Arm Performance Libraries Reference Guide

Version 19.2.0

Document Number 101004_1920_00

Release Information

Issue	Date	Confidentiality	Change
1830-00	20 June 2018	Non-Confidential	Document release for Arm Performance Libraries version 18.3
1840-00	17 July 2018	Non-Confidential	Update for Arm Performance Libraries version 18.4
1900-00	2 November 2018	Non-Confidential	Update for Arm Performance Libraries version 19.0
1910-00	8 March 2019	Non-Confidential	Update for Arm Performance Libraries version 19.1
1920-00	07 June 2019	Non-Confidential	Update for Arm Performance Libraries version 19.2

Arm Limited. Company 02557590 registered in England.

110 Fulbourn Road, Cambridge, England CB1 9NJ.

LES-PRE-20349

Contents

1 Introduction **3**
1.1 Arm Performance Libraries . . . 3
1.2 References . . . 3

2 General Information **5**
2.1 Accessing the Library . . . 5
2.2 Arm Performance Libraries Fortran and C interfaces . . . 6
2.3 Arm Performance Libraries variant using 64-bit integer (INTEGER*8) arguments . . . 7
2.4 Library Version and Build Information . . . 7
2.4.1 Fortran specifications . . . 7
2.4.2 C specifications . . . 7
2.5 Example programs calling Arm Performance Libraries . . . 7

3 BLAS Basic Linear Algebra Subprograms **9**
3.1 Overview . . . 9
3.2 BLAS level 1 . . . 10
3.2.1 caxpy . . . 10
3.2.2 ccopy . . . 11
3.2.3 cdotc . . . 12
3.2.4 cdotu . . . 13
3.2.5 crot . . . 14
3.2.6 crotg . . . 15
3.2.7 cscal . . . 16
3.2.8 csrot . . . 17
3.2.9 csscal . . . 18
3.2.10 cswap . . . 19
3.2.11 dasum . . . 20
3.2.12 daxpy . . . 20
3.2.13 dcopy . . . 21
3.2.14 ddot . . . 22
3.2.15 dnrm2 . . . 23
3.2.16 drot . . . 24
3.2.17 drotg . . . 25
3.2.18 drotm . . . 26
3.2.19 drotmg . . . 27
3.2.20 dscal . . . 28
3.2.21 dsdot . . . 29
3.2.22 dswap . . . 30
3.2.23 dzasum . . . 30
3.2.24 dznrm2 . . . 31
3.2.25 icamax . . . 32
3.2.26 idamax . . . 33
3.2.27 isamax . . . 33
3.2.28 izamax . . . 34
3.2.29 sasum . . . 35
3.2.30 saxpy . . . 36
3.2.31 scasum . . . 37
3.2.32 scnrm2 . . . 37

3.2.33 scopy . . . 38
3.2.34 sdot . . . 39
3.2.35 sdsdot . . . 40
3.2.36 snrm2 . . . 41
3.2.37 srot . . . 42
3.2.38 srotg . . . 43
3.2.39 srotm . . . 44
3.2.40 srotmg . . . 45
3.2.41 sscal . . . 46
3.2.42 sswap . . . 47
3.2.43 zaxpy . . . 47
3.2.44 zcopy . . . 48
3.2.45 zdotc . . . 49
3.2.46 zdotu . . . 50
3.2.47 zdrot . . . 51
3.2.48 zdscal . . . 53
3.2.49 zrot . . . 53
3.2.50 zrotg . . . 55
3.2.51 zscal . . . 55
3.2.52 zswap . . . 56
3.3 BLAS level 2 . . . 57
3.3.1 cgbmv . . . 57
3.3.2 cgemv . . . 59
3.3.3 cgerc . . . 61
3.3.4 cgeru . . . 62
3.3.5 chbmv . . . 64
3.3.6 chemv . . . 66
3.3.7 cher . . . 68
3.3.8 cher2 . . . 69
3.3.9 chpmv . . . 70
3.3.10 chpr . . . 72
3.3.11 chpr2 . . . 73
3.3.12 cspmv . . . 75
3.3.13 cspr . . . 76
3.3.14 csymv . . . 78
3.3.15 csyr . . . 79
3.3.16 ctbmv . . . 81
3.3.17 ctbsv . . . 83
3.3.18 ctpmv . . . 85
3.3.19 ctpsv . . . 86
3.3.20 ctrmv . . . 88
3.3.21 ctrsv . . . 89
3.3.22 dgbmv . . . 91
3.3.23 dgemv . . . 93
3.3.24 dger . . . 94
3.3.25 dsbmv . . . 96
3.3.26 dspmv . . . 98
3.3.27 dspr . . . 99
3.3.28 dspr2 . . . 100
3.3.29 dsymv . . . 102
3.3.30 dsyr . . . 103
3.3.31 dsyr2 . . . 105
3.3.32 dtbmv . . . 106
3.3.33 dtbsv . . . 108
3.3.34 dtpmv . . . 110
3.3.35 dtpsv . . . 112
3.3.36 dtrmv . . . 113
3.3.37 dtrsv . . . 115

