Preface

This preface introduces the *ARM® Compiler v5.04 for μVision Getting Started Guide*.

It contains the following:

- [About this book on page 9.](#)

About this book

ARM Compiler for μ Vision Getting Started Guide provides an overview of the μ Vision tools, standards supported, and compliance with the ARM *Application Binary Interface (ABI)*.

Using this book

This book is organized into the following chapters:

Chapter 1 Overview of ARM® Compiler for μ Vision

Gives general information about ARM® Compiler for μ Vision.

Chapter 2 Getting Started with the Compilation Tools

Describes how to create an application using the tools provided by ARM Compiler.

Glossary

The ARM Glossary is a list of terms used in ARM documentation, together with definitions for those terms. The ARM Glossary does not contain terms that are industry standard unless the ARM meaning differs from the generally accepted meaning.

See the *ARM Glossary* for more information.

Typographic conventions

italic

Introduces special terminology, denotes cross-references, and citations.

bold

Highlights interface elements, such as menu names. Denotes signal names. Also used for terms in descriptive lists, where appropriate.

monospace

Denotes text that you can enter at the keyboard, such as commands, file and program names, and source code.

monospace

Denotes a permitted abbreviation for a command or option. You can enter the underlined text instead of the full command or option name.

monospace italic

Denotes arguments to monospace text where the argument is to be replaced by a specific value.

monospace bold

Denotes language keywords when used outside example code.

<and>

Encloses replaceable terms for assembler syntax where they appear in code or code fragments. For example:

```
MRC p15, 0 <Rd>, <CRn>, <CRm>, <Opcode_2>
```

SMALL CAPITALS

Used in body text for a few terms that have specific technical meanings, that are defined in the *ARM glossary*. For example, IMPLEMENTATION DEFINED, IMPLEMENTATION SPECIFIC, UNKNOWN, and UNPREDICTABLE.

Feedback

Feedback on this product

If you have any comments or suggestions about this product, contact your supplier and give:

- The product name.
- The product revision or version.

- An explanation with as much information as you can provide. Include symptoms and diagnostic procedures if appropriate.

Feedback on content

If you have comments on content then send an e-mail to errata@arm.com. Give:

- The title.
- The number ARM DUI0592C.
- The page number(s) to which your comments refer.
- A concise explanation of your comments.

ARM also welcomes general suggestions for additions and improvements.

1.1 About ARM® Compiler for μVision

ARM Compiler for μVision enables you to build applications for the ARM family of processors from C, C++, or ARM assembly language source.

The toolchain comprises:

armcc

The ARM and Thumb® compiler. This compiles your C and C++ code. It supports inline and embedded assemblers.

armasm

The ARM and Thumb assembler. This assembles ARM and Thumb assembly language sources.

armlink

The linker. This combines the contents of one or more object files with selected parts of one or more object libraries to produce an executable program.

armar

The librarian. This enables sets of ELF object files to be collected together and maintained in archives or libraries. You can pass such a library or archive to the linker in place of several ELF files. You can also use the archive for distribution to a third party for further application development.

fromelf

The image conversion utility. This can also generate textual information about the input image, such as its code and data size.

ARM C++ libraries

The ARM C++ libraries provide:

- Helper functions when compiling C++.
- Additional C++ functions not supported by the Rogue Wave library.

ARM C libraries

The ARM C libraries provide:

- An implementation of the library features as defined in the C and C++ standards.
- Extensions specific to the compiler, such as `_fisatty()`, `__heapstats()`, and `__heapvalid()`.
- GNU extensions.
- Common nonstandard extensions to many C libraries.
- POSIX extended functionality.
- Functions standardized by POSIX.

ARM C microlib

The ARM C microlib provides a highly optimized set of functions. These functions are for use with deeply embedded applications that have to fit into extremely small amounts of memory.

Rogue Wave C++ library

The Rogue Wave C++ library provides an implementation of the standard C++ library.

C++ *Standard Template Library* (STL)

An ARM implementation of the C++ Standard Template Library.

———— **Note** —————

ARM Compiler does not support systems with ECC or parity protection where the memory is not initialized.

