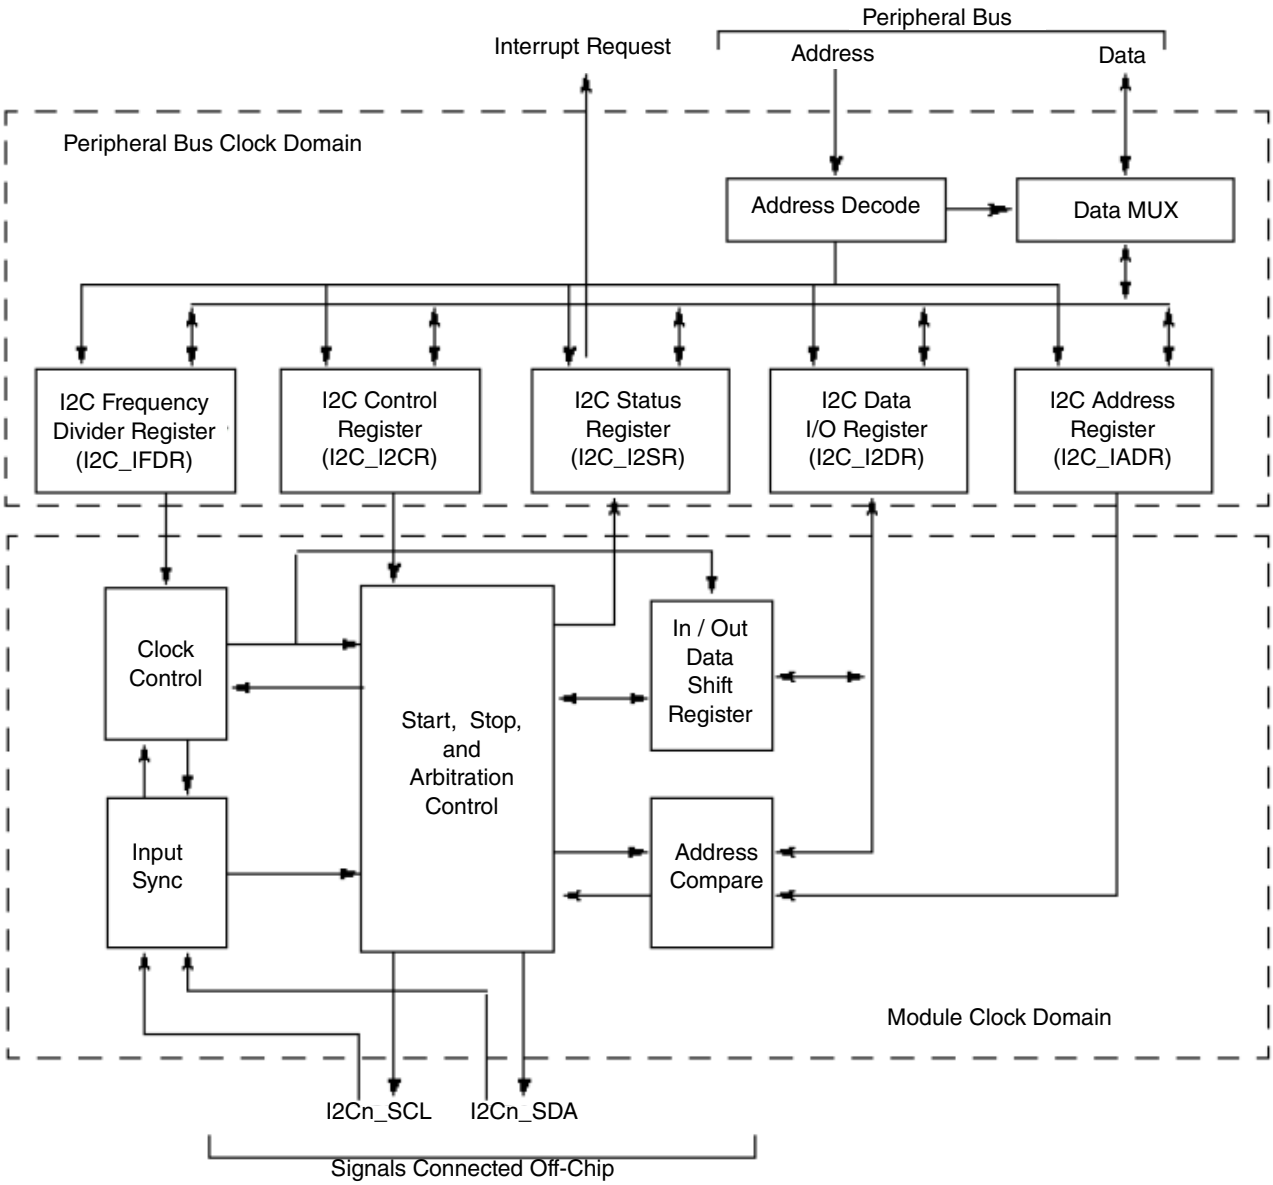

Figure 16-2. I2C block diagram

16.1.1.1 Features

The I2C has the following key features:

- Compatibility with I2C bus standard
- Multimaster operation
- Software programmability for one of 64 different serial clock frequencies
- Software-selectable acknowledge bit
- Interrupt-driven, byte-by-byte data transfer
- Arbitration-lost interrupt with automatic mode switching from master to slave

- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated Start signal generation
- Acknowledge bit generation/detection
- Bus-busy detection

16.1.1.2 Modes and operations

The I2C operates primarily in two functional modes: Standard mode and Fast mode.

- In Standard mode, I2C supports the data transfer rates up to 100 kbits/s.
- In Fast mode, data transfer rates up to 400 kbits/s can be achieved. Per block operation, there is no special configuration required for Fast or Standard mode. It is the data transfer rate that distinguishes Standard and Fast mode.

16.1.2 External Signals

This section discusses I2C signals that connect off-chip.

For I2C compliance, all devices connected to the I2Cn_SCL and I2Cn_SDA signals must have open-drain or open-collector outputs. The logic AND function is implemented on both lines with external pull-up resistors.

Inputs of I2Cn_SCL and I2Cn_SDA also need to be manually enabled by setting the SION bit in the IOMUX after the corresponding PADs are selected as I2C function.

16.1.3 Clocks

There are two input clocks for I2C.

The following table describes the clock sources for I2C. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 16-1. I2C Clocks

Clock name	Clock Root	Description
ipg_clk_patref		Module clock
ipg_clk_s		Peripheral access clock

- Peripheral clock: This clock is used for peripheral bus register read/writes.
- Module clock: This is the functional clock of the I2C. The serial bit clock frequency is derived from the module clock. The module clock and peripheral clocks are synchronous with each other. The minimum frequency of the module clock should be 12.8 MHz for Fast mode to achieve 400-kbps operation.

16.1.4 Functional description

This section provides a complete functional description of the block.

16.1.4.1 I2C system configuration

After a reset, the I2C defaults to Slave Receive operations. Thus, when not operating as a master or responding to a slave transmit address, the I2C defaults to the Slave Receive state.

For exceptions, see Initialization sequence.

NOTE

The I2C is designed to be compatible with the Philips™ I2C bus protocol. For information on system configuration, protocol, and restrictions, see the *I2C Bus Specification*, version 2.1, by Philips Semiconductors. The I2C supports Standard and Fast modes only.

16.1.4.2 Arbitration procedure

If multiple devices simultaneously request the bus, the bus clock is determined by a synchronization procedure in which the low period equals the longest clock-low period among the devices, and the high period equals the shortest. A data arbitration procedure determines the relative priority of competing devices.

A device loses arbitration if it sends logic high while another sends logic low; it immediately switches to Slave Receive mode and stops driving I2Cn_SDA. In this case, the transition from master to Slave mode does not generate a Stop condition. Meanwhile, hardware sets the arbitration lost bit in the I2C Status register (I2C_I2SR[IAL] to indicate loss of arbitration).

16.1.4.3 Clock synchronization

Because wire-AND logic is used, a high-to-low transition on SCL affects devices connected to the bus. Devices start counting their low period when the master drives SCL low. When a device clock goes low, it holds SCL low until the Clock High state is reached. However, the low-to-high change in this device clock may not change the state of SCL if another device clock is still in its low period. Therefore, the device with the longest low period holds the synchronized clock SCL low.

Devices with shorter low periods enter a High Wait state during this time (see Figure 16-3). When all devices involved have counted off their low periods, the synchronized clock SCL is released and pulled high. There is then no difference between device clocks and the state of SCL, so all of the devices start counting their high periods. The first device to complete its high period pulls SCL low again.

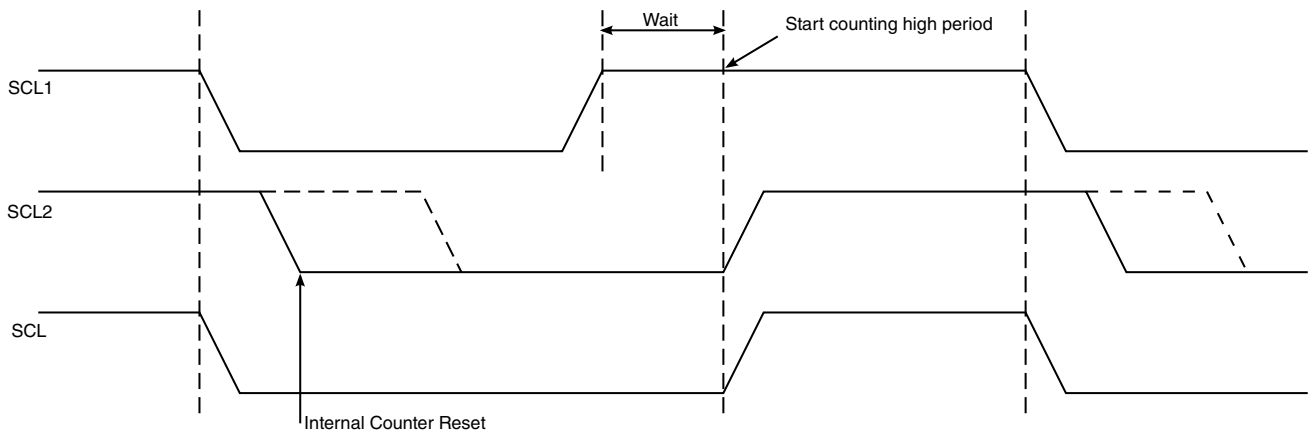

Figure 16-3. Synchronized clock SCL

16.1.4.4 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfers. Slave devices can hold SCL low after completing one byte transfer (9 bits). In such a case, the clock mechanism halts the bus clock and forces the master clock into a Wait state until the slave releases SCL.

16.1.4.5 Clock stretching

Slaves can use the clock synchronization mechanism to slow down the transfer bit rate. After the master has driven SCL low, the slave can drive SCL low for the required period and then release it. If the slave SCL low period is longer than the master SCL low period, the resulting SCL bus signal low period is stretched.

16.1.4.6 Peripheral bus accesses

I2C is a 16-bit block. Only half-word accesses should be performed to the block.

16.1.4.7 Generation of transfer error on IP bus

If an address is received on the peripheral slave bus interface but it is not implemented, an access error is generated.

16.1.4.8 Reset

The I2C can be reset in the following ways:

- Global reset: A hard asynchronous reset of the whole I2C
- Software reset: An internal reset for the whole I2C (except for I2C_IADR and I2C_IFDR registers) initiated by deasserting the I2C_I2CR[IEN] bit

16.1.4.9 Interrupts

There is only one interrupt from the block, which is enabled by setting the I2C_I2CR[IIEN] bit.

The interrupt is generated in any one of the following conditions:

- One byte transfer is completed (the interrupt is set at the falling edge of the ninth clock).
- An address is received that matches its own specific address in Slave Receive mode.
- Arbitration is lost.

16.1.4.10 Byte order

The block only supports the Little-Endian mode.

16.1.5 Initialization

NOTE

Ensure the input select pins for IOMUXC are configured correctly for I2C.

16.1.5.1 Initialization sequence

Before the interface can transfer serial data, registers must be initialized, as listed here.

1. Set the data sampling rate (I2C_IFDR[IC] to obtain SCL frequency from the system bus clock.
2. Update the address in the (I2C_IADR) to define its slave address (address can range from 0 to 0x7f).
3. Set the I2C enable bit (I2C_I2CR[IEN]) to enable the I2C bus interface system.
4. Modify the bits in the I2C_I2CR to select Master/Slave mode, Transmit/Receive mode, and Interrupt-Enable or not.

16.1.5.2 Generation of Start

After completion of the initialization procedure, serial data can be transmitted by selecting the Master Transmit mode. On a multimaster bus system, the busy bus (I2C_I2SR[IBB]) must be tested to determine whether the serial bus is free. If the bus is free (IBB = 0), the Start signal and the first byte (the slave address) can be sent. The data written to the data register comprises the address of the desired slave and the LSB indicates the transfer direction.

The free time between a Stop and the next Start condition is built into the hardware that generates the Start cycle. Depending on the relative frequencies of the system clock and the SCL period, it may be necessary to wait until the I2C is not busy after writing the calling address to the data register (I2C_I2DR), before proceeding to load data into the data register (I2C_I2DR).

16.1.5.3 Post-transfer software response

Sending or receiving a byte sets the data transferring bit (I2C_I2SR[ICF]), which indicates one byte of communication is finished. Upon completion, the interrupt status (I2C_I2SR[IIF]) is also set. An external interrupt is generated if the interrupt enable (I2C_I2CR[IIEN]) is set. The software must first clear the interrupt status (I2C_I2SR[IIF]) in the interrupt routine.

See the flow chart in Figure 16-5.

The data transferring bit (I2C_I2SR[ICF]) is cleared either by reading from I2C_I2DR in Receive mode or by writing to this register in Transmit mode.

The software can service the I2C I/O in the main program by monitoring the interrupt status (I2C_I2SR[IIF]) if the interrupt enable is deasserted. In this case, the interrupt status should be polled in the data transferring bit (I2C_I2SR[ICF]) because the operation is different when arbitration is lost.

When an interrupt occurs at the end of the address cycle, the master is always in Transmit mode; that is, the address is sent. If Master Receive mode is required, then I2C_I2CR[MTX] should be toggled and a dummy read of the I2C_I2DR register must be executed to trigger receive data.

During Slave-mode address cycles (I2C_I2SR[IAAS] = 1), the slave read/write bit I2C_I2SR[SRW] is read to determine the direction of the next transfer. The transmit/receive bit (I2C_I2CR[MTX]) should also be programmed accordingly. For Slave-mode data cycles (IAAS = 0), SRW is invalid. MTX should be read to determine the current transfer direction.

16.1.5.4 Generation of Stop

A data transfer ends when the master signals a Stop, which can occur after all data is sent.

For a master receiver to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last data byte. This is done by setting the transmit acknowledge bit (I2C_I2CR[TXAK]) before reading the next-to-last byte. Before the last byte is read, a Stop signal must be generated.

16.1.5.5 Generation of Repeated Start

After the data transfer, if the master still requires the bus, it can signal another Start followed by another slave address without signaling a Stop.

16.1.5.6 Slave mode

In the slave interrupt service routine (see Figure 16-5), the block addressed as slave bit (IAAS) should be tested to check if a calling of its own address has just been received. If IAAS is set, software should set the Transmit/Receive mode select bit (I2C_I2CR[MTX]) according to the I2C_I2SR[SRW]. Writing to the I2C_I2CR clears the IAAS automatically. The only time IAAS is read as set is from the interrupt at the end of the address cycle where an address match occurred; interrupts resulting from subsequent data transfers will have IAAS cleared. A data transfer can now be initiated by writing information to I2C_I2DR for slave transmits, or read from I2C_I2DR in Slave Receive mode. A dummy read of I2C_I2DR in Slave Receive mode releases SCL, allowing the master to send data.

In the slave transmitter routine, the receive acknowledge bit (I2C_I2SR[RXAK]) must be tested before sending the next byte of data. Setting RXAK means an end-of-data signal from the master receiver, after which the software must switch it from Transmit to Receiver mode. Reading the data register (I2C_I2DR) then releases SCL so the master can generate a Stop signal.

16.1.5.7 Arbitration lost

If several devices try to engage the bus at the same time, one becomes master. Hardware immediately switches devices that lose arbitration to Slave Receive mode. Data output to 12Cn_SDA stops, but 12Cn_SCL is still generated until the end of the byte during which arbitration is lost. An interrupt occurs at the falling edge of the ninth clock of this transfer if the arbitration is lost (I2C_I2SR[IAL] = 1), and the Slave mode is selected (I2C_I2CR[MSTA] = 0).

See the flow chart in Figure 16-5.

If a device that is not a master tries to transmit or do a Start, hardware inhibits the transmission, clears MSTA without signaling a Stop, generates an interrupt to the Arm platform, and sets I2C_I2SR[IAL] to indicate a failed attempt to engage the bus. When considering these cases, the slave service routine should first test I2C_I2SR[IAL], and the software should clear it if it is set.

For Multimaster mode, when an I2C is enabled when the bus is busy and asserts Start, the I2C_I2SR[IAL] bit gets set only for 12Cn_SDA=0, 12Cn_SCL=0/1, 12Cn_SDA=1, and 12Cn_SCL=0; but not for 12Cn_SDA=1 and I2Cn_SCL=1, which is the equivalent of Bus Idle state.

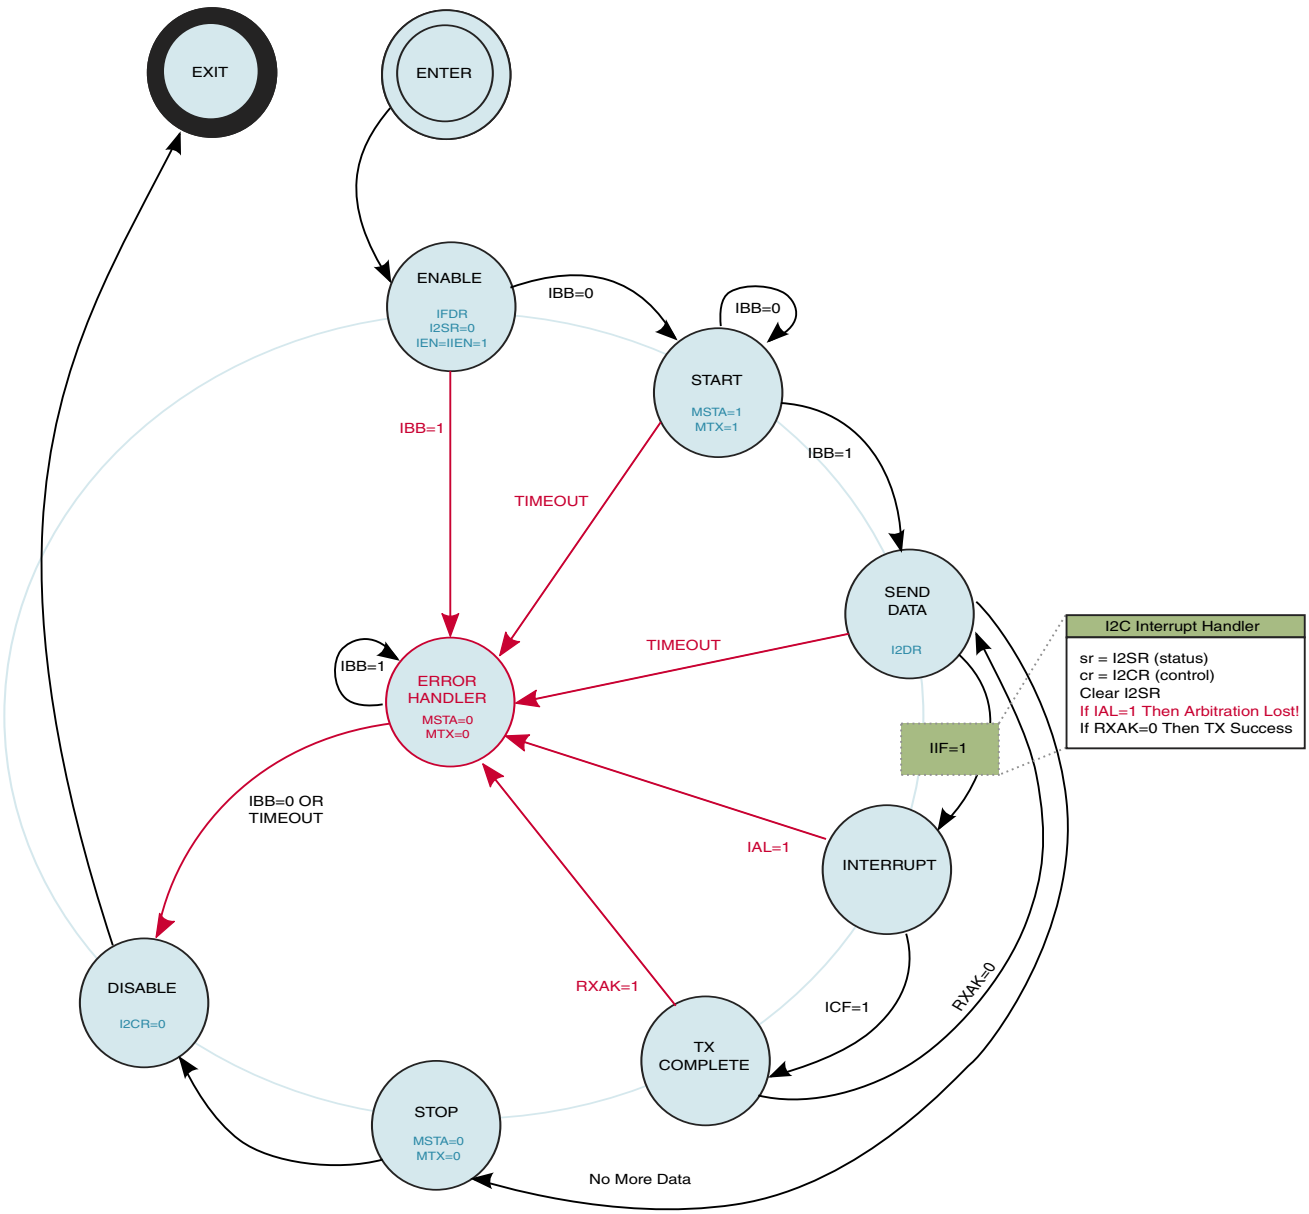

Figure 16-4. I2C Programming state diagram

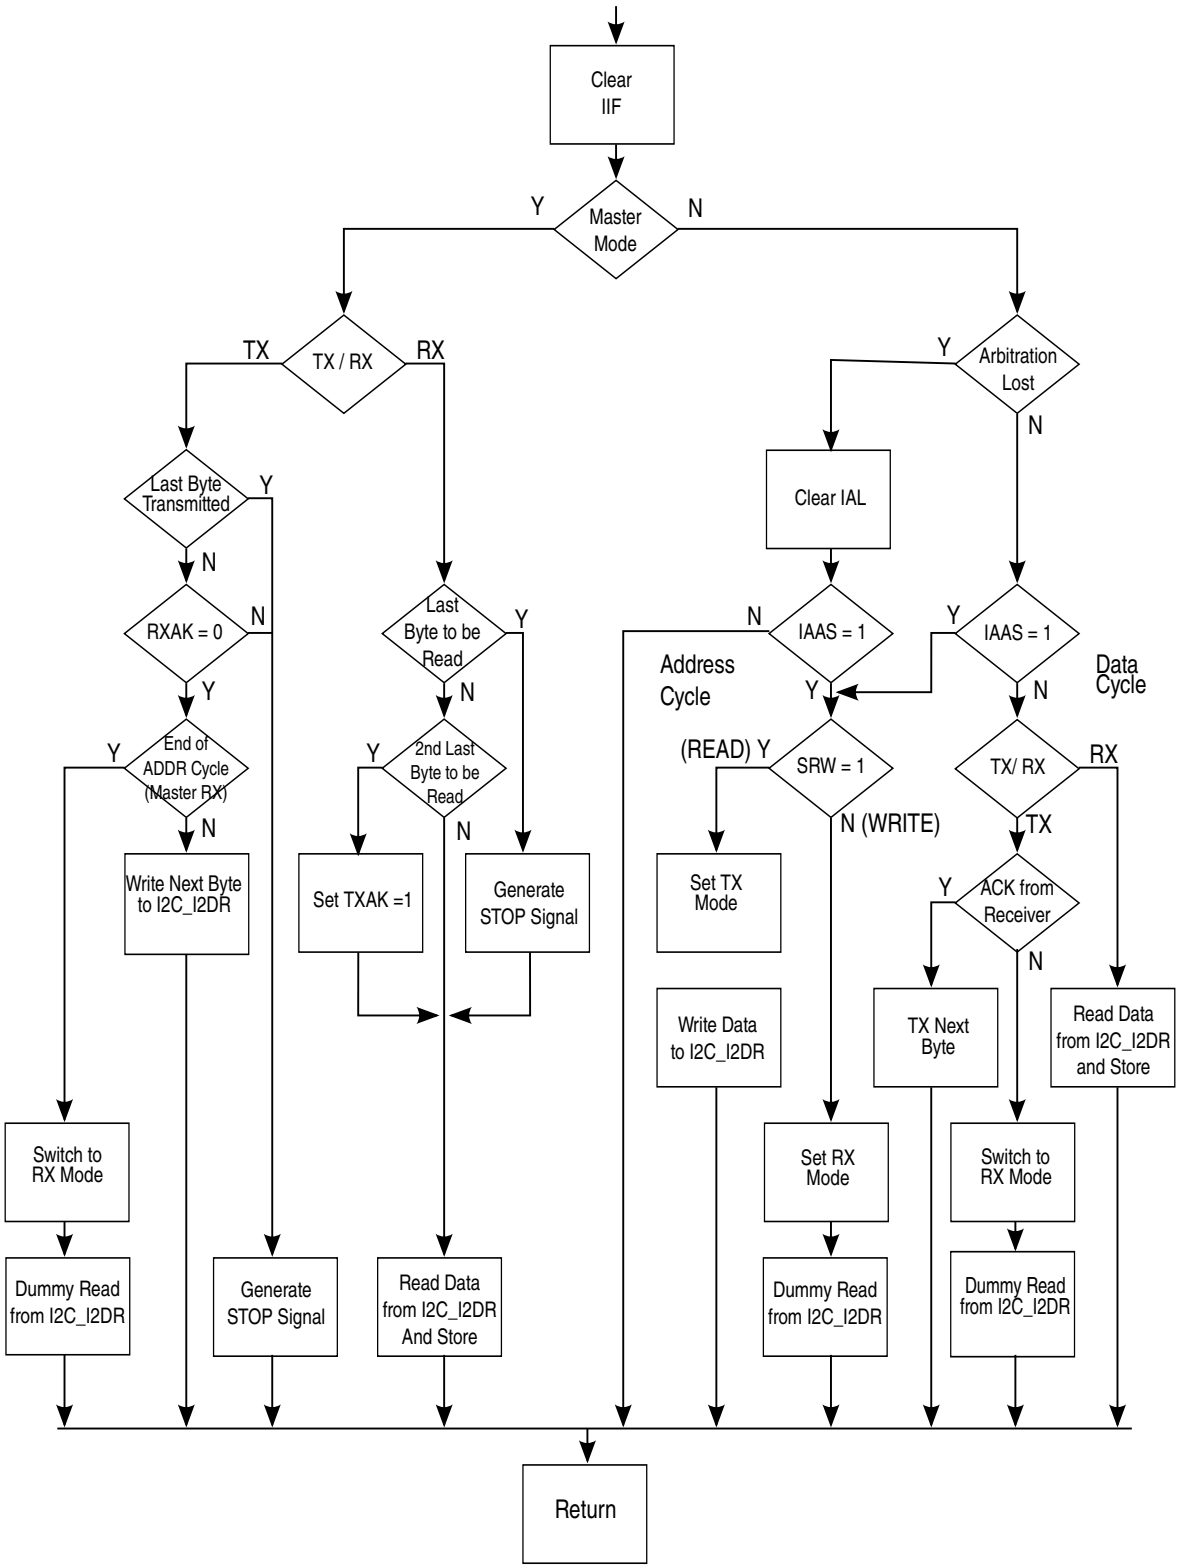

Figure 16-5. Flowchart of typical I2C interrupt routine

NOTE

For a Repeated Start only, the Stop-generation stage does not occur in Master mode. A loop repeats itself without stopping for the next start.