3.3.38 sgbmv . . . 116
3.3.39 sgemv . . . 118
3.3.40 sger . . . 120
3.3.41 ssbmv . . . 121
3.3.42 sspmv . . . 123
3.3.43 sspr . . . 125
3.3.44 sspr2 . . . 126
3.3.45 ssymv . . . 128
3.3.46 ssyr . . . 129
3.3.47 ssyr2 . . . 130
3.3.48 stbmv . . . 132
3.3.49 stbsv . . . 134
3.3.50 stpmv . . . 136
3.3.51 stpsv . . . 137
3.3.52 strmv . . . 139
3.3.53 strsv . . . 140
3.3.54 zgbmv . . . 142
3.3.55 zgemv . . . 144
3.3.56 zgerc . . . 146
3.3.57 zgeru . . . 147
3.3.58 zhbmv . . . 148
3.3.59 zhemv . . . 151
3.3.60 zher . . . 152
3.3.61 zher2 . . . 154
3.3.62 zhpmv . . . 155
3.3.63 zhpr . . . 157
3.3.64 zhpr2 . . . 158
3.3.65 zspmv . . . 159
3.3.66 zspr . . . 161
3.3.67 zsymv . . . 162
3.3.68 zsyr . . . 164
3.3.69 ztbmv . . . 165
3.3.70 ztbsv . . . 167
3.3.71 ztpmv . . . 169
3.3.72 ztpsv . . . 171
3.3.73 ztrmv . . . 172
3.3.74 ztrsv . . . 174
3.4 BLAS level 3 . . . 175
3.4.1 cgemm . . . 175
3.4.2 chemm . . . 178
3.4.3 cher2k . . . 180
3.4.4 cherk . . . 182
3.4.5 csymm . . . 183
3.4.6 csyr2k . . . 185
3.4.7 csyrk . . . 187
3.4.8 ctrmm . . . 189
3.4.9 ctrsm . . . 191
3.4.10 dgemm . . . 193
3.4.11 dsymm . . . 195
3.4.12 dsyr2k . . . 197
3.4.13 dsyrk . . . 199
3.4.14 dtrmm . . . 201
3.4.15 dtrsm . . . 203
3.4.16 sgemm . . . 205
3.4.17 ssymm . . . 207
3.4.18 ssyr2k . . . 209
3.4.19 ssyrk . . . 211
3.4.20 strmm . . . 213

3.4.21 strsm . . . 215
3.4.22 zgemm . . . 217
3.4.23 zhemm . . . 219
3.4.24 zher2k . . . 221
3.4.25 zherk . . . 223
3.4.26 zsymm . . . 225
3.4.27 zsyr2k . . . 227
3.4.28 zsyrk . . . 229
3.4.29 ztrmm . . . 230
3.4.30 ztrsm . . . 232
3.5 CBLAS functions . . . 234
3.5.1 cblas_caxpby . . . 234
3.5.2 cblas_caxpy . . . 235
3.5.3 cblas_ccopy . . . 236
3.5.4 cblas_cgbmv . . . 236
3.5.5 cblas_cgemm . . . 237
3.5.6 cblas_cgemm3m . . . 237