Supporting software

You can debug the output from the toolchain with any debugger that is compatible with the ELF, DWARF 2, and DWARF 3 specifications.

Updates and patches to the toolchain are available from the ARM web site as they become available.

1.2 Host platform support for ARM® Compiler for μVision

ARM Compiler for μVision supports various Windows platforms.

Except where stated, the ARM Compiler for μVision supports both 32-bit and 64-bit versions of the following OS platforms:

- Windows 7 Enterprise Edition SP1 (32-bit and 64-bit).
- Windows 7 Professional Edition SP1 (32-bit and 64-bit).
- Windows XP Professional SP3 (32-bit only).
- Windows Server 2003 (32-bit and 64-bit).
- Windows Server 2008 R2 (32-bit and 64-bit).

———— **Note** —————

You can also use ARM Compiler for μVision with Cygwin on the supported Windows platforms. However, Cygwin path translation enabled by CYGPATH is only supported on 32-bit Windows platforms.

1.3 About the toolchain documentation

μVision contains a suite of documents that describe how to use the tools and provides information on migration from, and compatibility with, earlier toolchain versions.

The toolchain documentation comprises:

Getting Started Guide (ARM DUI 0592) - this document

This document gives an overview of the toolchain and features.

armcc User Guide (ARM DUI 0375)

This document describes how to use the various features of the compiler, armcc.

See [armcc User Guide](#).

ARM C and C++ Libraries and Floating-Point Support User Guide (ARM DUI 0378)

This document describes the features of the ARM C and C++ libraries, and how to use them. It also describes the floating-point support of the libraries.

See [ARM® C and C++ Libraries and Floating-Point Support User Guide](#).

armasm User Guide (ARM DUI 0379)

This document describes how to use the various features of the assembler, armasm.

See [armasm User Guide](#).

armlink User Guide (ARM DUI 0377)

This document describes how to use the various features of the linker, armlink.

See [armlink User Guide](#).

armar User Guide (ARM DUI 0590)

This document describes how to use the various features of the librarian, armar. It also provides a detailed description of each armar command-line option.

See [armar User Guide](#).

fromelf User Guide (ARM DUI 0459)

This document describes how to use the various features of the ELF image converter, fromelf. It also provides a detailed description of each fromelf command-line option.

See [fromelf User Guide](#).

Errors and Warning Reference Guide (ARM DUI 0591)

This document describes the errors and warnings that might be generated by each of the build tools in μVision.

See [Errors and Warnings Reference Guide](#).

Migration and Compatibility Guide (ARM DUI 0593)

This document describes the differences you must be aware of in μVision, when migrating your software from earlier toolchain versions, such as ARM RVCT v4.0.

See [Migration and Compatibility Guide](#).

1.4 Licensed features of ARM® Compiler

ARM Compiler requires a license.

If you purchased the toolchain with another ARM product, see the *Getting Started* document of that product for details of the licenses that are included.

Licensing of the ARM development tools is controlled by the FlexNet license management system.

To request a license, go to [ARM Web Licensing](#) and follow the online instructions.

Related information

[ARM DS-5 License Management Guide](#).

1.5 Standards compliance in ARM® Compiler

ARM Compiler conforms to the ISO C, ISO C++, ELF, DWARF 2, and DWARF 3 standards.

The level of compliance for each standard is:

ar

armar produces, and armlink consumes, UNIX-style object code archives. armar can list and extract most ar-format object code archives, and armlink can use an ar-format archive created by another archive utility providing it contains a symbol table member.

DWARF 3

DWARF 3 debug tables (DWARF Debugging Standard Version 3) are supported by the toolchain.

DWARF 2

DWARF 2 debug tables are supported by the toolchain, and by ELF DWARF 2 compatible debuggers from ARM.

ISO C

The compiler accepts ISO C 1990 and 1999 source as input.

ISO C++

The compiler accepts ISO C++ 2003 source as input.

ELF

The toolchain produces relocatable and executable files in ELF format. The fromelf utility can translate ELF files into other formats.

Note

The DWARF 2 and DWARF 3 standards are ambiguous in some areas such as debug frame data. This means that there is no guarantee that third-party debuggers can consume the DWARF produced by ARM code generation tools or that an ARM debugger can consume the DWARF produced by third-party tools.