For Master Receive mode, I2C is programmed as Master Transmit during Address mode and after slave address transfer; the MTX bit should be cleared and a dummy read on the I2C_I2DR register should be performed so I2C can read the next receive data.

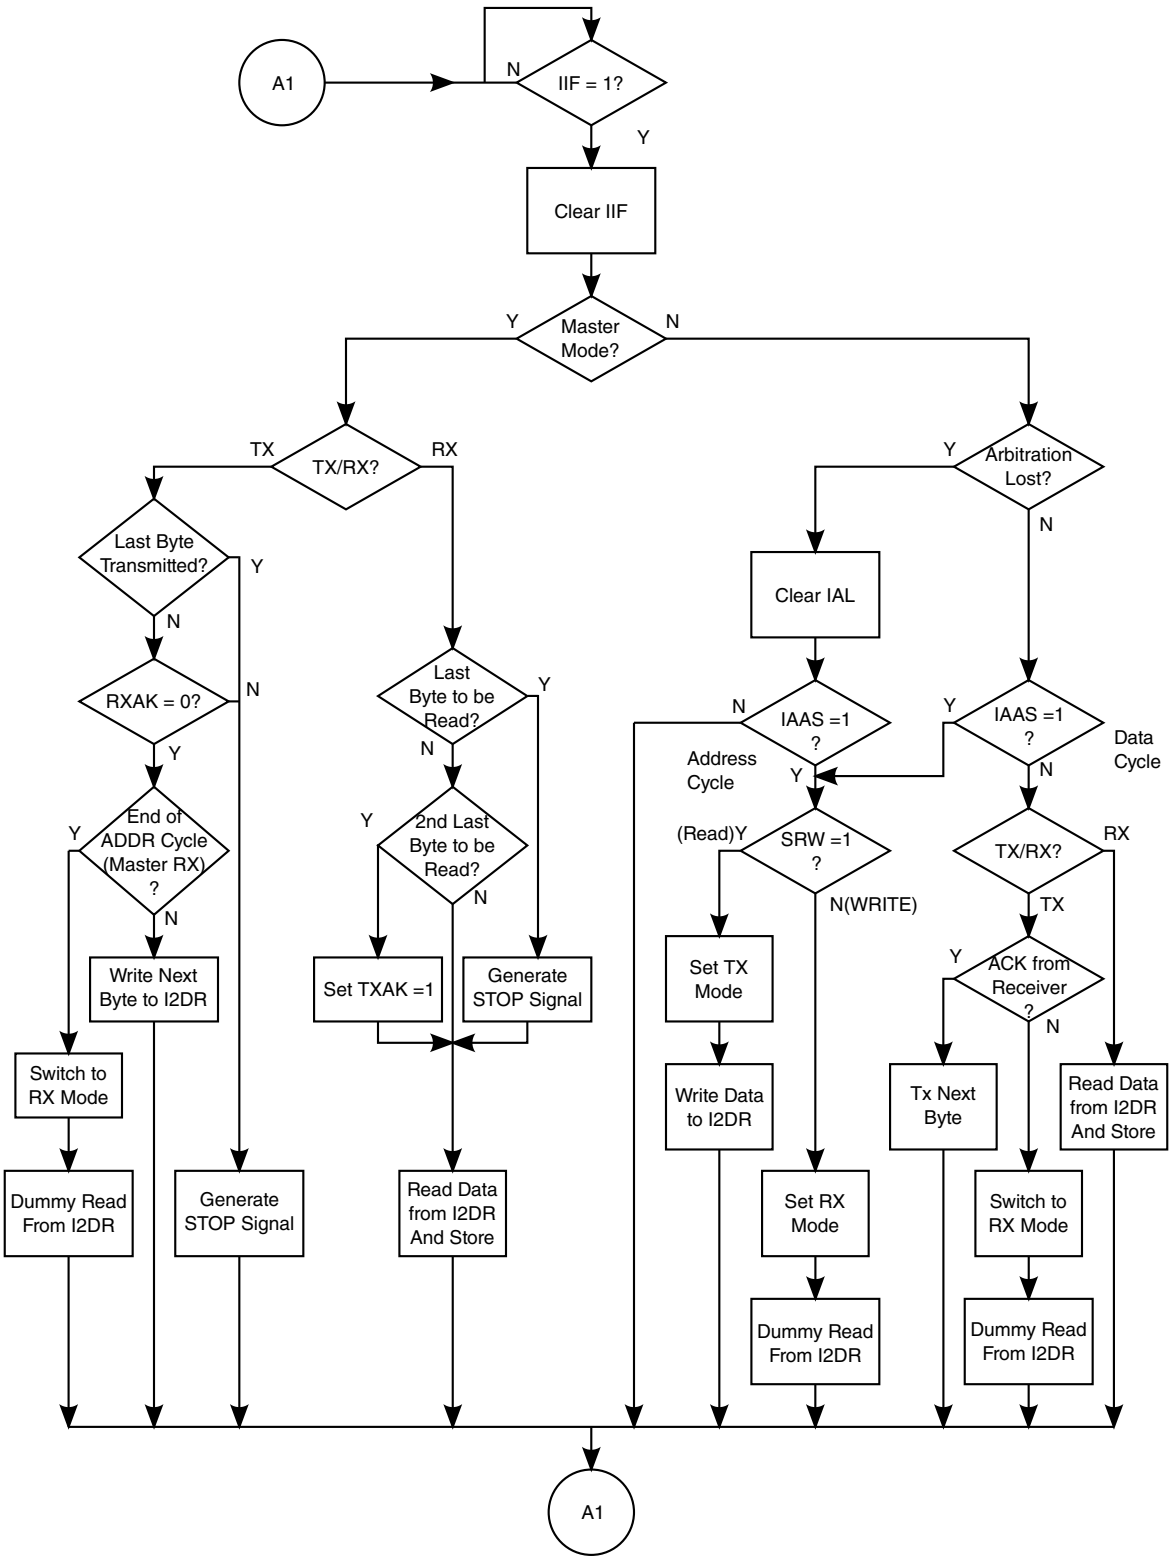

Figure 16-6. Flowchart for typical I2C polling routine

NOTE

The timeout value depends on the bus frequency at which I2C is operating. The minimum timeout for polling the IIF bit at a maximum I2C bus frequency of 400 kHz is T_{min} = 25 µs (=2.5 x 10 µs). This value can be calculated for any bus frequency. The formula is $T_{min} = 10/F_{SCL}$, where F_{SCL} is the frequency of the I2C clock (SCL).

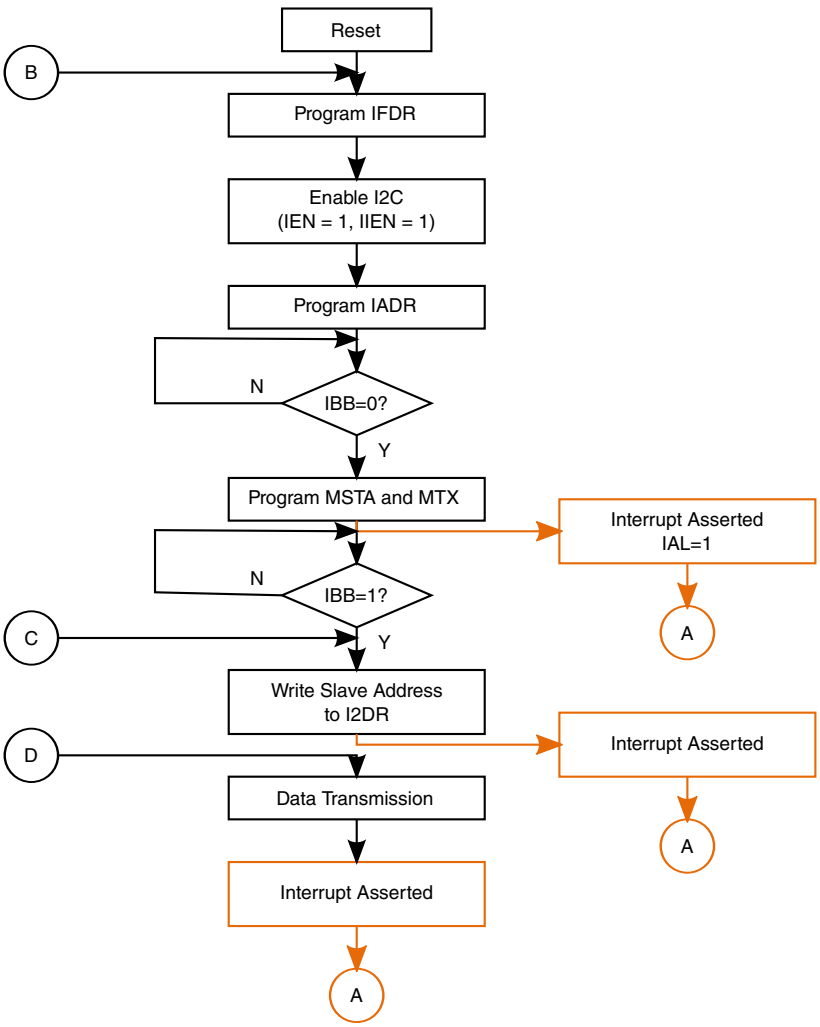

Figure 16-7. Detailed flowchart of a typical I2C Master Transmit mode, part 1

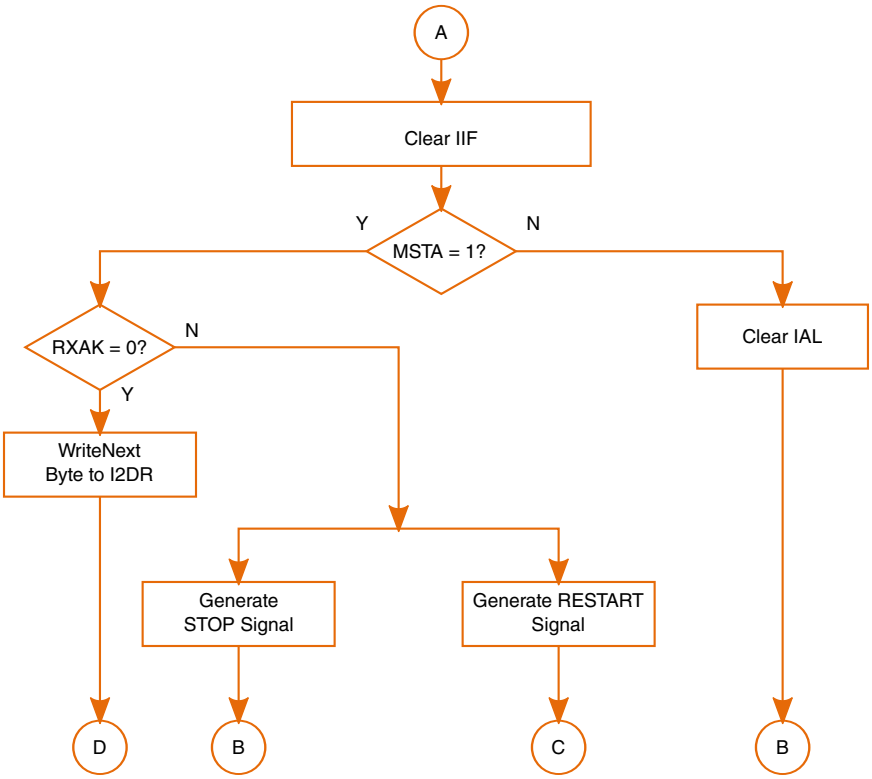

Figure 16-8. Detailed flowchart of a typical I2C Master Transmit mode, part 2

Figure 16-7 and Figure 16-8 show the Master Transmit mode operation with interrupt subroutine. If an interrupt is generated and the MSTA bit is 0, then bus arbitration is lost and IAL is set. Software can clear the IAL bit and reprogram I2C. If the MSTA bit is 1, then it is a transfer-generated interrupt. In this case, software can check the RXAK bit for a data receive acknowledgement by the slave and, accordingly, decide to do one of the following:

- Generate a STOP
- Generate a REPEATED START by writing to the I2C_I2CR register
- Perform the next data transfer by writing to the I2C_I2DR register

NOTE

The IBB bit is asserted by a Start condition on the bus, and it is deasserted by a Stop condition on the bus. Therefore, if arbitration is lost due to an unexpected Stop condition during transfer, then IBB is cleared. If arbitration is lost due to a data mismatch, then it is not cleared. Software should always clear the IEN bit and then set it if arbitration is lost.

16.1.6 Software restriction

Software should ensure that there is a delay of at least two module clock cycles after it sets the I2C_I2CR[RSTA] bit and before writing to the I2C_I2DR register. The maximum possible clock period of the module clock is 78 ns.

16.1.7 I2C Memory Map/Register Definition

The I2C contains five 16-bit registers.

NOTE

Registers at offsets 0x0002, 0x0006, 0x000A, and 0x000E are reserved for future additions.

I2C memory map

16.1.7.1 I2C Address Register (I2Cx_IADR)

Address: Base address + 0h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								ADR							0
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2Cx_IADR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value 0.
7–1 ADR	Slave address. Contains the specific slave address to be used by the I2C. Slave mode is the default I2C mode for an address match on the bus. **NOTE:** The I2C_IADR holds the address to which the I2C responds when addressed as a slave. The slave address is not the address sent on the bus during the address transfer. The register is not reset by a software reset.
0 Reserved	This read-only field is reserved and always has the value 0.

16.1.7.2 I2C Frequency Divider Register (I2Cx_IFDR)

The I2C_IFDR provides a programmable prescaler to configure the clock for bit-rate selection. The register does not get reset by a software reset.

The following table describes the divider and register values for the register field "IC."

Table 16-2. I2C_IFDR Register Field Values

IC	Divider		IC	Divider		IC	Divider		IC	Divider
0x00	30		0x10	288		0x20	22		0x30	160

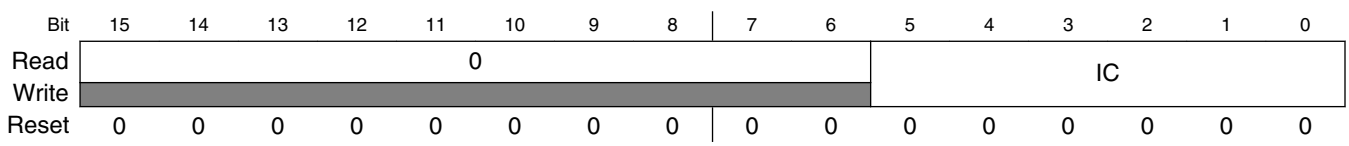
Address: Base address + 4h offset



I2Cx_IFDR field descriptions

Field	Description
15–6 Reserved	This read-only field is reserved and always has the value 0.
IC	I2C clock rate. Prescales the clock for bit-rate selection. Due to potentially slow I2Cn_SCL and I2Cn_SDA rise and fall times, bus signals are sampled at the prescaler frequency. The serial bit clock frequency may be lower than IPG_CLK_ROOT divided by the divider shown in the I2C Data I/O Register. **NOTE:** The IC value should not be changed during the data transfer, however, it can be changed before a Repeat Start or Start programming sequence in I2C. The I2C protocol supports bit rates of up to 400 kbps. The IC bits need to be programmed in accordance with this constraint.

16.1.7.3 I2C Control Register (I2Cx_I2CR)

The I2C_I2CR is used to enable the I2C and the I2C interrupt. It also contains bits that govern operation as a slave or a master.

Address: Base address + 8h offset

Bit	15	14	13	12	11	10	9	8
Read	0							
Write								
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read	IEN	IIEN	MSTA	MTX	TXAK	0	0	
Write						RSTA		
Reset	0	0	0	0	0	0	0	0

I2Cx_I2CR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value 0.
7 IEN	I2C enable. Also controls the software reset of the entire I2C. Resetting the bit generates an internal reset to the block. If the block is enabled in the middle of a byte transfer, Slave mode ignores the current bus transfer and starts operating when the next Start condition is detected. Master mode is not aware that the bus is busy, so initiating a start cycle may corrupt the current bus cycle, ultimately causing either the current master or the I2C to lose arbitration. Subsequently, bus operation returns to normal. 0 The block is disabled, but registers can still be accessed. 1 The I2C is enabled. This bit must be set before any other I2C_I2CR bits have an effect.
6 IIEN	I2C interrupt enable. **NOTE:** If data is written during the Start condition, that is, just after setting the I2C_I2CR[MSTA] and I2C_I2CR[MTX] bits, then the ICF bit is cleared at the falling edge of SCLK after Start. If data is written after the Start condition and falling edge of SCLK, then the ICF bit is cleared as soon as data is written. 0 I2C interrupts are disabled, but the status flag I2C_I2SR[IIF] continues to be set when an Interrupt condition occurs. 1 I2C interrupts are enabled. An I2C interrupt occurs if I2C_I2SR[IIF] is also set.
5 MSTA	Master/Slave mode select bit. If the master loses arbitration, MSTA is cleared without generating a Stop signal. **NOTE:** The module clock should be on for writing to the MSTA bit. **NOTE:** The MSTA bit is cleared by software to generate a Stop condition; it can also be cleared by hardware when the I2C loses the bus arbitration.

Table continues on the next page...

I2Cx_I2CR field descriptions (continued)

Field	Description
	0 Slave mode. Changing MSTA from 1 to 0 generates a Stop and selects Slave mode. 1 Master mode. Changing MSTA from 0 to 1 signals a Start on the bus and selects Master mode.
4 MTX	Transmit/Receive mode select bit. Selects the direction of master and slave transfers. 0 Receive. When a slave is addressed, the software should set MTX according to the slave read/write bit in the I2C status register (I2C_I2SR[SRW]). 1 Transmit. In Master mode, MTX should be set according to the type of transfer required. Therefore, for address cycles, MTX is always 1.
3 TXAK	Transmit acknowledge enable. Specifies the value driven onto I2Cn_SDA during acknowledge cycles for both master and slave receivers. **NOTE:** Writing TXAK applies only when the I2C bus is a receiver. 0 An acknowledge signal is sent to the bus at the ninth clock bit after receiving one byte of data. 1 No acknowledge signal response is sent (that is, the acknowledge bit = 1).
2 RSTA	Repeat start. Always reads as 0. Attempting a repeat start without bus mastership causes loss of arbitration. 0 No repeat start 1 Generates a Repeated Start condition
Reserved	This read-only field is reserved and always has the value 0.

16.1.7.4 I2C Status Register (I2Cx_I2SR)

The I2C_I2SR contains bits that indicate transaction direction and status.

Address: Base address + Ch offset

Bit	15	14	13	12	11	10	9	8
Read	0							
Write

I2Cx_I2SR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value 0.
7 ICF	Data transferring bit. While one byte of data is transferred, ICF is cleared. 0 Transfer is in progress. 1 Transfer is complete. This bit is set by the falling edge of the ninth clock of the last byte transfer.
6 IAAS	I2C addressed as a slave bit. The Arm platform is interrupted if the interrupt enable (I2C_I2CR[IIEN]) is set. The Arm platform must check the slave read/write bit (SRW) and set its Transfer/Receive mode accordingly. Writing to I2C_I2CR clears this bit. 0 Not addressed 1 Addressed as a slave. Set when its own address (I2C_IADR) matches the calling address.
5 IBB	I2C bus busy bit. Indicates the status of the bus. **NOTE:** When I2C is enabled (I2C_I2CR[IEN] = 1), it continuously polls the bus data (SDA) and clock (SCL) signals to determine a Start or Stop condition. 0 Bus is idle. If a Stop signal is detected, IBB is cleared. 1 Bus is busy. When Start is detected, IBB is set.
4 IAL	Arbitration lost. Set by hardware in the following circumstances (IAL must be cleared by software by writing a "0" to it at the start of the interrupt service routine): • I2Cn_SDA input samples low when the master drives high during an address or data-transmit cycle. • I2Cn_SDA input samples low when the master drives high during the acknowledge bit of a data-receive cycle. For the above two cases, the bit is set at the falling edge of the ninth I2Cn_SCL clock during the ACK cycle. • A Start cycle is attempted when the bus is busy. • A Repeated Start cycle is requested in Slave mode. • A Stop condition is detected when the master did not request it. **NOTE:** Software cannot set the bit. 0 No arbitration lost. 1 Arbitration is lost.
3 Reserved	This read-only field is reserved and always has the value 0.
2 SRW	Slave read/write. When the I2C is addressed as a slave, IAAS is set, and the slave read/write bit (SRW) indicates the value of the R/W command bit of the calling address sent from the master. SRW is valid only when a complete transfer has occurred, no other transfers have been initiated, and the I2C is a slave and has an address match. 0 Slave receive, master writing to slave 1 Slave transmit, master reading from slave
1 IIF	I2C interrupt. Must be cleared by the software by writing a "0" to it in the interrupt routine. **NOTE:** The software cannot set the bit. 0 No I2C interrupt pending. 1 An interrupt is pending.

Table continues on the next page...

I2Cx_I2SR field descriptions (continued)

Field	Description
	This causes a processor interrupt request (if the interrupt enable is asserted [IIEN = 1]). The interrupt is set when one of the following occurs: • One byte transfer is completed (the interrupt is set at the falling edge of the ninth clock). • An address is received that matches its own specific address in Slave Receive mode. • Arbitration is lost.
0 RXAK	Received acknowledge. This is the value received from the I2Cn_SDA input for the acknowledge bit during a bus cycle. 0 An "acknowledge" signal was received after the completion of an 8-bit data transmission on the bus. 1 A "No acknowledge" signal was detected at the ninth clock.

16.1.7.5 I2C Data I/O Register (I2Cx_I2DR)

In Master Receive mode, reading the data register allows a read to occur and initiates the next byte to be received. In Slave mode, the same function is available after it is addressed.

Address: Base address + 10h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								DATA							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2Cx_I2DR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value 0.
DATA	Data Byte. Holds the last data byte received or the next data byte to be transferred. Software writes the next data byte to be transmitted or reads the data byte received. **NOTE:** The core-written value in I2C_I2DR cannot be read back by the core. Only data written by the I2C bus side can be read.

16.2 Universal Asynchronous Receiver/Transmitter(UART)

16.2.1 Overview

Universal Asynchronous Receiver/Transmitter (UART) provides serial communication capability with external devices through a level converter and an RS-232 cable or through use of external circuitry that converts infrared signals to electrical signals (for reception) or transforms electrical signals to signals that drive an infrared LED (for transmission) to provide low speed IrDA compatibility.

UART supports NRZ encoding format , RS485 compatible 9 bit data format and IrDA-compatible infrared slow data rate (SIR) format.

Figure 16-9 is the UART block diagram.

The "Module Clock" is the UART_CLK which comes from CCM. The "Peripheral Clock" is the IPG_CLK which comes from CCM.