CHAPTER

ONE

INTRODUCTION

1.1 Arm Performance Libraries

The Arm Performance Libraries are a set of numerical routines tuned specifically for Arm processors. The routines, which are available using both the Fortran and C interfaces, include:

- BLAS: Basic Linear Algebra Subprograms (including XBLAS, the extended precision BLAS).
- LAPACK: A comprehensive package of higher-level linear algebra routines.
- FFT: A set of Fast Fourier Transform routines for real and complex data.
- Sparse: A selection of basic linear algebra routines for working with sparse data.

The BLAS and LAPACK routines provide a portable, standard set of interfaces for common numerical linear algebra operations. Full documentation for BLAS and LAPACK are available online. This manual provides:

- Brief descriptions of BLAS and LAPACK.
- Links to the documentation for BLAS and LAPACK. See *BLAS Basic Linear Algebra Subprograms*, and *LAPACK Linear Algebra Package*.
- Links to other materials.

The FFT is an implementation of the Discrete Fourier Transform (DFT). FFT uses symmetries in the definition to reduce the number of operations that are required from O(n*n) to O(n*log n). FFTs in Arm Performance Libraries are provided using the same interface as the popular Open Source package FFTW3. See *Fast Fourier Transforms FFTs Introduction*.

Sparse routines are provided by using an API that separates the description of a sparse problem from its execution. The basic flow is to first create a handle to a sparse matrix by providing the matrix in a common format (for example Compressed Sparse Rows). Next, the handle is used to identify the matrix in order to describe its characteristics and perform optimizations. Finally, the handle is passed to an execution step. This workflow gives the library the opportunity to create new data structures that are more suited to solving the problem on the hardware.

General Information *General Information* provides the following details:

- Linking a user program to Arm Performance Libraries.
- Fortran and C interfaces to Arm Performance Libraries routines.
- Getting the Arm Performance Libraries version and build information.
- Accessing the Arm Performance Libraries documentation.

CHAPTER

TWO

GENERAL INFORMATION

2.1 Accessing the Library

Arm Performance Libraries is compatible with two compilers: GNU GCC (gcc/gfortran) and the Arm C/C++/Fortran Compiler (armclang/armflang) that is packaged with the Arm Allinea Studio. Separate binary distributions of the library are supplied for these two compilers. To manage access to the correct library for your choice of compiler, Arm recommends using the environment modules provided. The environment modules set the `ARMPL_DIR` environment variable appropriately.

Note: If you are not using the environment modules, you can assume that `${ARMPL_DIR}` is set to `/opt/arm/armpl-..._CPU_DISTRO`.

Use the following command to compile the program driver.f90 using `armflang` and link the program to Arm Performance Libraries:

```
armflang driver.f90 -L${ARMPL_DIR}/lib -larmpl_lp64
```

Use the following command to compile the program driver.f90 using `gfortran` and link the program to Arm Performance Libraries:

```
gfortran driver.f90 -L${ARMPL_DIR}/lib -larmpl_lp64
```

The Arm Performance Libraries are supplied in both static and shareable versions, `libarmpl_lp64.a` and `libarmpl_lp64.so`. By default, the commands given above link to the shareable version of the library, `libarmpl_lp64.so`, if that version exists in the specified directory.

To force linking with the static library, use the compiler flag `-static`, for example:

```
armflang driver.f90 -L${ARMPL_DIR}/lib -static -larmpl_lp64 -lrt
```

```
gfortran driver.f90 -L${ARMPL_DIR}/lib -static -larmpl_lp64 -lrt
```

Alternatively, insert the name of the static library in the command line, for example:

```
armflang driver.f90 ${ARMPL_DIR}/lib/libarmpl_lp64.a -lrt
```

```
gfortran driver.f90 ${ARMPL_DIR}/lib/libarmpl_lp64.a -lrt
```

Note: When using the supplied environment modules, check to see that the `LD_LIBRARY_PATH` is automatically updated; if you do not use the supplied environment variable, you must set `LD_LIBRARY_PATH` yourself when linking to the shareable library.