1.6 Compliance with the ABI for the ARM Architecture (Base Standard)

The ABI for the ARM Architecture (Base Standard) is a collection of standards. Some of these standards are open. Some are specific to the ARM architecture.

The *Application Binary Interface (ABI) for the ARM Architecture (Base Standard)* (BSABI) regulates the inter-operation of binary code and development tools in ARM architecture-based execution environments, ranging from bare metal to major operating systems such as ARM Linux.

By conforming to this standard, objects produced by the toolchain can work together with object libraries from different producers.

The BSABI consists of a family of specifications including:

AADWARF

DWARF for the ARM Architecture. This ABI uses the DWARF 3 standard to govern the exchange of debugging data between object producers and debuggers.

AAELF

ELF for the ARM Architecture. Builds on the generic ELF standard to govern the exchange of linkable and executable files between producers and consumers.

AAPCS

Procedure Call Standard for the ARM Architecture. Governs the exchange of control and data between functions at runtime. There is a variant of the AAPCS for each of the major execution environment types supported by the toolchain.

BPABI

Base Platform ABI for the ARM Architecture. Governs the format and content of executable and shared object files generated by static linkers. Supports platform-specific executable files using post linking. Provides a base standard for deriving a platform ABI.

CLIBABI

C Library ABI for the ARM Architecture. Defines an ABI to the C library.

CPPABI

C++ ABI for the ARM Architecture. Builds on the generic C++ ABI (originally developed for IA-64) to govern interworking between independent C++ compilers.

DBGOVL

Support for Debugging Overlaid Programs. Defines an extension to the *ABI for the ARM Architecture* to support debugging overlaid programs.

EHABI

Exception Handling ABI for the ARM Architecture. Defines both the language-independent and C++-specific aspects of how exceptions are thrown and handled.

RTABI

Run-time ABI for the ARM Architecture. Governs what independently produced objects can assume of their execution environments by way of floating-point and compiler helper function support.

If you are upgrading from a previous toolchain release, ensure that you are using the most recent versions of the ARM specifications.

1.7 Toolchain environment variables

Except for `ARMLMD_LICENSE_FILE`, does not require any other environment variables to be set. However, there are situations where you might want to set environment variables.

For example, if you want to specify additional command-line options for `armasm`, but you do not want to modify your build scripts, then you can specify the options using `_CCOPT`.

The environment variables used by the toolchain are:

Table 1-1 Environment variables used by the toolchain

Environment variable	Setting
<code>ARMLMD_LICENSE_FILE</code>	<p>This environment variable must be set, and specifies the location of your ARM license file. See the <i>ARM® DS-5™ License Management Guide</i> for information on this environment variable.</p> <p>———— Note —————</p> <p>On Windows, the length of <code>ARMLMD_LICENSE_FILE</code> must not exceed 260 characters.</p>
<code>ARMROOT</code>	Your installation directory root, <i>install_directory</i> .
<code>ARMCC5_ASMOPT</code>	<p>An optional environment variable to define additional assembler options that are to be used outside your regular makefile. For example:</p> <pre>--licretry</pre> <p>The options listed appear before any options specified for the <code>armasm</code> command in the makefile. Therefore, any options specified in the makefile might override the options listed in this environment variable.</p>
<code>ARMCC5_CCOPT</code>	<p>An optional environment variable to define additional compiler options that are to be used outside your regular makefile. For example:</p> <pre>--licretry</pre> <p>The options listed appear before any options specified for the <code>armcc</code> command in the makefile. Therefore, any options specified in the makefile might override the options listed in this environment variable.</p>
<code>ARMCC5_FROMELFOPT</code>	<p>An optional environment variable to define additional <code>fromelf</code> image converter options that are to be used outside your regular makefile. For example:</p> <pre>--licretry</pre> <p>The options listed appear before any options specified for the <code>fromelf</code> command in the makefile. Therefore, any options specified in the makefile might override the options listed in this environment variable.</p>
<code>ARMCC5_LINKOPT</code>	<p>An optional environment variable to define additional linker options that are to be used outside your regular makefile. For example:</p> <pre>--licretry</pre> <p>The options listed appear before any options specified for the <code>armlink</code> command in the makefile. Therefore, any options specified in the makefile might override the options listed in this environment variable.</p>