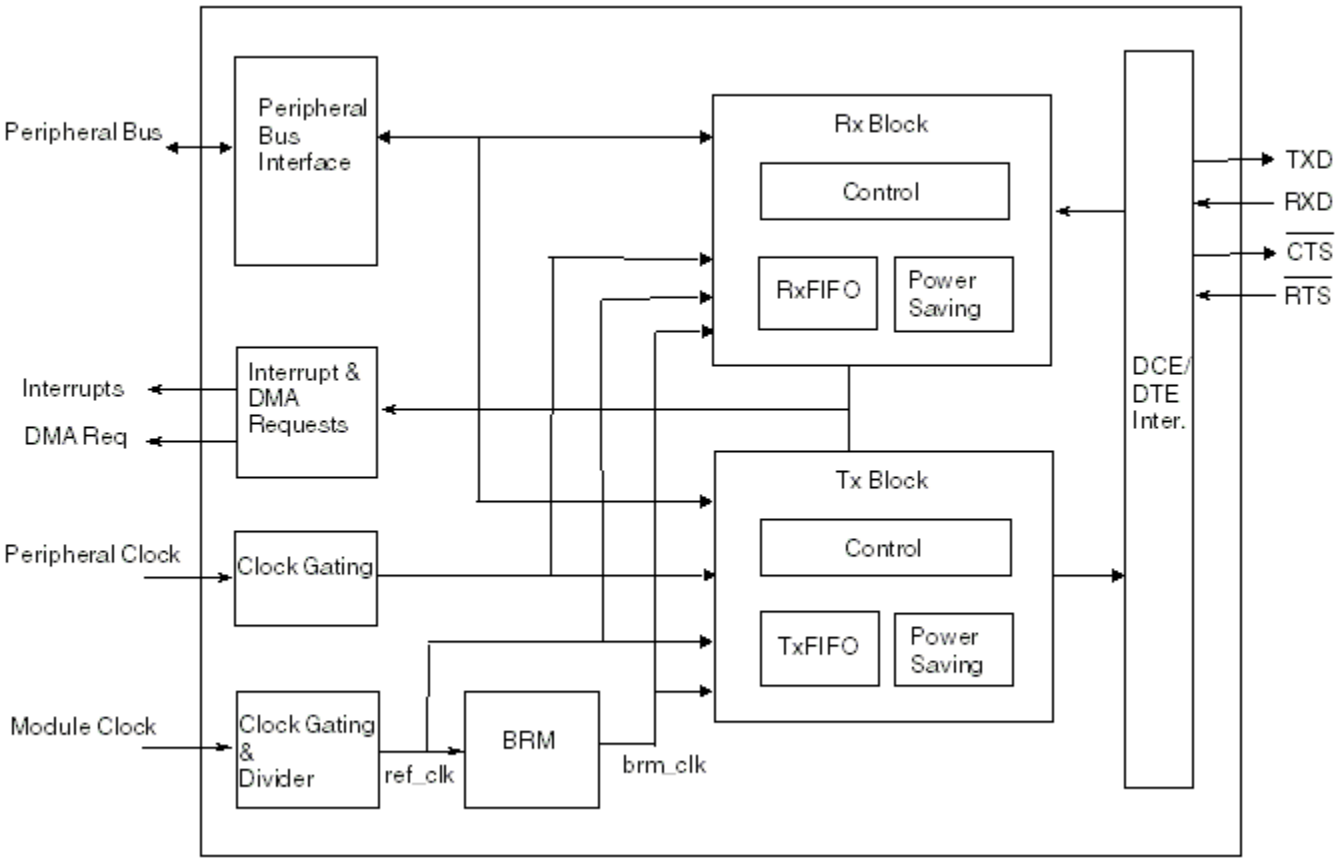

Figure 16-9. UART Block Diagram

16.2.1.1 Features

The UART includes the following features:

- High-speed TIA/EIA-232-F compatible, up to Mbit/s
- Serial IR interface low-speed, IrDA-compatible (up to 115.2 Kbit/s)
- 9-bit or Multidrop mode (RS-485) support (automatic slave address detection)
- 7 or 8 data bits for RS-232 characters, or 9 bit RS-485 format
- 1 or 2 stop bits
- Programmable parity (even, odd, and no parity)
- Hardware flow control support for request to send (RTS_B) and clear to send (CTS_B) signals
- RS-485 driver direction control via CTS_B signal
- Edge-selectable RTS_B and edge-detect interrupts
- Status flags for various flow control and FIFO states
- Voting logic for improved noise immunity (16x oversampling)
- Transmitter FIFO empty interrupt suppression

- UART internal clocks enable/disable
- Auto baud rate detection (up to 115.2 Kbit/s)
- Receiver and transmitter enable/disable for power saving
- RX_DATA input and TX_DATA output can be inverted respectively in RS-232/ RS-485 mode
- DCE/DTE capability
- RTS_B, IrDA asynchronous wake (AIRINT), receive asynchronous wake (AWAKE) interrupts wake the processor from STOP mode
- Maskable interrupts
- Two DMA Requests (TxFIFO DMA Request and RxFIFO DMA Request)
- Escape character sequence detection
- Software reset (SRST_B)
- Two independent, 32-entry FIFOs for transmit and receive
- The peripheral clock can be totally asynchronous with the module clock. The module clock determines baud rate. This allows frequency scaling on peripheral clock (such as during DVFS mode) while remaining the module clock frequency and baud rate.

16.2.1.2 Modes of operation

- Serial RS-232NRZ mode
- 9-bit RS-485 mode
- IrDA mode

To set UART in different modes, see the table below.

Table 16-3. UART mode definition

MDEN (UMCR[0])	IREN (UCR1[7])	UART Mode	Descriptioin
0	0	RS-232	RXD/TXD data is serial RS-232 NRZ format
0	1	IrDA (Interface)	RXD/TXD data is IrDA-compatible infrared slow data rate (SIR) format
1	0	RS-485	RXD/TXD data is RS485 compatible 9 bit data format
1	1	Undefined	Undefined

16.2.2 External Signals

The chip-level IOMUX modifies the direction and routing of the UART signals based on whether the UART is operating in DCE mode (UARTn_UFCR[DCEDTE]=0) or DTE mode (UARTn_UFCR[DCEDTE]=1). The routing of the external signals to the UART module is shown in the figure below.

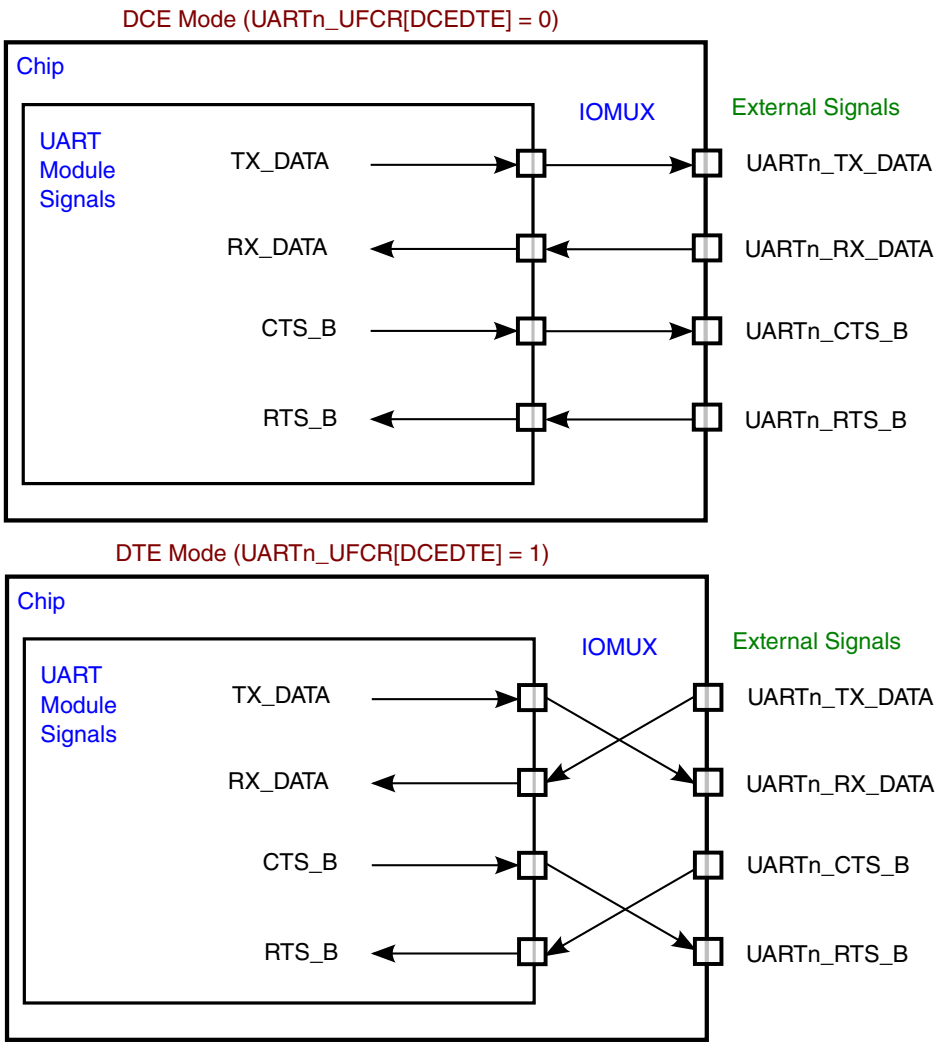

Figure 16-10. UART external signals to module signals routing with respect to DCE/DTE mode

The user must configure the input path to the UART by properly configuring the DAISY bits in the IOMUXC_UARTn_RX_DATA_INPUT and the IOMUXC_UARTn_UART_RTS_B_SELECT_INPUT registers.

For IOMUXC_UARTn_UART_RTS_B_SELECT_INPUT[DAISY]:

- Configurations that select UARTn_RTS_B for the pad are only valid when UARTn_UFCR[DCEDTE]=0 (DCE mode)
- Configurations that select UARTn_CTS_B for the pad are only valid when UARTn_UFCR[DCEDTE]=1 (DTE mode)

For IOMUXC_UARTn_UART_RX_DATA_B_SELECT_INPUT[DAISY]:

- Configurations that select UARTn_RX_DATA for the pad are only valid when UARTn_UFCR[DCEDTE]=0 (DCE mode)
- Configurations that select UARTn_TX_DATA for the pad are only valid when UARTn_UFCR[DCEDTE]=1 (DTE mode)

16.2.2.1 Detailed Signal Descriptions

16.2.2.1.1 Interrupt Signals

16.2.2.1.1.1 *interrupt_uart* - UART Interrupt

Output interrupt request.

16.2.2.1.2 DMA Request Signals

16.2.2.1.2.1 *dma_req_rx* - Receiver DMA Request

Output DMA Request signal for receiver interface.

16.2.2.1.2.2 *dma_req_tx* - Transmitter DMA Request

Output DMA Request signal for transmitter interface. Set at 0 when TXDMAEN (UCR1[3]) is at 1 and TRDY (USR1[13]) is also at 1.

16.2.2.1.3 Special Signals

16.2.2.1.3.1 *stop_req* - Stop Mode

Input stop mode. Indicates to UART that Arm platform is going to enter in Stop Mode and clocks are going to stop running.

See Low Power Modes for more information about Stop Mode.

16.2.2.1.3.2 *doze_req* - Doze Mode

Input doze mode. Arm platform requests UART to switch in doze mode (power saving mode).

See Low Power Modes for more information about Doze Mode.

16.2.2.1.3.3 *debug_req* - Debug Mode

Input debug mode. Indicates UART it has to enter in debug mode.

See UART Operation in System Debug State, for more information about Debug Mode.

16.2.3 Clocks

The table found here describes the clock sources for UART.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 16-4. UART Clocks

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_s	ipg_clk_root	Peripheral access clock
ipg_perclk	uart_clk_root	Module clock

16.2.4 Functional Description

This section provides a complete functional description of the block.

16.2.4.1 Interrupts and DMA Requests

See the following table for the lists of all interrupt and DMA signals and associated interrupt and DMA sources of the UART. See register description section for explanation of interrupt/DMA enable and status.

Table 16-5. Interrupts and DMA

Interrupt/DMA Output	Interrupt/DMA Enable	Enable Register Location	Interrupt/DMA Flag	Flag Register Location
interrupt_uart	RRDYEN	UCR1 (bit 9)	RRDY	USR1 (bit 9)
	IDEN	UCR1 (bit 12)	IDLE	USR2 (bit 12)
	DREN	UCR4 (bit 0)	RDR	USR2 (bit 0)
	RXDSEN	UCR3 (bit 6)	RXDS	USR1 (bit 6)
	ATEN	UCR2 (bit 3)	AGTIM	USR1 (bit 8)
interrupt_uart	TXMPTYEN	UCR1 (bit 6)	TXFE	USR2 (bit 14)

Table continues on the next page...

Table 16-5. Interrupts and DMA (continued)

Interrupt/DMA Output	Interrupt/DMA Enable	Enable Register Location	Interrupt/DMA Flag	Flag Register Location
	TRDYEN	UCR1 (bit 13)	TRDY	USR1 (bit 13)
	TCEN	UCR4 (bit 3)	TXDC	USR2 (bit 3)
interrupt_uart	OREN	UCR4 (bit 1)	ORE	USR2 (bit 1)
	BKEN	UCR4 (bit 2)	BRCD	USR2 (bit 2)
	WKEN	UCR4 (bit 7)	WAKE	USR2 (bit 7)
	ADEN	UCR1 (bit 15)	ADET	USR2 (bit 15)
	ACIEN	UCR3 (bit 0)	ACST	USR2 (bit 11)
	ESCI	UCR2 (bit 15)	ESCF	USR1 (bit 11)
	ENIRI	UCR4 (bit 8)	IRINT	USR2 (bit 8)
	AIRINTEN	UCR3 (bit 5)	AIRINT	USR1 (bit 5)
	AWAKEN	UCR3 (bit 4)	AWAKE	USR1 (bit 4)
	FRAERREN	UCR3 (bit 11)	FRAERR	USR1 (bit 10)
	PARERREN	UCR3 (bit 12)	PARITYERR	USR1 (bit 15)
	RTSDEN	UCR1 (bit 5)	RTSD	USR1 (bit 12)
	RTSEN	UCR2 (bit 4)	RTSF	USR2 (bit 4)
	DTREN (DCE)	UCR3 (bit 13)	DTRF	USR2 (bit 13)
	RI (DTE)	UCR3 (bit 8)	RIDELT	USR2 (bit 10)
	DCD (DTE)	UCR3 (bit 9)	DCDDELT	USR2 (bit 6)
	DTRDEN	UCR3 (bit 3)	DTRD	USR1 (bit 7)
	SADEN	UMCR (bit 3)	SAD	USR1 (bit 3)
dma_req_rx	RXDMAEN	UCR1 (bit 8)	RRDY	USR1 (bit 9)
	ATDMAEN	UCR1 (bit 2)	AGTIM	USR1 (bit 8)
	IDDMAEN	UCR4 (bit 6)	IDLE	USR2 (bit 12)
dma_req_tx	TXDMAEN	UCR1 (bit 3)	TRDY	USR1 (bit 13)

16.2.4.2 Clocks

This section describes clocks and special clocking requirements of the UART.

16.2.4.2.1 Clock requirements

UART module receives 2 clocks, *peripheral_clock* and *module_clock*. The *peripheral_clock* is used as write clock of the TxFIFO, read clock of the RxFIFO and synchronization of the modem control input pins. It must always be running when UART is enabled. There is an exception in stop mode (see Clocking in Low-Power Modes).

The *module_clock* is for all the state machines, writing RxFIFO, reading TxFIFO, etc. It must always be running when UART is sending or receiving characters.This clock is used in order to allow frequency scaling on *peripheral_clock* without changing configuration of baud rate (*module_clock* staying at a fixed frequency).

The constraints on *peripheral_clock* and *module_clock* are as follows:

- *peripheral_clock* and *module_clock* can totally be asynchronous. They can also be synchronous.
- Due to the 16x oversampling of the incoming characters, *module_clock* frequency must always be greater or equal to 16x the maximum baud rate. For example, if max baud rate is 4 Mbit/s, *module_clock* must be greater or equal to 4 M x 16 = 64 MHz.

NOTE

The restriction that *peripheral_clock* frequency must be higher or equal to 16x baud rate has been removed. There is no limitation on *peripheral_clock* frequency to baud rate.

16.2.4.2.2 Maximum Baud Rate

The max baud rate the UART can support is determined by the max frequency of the module_clock.

For example, if the SoC can provide the fastest module_clock 66.5 MHz, the UART can transmit and receive serial data with the maximum baud rate 66.5M/16 = 4.15 Mbit/s.

The UART supports serial IR interface low speed. In the low speed IrDA mode, the max baud rate is 115.2 Kbit/s. To support the 115.2 Kbit/s, module_clock frequency must be higher or equal to 1.8432 MHz.

16.2.4.2.3 Clocking in Low-Power Modes

The UART supports 2 low-power modes: DOZE and STOP.

In STOP mode (input pin *stop_req* is at '1'), the UART doesn't need any clock. In this mode the UART can wake-up the Arm platform with the asynchronous interrupts (see Low Power Modes).

- If before entering in STOP mode the software has enabled RTSDEN interrupt, when RTS will change state (put at '0' by external device started to send), the asynchronous interrupt will wake-up the system, *peripheral_clock* and *module_clock* will be provided to the UART before first start bit, so that no data will be lost.
- If RTS doesn't change state (already at '0' before entering in STOP mode), then wake-up interrupt (AWAKE) will be sent at the arrival of first Start bit (on falling

edge). In this case, the UART must receive the *peripheral_clock* and *module_clock* during the first half of start bit to correctly receive this character (for example, at 115.2 Kbit/s, UART must receive *peripheral_clock* and *module_clock* at maximum 4.3 microseconds after falling edge of Start bit). If the UART receives *peripheral_clock* and *module_clock* too late, first character will be lost, and so should be dropped. Also, if autobaud detection is enabled, the first character won't be correctly received and another autobaud detection will need to be initiated.

In Doze mode, UART behavior is programmable through DOZE bit (UCR1[1]). If DOZE bit is set to '1', then UART is disabled in Doze mode, and in consequence, UART clocks can be switched-off (after being sure UART is not transmitting nor receiving). On the contrary, if DOZE bit is set to '0', UART is enabled and it must receive *peripheral_clock* and *module_clock* .

16.2.4.3 General UART Definitions

Definitions of terms that occurs the following discussions are given in this section.

- Bit Time-The period of time required to serially transmit or receive 1 bit of data (1 cycle of the baud rate frequency).
- Start bit-The bit time of a logic 0 that indicates the beginning of a data frame. A start bit begins with a 1-to-0 transition, and is preceded by at least 1 bit time of logic 1.
- Stop bit-1 bit time of logic 1 that indicates the end of a data frame.
- BREAK-A frame in which all of the data bits, including the stop bit, are logic 0. This type of frame is usually sent to signal the end of a message or the beginning of a new message.
- Mark - When no data is being sent, the serial port's transmit pin's voltage is 1 and is said to be in a MARK state.
- Space - The serial port can also be forced to keep the transmit pin at a 0 and is said to be the SPACE or BREAK state.
- Frame-A start bit followed by a specified number of data or information bits and terminated by a stop bit. The number of data or information bits depends on the format specified and must be the same for the transmitting device and the receiving device. The most common frame format is 1 start bit followed by 8 data bits (least significant bit first) and terminated by 1 stop bit. An additional stop bit and a parity bit also can be included.
- Framing Error-An error condition that occurs when the stop bit of a received frame is missing, usually when the frame boundaries in the received bit stream are not synchronized with the receiver bit counter. Framing errors can go undetected if a data bit in the expected stop bit time happens to be a logic 1. A framing error is always present on the receiver side when the transmitter is sending BREAKs. However,

when the UART is programmed to expect 2 stop bits and only the first stop bit is received, this is not a framing error by definition.
- Parity Error-An error condition that occurs when the calculated parity of the received data bits in a frame does not match the parity bit received on the RX_DATA input. Parity error is calculated only after an entire frame is received.
- Idle-One in NRZ encoding format and selectable polarity in IrDA mode.
- Overrun Error-An error condition that occurs when the latest character received is ignored to prevent overwriting a character already present in the UART receive buffer (RxFIFO). An overrun error indicates that the software reading the buffer (RxFIFO) is not keeping up with the actual reception of characters on the RX_DATA input.

16.2.4.3.1 RTS_B - UART Request To Send

The UART Request To Send input controls the transmitter. The modem or other terminal equipment signals the UART when it is ready to receive by setting '0' on the RTS_B pin.

Normally, the transmitter waits until this signal is active (low) before transmitting a character, however when the Ignore RTS (IRTS) bit is set, the transmitter sends a character as soon as it is ready to transmit. An interrupt (RTSD) can be posted on any transition of this pin and can wake the Arm platform from STOP mode on its assertion. When RTS_B is set to '1' during a transmission, the UART transmitter finishes transmitting the current character and shuts off. The contents of the TxFIFO (characters to be transmitted) remain undisturbed. The operation of this input is the same regardless of whether the UART is in DTE or DCE mode.

16.2.4.3.2 RTS Edge Triggered Interrupt

The input to the RTS_B pin can be programmed to generate an interrupt on a selectable edge.

See the table below for summary of the operation of the RTS edge triggered interrupt (RTSF).

To enable the RTS_B pin to generate an interrupt, set the request to send interrupt enable (RTSEN) bit (UCR2[4]) to 1. Writing 1 to the RTS_B edge triggered interrupt flag (RTSF) bit (USR2[4]) clears the interrupt flag. The interrupt can occur on the rising edge, falling edge, or either edge of the RTS_B input. The request to send edge control (RTEC) field (UCR2[10:9]) programs the edge that generates the interrupt. When RTEC is set to 0x00 and RTSEN = 1, the interrupt occurs on the rising edge (default). When RTEC is set to 0x01 and RTSEN = 1, the interrupt occurs on the falling edge. When RTEC is set to 0x1X and RTSEN = 1, the interrupt occurs on either edge. This is a synchronous interrupt. The RTSF bit is cleared by writing 1 to it. Writing 0 to RTSF has no effect.

Table 16-6. RTS_B Edge Triggered Interrupt Truth Table

RTS_B	RTSEN	RTEC [1]	RTEC [0]	RTSF	Interrupt Occurs On…	interrupt_uart
X	0	X	X	0	Interrupt disabled	1
1->0	1	0	0	0	Rising edge	1
0->1	1	0	0	1	Rising edge	0
1->0	1	0	1	1	Falling edge	0
0->1	1	0	1	0	Falling edge	1
1->0	1	1	X	1	Either edge	0
0->1	1	1	X	1	Either edge	0

There is another RTS_B interrupt that is not programmable. The status bit RTSD asserts the *interrupt_uart* interrupt when the RTS_B delta interrupt enable = 1. This is an asynchronous interrupt. The RTSD bit is cleared by writing 1 to it. Writing 0 to the RTSD bit has no effect.

16.2.4.3.3 CTS_B - Clear To Send

This output pin serves two purposes. Normally, the receiver indicates that it is ready to receive data by asserting this pin (low). When the CTS_B trigger level is programmed to trigger at 32 characters received and the receiver detects the valid start bit of the 33 character, it de-asserts this pin. The operation of this output is the same regardless of whether the UART is in DTE or DCE mode.

16.2.4.3.4 Programmable CTS_B Deassertion

The CTS_B output can also be programmed to deassert when the RxFIFO reaches a certain level. Setting the CTS trigger level (UCR4[15:10]) at any value less than 32 deasserts the CTS_B pin on detection of the valid start bit of the N + 1 character (where N is the trigger level setting). However, the receiver continues to receive characters until the RxFIFO is full.

16.2.4.3.5 TX_DATA - UART Transmit

This is the transmitter serial output. When operating in RS-232/RS-485 mode, NRZ encoded data is transmitted, and the data can be inverted (controlled by INVT (UCR3[1])) before transmitted. When operating in infrared mode, a 3/16 bit-period pulse is output for each 0 bit transmitted, and no pulse is output for each 1 bit transmitted.

For RS-232/RS-485 applications, this pin must be connected to an RS-232/RS-485 transmitter. The operation of this output is the same regardless of whether the UART is in DTE or DCE mode. See Figure 16-11.

16.2.4.3.6 RX_DATA - UART Receive

This is the receiver serial input. When operating in RS-232/RS-485 mode, NRZ encoded data is expected, and the data can be inverted (controlled by INVR (UCR4[9])) before sampled. When operating in infrared mode, a narrow pulse is expected for each 0 bit received and no pulse is expected for each 1 bit received.

External circuitry must convert the IR signal to an electrical signal. RS-232/RS-485 applications require an external RS-232/RS-485 receiver to convert voltage levels. The operation of this input is the same regardless of whether the UART is in DTE or DCE mode. See the figure below.