Table 1-1 Environment variables used by the toolchain (continued)

Environment variable	Setting
ARMCC5INC	<p>The default system include path. That is, the path used by the compiler to search for header filenames enclosed in angle-brackets. The compiler option <code>-J</code> overrides this environment variable.</p> <p>The default location of the compiler include files is:</p> <p><code>install_directory\include</code></p>
ARMCC5LIB	<p>The default location of the ARM standard C and C++ library files:</p> <p><code>install_directory\lib</code></p> <p>The compiler option <code>--libpath</code> overrides this environment variable.</p> <p>———— Note —————</p> <p>If you include a path separator at the end of the path, the linker searches that directory and the subdirectories. So for <code>install_directory\lib</code> the linker searches:</p> <p><code>install_directory\lib</code> <code>install_directory\lib\armlib</code> <code>install_directory\lib\cpplib</code></p>
ARMINC	<p>Used only if you do not specify the compiler option <code>-J</code> and <code>ARMCC5INC</code> is either not set or is empty.</p> <p>See the description of <code>ARMCC5INC</code> for more information.</p>
ARMLIB	<p>Used only if you do not specify the compiler option <code>--libpath</code> and <code>ARMCC5LIB</code> is either not set or is empty.</p> <p>See the description of <code>ARMCC5LIB</code> for more information.</p>
CYGPATH	<p>The location of the <code>cygpath.exe</code> file on your system in Cygwin path format. For example:</p> <p><code>C:/cygwin/bin/cygpath.exe</code></p> <p>You must set this if you want to specify paths in Cygwin format for the compilation tools.</p> <p>———— Note —————</p> <p>Cygwin path translation enabled by <code>CYGPATH</code> is only supported on 32-bit Windows platforms.</p>
TMP	<p>Used on Windows platforms to specify the directory to be used for temporary files. If <code>TMP</code> is not defined, or if it is set to the name of a directory that does not exist, temporary files are created in the current working directory.</p>

1.8 ARM architectures supported by the toolchain

ARM Compiler includes support for all ARM architectures from ARMv4™ onwards that are currently supported by ARM.

All architectures before ARMv4 are obsolete and are no longer supported.

You can specify a target processor or architecture to take advantage of extra features specific to the selected processor or architecture. To do this, use the following command-line options:

- `--cpu=name`.
- `--fpu=name`.

You can specify the startup instruction set, ARM or Thumb, with the `--arm` or `--thumb` command-line options.

You can force an ARM-only instruction set with the `--arm_only` option.

The compilation tools provide support for mixing ARM and Thumb code. This is known as interworking and enables branching between ARM code and Thumb code.

1.9 ARM® Compiler for μVision support on 64-bit host platforms

ARM Compiler for μVision provides 32-bit and 64-bit versions of `armlink`.

Although ARM Compiler for μVision is supported on certain 64-bit platforms, the tools are 32-bit applications. This limits the virtual address space and file size available to the tools. If these limits are exceeded, `armlink` reports an error message to indicate that there is not enough memory. This might cause confusion because sufficient physical memory is available but the application cannot access it.

Related references

1.10 Special characters on the command line

You can use special characters to select multiple symbolic names in some compilation tools command arguments.

If you are using a special character on Unix platforms, you must enclose the options in quotes to prevent the shell expanding the selection.

- The wildcard character `*` matches any name.
- The wildcard character `?` matches any single character.

For example, enter `'*,~*.*'` instead of `*,~*.*`.

Note

The `armar` command-line options must be preceded by a `-`. This is different from some earlier versions of `armar`, and from some third-party archivers.

Examples

The following examples show the use of these characters:

- `armar --create mylib.a *.o`, creates the archive `mylib.a` containing all object files in the current directory.
 - `armar -t mylib.a s*.o`, lists all object files beginning with `s` in the `mylib.a`.
 - `armlink hello.o mylib.a(?*.o) -o tst.axf`, links `hello.o` with all object files in `mylib.a` that have a single letter filename.
 - `fromelf --info=sizes,totals mylib.a(s*.o)`, lists the code and data sizes for all object files beginning with `s` in `mylib.a`.

1.11 Rules for specifying command-line options

There are certain rules you must follow when using command-line options. These rules depend on the type of option.

The following rules apply:

Single-letter options

All single-letter options, including single-letter options with arguments, are preceded by a single dash -. You can use a space between the option and the argument, or the argument can immediately follow the option. For example:

```
-J directory  
-Jdirectory
```

Keyword options

All keyword options, including keyword options with arguments, are preceded by a double dash --. An = or space character is required between the option and the argument. For example:

```
--depend=file.d  
--depend file.d
```

Compilation tools options that contain non-leading - or _ can use either of these characters. For example, --force_new_nothrow is the same as --force-new-nothrow.

To compile files with names starting with a dash, use the POSIX option -- to specify that all subsequent arguments are treated as filenames, not as command switches. For example, to compile a file named -ifile_1, use:

```
armcc -c -- -ifile_1
```

In some Unix shells, you might have to include quotes when using arguments to some command-line options, for example:

```
--keep='s.o(vect)'
```

1.12 Order of options on the command line

In general, command-line options can appear in any order. However, the effects of some options depend on how they are combined with other related options.

Where options override other options on the same command line, the options that appear closer to the end of the command line take precedence. Where an option does not follow this rule, this is noted in the description for that option.

Use the `--show_cmdline` option to see how the command line is processed. The commands are shown normalized.

Related information

--show_cmdline compiler option.

--show_cmdline assembler option.

--show_cmdline linker option.

--show_cmdline fromelf option.

--show_cmdline armar option.

1.13 Methods of specifying command-line options

You can specify command-line options directly. Some operating systems restrict the length of the command line, so you can also specify command-line options in environment variables or in a text file.

You can:

- Specify the commands directly on the command line. However, the number of options you can specify is limited by the command length supported by your operating system.
- Specify the commands in a text file, called a *via file*. A separate *via file* is required for each tool. You can use a *via file* to overcome the command length limitation of your operating system.
- Use tool-specific environment variables. These are:
 - ARMCC5_ASMOPT for the assembler.
 - ARMCC5_CCOPT for the compiler.
 - ARMCC5_FROMELFOPT for the fromelf image converter.
 - ARMCC5_LINKOPT for the linker.

The syntax is identical to the command-line syntax. The compilation tool reads the value of the environment variable and inserts it at the front of the command string. This means that you can override options specified in the environment variable by arguments on the command line.

Related information

--via compiler option.

--via assembler option.

--via linker option.

--via fromelf option.

--via armar option.

1.14 Precedence of command-line options when using them in a text file

The compilation tools read command-line options from a specified text file and combine them with any additional options you have specified for the tool. Some options might take precedence over other options.

The precedence given to a command-line option depends on:

- The command-line option.
- The position of the `--via` option on the command line.

To see a command line equivalent to the result of combining the options, specify the `--show_cmdline` option. For example, if `armcc.txt` contains the options `--debug --cpu=ARM926EJ-S`:

- `armcc -c --show_cmdline --cpu=ARM7TDMI --via=armcc.txt hello.c [armcc --show_cmdline --debug -c --cpu=ARM926EJ-S hello.c]`

In this case, `--cpu=ARM7TDMI` is not used because `--cpu=ARM926EJ-S` is the last instance of `--cpu` on the command-line.

- `armcc --via=armcc.via -c --show_cmdline --cpu=ARM7TDMI hello.c [armcc --show_cmdline --debug -c hello.c]`

In this case, `--cpu=ARM926EJ-S` is not used because `--cpu=ARM7TDMI` is the last instance of `--cpu` on the command line. In addition, `--cpu=ARM7TDMI` is not shown in the output, because this is the default option for `--cpu`.

1.15 Portability of source files between hosts

There are guidelines you can follow to assist portability of source files between hosts.

The guidelines are:

- Ensure that filenames do not contain spaces. If you have to use path names or filenames containing spaces, enclose the path and filename in double (") or single (') quotes.
- Make embedded path names relative rather than absolute.
- Use forward slashes (/) in embedded path names, not backslashes (\).