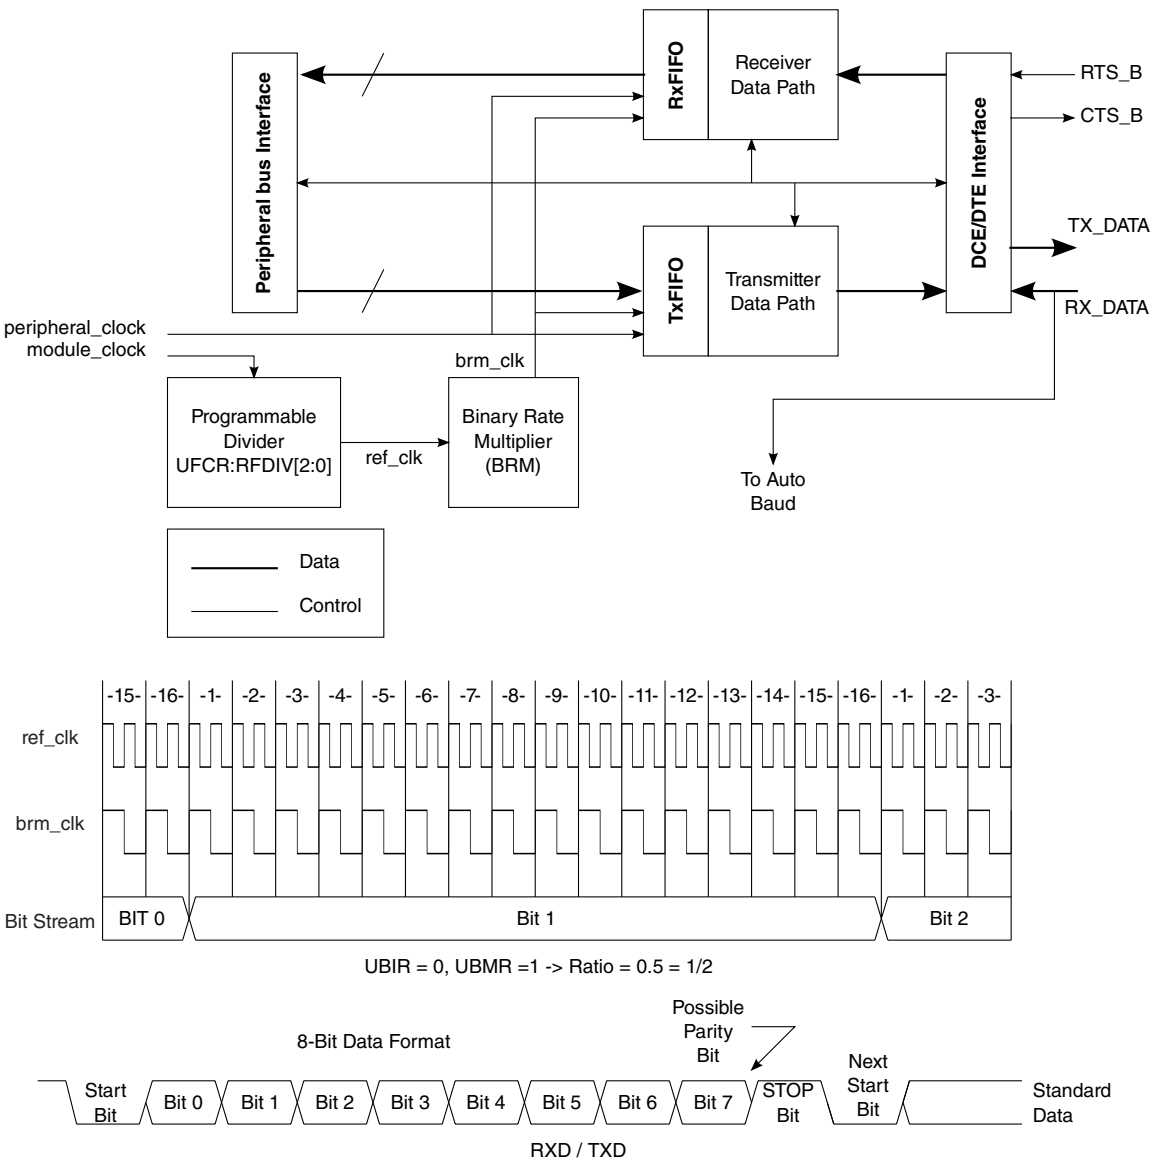

Figure 16-11. UART Simplified Block and Clock Generation Diagrams

16.2.4.4 Transmitter

The transmitter accepts a parallel character from the Arm platform and transmits it serially. The start, stop, and parity (when enabled) bits are added to the character.

When the ignore RTS bit (IRTS) is set, the transmitter sends a character as soon as it is ready to transmit. RTS_B can be used to provide flow-control of the serial data. When RTS_B is set to '1', the transmitter finishes sending the character in progress (if any), stops, and waits for RTS_B to be set to '0' again. Generation of BREAK characters and parity errors (for debugging purposes) is supported. The transmitter operates from the clock provided by the Binary Rate Multiplier(BRM). Normal NRZ encoded data is transmitted when the IR interface is disabled.

The transmitter FIFO (TxFIFO) contains 32 bytes. The data is written to TxFIFO by writing to the UTXD register with the byte data to the [7:0] bits. The data is written consecutively if the TxFIFO is not full. It is read (internally) consecutively if the TxFIFO is not empty. TXFULL bit (UTS[4]) can be used to control whether TXFIFO is full or not. The TxFIFO can be written regardless of the transmitter is disabled or enabled. If the UART is disabled, user can still write data into the TxFIFO correctly. But in this case the write access will yield to a transfer error.

16.2.4.4.1 Transmitter FIFO Empty Interrupt Suppression

The transmitter FIFO empty interrupt suppression logic suppresses the TXFE interrupt between writes to the TxFIFO.

When TxFIFO is empty, the software can either send one or several characters. If the software sends one character, it would write the character into the UTXD register, then that character is immediately transferred to the transmitter shift register, assuming the transmitter is already enabled. Without interrupt suppression logic, the TXFE interrupt flag would be set immediately. But, with this logic, the interrupt flag is set when the last bit of the character has been transmitted, for example, before the transmission of the parity bit (if exists) and the stop bit(s).

So, the suppression logic doesn't immediately send the TXFE interrupt flag. It allows the software to write another character to the TxFIFO before the interrupt flag is asserted.

When the transmitter shift register empties before another character is written to the TxFIFO, the interrupt flag is asserted. Writing data to the TxFIFO would release the interrupt flag. The interrupt flag is asserted on the following conditions:

- System Reset
- UART software reset

- When a single character has been written to Transmitter FIFO and then the Transmitter FIFO and the Transmitter Shift Register become empty until another character is written to the Transmitter FIFO
- The last character in the TxFIFO is transferred to the shift register, when TxFIFO contains two or more characters. See the figure below.

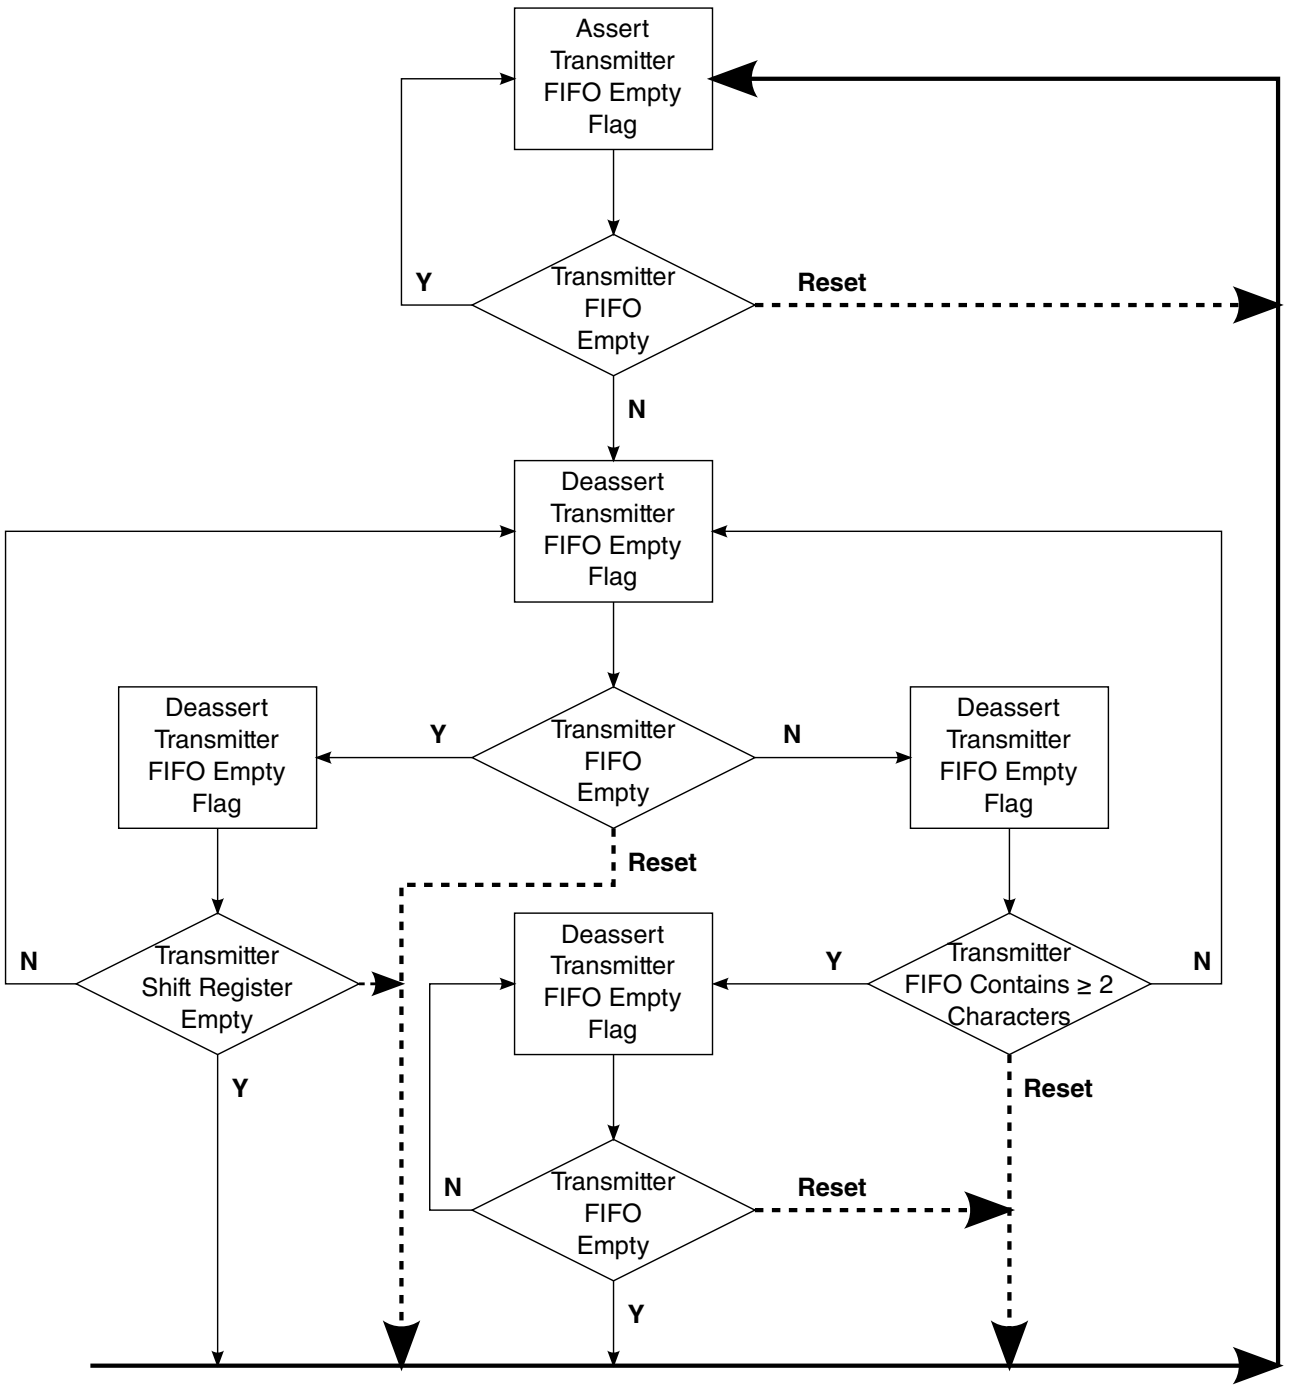

Figure 16-12. Transmitter FIFO Empty Interrupt Suppression Flow Chart

16.2.4.4.2 Transmitting a Break Condition

Asserting SNDBRK bit of the UCR1 Register forces the transmitter to send a break character (continuous zeros). The transmitter will finish sending the character in progress (if any) before sending break until this bit is reset.

The user is responsible to ensure that this bit is high for long enough to generate a valid BREAK. The transmitter samples SNDBRK after every bit is transmitted. Following completion of the BREAK transmission, the UART will transmit two mark bits. The user can continue to fill the FIFO and any character remaining will be transmitted when the break is terminated.

16.2.4.5 Receiver

See the figure below for the receiver flow chart.

The receiver accepts a serial data stream and converts it into parallel characters. When enabled, it searches for a start bit, qualifies it, and samples the following data bits at the bit-center.

Jitter tolerance and noise immunity are provided by sampling at a 16x rate and using voting techniques to clean up the samples. Once the start bit is found, the data bits, parity bit (if enabled), and stop bits (either 1 or 2 depending on user selection) are shifted in. Parity is checked and its status reported in the URXD register when parity is enabled. Frame errors and BREAKs are also checked and reported. When a new character is ready to be read by the Arm platform from the RxFIFO, the receive data ready (RDR = USR2[0]) bit is asserted and an interrupt is posted (if DREN = UCR4[0] = 1). If the receiver trigger level is set to 2 (RXTL[5:0] = UFCR[5:0] = 2), and 2 chars have been received into RxFIFO, the receiver ready interrupt flag (RRDY = USR1[9]) is asserted and an interrupt is posted if the receiver ready interrupt enable bit is set (RRDYEN = UCR1[9] = 1). If the UART Receiver Register (URXD) is read once, and in consequence there is only 1 character in the RxFIFO, the interrupt generated by the RDR bit is automatically cleared. The RRDY bit is cleared when the data in the RxFIFO falls below the programmed trigger level.

Normal NRZ encoded data is expected when the IR interface is disabled. The RxFIFO contains 32 half-word entries. Characters received are written consecutively into this FIFO. If the FIFO is full and a 33rd characters is received, this character will be ignored and the USR2[ORE] bit will be set.

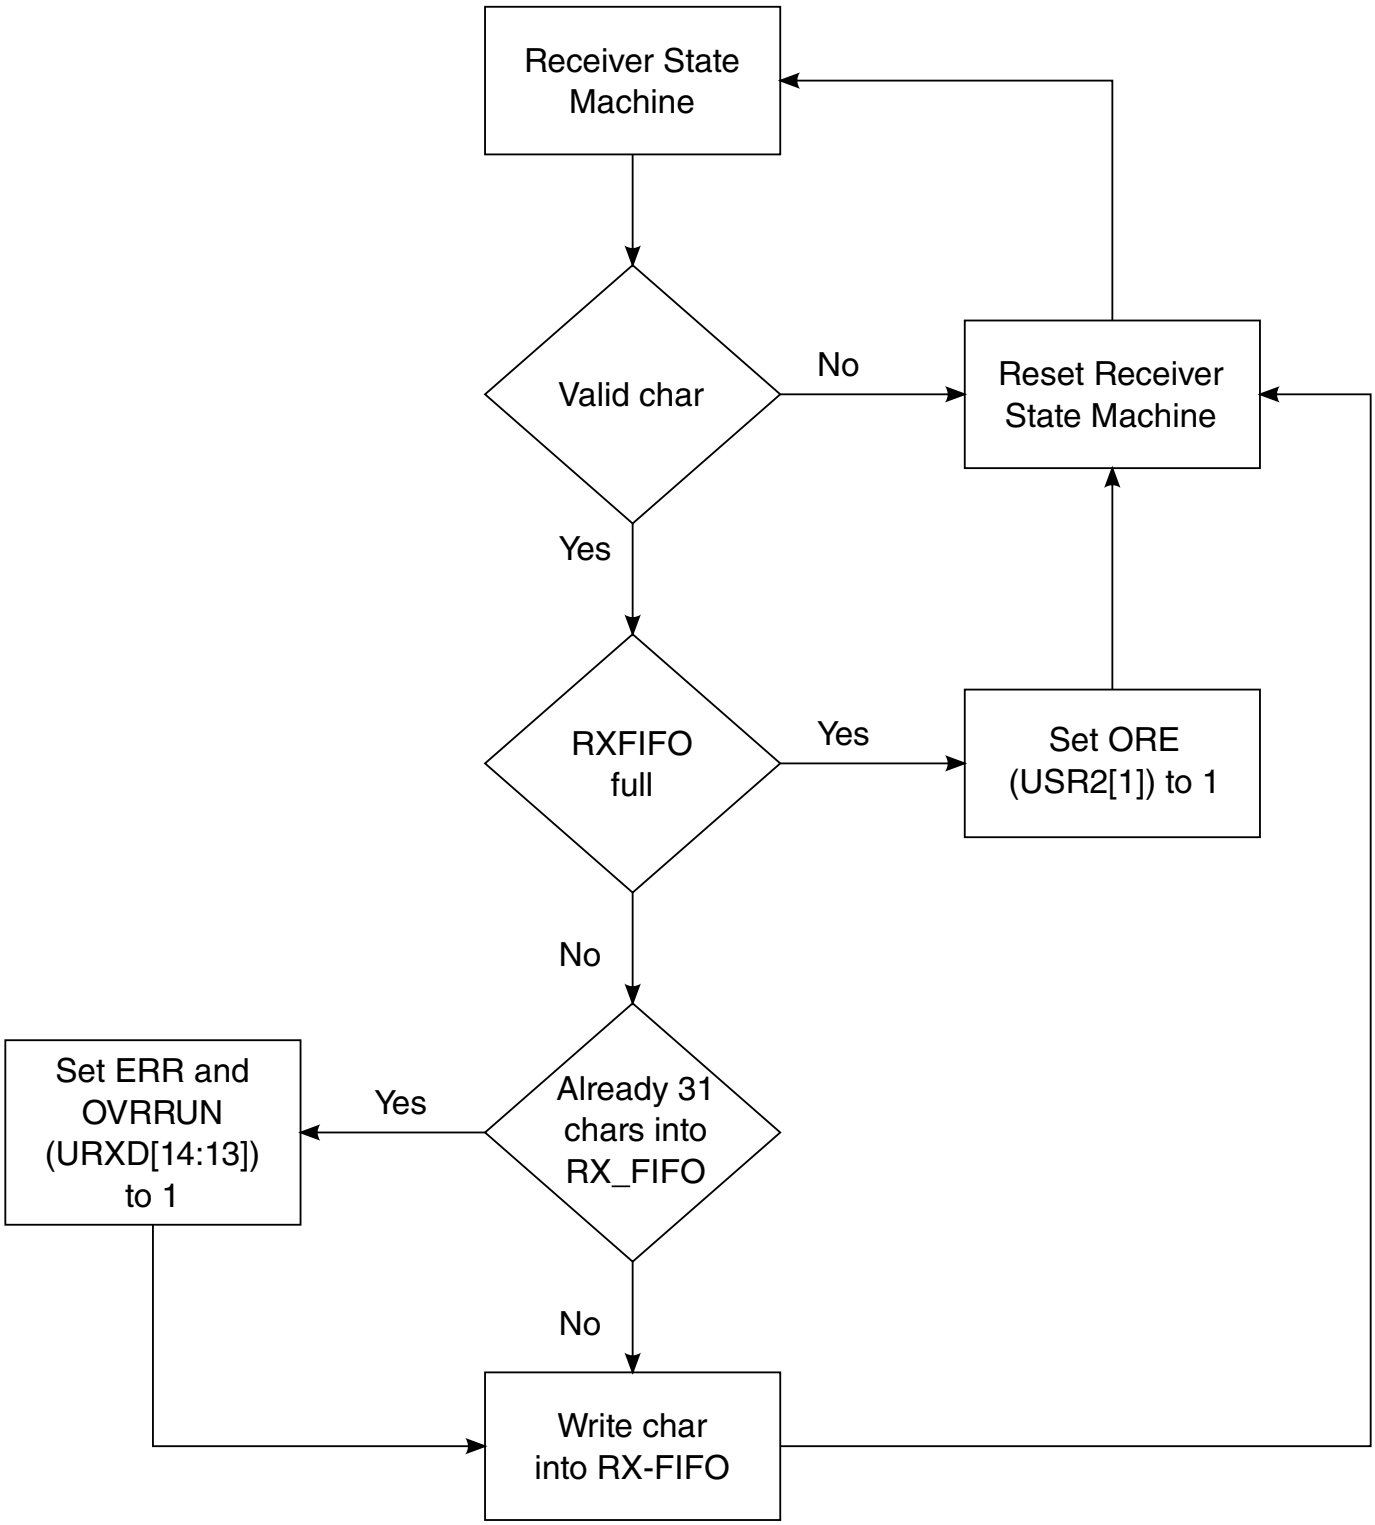

Figure 16-13. Receiver Flow Chart

16.2.4.5.1 Idle Line Detect

The receiver logic block includes the ability to detect an idle line. Idle lines indicate the end or the beginning of a message.

For an idle condition to occur:

- RxFIFO must be empty and
- RX_DATA pin must be idle for more than a configured number of frames (ICD[1:0] = UCR1[11:10]).

When the idle condition detected interrupt enable (IDEN = UCR1[12]) is set and the line is idle for 4 (default), 8, 16, or 32 (maximum) frames, the detection of an idle condition flags an interrupt (see the table below). When an idle condition is detected, the IDLE (USR2[12]) bit is set. Clear the IDLE bit by writing 1 to it. Writing 0 to the IDLE bit has no effect.

Table 16-7. Detection Truth Table

IDEN	ICD [1]	ICD [0]	IDLE	*interrupt_uart*
0	X	X	0	1
1	0	0	asserted after 4 idle frames	asserted after 4 idle frames
1	0	1	asserted after 8 idle frames	asserted after 8 idle frames
1	1	0	asserted after 16 idle frames	asserted after 16 idle frames
1	1	1	asserted after 32 idle frames	asserted after 32 idle frames
NOTE: This table assumes that no other interrupt is set at the same time this interrupt is set for the *interrupt_uart* signal. This table shows how this interrupt affects the *interrupt_uart* signal.				

During a normal message there is no idle time between frames. When all of the information bits in a frame are logic 1s, the start bit ensures that at least one logic 0 bit time occurs for each frame so that the IDLE bit is not asserted.

16.2.4.5.2 Aging Character Detect

The receiver block also includes the possibility to detect when at least one character has been sitting into the RxFIFO for a time corresponding to 8 characters. This aging character capability allows the UART to inform the Arm platform that there is less character into the RxFIFO than the Rx trigger and, no new character has been detected on the RXD line.

The aging capability is a timer which starts to count as soon as the RxFIFO is not empty and its trigger level is not reached (RRDY=0). This counter is reset when either a RxFIFO read is performed or another character starts to present on the RXD line. If none of those two events occurs, the bit AGTIM (USR1[8]) is set when the counter has

measured a time corresponding to 8 characters. AGTIM is cleared by writing a 1 to it. AGTIM can flag an interrupt to Arm platform on *interrupt_uart* if ATEN (UCR2[3]) has been set.

To summarize, AGTIM is set when:

- There is at least one character into RxFIFO.
- No read has occurred on RxFIFO and RXD line has stayed high, for a time corresponding to 8 characters.
- The RxFIFO trigger is not reached (RRDY=0)

16.2.4.5.3 Receiver Wake

The WAKE bit (USR2[7]) is set when the receiver detects a qualified Start bit. For this, two conditions must be fulfilled, firstly a falling edge on RX_DATA line must be detected and secondly the RX_DATA line must stays at low level for more than a half-bit duration.

When the wake interrupt enable WKEN (UCR4[7]) bit is enabled, the receiver flags an interrupt (*interrupt_uart*) if the WAKE status bit is set. The WAKE bit is cleared by writing 1 to it. Writing 0 to the WAKE bit has no effect. The WAKE status bit can be asserted in either serial RS-232 mode or IR mode. The generation of the WAKE interrupt needs the clock *module_clock* .

When the asynchronous wake interrupt (AWAKE) is enabled (AWAKEN = UCR3[4] = 1), and the Arm platform is in STOP mode, and UART clocks have been shut-off, then a falling edge detected on the receive pin (RX_DATA) asserts the AWAKE bit (USR1[4]) and the *interrupt_uart* interrupt to wake the Arm platform from STOP mode. Re-enable UART clocks and clear the AWAKE bit by writing 1 to it. Writing 0 to the AWAKE bit has no effect. When IR interface is enabled (UCR1[7]=1), the AWAKE bit is always not asserted. The generation of the asynchronous AWAKE interrupt does not need any clocks.

In IR mode, if the asynchronous IR WAKE interrupt is enabled (AIRINTEN = UCR3[5] = 1), and if the Arm platform is in STOP mode (UART clocks are off when Arm platform in STOP mode), then the detection of a falling edge on the receive pin (RXD_IR), asserts the AIRINT bit (USR1[5]), and the *interrupt_uart* interrupt. This interrupt wakes the Arm platform from STOP mode. Software re-enables UART clocks and clear the AIRINT bit by writing 1 to it. Writing 0 to the AIRINT bit has no effect. When IR interface is disabled (UCR1[7]=0), the AIRINT bit is always not asserted. The generation of the asynchronous AIRINT interrupt does not need any clocks.

Recommended procedure for programming the asynchronous interrupts is to first clear them by writing 1 to the appropriate bit in the UART Status Register 1 (USR1). Poll or enable the interrupt for the Receiver IDLE Interrupt Flag (RXDS) in the USR1. When asserted, the RXDS bit indicates to the software that the receiver state machine is in the idle state, the next state is idle, and the RX_DATA pin is idle (high). After following this procedure, enable the asynchronous interrupt and enter STOP mode.

16.2.4.5.4 Receiving a BREAK Condition

A BREAK condition is received when the receiver detects all 0s (including a 0 during the bit time of the stop bit) in a frame. The BREAK condition asserts the BRCD bit (USR2[2]) and writes only the first BREAK character to the RxFIFO. Clear the BRCD bit by writing 1 to it. Writing 0 to the BRCD bit has no effect.

Asserting BRCD would generate an interrupt on *interrupt_uart*. The interrupt generation can be masked using the control bit BKEN (UCR4[2]). Receiving a break condition will also effect the following bits in the receiver register URXD:

URXD(11) = BRK. While high this bit indicates that the current char was detected as a break.

URXD(12) = FRMERR. The frame error bit will always be set when BRK is set.

URXD(10) = PRERR. If odd parity was selected the parity error bit will also be set when BRK is set.

URXD(14) = ERR. The error detect bit indicates that the character present in the rx data field has an error status. This can be asserted by a break.

16.2.4.5.5 Vote Logic

The vote logic block provides jitter tolerance and noise immunity by sampling with respect to a 16x clock (*brm_clk*) and using voting techniques to clean up the samples. The voting is implemented by sampling the incoming signal constantly on the rising edge of the *brm_clk*.

See Figure 16-14. The receiver is provided with the majority vote value, which is 2 out of the 3 samples. For examples of the majority vote results of the vote logic, see the following table.

Table 16-8. Majority Vote Results

Samples	Vote
000	0

Table continues on the next page...