1.16 TMP environment variable for temporary file directories

The compilation tools use a temporary directory when processing files.

Use the TMP environment variable name to refer to the temporary directory. If TMP is not defined, or if it is set to the name of a directory that does not exist, temporary files are created in the current working directory.

TMP is typically set up by a system administrator. However, it is permissible for you to change it.

1.17 Autocompletion of command-line options

You can specify a shortened version of a command-line option with the autocompletion feature.

To use the autocompletion feature, insert a full stop (.) after the characters to be autocompleted.

The following rules apply to the autocompletion feature:

- You must separate arguments from the full stop by an equals (=) character or a space character.
- You cannot use autocompletion for the arguments to an option.
- You must include sufficient characters to make the autocompleted option unique.

For example, use `--diag_su.=223` to specify `--diag_suppress=223` on the command line.

Specifying `--diag.=223` is not valid, because `--diag.` does not identify a single unique command-line option.

1.18 About specifying Cygwin paths in compilation tools on Windows

You must use an environment variable to specify Cygwin paths for compilation tools on Windows.

By default on Windows, the compilation tools require path names to be in the Windows DOS format, for example, C:\myfiles. If you want to use Cygwin path names, then set the CYGPATH environment variable to the location of the cygpath.exe file on your system. For example:

```
set CYGPATH=C:/cygwin/bin/cygpath.exe
```

You can now specify file locations in the compilation tools command-line options using the Cygwin path format. The paths are translated by cygpath.exe. For example, to compile the file /cygdrive/h/main.c, enter the command:

```
armcc -c --debug /cygdrive/h/main.c
```

You can still specify paths that start with:

- A drive letter, for example C:\ or C:/.
- UNC, for example, \\computer.

The compilation tools do not translate these paths because the paths are already in a form that Windows understands.

Limitations of CYGPATH

Be aware of the following limitations with CYGPATH:

- Cygwin path translation enabled by CYGPATH is only supported on 32-bit Windows platforms.
- When using a Cygwin style path with spaces or other special terminal characters, the path must be double quoted:
 - The use of single quotes or escaping characters is not supported.
 - The use of literal doublequote characters in path names is not supported.

Getting Started with the Compilation Tools

Describes how to create an application using the tools provided by ARM Compiler.

It contains the following sections:

- [2.1 About the ARM compilation tools](#) on page 2-36.
- [2.2 The ARM compiler command](#) on page 2-37.
- [2.3 The ARM linker command](#) on page 2-39.

2.1 About the ARM compilation tools

The compilation tools allow you to build executable images, partially linked object files, and shared object files, and to convert images to different formats.

A typical application development might involve the following:

- Compiling C/C++ source code for the main application (`armcc`).
- Assembling ARM assembly source code for near-hardware components, such as interrupt service routines (`armasm`).
- Linking all objects together to generate an image (`armlink`).
- Converting an image to flash format in plain binary, Intel Hex, and Motorola-S formats (`fromelf`).

The following figure shows how the compilation tools are used for the development of a typical application.

2.2 The ARM compiler command

The compiler, `armcc`, can compile C and C++ source code into ARM and Thumb code.

Typically, you invoke the compiler as follows:

```
armcc [options] file_1 ... file_n
```

You can specify one or more input files. The compiler produces one object file for each source input file.

Building an example image from C++ source

To compile a C++ file called `shapes.cpp`:

1. Compile the C++ file `shapes.cpp` with the following command:

```
armcc -c --cpp --debug -O1 shapes.cpp -o shapes.o
```

2. The following options are commonly used:

-c

Tells the compiler to compile only, and not link.

--cpp

Tells the compiler that the source is C++.

--debug

Tells the compiler to add debug tables for source-level debugging.

-O1

Tells the compiler to generate code with restricted optimizations applied to give a satisfactory debug view with good code density and performance.

-o filename

Tells the compiler to create an object file with the specified *filename*.

———— **Note** —————

Be aware that `--arm` is the default compiler option.

3. Link the file:

```
armlink shapes.o --info totals -o shapes.axf
```

4. Use an ELF, DWARF 2, and DWARF 3 compatible debugger to load and run the image.

Command-line options for compiling ARM code

The following compiler options generate ARM code:

--arm

Tells the compiler to generate ARM code in preference to Thumb code. However, `#pragma thumb` overrides this option.

This is the default compiler option.

--arm_only

Forces the compiler to generate only ARM code. The compiler behaves as if Thumb is absent from the target architecture. Any `#pragma thumb` declarations are ignored.

Command-line options for compiling Thumb code

The following compiler option generates Thumb code:

--thumb

Tells the compiler to generate Thumb code in preference to ARM code. However, `#pragma arm` overrides this option.

2.3 The ARM linker command

The linker combines the contents of one or more object files with selected parts of one or more object libraries to produce an image or object file.

Typically, you invoke the linker as follows:

```
armlink [options] file_1 ... file_n
```

Linking an example object file

To link the object file `shapes.o`, enter:

```
armlink shapes.o --info totals -o shapes.axf
```

- o Specifies the output file as `shapes.axf`.
- info totals Tells the linker to display totals of the Code and Data sizes for input objects and libraries.

2.4 The ARM assembler command

The assembler, `armasm`, can assemble ARM assembly code into ARM and Thumb code.

Typically, you invoke the assembler as follows:

```
armasm [options] inputfile
```

Building an example from assembly source

To build the assembler program `word.s`:

1. Assemble the source file:

```
armasm --debug word.s
```

2. Link the object file:

```
armlink word.o -o word.axf
```

3. Use an ELF, DWARF 2, and DWARF 3 compatible debugger to load and run the image. Step through the program and examine the registers to see how they change.

2.5 Execute-only memory

Execute-only memory (XOM) allows only instruction fetches. Read and write accesses are not allowed.

Execute-only memory allows you to protect your intellectual property by preventing executable code being read by users. For example, you can place firmware in execute-only memory and load user code and drivers separately. Placing the firmware in execute-only memory prevents users from trivially reading the code.

———— **Note** —————

The ARM architecture does not directly support execute-only memory. Execute-only memory is supported at the memory device level.

Related tasks

[2.6 Building applications for execute-only memory on page 2-42.](#)

2.6 Building applications for execute-only memory

Placing code in execute-only memory prevents users from trivially reading that code.

To build an application with code in execute-only memory:

Procedure

1. Compile your C or C++ code or assemble your ARM assembly code using the `--execute_only` option

```
armcc -c --execute_only test.c -o test.o
```

The `--execute_only` option prevents the compiler from generating any data accesses to the code sections.

To keep code and data in separate sections, the compiler disables the placement of literal pools inline with code.

Compiled code sections have the `EXECONLY` attribute:

```
AREA ||.text||, CODE, EXECONLY, ALIGN=1
```

The assembler faults any attempts to define data in an `EXECONLY` code section.

2. Specify the memory map to the linker using either of the following:

- The `+X0` selector in a scatter file.
- The `armlink --xo-base` option on the command-line.

```
armlink --xo-base=0x8000 test.o -o test.axf
```

The XO execution region is placed in a separate load region from the RO, RW, and ZI execution regions.

————— **Note** —————

If you do not specify `--xo-base`, then by default:

- The XO execution region is placed immediately before the RO execution region, at address `0x8000`.
- All execution regions are in the same load region.

2.7 The fromelf image converter command

fromelf allows you to convert ELF files into different formats and display information about them.

The features of the fromelf image converter include:

- Converting an executable image in ELF executable format to other file formats.
- Controlling debug information in output files.
- Printing information about an ELF image or an ELF object file.

Examples

The following examples show how to use fromelf:

```
fromelf --text -c -s --output=outfile.lst infile.axf
```

Creates a plain text output file that contains the disassembled code and the symbol table of an elf image.

```
fromelf --bin --16x2 --output=outfile0.bin infile.axf
```

Creates two files in binary format (outfile0.bin and outfile1.bin) for a target system with a memory configuration of a 16-bit memory width in two banks.

The output files in the last example are suitable for writing directly to a 16-bit Flash device.