Table 16-8. Majority Vote Results (continued)

Samples	Vote
101	1
001	0
111	1

The vote logic captures a sample on every rising edge of *brm_clk*, however the receiver uses 16x oversampling to take its value in the middle of the sample character.

The receiver starts to count when the Start bit is set however it does not capture the contents of the RxFIFO at the time the Start bit is set. The start bit is validated when 0s are received for 7 consecutive 1/16 of bit times following the 1-to-0 transition. Once the counter reaches 0xF, it starts counting on the next bit and captures it in the middle of the sampling frame (see Table 16-8). All data bits are captured in the same manner. Once the stop bit is detected, the receiver shift register (SIPO_OUT) data is parallel shifted to the RxFIFO.

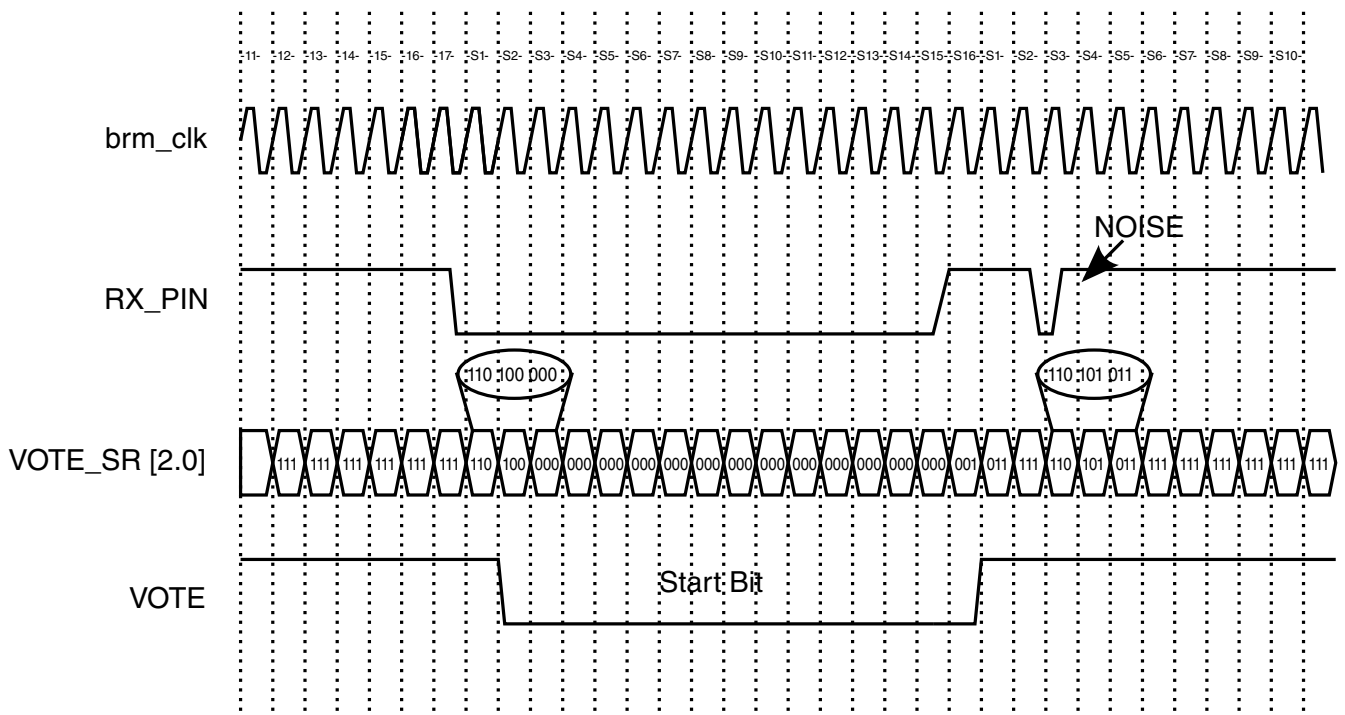

Figure 16-14. Majority Vote Results

A new feature has been recently implemented, it allows to re-synchronize the counter on each edge of RX_DATA line. This is automatic and allows to improve the immunity of UART against signal distortion.

There is a special case when the *brm_clk* frequency is too low and is unable to capture a 0 pulse in IrDA. In this case, the software must set the IRSC (UCR4[5]) bit so that the reference clock (after internal divider) is used for the voting logic. The pulse is validated by counting the length of the pulse.

Refer to Infrared Interface for more details.

16.2.4.5.6 Baud Rate Automatic Detection Logic

When the baud rate automatic detection logic is enabled, the UART locks onto the incoming baud rate. To enable this feature, set the automatic detection of baud rate bit (ADBR = UCR1[14] = 1) and write 1 to the ADET bit (USR2[15]) to clear it.

When ADET=0 and ADBR =1, the detection starts. Then, once the beginning of start bit (transition from 1-to-0 of RX_DATA) has been detected, UART starts a counter (UBRC) working at reference frequency. Once the end of start bit is detected (transition from 0-to-1 of RX_DATA), the value of UBRC - 1 is directly copied into UBMR register. UBIR register is filled with 0x000F.

So, at the end of start bit, registers gets following values:

```
UBRC = number of reference clock periods (after divider) during Start bit.
UBIR = 0x000F
UBMR = UBRC - 1
```

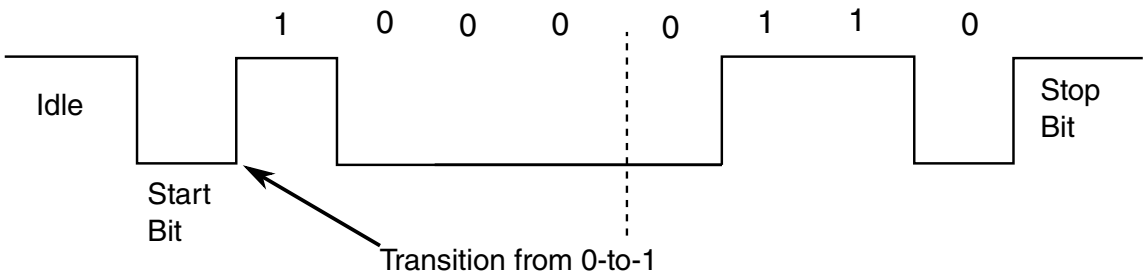
The updated values of the 3 registers can be read.

See Table 16-9 for list of parameters for baud rate detection and Figure 16-15 for baud rate detection protocol diagram.

If any of the UART BRM registers are simultaneously written by the baud rate automatic detection logic and by the peripheral data bus, the peripheral data bus would have lower priority.

Table 16-9. Baud Rate Automatic Detection

ADBR	ADET	Baud Rate Detection	*interrupt_uart*
0	X	Manual Configuration	1
1	0	Auto Detection Started	1
1	1	Auto Detection Complete	0
NOTE: This table assumes that no other interrupt is set at the same time this interrupt is set for the *interrupt_uart* signal.			



Note: LSB Transmitted first.

Figure 16-15. Baud Rate Detection Protocol Diagram

16.2.4.5.6.1 Baud Rate Automatic Detection Protocol

The receiver must receive an ASCII character "A" or "a" to verify proper detection of the incoming baud rate. When an ASCII character "A" (0x41) or "a" (0x61) is received and no error occurs, the Automatic Detect baud rate bit is set (ADET=1) and if the interrupt is enabled (ADEN=UCR1[15]=1), an interrupt *interrupt_uart* is generated.

When an ASCII character "A" or "a" is not received (because of a bit error or the reception of another character), the auto detection sequence restarts and waits for another 1-to-0 transition.

As long as ADET = 0 and ADBR = 1, the UART continues to try to lock onto the incoming baud rate. Once the ASCII character "A" or "a" is detected and the ADET bit is set, the receiver ignores the ADBR bit and continues normal operation with the calculated baud rate.

The UART interrupt is active (*interrupt_uart* = 0) as long as ADET = 1 and ADBR = 1. This can be disabled by clearing the automatic baud rate detection interrupt enable bit (ADEN = 0). Before starting an automatic baud rate detection sequence, set ADET = 0 and ADBR = 1.

The RxFIFO must contain the ASCII character "A" or "a" following the automatic baud rate detection interrupt.

The 16-bit UART Baud Rate Count Register (UBRC) is reset to 4 and stays at 0xFFFF when an overflow occurs. The UBRC register counts (measures) the duration of start bit. When the start bit is detected and counted, the UART Baud Rate Count Register retains its value until the next automatic baud rate detection sequence is initiated.

The Baud Rate Count Register counts only when auto detection is enabled.

16.2.4.5.6.2 New Baud Rate Determination

In order to fight against the problems caused by the distortion and the noise on the RX_DATA line, the duration of the baud rate measurement has been extended.

Previously, as described above, this determination was based on the measurement of the START bit duration. Now, this measurement is based on the duration of START bit + bit0. Bit0 is the first bit following the START bit. In fact, the counter which is started at the falling edge of START bit is no longer stopped at next rising edge (end of START bit), but it is stopped at the next falling edge (end of bit0). As the character sent is always a "A" (41h) or a "a" (61h), this second falling edge will always be present and it will indicate the end of bit0. Once this counter is stopped, the result is divided by 2 and used by the BRM to determine the incoming baud rate.

NOTE

UBRC register contains the result of this division by two, in consequence it reflects the measurement of the duration of one bit.

16.2.4.5.6.2.1 New Autobaud Counter Stopped bit and Interrupt

A new bit has been added in USR2 register: ACST (USR2[11]). This bit is set immediately after the determination of the baud rate.

So,

- if ADNIMP is not set (default), ACST is set to 1 after the end of bit0,
- If ADNIMP is set to 1, ACST is set to 1 at the end of START bit.

If ACIEN (UCR3[0]) is set to 1, ACST will flag an interrupt on *interrupt_uart* signal. This interrupt informs the Arm platform that the BRM has just been set with the result of the bit length measurement. If needed, the Arm platform can perform a read of UBMR (or UBRC) register and determine by itself the baud rate measured. Then the Arm platform has the possibility to correct the BRM registers with the nearest standardized baud rate.

NOTE

ACST is set only if ADBR is set to 1, for example, the UART is autobauding.

Clear the ACST bit by writing 1 to it. Writing 0 to the ACST bit has no effect.

16.2.4.6 Escape Sequence Detection

An escape sequence typically consists of 3 characters entered in rapid succession (such as +++). Because these are valid characters by themselves, the time between characters determines if it is a valid escape sequence.

Too much time between two of the "+" characters is interpreted as two "+" characters, and not part of an escape sequence.

The software chooses the escape character and writes its value to the UART Escape Character Register (UESC). The software must also enable escape detection feature by setting ESCEN (UCR2[11]) to 1. The hardware compares this value to incoming characters in the RxFIFO. When an escape character is detected, the internal escape timer starts to count. The software specifies a time-out value for the maximum allowable time between 2 successive escape characters (see the table below). The escape timer is programmable in intervals of 2 ms to a maximum interval of 8.192 seconds.

Table 16-10. Escape Timer Scaling

UTIM Register	Maximum Time Between Specified Escape Characters
0x000	2 ms
0x001	4 ms
0x002	6 ms
0x003	8 ms
0x004	10 ms
...	...
0F8	498 ms
0F9	500 ms
...	...
9C3	5 s
...	...
FFD	8.188 s
FFE	8.190 s
FFF	8.192 s
NOTE: To calculate the time interval: (UTIM_Value + 1) x 0.002 = Time_Interval Example: (09C3 + 1) x 0.002 = 5 s.	

The escape sequence detection feature is available for all the reference frequencies. Before using Escape Sequence Detection, the user must fill the ONEMS register. This 24-bit register must contain the value of the UART internal frequency divided by 1000. The internal frequency is obtained after the UART internal divider which is applied on *module_clock* clock.

Example I:

- If the input clock *module_clock* frequency is 66.5 MHz.
- And if the input clock *module_clock* is divided by 2 with the internal divider: UFCR[9:7] = 3'b100

$$ONEMS = \frac{66.5 \times 10^6}{2 \times 1000} = 33250 = 81E2h$$

Figure 16-16. Calculation of Frequency for ONEMS Register

Example II:

- If the input clock *module_clock* frequency is 66.5 MHz.
- And if the input clock *module_clock* is divided by 1with the internal divider: UFCR[9:7] = 3'b101

$$ONEMS = \frac{66.5 \times 10^6}{1000} = 66500 = 103C4h$$

Figure 16-17. Calculation of Frequency for ONEMS Register

The escape sequence detection interrupt is asserted when the escape sequence interrupt enable (ESCI) bit is set and an escape sequence is detected (ESCF set). Clear the ESCF bit by writing 1 to it. Writing 0 to the ESCF bit has no effect.

16.2.5 Binary Rate Multiplier (BRM)

The BRM sub-block receives *ref_clk* (*module_clock* clock after divider). From this clock, and with integer and non-integer division, BRM generates a 16x baud rate clock .

The UART transmitte will shift data out based on this 16x baud rate clock. The UART receiver will sample the serial data line based on this 16x baud rate clock. The input and output frequency ratio is programmed in the UART BRM Incremental Register (UBIR) and UART BRM MOD Register (UBMR). The output frequency is divided by the input frequency to produce this ratio. For integer division, set the UBIR = 0x000F and write the divisor to the UBMR register. All values written to these registers must be one less than the actual value to eliminate division by 0 (undefined), and to increase the maximum range of the registers.

Updating the BRM registers requires writing to both registers. The UBIR register must be written before writing to the UBMR register. If only one register is written to by the software, the BRM continues to use the previous values.

The following examples show how to determine what values are to be programmed into UBIR and UBMR for a given reference frequency and desired baud rate. The following equation can be used to help determine these values:

$$\text{BaudRate} = \frac{\text{Ref Freq}}{\left(16 \times \frac{\text{UBMR} + 1}{\text{UBIR} + 1} \right)}$$

Figure 16-18. Frequency and Baud Rate for UBIR and UBMR

With:

Reference Frequency (Hz): UART Reference Frequency (*module_clock* after RFDIV divider)

Baud Rate (bit/s): Desired baud rate.

Integer Division ÷ 21

Reference Frequency = 19.44 MHz

UBIR = 0x000F

UBMR = 0x0014

Baud Rate = 925.7 kbit/s

NOTE

Observe that each value written to the registers is one less than the actual value.

Non-Integer Division

```
Reference Frequency = 16 MHz
Desired Baud Rate = 920 Kbits/s
```

$$\frac{UBMR + 1}{UBIR + 1} = \frac{RefFreq}{16 \times BaudRate} = \frac{16 \times 10^6}{16 \times 920 \times 10^3} = 1.087$$

```
Ratio = 1.087 = 1087 / 1000
UBIR = 999 (decimal)= 0x3E7
UBMR = 1086 (decimal)= 0x43E
Non-Integer Division
Reference Frequency = 25 MHz
Desired Baud Rate = 920 kbit/s
Ratio = 1.69837 = 625 / 368
UBIR = 367 (decimal)= 0x16F
UBMR = 624 (decimal)= 0x270
```

Non-Integer Division

```
Reference Frequency: 30 MHz
Desired Baud Rate = 115.2 kbit/s
Ratio = 16.276043 = 65153 / 4003
UBIR = 4002 (decimal) = 0x0FA2
UBMR = 65152 (decimal) = 0xFE80
```

16.2.6 Infrared Interface

16.2.6.1 Generalities-Infrared

The Infrared interface is selected when IREN (UCR1[7]) is set to 1.

The Infrared Interface is compatible with IrDA Serial Infrared Physical Layer Specification. In this specification, a "zero" is represented by a positive pulse, and a "one" is represented by no pulse (line remains low).

In the UART:

In TX: For each "zero" to be transmitted, a narrow positive pulse which is 3/16 of a bit time is generated. For each "one" to be transmitted no pulse is generated (output is low). External circuitry has to be provided to drive an Infrared LED.

In RX: When receiving, a narrow negative pulse is expected for each "zero" transmitted while no pulse is expected for each "one" transmitted (input is high).

NOTE

Rx part of IR block expects to receive an inverted signal compared to IrDA specification. Circuitry external to the IC transforms the Infrared signal to an electrical signal.

The IR interface has an edge triggered interrupt (IRINT). This interrupt validates a zero bit being received. This interrupt is enabled by writing a "one" to ENIRI bit.

The behavior of Infrared Interface is determined by 3 bits INVT (UCR3[1]), INVR (UCR4[9]) and IRSC (UCR4[5]).

16.2.6.2 Inverted Transmission and Reception bits (INVT & INVR)

The values of INVT and INVR depend of the IrDA transceiver connected on the TXD_IR and RXD_IR pins of the UART. If this transceiver is not inverting on both paths Tx and Rx, a Zero is represented by a positive pulse and a One is represented by no pulse (line remains low). In this case, the bit INVT must be set to 0 and the bit INVR must be set to 1 (because Rx IR block expects an inverted signal).

On the contrary user must set INVT=1 and INVR=0 if both paths of the transceiver are inverting, that is, a Zero is represented as a negative pulse and a One is represented by no pulse (line remains high). The transceiver can also be inverting on only one path (Tx or Rx), in this case INVT and INVR must be together equal to 1 or to 0, depending on which path is inverted.

16.2.6.3 InfraRed Special Case (IRSC) Bit

The value to apply to IRSC bit is based on 2 parameters: the baud rate and the Minimum Pulse Duration (MPD) of the transceiver.

According to IrDA Standard Specification, for SIR (Serial IR) baud rates from 2.4 Kbit/s to 115.2 Kbit/s this nominal pulse duration is equal to 3/16 of a bit duration (at the selected baud rate). But, for all the baud rates a Minimum Pulse Duration is also specified. According to IrDA Standard, a Zero is represented by a light pulse, so the IrDA transceiver can't emit a light pulse shorter than the MPD. For SIR, the MPD is constant and equal to 1.41 µs.

But user must take into account the electrical MPD associated with the transceiver on the receiver path. Typically this value is 2.0 µs, but for some manufacturers MPD can go down to 1.0 µs.

In order to understand the meaning of IRSC bit, one must understand how the RX path works in IrDA mode.

When the UART is in IrDA mode, a Zero is not only detected by the state of the RXD_IR line, but also with the duration of the pulse. This pulse duration can be measured with 2 different clocks. In this case, clock is selected with the IRSC bit.

- If IRSC = 0, the clock used is the BRM clock.
- If IRSC = 1, the clock used is the UART internal clock (UART clock after the divider (RFDIV)).

In normal operation, IRSC=0. This means that at any time, the user must ensure that the frequency of BRM_clock is high enough to measure the pulse. The pulse must last at least 2 BRM clock cycles. If this condition is not fulfilled, IRSC must be set to 1.

Let's examine two examples, for a Minimum Pulse Duration equal to the MPD from the IrDA SIR specification (i.e., 1.41 µs).

1: Calculation of BRM Clock Period (Clock Period < 1.41 µs)

The user wants to receive IrDA data at 115.2 Kbit/s. The UBIR and UBMR registers are set in order to create the BRM_clock with a frequency of 16*baud rate = 16 * 115.2K = 1.843 MHz. But at the same time, in order to correctly detect the pulse, the user must be sure that 2* BRM_clock period is lower than 1.41 µs. Lets check:

BRM_clock period = 1/1843000 = 542 ns

So 2*BRM_clock period = 1.09 µs < 1.41 µs. It is fine.

2: Calculation of BRM Clock Period (Clock Period > 1.41 µs)

This time the user wants to receive at 19.2 Kbit/s. So, the BRM_clock is set to 16*19200 = 307.2 kHz. Let's check if 2* BRM_clock period < 1.41 µs:

1. BRM_clock period =1/307200 = 3.25 µs

   So 2*BRM_clock period = 6.50 µs >> 1.41 µs. It doesn't work.

   So, in this case, the BRM clock can't be used to measure the pulse duration and the user must select the UART internal clock by setting IRSC =1.

NOTE

Like for Escape character detection, when IR Special Case is enabled (IRSC=1), the UART must measure a duration. In order to do that, the user must fill the ONEMS register. Refer to Escape Sequence Detection.

16.2.6.4 IrDA interrupt

Serial infrared mode (SIR) uses an edge triggered interrupt flag IRINT (USR2[8]). When INVR =0, detection of a falling edge on the RXD pin asserts the IRINT bit. When INVR=1, detection of a rising edge on the RXD pin asserts the IRINT bit. When IRINT and ENIRI bits are both asserted, the *interrupt_uart* interrupt is asserted. Clear the IRINT bit by writing 1 to it. Writing 0 to the IRINT bit has no effect.

16.2.6.5 Conclusion about IrDA

Before using the UART in IrDA, the baud rate limit must be calculated. This baud rate limit will inform the user if IRSC bit has to be set or not.

Let's determine this limit:

As already described, if IRSC = 0, the following condition must always be fulfilled

$$2 \times BRMClockPeriod < MinPulseDuration$$

Figure 16-19. Calculation of Baud Rate

So,

$$BRMClockFrequency > \frac{2}{MPD}$$

So, knowing BRM_clock frequency = 16 * Baud Rate, we get:

$$BaudRate > \frac{1}{8 \times MinPulseDuration}$$

So, the user needs to set IRSC = 0 when:

- If Minimum Pulse Duration = 2.5 us and Baud Rate > 50 Kbit/s.
- If Minimum Pulse Duration = 2.0 us and Baud Rate > 62.5 Kbit/s.
- If Minimum Pulse Duration = 1.41 us and Baud Rate > 88.6 Kbit/s.

NOTE

For baud rates lower than the limit, IRSC must be set to1.

16.2.6.6 Programming IrDA Interface

16.2.6.6.1 High Speed

As an example, the following sequence can be used to program the IrDA interface in order to send and receive characters at 115.2 Kbit/s.

Assumptions:

- Input UART clock = 90 MHz
- Internal clock divider = 3 (divide Input UART clock by 3)
- Baud rate = 115.2 Kbit/s
- IrDA transceiver is not inverting on both channels: for Tx and Rx, a Zero is represented by a positive pulse, and a One is represented by no pulse (line stays low).
- Interrupt: Sent to Arm platform when 1 char is received into the Rx FIFO (RDR)

Registers values and Programming orders:

```
UCR1 = 0x0085
UCR1[7] = IREN = 1: Enable IR interface
UCR1[0] = UARTEN = 1: Enable UART
UTS = 0x0000
UFCR = 0x0981
TXTL[5:0] = 0x02: Default value
RFDIV[2:0] = 0x3: Divide Input UART clock by 3 (resulting internal clock  is 30 MHz)
RXTL[5:0] = 0x01: Default value
UBIR = 0x0202
UBMR = 0x20BE Baud rate = 115.2 kbit/s with internal clock = 30 MHz
UCR2 = 0x4027
UCR2[14] = IRTS = 1: Ignore level of RTS input signal
UCR2[5] = WS = 1: Characters are 8-bit length
UCR2[2] = TXEN = 1: Enable Rx path
UCR2 [1] = RXEN = 1: Enable Tx path
UCR2[0] = SRST_B = 1: No software reset
UCR3 = 0x0000

         UCR4 = 0x8201
CTSTL[5:0] = 0x20: Default value
UCR4[9] = INVR = 1: Inverted Infrared Reception (because IrDA transceiver is not inverting)
UCR4[1] = DREN = 1: To enable RDR interrupt (sent when one char is received)
```

The UART is ready to send a character as soon as there is a write into UTXD register. And an interrupt will be sent to Arm platform when a character is received.

16.2.6.6.2 Low Speed

This time, we keep the same assumptions but the speed is now 9.6 Kbit/s. So, this baud rate is below the limit (even with a Min. Pulse Duration of 2.5 us) and thus IRSC must be set to 1.

Assumptions:

- Input UART clock = 90 MHz
- Internal clock divider = 3 (divide Input UART clock by 3)
- Baud rate = 9.6 Kbit/s
- IrDA transceiver is not inverting on both channels: for Tx and Rx, a Zero is represented by a positive pulse, and a One is represented by no pulse (line stays low).
- Interrupt: Sent to Arm platform when 1 char is received into the Rx FIFO (RDR).

Registers values and Programming orders:

```
UCR1 = 0x0085
UCR1[7] = IREN = 1: Enable IR interface
UCR1[0] = UARTEN = 1: Enable UART
UFCR = 0x0981
UFCR[15:10] = TXTL[5:0] = 0x02: Default value
RFDIV[2:0] = 0x3: Divide Input UART clock by 3 (resulting internal clock  is 30 MHz)
UFCR[5:0] = RXTL[5:0] = 0x01: Default value
UBIR = 0x00FF
UBMR = 0xC354 Baud rate = 9.6 kbit/s with internal clock = 30 MHz
UCR2 = 0x4027
UCR2[14] = IRTS = 1: Ignore level of RTS input signal
UCR2[5] = WS = 1: Characters are 8-bit length
UCR2[2] = TXEN = 1: Enable Rx path
UCR2 [1] = RXEN = 1: Enable Tx path
UCR2[0] = SRST_B = 1: No software reset
UCR3 = 0x0000
UCR3[1] = INVT = 0: Positive pulse represents 0.
UCR4 = 0x8221
UCR4[15:10] = CTSTL[5:0] = 0x20: Default value
UCR4[9] = INVR = 1: Inverted Infrared Reception (because IrDA transceiver is not inverting)
UCR4[5] = IRSC = 1: Because data rate is below the limit and thus the UART internal clock is
used to measure the pulse duration.
UCR4[1] = DREN = 1: To enable RDR interrupt (sent when one char is received)
```

The UART is now ready to send a character as soon as there is a write into UTXD register. An interrupt will be sent to Arm platform when a character is received.

16.2.7 9-bit RS-485 Mode

16.2.7.1 Generalities

The UART provides a 9-bit mode to facilitate multidrop (RS-485) network communication. To enable this mode, set MDEN bit in the UMCR register to 1. When 9-bit RS-485 mode is enabled, UART transmitter can transmit the ninth bit (9^{th} bit) set by TXB8, and UART receiver can differentiate between data frames (9^{th} bit = 0) and address frames (9^{th} bit = 1).

The CTS_B pin can be used to control RS-485 output driver outside the chip.

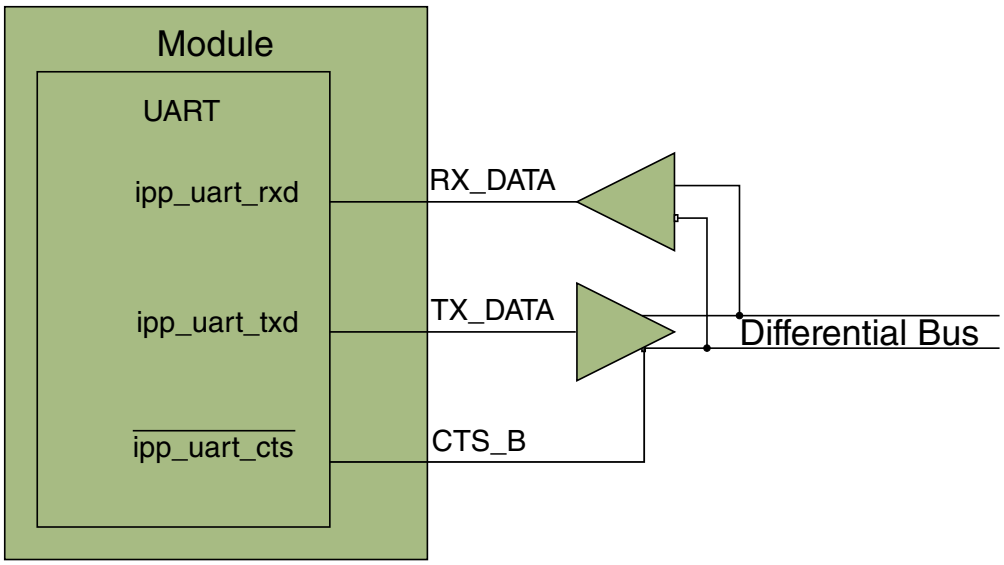


Figure 16-20. RS-485 driver connection (UART in DCE mode)

16.2.7.2 Transmit 9-bit RS-485 frames

To transmit 9-bit RS-485 frames, user need to enable parity (PREN=1) to enable trasmitting the ninth data bit, set 8-bit data word size (WS=1), and write TXB8 (UMCR[2]) as the 9th bit (bit [8]) to be transmitted (write '0' to TXB8 to transmit a data frame, write '1' to transmit a address frame). The other data bit [7:0] is written to TxFIFO by writing to the UTXD same as normal RS-232 operation.

16.2.7.3 Receive 9-bit RS-485 frames

To receive 9-bit RS-485 frames, user need to enable parity (PREN=1) to enable receiving the ninth data bit, set 8-bit data word size (WS=1). The receiver will save the 9-bit data to RxFIFO, and user should read the 9th databit (bit [8]) by reading the PRERR (URXD[10]) bit, and read data bit [7:0] by reading the RX_DATA (URXD[7:0]).

There are two slave address detect modes, normal detect mode and automatic detect mode, and can be selected by SLAM (UMCR[1]).

16.2.7.3.1 RS-485 Slave Address Normal Detect Mode

To enable Normal Detect mode, clear SLAM (UMCR[1] to 0). The receiver ignores all data frames (9th bit = 0) until an address frame is received (9th bit = 1). At that time, the slave address detected (SAD = USR1[3]) bit is asserted and the *interrupt_uart* interrupt is

generated (if SADEN = UMCR[3] = 1). The address byte and sebsequent bytes are all put into RxFIFO along with their 9th bit. The UART will also generate DMA request *dma_req_rx* when the RxFIFO reaches the selected threshold (controlled by RXTL) if receive ready DMA (RXDMAEN = UCR1[8]) request is enabled.

User should read the 9th databit (bit [8]) by reading the PRERR (URXD[10]) bit, and read data bit [7:0] by reading the RX_DATA (URXD[7:0]).

In this mode, once the UART has detected a 9th bit is equal to '1', it will always save the subsequent frames to RxFIFO. So the software must decide whether the address and data in RxFIFO are needed or not.

16.2.7.3.2 RS-485 Slave Address Automatic Detect Mode

To enable Automatic Detect Mode, set SLAM (UMCR[1]) to 1. The receiver tries to detect an address byte (frame 9th bit = 1) that matches the programmed SLADDR (UMCR[15:8]) character. If the received byte is a data or an address byte that does not match the programmed SLADDR character, the receiver will discard these data.

Once the UART receives a matching address byte, it will assert the slave address detected (SAD = USR1[3]) bit and the *interrupt_uart* interrupt will be generated (if SADEN = UMCR[3] = 1). The address byte and sebsequent bytes are all put into RxFIFO along with their 9th bit. If receive ready DMA(RXDMAEN = UCR1[8]) request is enabled, the UART will also generate DMA request *dma_req_rx* when the RxFIFO reaches the selected threshold (controlled by RXTL).

If another address byte is received and this address byte does not match SLADDR character, the receiver will discard the address byte and subsequent data byte. If the address byte again matches SLADDR character, the receiver will put this address byte and subsequent data byte in the RxFIFO along with their 9th bit.

User should read the 9th databit (bit [8]) by reading the PRERR (URXD[10]) bit, and read data bit [7:0] by reading the RX_DATA (URXD[7:0]).

See Initialization for 9-bit RS-485 programming guide.

16.2.8 Low Power Modes

These modes are controlled by the signals *doze_req* and *stop_req*. The control/status/data registers won't change when getting in/out of low power modes.

Table 16-11. UART Low Power State Operation

	Normal State (*doze_req* = 1'b0 & *stop_req* = 1'b0)	Doze State (*doze_req* = 1'b1)		Stop State (*stop_req* = 1'b1)
		DOZE bit = 0	DOZE bit = 1	
UART-Clock	ON	ON	ON	OFF
UART Serial / IrDA	ON	ON	OFF	OFF

16.2.8.1 UART Operation in System Doze Mode

While in Doze State (when *doze_req* input pin is set to 1'b1), the UART behavior depends on the DOZE (UCR1[1]) control bit.

While the DOZE bit is negated, the UART serial interface is enabled. While the system is in the Doze State, and the DOZE bit is asserted, the UART is disabled. If the Doze State is entered with the DOZE bit asserted while the UART serial interface was receiving or transmitting data, it will complete the receive/transmit of the current character and signal to the far-end transmitter/receiver to stop sending/receiving.

16.2.8.2 UART Operation in System Stop Mode

The internal baud rate clocks of the transmitter and receiver are gated off if the *stop_req* signal to UART is asserted. Even though the clocks at the input of the UART continue to run during system Stop mode, the UART will not do any transmission or reception.

The following UART interrupts wake the Arm platform processor from STOP mode:

- RTS (RTSD)
- IrDA Asynchronous WAKE (AIRINT)
- Asynchronous WAKE (AWAKE)
- RI (RIDELT in DTE mode only)
- DCD (DCDDELT in DTE mode only)
- DTR (DTRD in DCE mode only)
- DSR (DTRD in DTE mode only)

When an asynchronous WAKE (awake) interrupt exits the Arm platform from STOP mode, make sure that a dummy character is sent first because the first character may not be received correctly.

16.2.8.3 Power Saving Method in UART

The RXEN (UCR2[1]), TXEN (UCR2[2]) and UARTEN (UCR1[0]) bits are set by the user and provide software control of low-power modes.

Setting the UARTEN (UCR1[0]) bit to 0 shuts off the receiver and transmitter logic and the associated clocks.

If the UART is used only in transmit mode, UARTEN and TXEN must be set to 1. If the UART is used only in receive mode, UARTEN and RXEN must be set to 1. Setting TXEN or RXEN to 0 allows to save a lot of power.

16.2.9 UART Operation in System Debug State

The bit UTS [11] controls whether the UART will respond to the input signal *debug_req*, or whether it will continue to run as normal.

If the UART is programmed to respond to *debug_req*:

1. The UART will halt all operations upon detecting the *debug_req* input.
2. A transfer in progress, either to/from a core (using the IP Bus interface) or to/from an external device, will be completed before halting. This means a single byte/word transfer, not an entire FIFO. Reception of any further data from an external device will be disabled.
3. Internal registers will continue to be writable and readable using the IP Bus interface. A read will leave the contents unaffected.
4. The RX FIFO is affected in debug mode in the following way:
   - All writes into the RX FIFO are prevented.
   - The bit RXDBG (UTS[9]) is used to select the readability of the RX FIFO during debug mode:

     RXDBG = 0: hold the read pointer at the location it had upon entering debug mode, and URXD register returns only the data value at that location, no matter how many reads attempted.

RXDBG = 1, selectable at any time: Allow to read the characters received in Rx FIFO. It will not be possible to re-read previously read locations, nor will it be possible to readjust the read pointer to the value it had prior to entering debug mode.

16.2.10 Reset

This section describes how to reset the block and explains special requirements related to reset.

16.2.10.1 Hardware reset

All of registers, FIFOs, state machines and sequential elements can be reset to their initial values by hardware reset or power on reset.

16.2.10.2 Software reset

The status registers USR1 and USR2, BRM registers UBIR and UBMR, TxFIFO and RxFIFO, and transmitter and receiver state machines can be reset by software reset. Internal logic will keep the software reset asserted for about 4 *module_clock* cycles.

Programmer can follow the following software reset sequence:

1. Clear the SRST_B bit (UCR2[0])
2. Wait for software reset complete: poll SOFTRST bit (UTS[0]) until it is 0.
3. Re-program baud rate registers: Re-write UBIR and UBMR.

16.2.11 Transfer Error

The UART can generate a transfer error on the peripheral bus in the following cases:

- Core is writing into a read-only register.
- Core is accessing (read or write) an unused location within the assigned address space reserved to UART.
- Core is writing into UTXD register with transmit interface disabled (TXEN=0 or UARTEN=0)
- Core is reading URXD register with receive interface disabled (RXEN=0 or UARTEN=0)

16.2.12 Functional Timing

This section includes timing diagrams for functional signaling.

16.2.12.1 IrDA Mode

According to IrDA specification, the low speed (115.2Kbit/s and below) IR frame format is compatible with UART frame.

In this figure, an example data 0x65 is used.

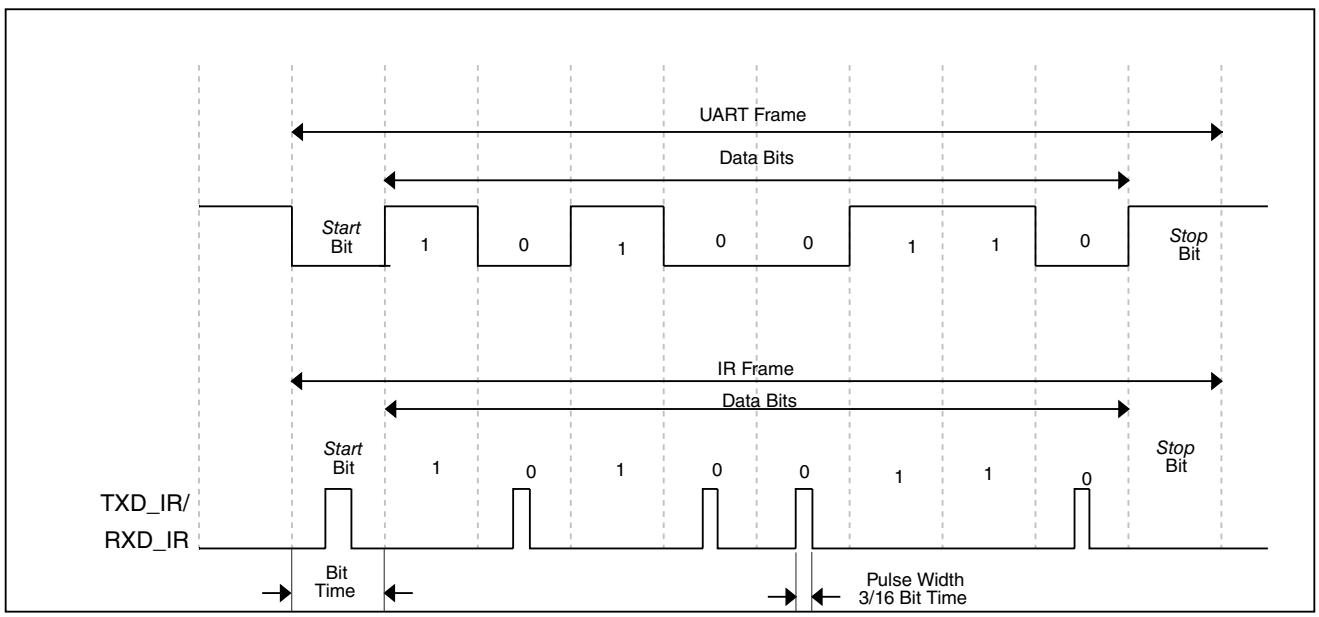

Figure 16-21. Timing diagram of Low Speed IR (<=115.2 Kbit/s) Data Line

16.2.13 Initialization

16.2.13.1 Programming the UART in RS-232 mode

As an example, the following sequence can be used to program the UART in order to send and receive characters in RS-232 mode.

Assumptions:

- Input uart clock = 100 MHz
- Baud rate = 921.6 Kbps

- Data bits = 8 bits
- Parity = Even
- Stop bits = 1 bit
- Flow control = Hardware

Main program:

1. UCR1 = 0x0001

   Enable the UART.

2. UCR2 = 0x2127

   Set hardware flow control, data format and enable transmitter and receiver.

3. UCR3 = 0x0704

   Set UCR3[RXDMUXSEL] = 1.

4. UCR4 = 0x7C00

   Set CTS trigger level to 31,

5. UFCR = 0x089E

   Set internal clock divider = 5 (divide input uart clock by 5). So the reference clock is 100 MHz/5 = 20 MHz.

   Set TXTL = 2 and RXTL = 30.

6. UBIR = 0x08FF
7. UBMR = 0x0C34

   In the above two steps, set baud rate to 921.6Kbps based on the 20MHz reference clock.

8. UCR1 = 0x2201

   Enable the TRDY and RRDY interrupts.

9. UMCR = 0x0000

   UMCR stay at default value 0x0000

Interrupt service routine for the transmitter:

- Write characters into UTXD

The TRDY interrupt will be automatically de-asserted when the data level of the TxFIFO exceeds the TXTL=2. Note: For the first time the interrupt may be de-asserted after 4 characters are written into the TxFIFO because of the shift register.

Interrupt service routine for the receiver:

- Read characters from URXD

The RRDY interrupt will be automatically de-asserted when the data level of the RxFIFO is below the RXTL=30.

16.2.13.2 Programming the UART in 9-bit RS-485 mode

As an example, the following sequence can be used to program the UART in order to send and receive frames in RS-485 mode.

Assumptions:

- Input uart clock = 100 MHz
- Baud rate = 5 Mbps

Main program:

1. UCR1 = 0x0001

   Enable the UART.

2. UCR2 = 0x4127

   Set software flow control ($\overline{\text{CTS}}$ pin is controlled by UCR2[12]), enable parity(enable 9^{th} bit rxd/txd), 8-bit word size , and enable transmitter and receiver.

3. UCR4 = 0x7C00

   Set CTS trigger level to 31,

4. UFCR = 0x0A9E

   Set RFDIV = 5 (divide input uart clock by 1), so the reference clock is 100 MHz. Set UART in DCE mode (RS-485 driver connection outside the chip is the same as Figure 16-20)

   Set TXTL = 2 and RXTL = 30.

5. UBIR = 0x0003
6. UBMR = 0x0004

   In the above two steps, set baud rate to 5 Mbps based on the 100 MHz reference clock.

7. UCR1 = 0x2001 when UART as a master ,

   or UCR1 = 0x0201 (or 0x0101) when UART as a slave.

Enable TRDY interrupt when UART as a master, enable RRDY interrupt or DMA request when UART as a slave.

8. UMCR = 0xA50B

   Enable 9-bit RS-485 mode, enable SAD interrupt, set automatic slave address detect mode, set slave address is 0xA5.

Interrupt service routine for the transmitter:

- Transmit data: write its ninth bit (bit[8]) to UMCR[2], write its bit [7:0] into UTXD[7:0]

The TRDY interrupt will be automatically de-asserted when the data level of the TxFIFO exceeds the TXTL=2.

Note: For the first time the interrupt may be de-asserted after 4 characters are written into the TxFIFO because of the shift register.

Interrupt service routine for the receiver:

- Receive data: read its ninth bit (bit[8]) from URXD[10] , read its bit [7:0] from URXD[7:0].

Note: in RS-485 mode, URXD[10] bit is not the parity error, instead it holds the ninth bit (bit[8]) of the received data.

The SAD interrupt can not de-assert automatically, it needs MCU write 1 to USR1[3] to clear it . The RRDY interrupt or DMA request will be automatically de-asserted when the data level of the RxFIFO is below the RXTL=30.

16.2.15 UART Memory Map/Register Definition

UART supports 8-bit, 16-bit and 32-bit accesses to 32-bit memory-mapped addresses. Any access to unmapped memory location will yield a transfer error.

All registers except the ONEMS described in this section are 16-bit registers. The ONEMS register is a 24-bit register.

- For 32-bit write accesses, the upper two bytes will not be taken into account.
- For 32-bit read accesses the upper two bytes will return 0.

The ONEMS register is expanded from 16 bits to 24 bits in order to support the high frequency of the BRM internal clock *ref_clk* (*module_clock* after divider). The ONEMS register can be accessed as 8 bits, 16 bits or 32 bits.

- For 32-bit write accesses, the most significant byte of the ONEMS will be discarded.
- For 32-bit read accesses, the most significant byte of the ONEMS will be read as 0.

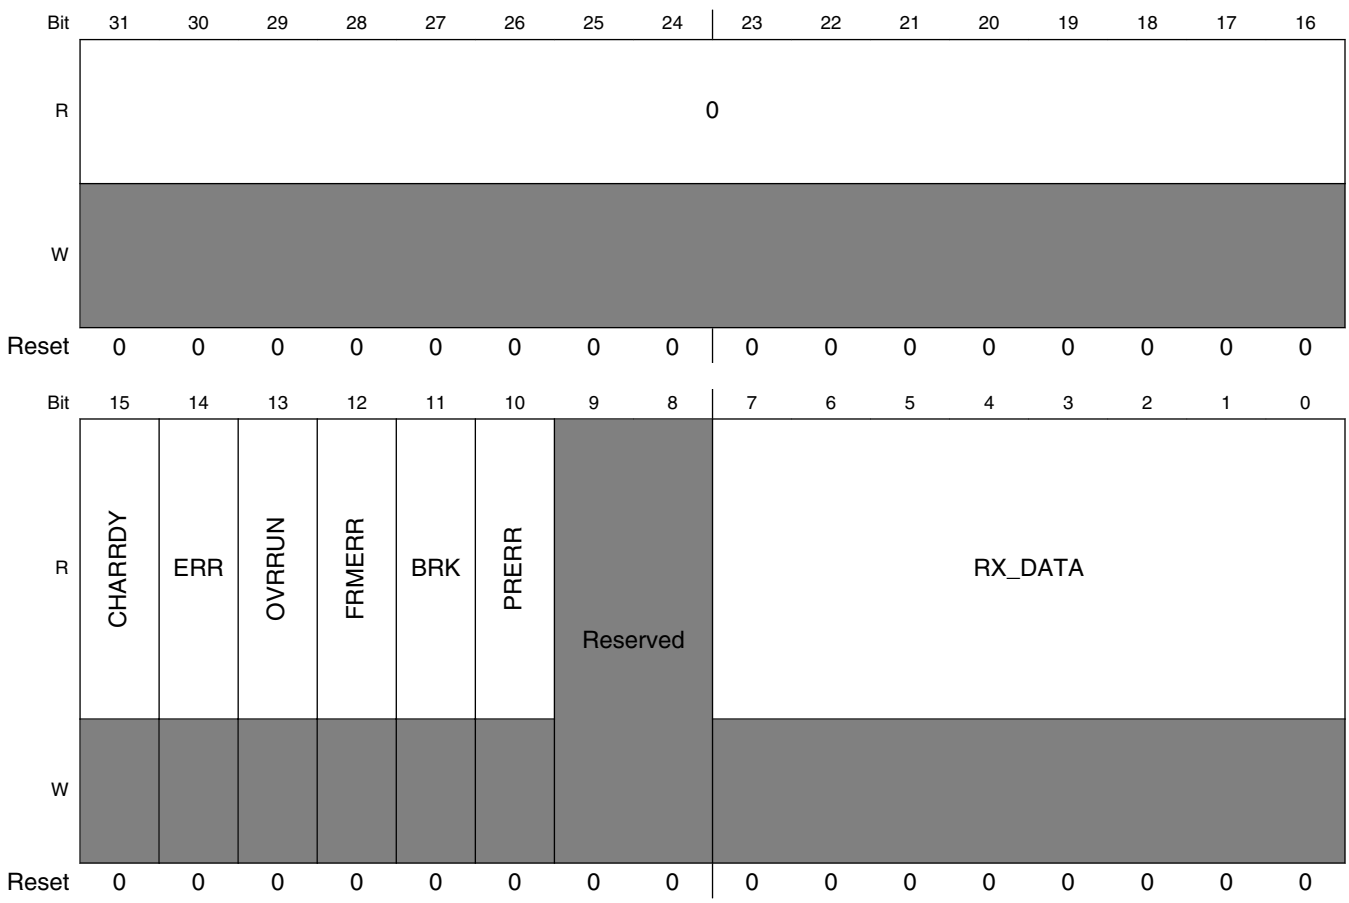
16.2.15.1 UART Receiver Register (UARTx_URXD)

NOTE

The UART will yield a transfer error on the peripheral bus when core is reading URXD register with receive interface disabled (RXEN=0 or UARTEN=0).

Address: Base address + 0h offset



UARTx_URXD field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 CHARRDY	Character Ready. This read-only bit indicates an invalid read when the FIFO becomes empty and software tries to read the same old data. This bit should not be used for polling for data written to the RX FIFO. 0 Character in RX_DATA field and associated flags are invalid. 1 Character in RX_DATA field and associated flags valid and ready for reading.

Table continues on the next page...

UARTx_URXD field descriptions (continued)

Field	Description
14 ERR	**Error Detect.** Indicates whether the character present in the RX_DATA field has an error (OVRRUN, FRMERR, BRK or PRERR) status. The ERR bit is updated and valid for each received character. 0 No error status was detected 1 An error status was detected
13 OVRRUN	**Receiver Overrun.** This read-only bit, when HIGH, indicates that the corresponding character was stored in the last position (32nd) of the Rx FIFO. Even if a 33rd character has not been detected, this bit will be set to '1' for the 32nd character. 0 No RxFIFO overrun was detected 1 A RxFIFO overrun was detected
12 FRMERR	**Frame Error.** Indicates whether the current character had a framing error (a missing stop bit) and is possibly corrupted. FRMERR is updated for each character read from the RxFIFO. 0 The current character has no framing error 1 The current character has a framing error
11 BRK	**BREAK Detect.** Indicates whether the current character was detected as a BREAK character. The data bits and the stop bit are all 0. The FRMERR bit is set when BRK is set. When odd parity is selected, PRERR is also set when BRK is set. BRK is valid for each character read from the RxFIFO. 0 The current character is not a BREAK character 1 The current character is a BREAK character
10 PRERR	**In RS-485 mode, it holds the ninth data bit (bit [8]) of received 9-bit RS-485 data** **In RS232/IrDA mode, it is the Parity Error flag**. Indicates whether the current character was detected with a parity error and is possibly corrupted. PRERR is updated for each character read from the RxFIFO. When parity is disabled, PRERR always reads as 0. 0 = No parity error was detected for data in the RX_DATA field 1 = A parity error was detected for data in the RX_DATA field
9–8 -	This field is reserved. **Reserved**
RX_DATA	**Received Data**. Holds the received character. In 7-bit mode, the most significant bit (MSB) is forced to 0. In 8-bit mode, all bits are active.

16.2.15.2 UART Transmitter Register (UARTx_UTXD)

NOTE

The UART will yield a transfer error on the peripheral bus when core is writing into UART_URXD register with transmit interface disabled (TXEN=0 or UARTEN=0).

Memory space between UART_URXD and UART_UTXD registers is reserved. Any read or write access to this space will be considered as an invalid access and yield a transfer error.

Address: Base address + 40h offset

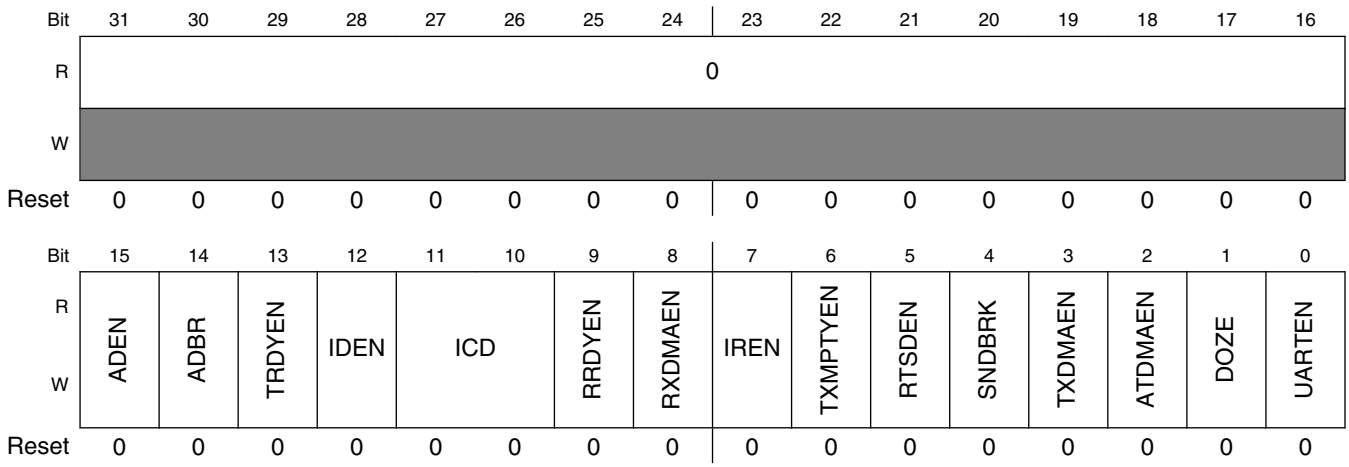
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																0															
W																									TX_DATA							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

UARTx_UTXD field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–8 Reserved	This read-only field is reserved and always has the value 0.
TX_DATA	**Transmit Data**. Holds the parallel transmit data inputs. In 7-bit mode, D7 is ignored. In 8-bit mode, all bits are used. Data is transmitted least significant bit (LSB) first. A new character is transmitted when the TX_DATA field is written. The TX_DATA field must be written only when the TRDY bit is high to ensure that corrupted data is not sent.

16.2.15.3 UART Control Register 1 (UARTx_UCR1)

Address: Base address + 80h offset



UARTx_UCR1 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 ADEN	**Automatic Baud Rate Detection Interrupt Enable**. Enables/Disables the automatic baud rate detect complete (ADET) bit to generate an interrupt (*interrupt_uart* = 0). 0 Disable the automatic baud rate detection interrupt 1 Enable the automatic baud rate detection interrupt
14 ADBR	**Automatic Detection of Baud Rate**. Enables/Disables automatic baud rate detection. When the ADBR bit is set and the ADET bit is cleared, the receiver detects the incoming baud rate automatically. The ADET flag is set when the receiver verifies that the incoming baud rate is detected properly by detecting an ASCII character "A" or "a" (0x41 or 0x61). 0 Disable automatic detection of baud rate 1 Enable automatic detection of baud rate
13 TRDYEN	**Transmitter Ready Interrupt Enable**. Enables/Disables the transmitter Ready Interrupt (TRDY) when the transmitter has one or more slots available in the TxFIFO. The fill level in the TXFIFO at which an interrupt is generated is controlled by TxTL bits. When TRDYEN is negated, the transmitter ready interrupt is disabled. **NOTE:** An interrupt will be issued as long as TRDYEN and TRDY are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TRDY interrupt. 0 Disable the transmitter ready interrupt 1 Enable the transmitter ready interrupt
12 IDEN	**Idle Condition Detected Interrupt Enable**. Enables/Disables the IDLE bit to generate an interrupt (*interrupt_uart* = 0). 0 Disable the IDLE interrupt 1 Enable the IDLE interrupt

Table continues on the next page...

UARTx_UCR1 field descriptions (continued)

Field	Description
11–10 ICD	**Idle Condition Detect**. Controls the number of frames RXD is allowed to be idle before an idle condition is reported. 00 Idle for more than 4 frames 01 Idle for more than 8 frames 10 Idle for more than 16 frames 11 Idle for more than 32 frames
9 RRDYEN	**Receiver Ready Interrupt Enable**. Enables/Disables the RRDY interrupt when the RxFIFO contains data. The fill level in the RxFIFO at which an interrupt is generated is controlled by the RXTL bits. When RRDYEN is negated, the receiver ready interrupt is disabled. 0 Disables the RRDY interrupt 1 Enables the RRDY interrupt
8 RXDMAEN	**Receive Ready DMA Enable**. Enables/Disables the receive DMA request *dma_req_rx* when the receiver has data in the RxFIFO. The fill level in the RxFIFO at which a DMA request is generated is controlled by the RXTL bits. When negated, the receive DMA request is disabled. 0 Disable DMA request 1 Enable DMA request
7 IREN	**Infrared Interface Enable**. Enables/Disables the IR interface. See the IR interface description in Infrared Interface, for more information. Note: MDEN(UMCR[0]) must be cleared to 0 when using IrDA interface. See Table 16-3 0 Disable the IR interface 1 Enable the IR interface
6 TXMPTYEN	**Transmitter Empty Interrupt Enable**. Enables/Disables the transmitter FIFO empty (TXFE) interrupt. *interrupt_uart*. When negated, the TXFE interrupt is disabled. **NOTE:** An interrupt will be issued as long as TXMPTYEN and TXFE are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TXFE interrupt. 0 Disable the transmitter FIFO empty interrupt 1 Enable the transmitter FIFO empty interrupt
5 RTSDEN	**RTS Delta Interrupt Enable**. Enables/Disables the RTSD interrupt. The current status of the RTS_B pin is read in the RTSS bit. 0 Disable RTSD interrupt 1 Enable RTSD interrupt
4 SNDBRK	**Send BREAK**. Forces the transmitter to send a BREAK character. The transmitter finishes sending the character in progress (if any) and sends BREAK characters until SNDBRK is reset. Because the transmitter samples SNDBRK after every bit is transmitted, it is important that SNDBRK is asserted high for a sufficient period of time to generate a valid BREAK. After the BREAK transmission completes, the UART transmits 2 mark bits. The user can continue to fill the TxFIFO and any characters remaining are transmitted when the BREAK is terminated. 0 Do not send a BREAK character 1 Send a BREAK character (continuous 0s)
3 TXDMAEN	**Transmitter Ready DMA Enable**. Enables/Disables the transmit DMA request *dma_req_tx* when the transmitter has one or more slots available in the TxFIFO. The fill level in the TxFIFO that generates the *dma_req_tx* is controlled by the TXTL bits.

Table continues on the next page...

UARTx_UCR1 field descriptions (continued)

Field	Description
	NOTE: A DMA request will be issued as long as TXDMAEN and TRDY are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the transmit DMA request. 0 Disable transmit DMA request 1 Enable transmit DMA request
2 ATDMAEN	**Aging DMA Timer Enable**. Enables/Disables the receive DMA request *dma_req_rx* for the aging timer interrupt (triggered with AGTIM flag in USR1[8]). 0 Disable AGTIM DMA request 1 Enable AGTIM DMA request
1 DOZE	**DOZE**. Determines the UART enable condition in the DOZE state. When *doze_req* input pin is at '1', (the Arm Platform executes a doze instruction and the system is placed in the Doze State), the DOZE bit affects operation of the UART. While in the Doze State, if this bit is asserted, the UART is disabled. See the description in Low Power Modes. 0 The UART is enabled when in DOZE state 1 The UART is disabled when in DOZE state
0 UARTEN	**UART Enable**. Enables/Disables the UART. If UARTEN is negated in the middle of a transmission, the transmitter stops and pulls the TXD line to a logic 1. UARTEN must be set to 1 before any access to UTXD and URXD registers, otherwise a transfer error is returned. This bit can be set to 1 along with other bits in this register. There is no restriction to the sequence of programing this bit and other control registers. 0 Disable the UART 1 Enable the UART

16.2.15.4 UART Control Register 2 (UARTx_UCR2)

Address: Base address + 84h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ESCI	IRTS	CTSC	CTS	ESCEN	RTEC		PREN	PROE	STPB	WS	RTSEN	ATEN	TXEN	RXEN	SRST
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

UARTx_UCR2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 ESCI	**Escape Sequence Interrupt Enable**. Enables/Disables the ESCF bit to generate an interrupt. 0 Disable the escape sequence interrupt 1 Enable the escape sequence interrupt
14 IRTS	**Ignore RTS Pin**. Forces the RTS input signal presented to the transmitter to always be asserted (set to low), effectively ignoring the external pin. When in this mode, the RTS pin serves as a general purpose input. 0 Transmit only when the RTS pin is asserted 1 Ignore the RTS pin
13 CTSC	CTS **Pin Control**. Controls the operation of the CTS_B module output. When CTSC is asserted, the CTS_B module output is controlled by the receiver. When the RxFIFO is filled to the level of the programmed trigger level and the start bit of the overflowing character (TRIGGER LEVEL + 1) is validated, the CTS_B module output is negated to indicate to the far-end transmitter to stop transmitting. When the trigger level is programmed for less than 32, the receiver continues to receive data until the RxFIFO is full. When the CTSC bit is negated, the CTS_B module output is controlled by the CTS bit. On reset, because CTSC is cleared to 0, the CTS_B pin is controlled by the CTS bit, which again is cleared to 0 on reset. This means that on reset the CTS_B signal is negated. 0 The CTS_B pin is controlled by the CTS bit 1 The CTS_B pin is controlled by the receiver
12 CTS	**Clear to Send**. Controls the CTS_B pin when the CTSC bit is negated. CTS has no function when CTSC is asserted. 0 The CTS_B pin is high (inactive) 1 The CTS_B pin is low (active)
11 ESCEN	**Escape Enable**. Enables/Disables the escape sequence detection logic. 0 Disable escape sequence detection 1 Enable escape sequence detection
10–9 RTEC	**Request to Send Edge Control**. Selects the edge that triggers the RTS interrupt. This has no effect on the RTS delta interrupt. RTEC has an effect only when RTSEN = 1 (see Table 16-6). 00 Trigger interrupt on a rising edge 01 Trigger interrupt on a falling edge 1X Trigger interrupt on any edge
8 PREN	**Parity Enable**. Enables/Disables the parity generator in the transmitter and parity checker in the receiver. When PREN is asserted, the parity generator and checker are enabled, and disabled when PREN is negated. 0 Disable parity generator and checker 1 Enable parity generator and checker
7 PROE	**Parity Odd/Even**. Controls the sense of the parity generator and checker. When PROE is high, odd parity is generated and expected. When PROE is low, even parity is generated and expected. PROE has no function if PREN is low. 0 Even parity 1 Odd parity

Table continues on the next page...

UARTx_UCR2 field descriptions (continued)

Field	Description
6 STPB	**Stop**. Controls the number of stop bits after a character. When STPB is low, 1 stop bit is sent. When STPB is high, 2 stop bits are sent. STPB also affects the receiver. 0 The transmitter sends 1 stop bit. The receiver expects 1 or more stop bits. 1 The transmitter sends 2 stop bits. The receiver expects 2 or more stop bits.
5 WS	**Word Size**. Controls the character length. When WS is high, the transmitter and receiver are in 8-bit mode. When WS is low, they are in 7-bit mode. The transmitter ignores bit 7 and the receiver sets bit 7 to 0. WS can be changed in-between transmission (reception) of characters, however not when a transmission (reception) is in progress, in which case the length of the current character being transmitted (received) is unpredictable. 0 7-bit transmit and receive character length (not including START, STOP or PARITY bits) 1 8-bit transmit and receive character length (not including START, STOP or PARITY bits)
4 RTSEN	**Request to Send Interrupt Enable.** Controls the RTS edge sensitive interrupt. When RTSEN is asserted and the programmed edge is detected on the RTS_B pin (the RTSF bit is asserted), an interrupt will be generated on the *interrupt_uart* pin. (See Table 16-6.) 0 Disable request to send interrupt 1 Enable request to send interrupt
3 ATEN	**Aging Timer Enable**. This bit is used to enable the aging timer interrupt (triggered with AGTIM) 0 AGTIM interrupt disabled 1 AGTIM interrupt enabled
2 TXEN	**Transmitter Enable**. Enables/Disables the transmitter. When TXEN is negated the transmitter is disabled and idle. When the UARTEN and TXEN bits are set the transmitter is enabled. If TXEN is negated in the middle of a transmission, the UART disables the transmitter immediately, and starts marking 1s. The transmitter FIFO cannot be written when this bit is cleared. 0 Disable the transmitter 1 Enable the transmitter
1 RXEN	**Receiver Enable**. Enables/Disables the receiver. When the receiver is enabled, if the RXD input is already low, the receiver does not recognize BREAK characters, because it requires a valid 1-to-0 transition before it can accept any character. 0 Disable the receiver 1 Enable the receiver
0 SRST	**Software Reset**. Once the software writes 0 to SRST_B, the software reset remains active for 4 *module_clock* cycles before the hardware deasserts SRST_B. The software can only write 0 to SRST_B. Writing 1 to SRST_B is ignored. 0 Reset the transmit and receive state machines, all FIFOs and register USR1, USR2, UBIR, UBMR, UBRC , URXD, UTXD and UTS[6-3]. 1 No reset

16.2.15.5 UART Control Register 3 (UARTx_UCR3)

Address: Base address + 88h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

UARTx_UCR3 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–14 DPEC	This bit is not used in this chip.
13 DTREN	This bit is not used in this chip.
12 PARERREN	**Parity Error Interrupt Enable. Enables/Disables the interrupt. When asserted, PARERREN causes the PARITYERR bit to generate an interrupt.** 0 Disable the parity error interrupt 1 Enable the parity error interrupt
11 FRAERREN	**Frame Error Interrupt Enable. Enables/Disables the interrupt. When asserted, FRAERREN causes the FRAMERR bit to generate an interrupt.** 0 Disable the frame error interrupt 1 Enable the frame error interrupt
10 DSR	This bit is not used in this chip.
9 DCD	This bit is not used in this chip.
8 RI	This bit is not used in this chip.
7 ADNIMP	**Autobaud Detection Not Improved-. Disables new features of autobaud detection (See Baud Rate Automatic Detection Protocol, for more details).** 0 Autobaud detection new features selected 1 Keep old autobaud detection mechanism

Table continues on the next page...

UARTx_UCR3 field descriptions (continued)

Field	Description
6 RXDSEN	Receive Status Interrupt Enable. Controls the receive status interrupt (*interrupt_uart*). When this bit is enabled and RXDS status bit is set, the interrupt *interrupt_uart* will be generated. 0 Disable the RXDS interrupt 1 Enable the RXDS interrupt
5 AIRINTEN	Asynchronous IR WAKE Interrupt Enable. Controls the asynchronous IR WAKE interrupt. An interrupt is generated when AIRINTEN is asserted and a pulse is detected on the RXD pin. 0 Disable the AIRINT interrupt 1 Enable the AIRINT interrupt
4 AWAKEN	Asynchronous WAKE Interrupt Enable. Controls the asynchronous WAKE interrupt. An interrupt is generated when AWAKEN is asserted and a falling edge is detected on the RXD pin. 0 Disable the AWAKE interrupt 1 Enable the AWAKE interrupt
3 DTRDEN	This bit is not used in this chip.
2 RXDMUXSEL	RXD Muxed Input Selected. Selects proper input pins for serial and Infrared input signal. **NOTE:** In this chip, UARTs are used in MUXED mode, so that this bit should always be set.
1 INVT	Invert TXD output in RS-232/RS-485 mode, set TXD active level in IrDA mode. In RS232/RS-485 mode(UMCR[0] = 1), if this bit is set to 1, the TXD output is inverted before transmitted. In **IrDA mode**, when INVT is cleared, the infrared logic block transmits a positive IR 3/16 pulse for all 0s and 0s are transmitted for 1s. When INVT is set (INVT = 1), the infrared logic block transmits an active low or negative infrared 3/16 pulse for all 0s and 1s are transmitted for 1s. 0 **TXD is not inverted** 1 **TXD is inverted** 0 **TXD** Active low transmission 1 **TXD** Active high transmission
0 ACIEN	**Autobaud Counter Interrupt Enable.** This bit is used to enable the autobaud counter stopped interrupt (triggered with ACST (USR2[11]). 0 ACST interrupt disabled 1 ACST interrupt enabled

16.2.15.6 UART Control Register 4 (UARTx_UCR4)

Address: Base address + 8Ch offset

UARTx_UCR4 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–10 CTSTL	**CTS Trigger Level**. Controls the threshold at which the CTS_B pin is deasserted by the RxFIFO. After the trigger level is reached and the CTS_B pin is deasserted, the RxFIFO continues to receive data until it is full. The CTSTL bits are encoded as shown in the Settings column. Settings 0 to 32 are in use. All other settings are Reserved. 000000 0 characters received 000001 1 characters in the RxFIFO ... — ... — 100000 32 characters in the RxFIFO (maximum)
9 INVR	**Invert RXD input in RS-232/RS-485 Mode, d**etermine **RXD input** logic level being sampled in **In IrDA mode.** **In RS232/RS-485 Mode(UMCR[0] = 1), if this bit is set to 1, the RXD input is inverted before sampled.** **In IrDA mode**,when cleared, the infrared logic block expects an active low or negative IR 3/16 pulse for 0s and 1s are expected for 1s. When INVR is set (INVR 1), the infrared logic block expects an active high or positive IR 3/16 pulse for 0s and 0s are expected for 1s. 0 **RXD input is not inverted** 1 **RXD input is inverted** 0 **RXD** active low detection 1 **RXD** active high detection
8 ENIRI	**Serial Infrared Interrupt Enable**. Enables/Disables the serial infrared interrupt. 0 Serial infrared Interrupt disabled 1 Serial infrared Interrupt enabled

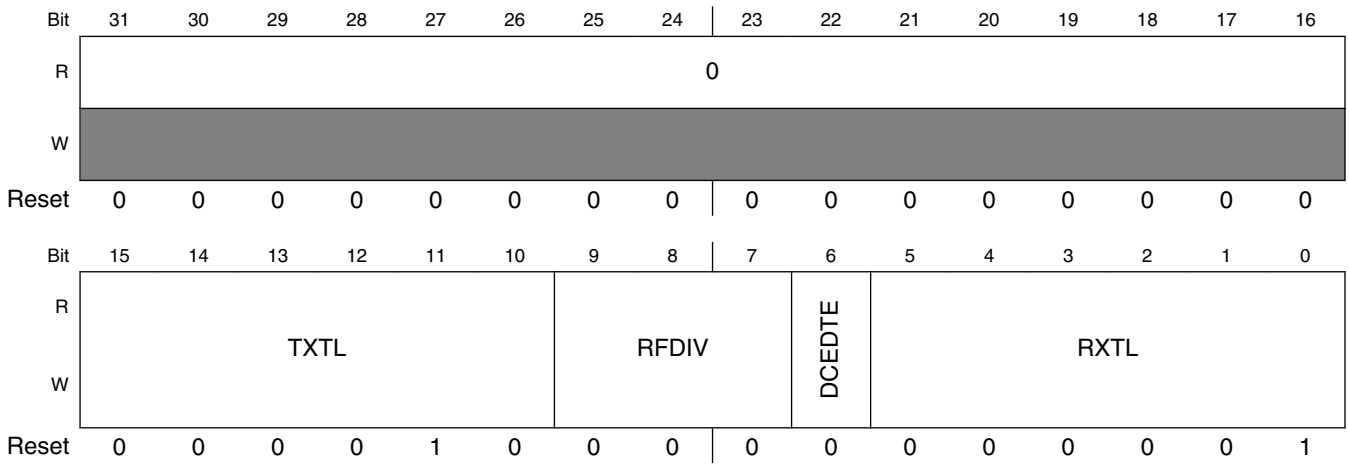
Table continues on the next page...

UARTx_UCR4 field descriptions (continued)

Field	Description
7 WKEN	**WAKE Interrupt Enable**. Enables/Disables the WAKE bit to generate an interrupt. The WAKE bit is set at the detection of a start bit by the receiver. 0 Disable the WAKE interrupt 1 Enable the WAKE interrupt
6 IDDMAEN	**DMA IDLE Condition Detected Interrupt Enable** Enables/Disables the receive DMA request *dma_req_rx* for the IDLE interrupt (triggered with IDLE flag in USR2[12]). 0 DMA IDLE interrupt disabled 1 DMA IDLE interrupt enabled
5 IRSC	**IR Special Case**. Selects the clock for the vote logic. When set, IRSC switches the vote logic clock from the sampling clock to the UART reference clock. The IR pulses are counted a predetermined amount of time depending on the reference frequency. See InfraRed Special Case (IRSC) Bit. 0 The vote logic uses the sampling clock (16x baud rate) for normal operation 1 The vote logic uses the UART reference clock
4 LPBYP	**Low Power Bypass**. Allows to bypass the low power new features in UART. To use during debug phase. 0 Low power features enabled 1 Low power features disabled
3 TCEN	**TransmitComplete Interrupt Enable**. Enables/Disables the TXDC bit to generate an interrupt (*interrupt_uart* = 0) **NOTE:** An interrupt will be issued as long as TCEN and TXDC are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TXDC interrupt. 0 Disable TXDC interrupt 1 Enable TXDC interrupt
2 BKEN	**BREAK Condition Detected Interrupt Enable**. Enables/Disables the BRCD bit to generate an interrupt. 0 Disable the BRCD interrupt 1 Enable the BRCD interrupt
1 OREN	**Receiver Overrun Interrupt Enable**. Enables/Disables the ORE bit to generate an interrupt. 0 Disable ORE interrupt 1 Enable ORE interrupt
0 DREN	**Receive Data Ready Interrupt Enable**. Enables/Disables the RDR bit to generate an interrupt. 0 Disable RDR interrupt 1 Enable RDR interrupt

16.2.15.7 UART FIFO Control Register (UARTx_UFCR)

Address: Base address + 90h offset



UARTx_UFCR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–10 TXTL	**Transmitter Trigger Level**. Controls the threshold at which a maskable interrupt is generated by the TxFIFO. A maskable interrupt is generated whenever the data level in the TxFIFO falls below the selected threshold. The bits are encoded as shown in the Settings column. Settings 0 to 32 are in use. All other settings are Reserved. 000000 Reserved 000001 Reserved 000010 TxFIFO has 2 or fewer characters ... — ... — 011111 TxFIFO has 31 or fewer characters 100000 TxFIFO has 32 characters (maximum)
9–7 RFDIV	Reference Frequency Divider. Controls the divide ratio for the reference clock. The input clock is *module_clock*. The output from the divider is *ref_clk* which is used by BRM to create the 16x baud rate oversampling clock (*brm_clk*). 000 Divide input clock by 6 001 Divide input clock by 5 010 Divide input clock by 4 011 Divide input clock by 3 100 Divide input clock by 2 101 Divide input clock by 1 110 Divide input clock by 7 111 Reserved
6 DCEDTE	**DCE/DTE mode select**. Select UART as data communication equipment (DCE mode) or as data terminal equipment (DTE mode).

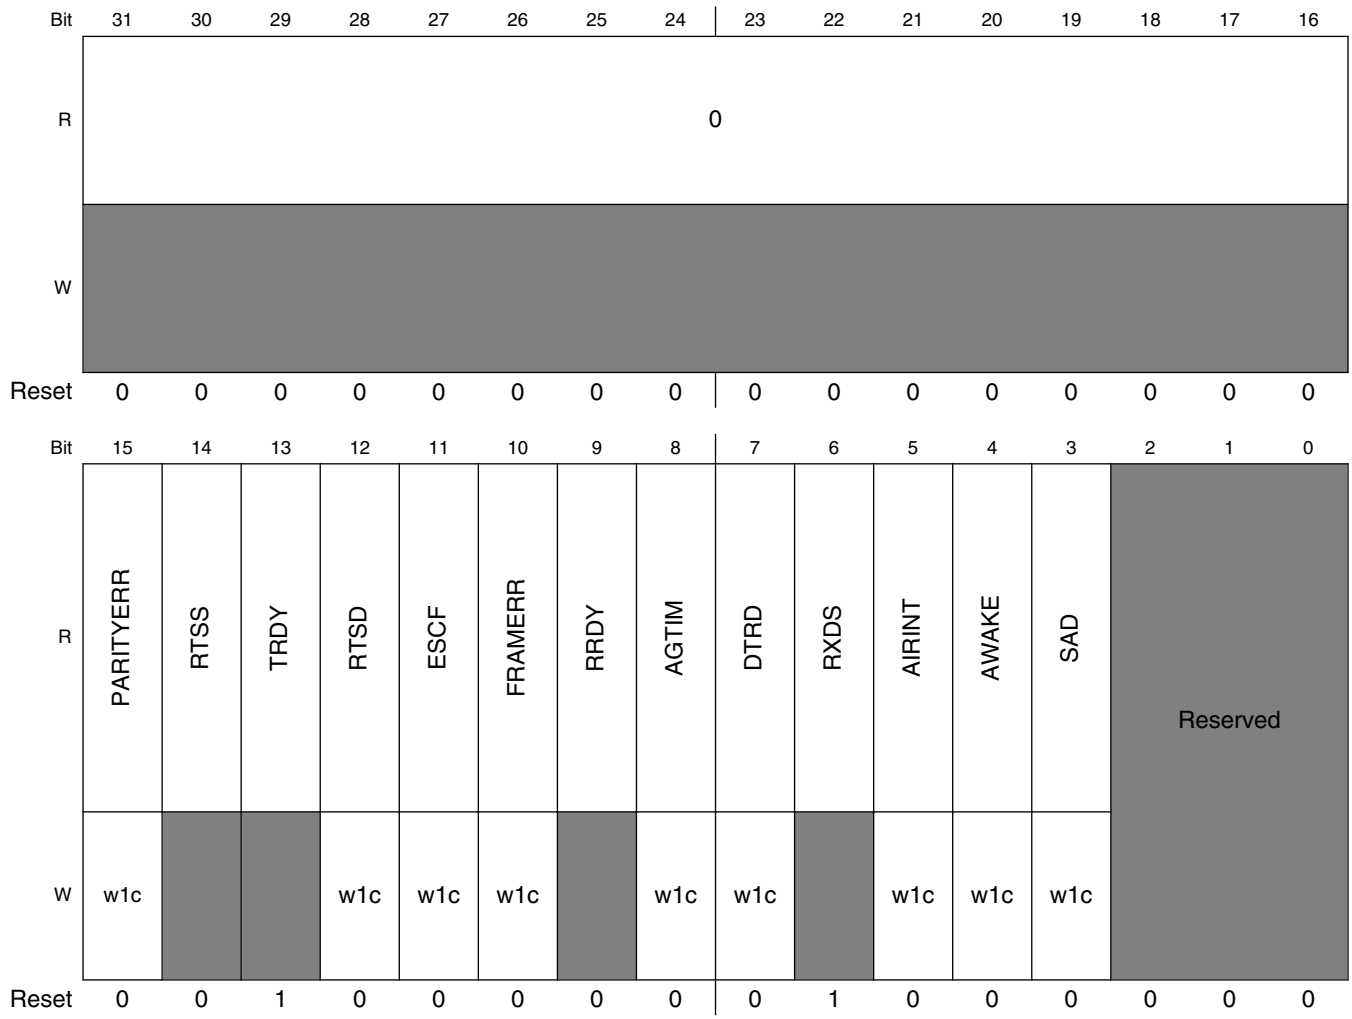
Table continues on the next page...

UARTx_UFCR field descriptions (continued)

Field	Description
	0 DCE mode selected 1 DTE mode selected
RXTL	**Receiver Trigger Level**. Controls the threshold at which a maskable interrupt is generated by the RxFIFO. A maskable interrupt is generated whenever the data level in the RxFIFO reaches the selected threshold. The RXTL bits are encoded as shown in the Settings column. Setting 0 to 32 are in use. All other settings are Reserved. 000000 0 characters received 000001 RxFIFO has 1 character ... — ... — 011111 RxFIFO has 31 characters 100000 RxFIFO has 32 characters (maximum)

16.2.15.8 UART Status Register 1 (UARTx_USR1)

Address: Base address + 94h offset



UARTx_USR1 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 PARITYERR	**Parity Error Interrupt Flag**. Indicates a parity error is detected. PARITYERR is cleared by writing 1 to it. Writing 0 to PARITYERR has no effect. When parity is disabled, PARITYERR always reads 0. At reset, PARITYERR is set to 0. 0 No parity error detected 1 Parity error detected (write 1 to clear)
14 RTSS	RTS_B **Pin Status**. Indicates the current status of the RTS_B pin. A "snapshot" of RTS_B is taken immediately before RTSS is presented to the data bus. RTSS cannot be cleared because all writes to RTSS are ignored. At reset, RTSS is set to 0.

Table continues on the next page...

UARTx_USR1 field descriptions (continued)

Field	Description
	0 The RTS_B module input is high (inactive) 1 The RTS_B module input is low (active)
13 TRDY	**Transmitter Ready Interrupt / DMA Flag**. Indicates that the TxFIFO emptied below its target threshold and requires data. TRDY is automatically cleared when the data level in the TxFIFO exceeds the threshold set by TXTL bits. At reset, TRDY is set to 1. 0 The transmitter does not require data 1 The transmitter requires data (interrupt posted)
12 RTSD	**RTS Delta.** Indicates whether the RTS_B pin changed state. It (RTSD) generates a maskable interrupt. When in STOP mode, RTS assertion sets RTSD and can be used to wake the processor. The current state of the RTS_B pin is available on the RTSS bit. Clear RTSD by writing 1 to it. Writing 0 to RTSD has no effect. At reset, RTSD is set to 0. 0 RTS_B pin did not change state since last cleared 1 RTS_B pin changed state (write 1 to clear)
11 ESCF	**Escape Sequence Interrupt Flag**. Indicates if an escape sequence was detected. ESCF is asserted when the ESCEN bit is set and an escape sequence is detected in the RxFIFO. Clear ESCF by writing 1 to it. Writing 0 to ESCF has no effect. 0 No escape sequence detected 1 Escape sequence detected (write 1 to clear).
10 FRAMERR	**Frame Error Interrupt Flag**. Indicates that a frame error is detected. The *interrupt_uart* interrupt will be generated if a frame error is detected and the interrupt is enabled. Clear FRAMERR by writing 1 to it. Writing 0 to FRAMERR has no effect. 0 No frame error detected 1 Frame error detected (write 1 to clear)
9 RRDY	**Receiver Ready Interrupt / DMA Flag**. Indicates that the RxFIFO data level is above the threshold set by the RXTL bits. (See the RXTL bits description in UART FIFO Control Register (UART_UFCR) for setting the interrupt threshold.) When asserted, RRDY generates a maskable interrupt or DMA request. RRDY is automatically cleared when data level in the RxFIFO goes below the set threshold level. At reset, RRDY is set to 0. 0 No character ready 1 Character(s) ready (interrupt posted)
8 AGTIM	Ageing Timer Interrupt Flag. Indicates that data in the RxFIFO has been idle for a time of 8 character lengths (where a character length consists of 7 or 8 bits, depending on the setting of the WS bit in UCR2, with the bit time corresponding to the baud rate setting) and FIFO data level is less than RxFIFO threshold level (RXTL in the UFCR). Clear by writing a 1 to it. 0 AGTIM is not active 1 AGTIM is active (write 1 to clear)
7 DTRD	This bit is not used in this chip.
6 RXDS	Receiver IDLE Interrupt Flag. Indicates that the receiver state machine is in an IDLE state, the next state is IDLE, and the receive pin is high. RXDS is automatically cleared when a character is received. RXDS is active only when the receiver is enabled. 0 Receive in progress 1 Receiver is IDLE

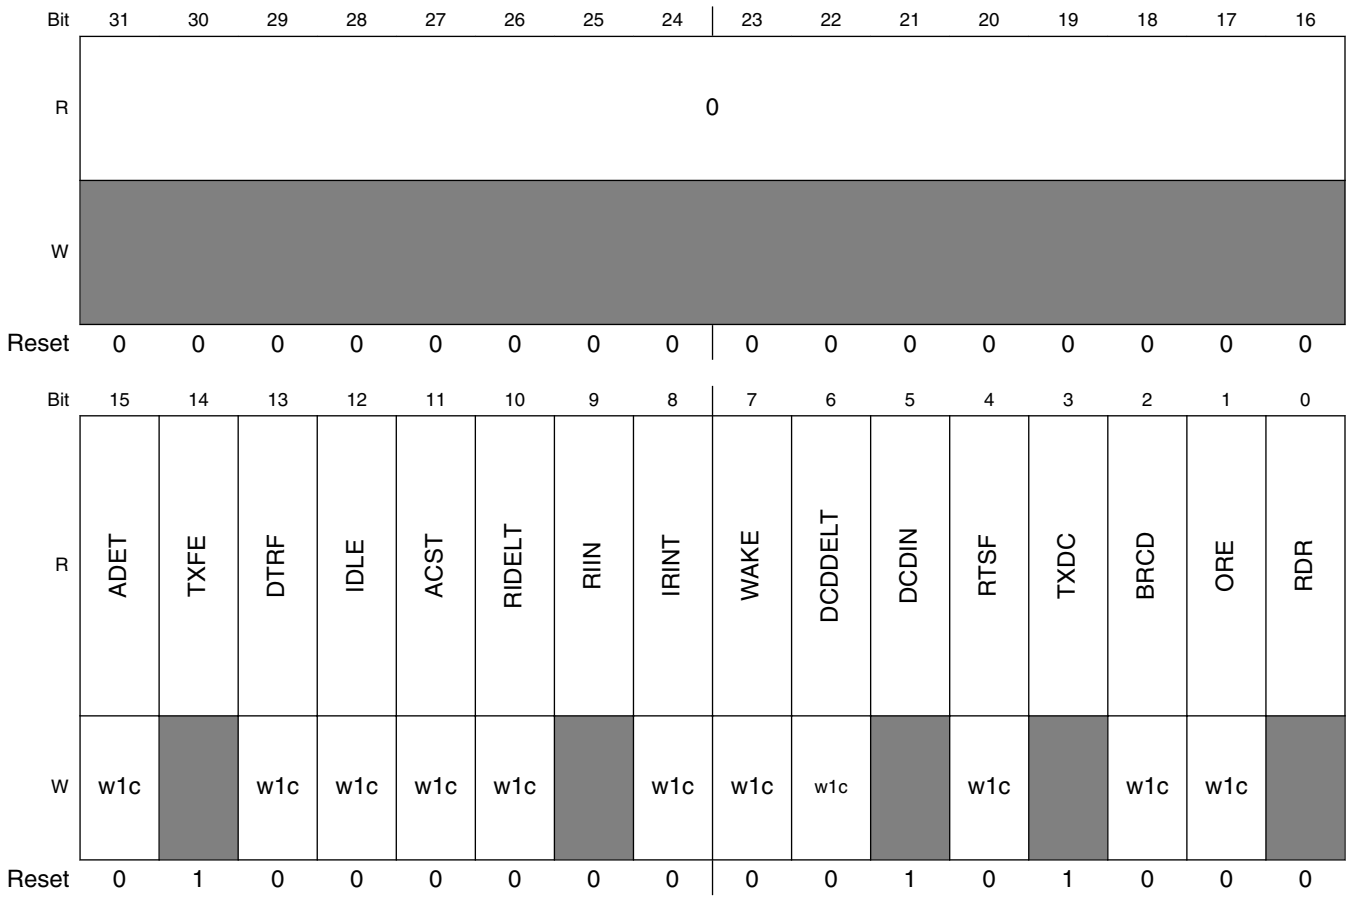
Table continues on the next page...

UARTx_USR1 field descriptions (continued)

Field	Description
5 AIRINT	Asynchronous IR WAKE Interrupt Flag. Indicates that the IR WAKE pulse was detected on the RXD pin. Clear AIRINT by writing 1 to it. Writing 0 to AIRINT has no effect. 0 No pulse was detected on the RXD IrDA pin 1 A pulse was detected on the RXD IrDA pin
4 AWAKE	Asynchronous WAKE Interrupt Flag. Indicates that a falling edge was detected on the RXD pin. Clear AWAKE by writing 1 to it. Writing 0 to AWAKE has no effect. 0 No falling edge was detected on the RXD Serial pin 1 A falling edge was detected on the RXD Serial pin
3 SAD	RS-485 Slave Address Detected Interrupt Flag. Indicates if RS-485 Slave Address was detected . SAD was asserted in RS-485 mode when the SADEN bit is set and Slave Address is detected in RxFIFO (in Nomal Address Detect Mode, the 9th data bit = 1; in Automatic Address Detect Mode, the received charater matches the programmed SLADDR). 0 No slave address detected 1 Slave address detected
-	This field is reserved. Reserved

16.2.15.9 UART Status Register 2 (UARTx_USR2)

Address: Base address + 98h offset



UARTx_USR2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 ADET	**Automatic Baud Rate Detect Complete**. Indicates that an "A" or "a" was received and that the receiver detected and verified the incoming baud rate. Clear ADET by writing 1 to it. Writing 0 to ADET has no effect. 0 ASCII "A" or "a" was not received 1 ASCII "A" or "a" was received (write 1 to clear)
14 TXFE	**Transmit Buffer FIFO Empty**. Indicates that the transmit buffer (TxFIFO) is empty. TXFE is cleared automatically when data is written to the TxFIFO. Even though TXFE is high, the transmission might still be in progress. 0 The transmit buffer (TxFIFO) is not empty 1 The transmit buffer (TxFIFO) is empty
13 DTRF	This bit is not used in this chip.

Table continues on the next page...

UARTx_USR2 field descriptions (continued)

Field	Description
12 IDLE	**Idle Condition**. Indicates that an idle condition has existed for more than a programmed amount frame (see Idle Line Detect. An interrupt can be generated by this IDLE bit if IDEN (UCR1[12]) is enabled. IDLE is cleared by writing 1 to it. Writing 0 to IDLE has no effect. 0 No idle condition detected 1 Idle condition detected (write 1 to clear)
11 ACST	**Autobaud Counter Stopped**. In autobaud detection (ADBR=1), indicates the counter which determines the baud rate was running and is now stopped. This means either START bit is finished (if ADNIMP=1), or Bit 0 is finished (if ADNIMP=0). See New Autobaud Counter Stopped bit and Interrupt, for more details. An interrupt can be flagged on *interrupt_uart* if ACIEN=1. 0 Measurement of bit length not finished (in autobaud) 1 Measurement of bit length finished (in autobaud). (write 1 to clear)
10 RIDELT	This bit is not used in this chip.
9 RIIN	This bit is not used in this chip.
8 IRINT	**Serial Infrared Interrupt Flag.** When an edge is detected on the RXD pin during SIR Mode, this flag will be asserted. This flag can cause an interrupt which can be masked using the control bit ENIRI: UCR4 [8]. 0 no edge detected 1 valid edge detected (write 1 to clear)
7 WAKE	**Wake**. Indicates the start bit is detected. WAKE can generate an interrupt that can be masked using the WKEN bit. Clear WAKE by writing 1 to it. Writing 0 to WAKE has no effect. 0 start bit not detected 1 start bit detected (write 1 to clear)
6 DCDDELT	This bit is not used in this chip.
5 DCDIN	This bit is not used in this chip.
4 RTSF	**RTS Edge Triggered Interrupt Flag. Indicates if** a programmed edge is detected on the RTS_B pin. The RTEC bits select the edge that generates an interrupt (see Table 16-6). RTSF can generate an interrupt that can be masked using the RTSEN bit. Clear RTSF by writing 1 to it. Writing 0 to RTSF has no effect. 0 Programmed edge not detected on RTS_B 1 Programmed edge detected on RTS_B (write 1 to clear)
3 TXDC	**Transmitter Complete**. Indicates that the transmit buffer (TxFIFO) and Shift Register is empty; therefore the transmission is complete. TXDC is cleared automatically when data is written to the TxFIFO. 0 Transmit is incomplete 1 Transmit is complete
2 BRCD	**BREAK Condition Detected**. Indicates that a BREAK condition was detected by the receiver. Clear BRCD by writing 1 to it. Writing 0 to BRCD has no effect. 0 No BREAK condition was detected 1 A BREAK condition was detected (write 1 to clear)
1 ORE	**Overrun Error**. When set to 1, ORE indicates that the receive buffer (RxFIFO) was full (32 chars inside), and a 33rd character has been fully received. This 33rd character has been discarded. Clear ORE by writing 1 to it. Writing 0 to ORE has no effect.

Table continues on the next page...

UARTx_USR2 field descriptions (continued)

Field	Description
	0 No overrun error 1 Overrun error (write 1 to clear)
0 RDR	**Receive Data Ready**-Indicates that at least 1 character is received and written to the RxFIFO. If the URXD register is read and there is only 1 character in the RxFIFO, RDR is automatically cleared. 0 No receive data ready 1 Receive data ready

16.2.15.10 UART Escape Character Register (UARTx_UESC)

Address: Base address + 9Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																ESC_CHAR															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0	1	1

UARTx_UESC field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value 0.
ESC_CHAR	**UART Escape Character**. Holds the selected escape character that all received characters are compared against to detect an escape sequence.

16.2.15.11 UART Escape Timer Register (UARTx_UTIM)

Address: Base address + A0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																				TIM											
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

UARTx_UTIM field descriptions

Field	Description
31–12 Reserved	This read-only field is reserved and always has the value 0.
TIM	UART Escape Timer. Holds the maximum time interval (in ms) allowed between escape characters. The escape timer register is programmable in intervals of 2 ms. See Escape Sequence Detection and Table 16-10 for more information on the UART escape sequence detection. Reset value 0x000 = 2 ms up to 0xFFF = 8.192 s.

16.2.15.12 UART BRM Incremental Register (UARTx_UBIR)

This register can be written by both software and hardware. When enabling the automatic baud rate detection feature hardware can write 0x000F value into the UBIR after finishing detecting baud rate. Hardware has higher priority when both software and hardware try to write it at the same cycle[3].

Please note software reset will reset the register to its reset value.

Address: Base address + A4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																INC															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

UARTx_UBIR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
INC	Incremental Numerator. Holds the numerator value minus one of the BRM ratio (see Binary Rate Multiplier (BRM)). The UBIR register MUST be updated before the UBMR register for the baud rate to be updated correctly. If only one register is written to by software, the BRM will ignore this data until the other register is written to by software. Updating this field using byte accesses is not recommended and is undefined.

16.2.15.13 UART BRM Modulator Register (UARTx_UBMR)

This register can be written by both software and hardware. When enabling the automatic baud rate detection feature hardware can write a proper value into the UBMR based on detected baud rate. Hardware has higher priority when both software and hardware try to write it at the same cycle[4].

Please note software reset will reset the register to its reset value.

Address: Base address + A8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																MOD															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

3. Note: The write priority in the new design is not same as the original UART. In the orginal design, software has higher priority than hardware when writing this register at the same time.
4. Note: The write priority in the new design is not same as the original UART. In the orginal design, software has higher priority than hardware when writing this register at the same time.

UARTx_UBMR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
MOD	**Modulator Denominator.** Holds the value of the denominator minus one of the BRM ratio (see Binary Rate Multiplier (BRM)). The UBIR register MUST be updated before the UBMR register for the baud rate to be updated correctly. If only one register is written to by software, the BRM will ignore this data until the other register is written to by software. Updating this register using byte accesses is not recommended and undefined.

16.2.15.14 UART Baud Rate Count Register (UARTx_UBRC)

Address: Base address + ACh offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																BCNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

UARTx_UBRC field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
BCNT	**Baud Rate Count Register.** This read only register is used to count the start bit of the incoming baud rate (if ADNIMP=1), or start bit + bit0 (if ADNIMP=0). When the measurement is done, the Baud Rate Count Register contains the number of UART internal clock cycles (clock after divider) present in an incoming bit. BCNT retains its value until the next Automatic Baud Rate Detection sequence has been initiated. The 16 bit Baud Rate Count register is reset to 4 and stays at hex FFFF in the case of an overflow.

16.2.15.15 UART One Millisecond Register (UARTx_ONEMS)

NOTE

This register has been expanded from 16 bits to 24 bits. In previous versions, the 16-bit ONEMS can only support the maximum 65.535MHz (0xFFFFx1000) *ref_clk*. To support 4Mbps Bluetooth application with 66.5MHz *module_clock*, the value 0x103C4 (66.5M/1000) should be written into this register. In this case, the 16 bits are not enough to contain the 0x103C4. So this register was expanded to 24 bits to support high frequency of the *ref_clk*.

Address: Base address + B0h offset

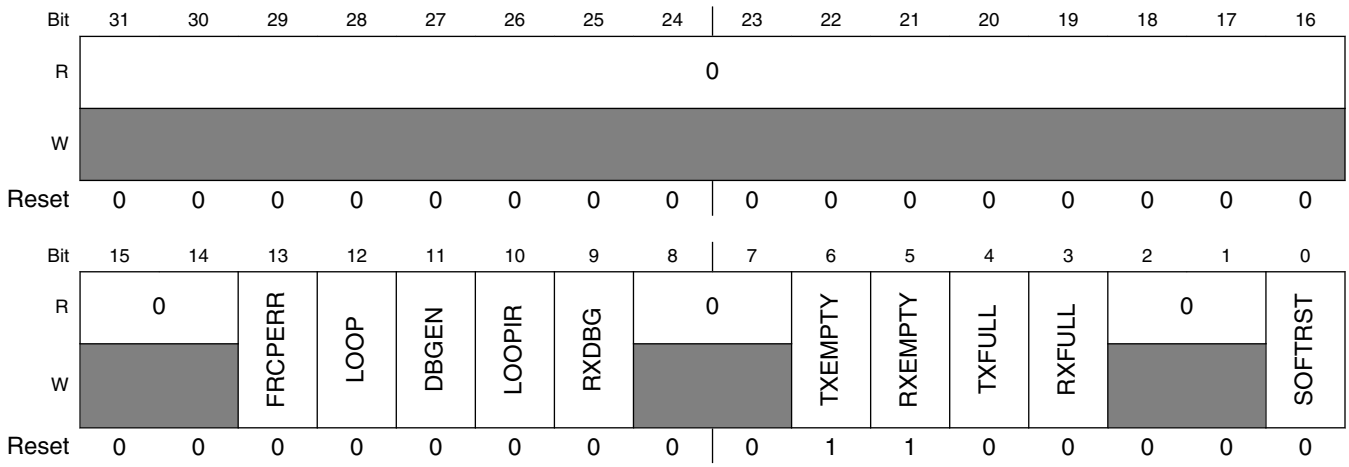
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								ONEMS																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

UARTx_ONEMS field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value 0.
ONEMS	**One Millisecond Register.** This 24-bit register must contain the value of the UART internal frequency (*ref_clk* in Figure 16-9) divided by 1000. The internal frequency is obtained after the UART BRM internal divider (F (*ref_clk*) = F(*module_clock*) / RFDIV). In fact this register contains the value corresponding to the number of UART BRM internal clock cycles present in one millisecond. The ONEMS (and UTIM) registers value are used in the escape character detection feature (Escape Sequence Detection) to count the number of clock cycles left between two escape characters. The ONEMS register is also used in infrared special case mode (IRSC = UCR4[5] = 1'b1), see InfraRed Special Case (IRSC) Bit.

16.2.15.16 UART Test Register (UARTx_UTS)

Address: Base address + B4h offset



UARTx_UTS field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value 0.
13 FRCPERR	Force Parity Error. Forces the transmitter to generate a parity error if parity is enabled. FRCPERR is provided for system debugging. 0 Generate normal parity 1 Generate inverted parity (error)
12 LOOP	Loop TX and RX for Test. Controls loopback for test purposes. When LOOP is high, the receiver input is internally connected to the transmitter and ignores the RXD pin. The transmitter is unaffected by LOOP. If RXDMUXSEL (UCR3[2]) is set to 1, the loopback is applied on serial and IrDA signals. If RXDMUXSEL is set to 0, the loopback is only applied on serial signals. 0 Normal receiver operation 1 Internally connect the transmitter output to the receiver input
11 DBGEN	This bit is not used in this chip. debug_enable_B**.** This bit controls whether to respond to the *debug_req* input signal. 0 UART will go into debug mode when *debug_req* is HIGH 1 UART will not go into debug mode even if *debug_req* is HIGH
10 LOOPIR	**Loop TX and RX for IR Test (LOOPIR)**. This bit controls loopback from transmitter to receiver in the InfraRed interface. 0 No IR loop 1 Connect IR transmitter to IR receiver
9 RXDBG	This bit is not used in this chip. **RX_fifo_debug_mode.** This bit controls the operation of the RX fifo read counter when in debug mode. 0 rx fifo read pointer does not increment 1 rx_fifo read pointer increments as normal

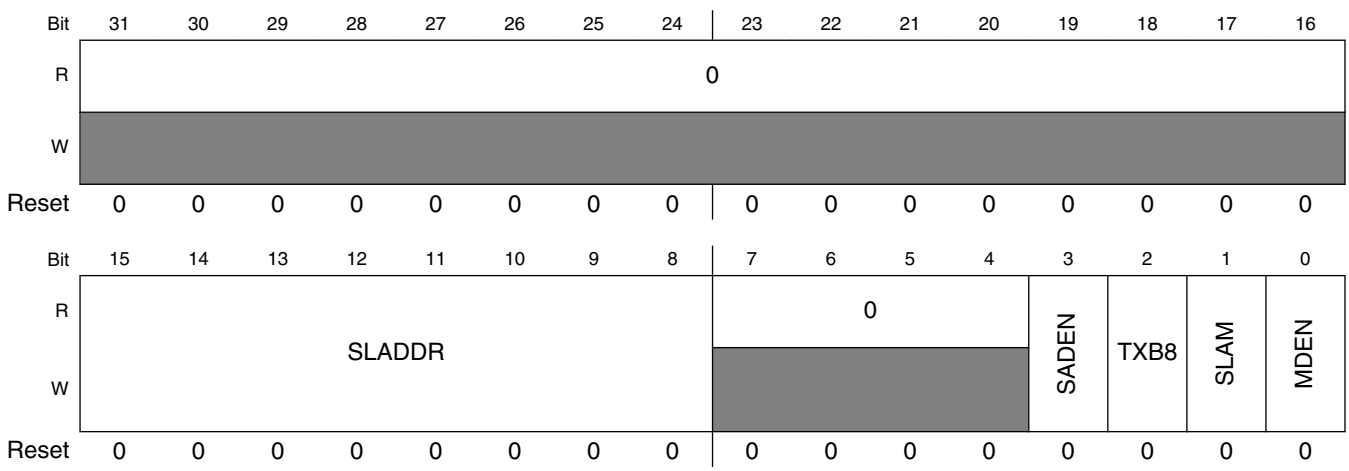
Table continues on the next page...

UARTx_UTS field descriptions (continued)

Field	Description
8–7 Reserved	This read-only field is reserved and always has the value 0.
6 TXEMPTY	TxFIFO Empty. Indicates that the TxFIFO is empty. 0 The TxFIFO is not empty 1 The TxFIFO is empty
5 RXEMPTY	RxFIFO Empty. Indicates the RxFIFO is empty. 0 The RxFIFO is not empty 1 The RxFIFO is empty
4 TXFULL	TxFIFO FULL. Indicates the TxFIFO is full. 0 The TxFIFO is not full 1 The TxFIFO is full
3 RXFULL	RxFIFO FULL. Indicates the RxFIFO is full. 0 The RxFIFO is not full 1 The RxFIFO is full
2–1 Reserved	This read-only field is reserved and always has the value 0.
0 SOFTRST	Software Reset. Indicates the status of the software reset (SRST_B bit of UCR2). 0 Software reset inactive 1 Software reset active

16.2.15.17 UART RS-485 Mode Control Register (UARTx_UMCR)

Address: Base address + B8h offset



UARTx_UMCR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–8 SLADDR	RS-485 Slave Address Character. Holds the selected slave adress character that the receiver wil try to detect.
7–4 Reserved	This read-only field is reserved and always has the value 0.
3 SADEN	RS-485 Slave Address Detected Interrupt Enable. 0 Disable RS-485 Slave Address Detected Interrupt 1 Enable RS-485 Slave Address Detected Interrupt
2 TXB8	Transmit RS-485 bit 8 (the ninth bit or 9th bit). In RS-485 mode, software writes TXB8 bit as the 9th data bit to be transmitted. 0 0 will be transmitted as the RS485 9th data bit 1 1 will be transmitted as the RS485 9th data bit
1 SLAM	RS-485 Slave Address Detect Mode Selection. 0 Select Normal Address Detect mode 1 Select Automatic Address Detect mode
0 MDEN	9-bit data or Multidrop Mode (RS-485) Enable. 0 Normal RS-232 or IrDA mode, see Table 16-3 for detail. 1 Enable RS-485 mode, see Table 16-3 for detail