To link against a multi-threaded version of Arm Performance Libraries, use the following commands, as appropriate:

```
armflang -fopenmp driver.f90 -L${ARMPL_DIR}/lib -larmpl_lp64_mp
```

```
gfortran -fopenmp driver.f90 -L${ARMPL_DIR}/lib -larmpl_lp64_mp
```

Note: The library names now include the suffix _mp.

To compile and link a C program with Arm Performance Libraries, use the following commands, as appropriate:

```
armclang -I${ARMPL_DIR}/include driver.c \
         -L${ARMPL_DIR}/lib -larmpl_lp64 -larmflang
```

```
gcc -I${ARMPL_DIR}/include driver.c \
     -L${ARMPL_DIR}/lib -larmpl_lp64 -lgfortran
```

The switch "-I${ARMPL_DIR}/include" tells the compiler to search the specified directory for the Arm Performance Libraries C header file armpl.h, which must be included by driver.c.

Note: When you link the program, you must add the Fortran compiler run-time library or libraries (-lgfortran or -lflang -lflangrti). If you are using the Arm Compiler, you can apply the -armpl flag to load the optimum version of Arm Performance Libraries for your target architecture and implementation. For more information, see Arm Performance Libraries Library Selection.

2.2 Arm Performance Libraries Fortran and C interfaces

Most routines in Arm Performance Libraries come with both Fortran and C interfaces. The Fortran interfaces typically follow the relevant standard, such as LAPACK and BLAS. In C code that uses Arm Performance Libraries routines, ensure that you include the header file armpl.h, which contains function prototypes for all Arm Performance Libraries C interfaces. The header file also contains C prototypes for Fortran interfaces so that you can call the Fortran interfaces from C if you need to do so.

For more details on the C interfaces, see *BLAS Basic Linear Algebra Subprograms*, *LAPACK Linear Algebra Package*, and *Fast Fourier Transforms FFTs Introduction*.

Arm Performance Libraries also includes Fortran interface block modules for user-callable routines. These modules define the type and arguments of each Arm Performance Libraries routine. Their purpose is to allow the Fortran compiler to check that Arm Performance Libraries routines are called correctly. The interface blocks allow the compiler to check that:

- Subroutines are called correctly.
- Functions are declared with the correct type.
- The correct number of arguments are passed.
- All arguments match in type and structure.

The interface block modules are not essential to calling Arm Performance Libraries from Fortran programs. However, the supplied example programs use the interface block modules and Arm recommends that you also use them in order to avoid common mistakes.

The interfaces to Arm Performance Libraries routines are declared in files armpl_blas.f90 and armpl_lapack.f90, and they are also combined into one module named armpl_library. You can find these modules in the Arm Performance Libraries **include** directory. For help on how to use these modules, see the Fortran programs in the Arm Performance Libraries examples directory.

2.3 Arm Performance Libraries variant using 64-bit integer (INTEGER*8) arguments

You can use the `INTEGER*8` version of the Arm Performance Libraries with Fortran programs that use `INTEGER*8` variables, and C programs that use 8-byte long variables.

The `INTEGER*8` versions of the libraries include the string "`_ilp64`" as part of the library name, instead of "`_lp64`" which is used in the name of 32-bit integer versions of the libraries. You can also find additional versions of the module files that are compiled to use `INTEGER*8` in the `include_ilp64` directory.

```
gfortran driver.f90 -L${ARMPL_DR}/lib -larmpl_ilp64 -I${ARMPL_DIR}/include_ilp64
```

```
armflang driver.f90 -L${ARMPL_DIR}/lib -larmpl_ilp64 -I${ARMPL_DIR}/include_ilp64
```

For these Arm Performance Libraries variants, ensure that the documentation which mentions Fortran `INTEGER` argument types refers to them as `INTEGER*8`, and refers to C `int` argument types as `long`.

You must ensure that you link to the ilp64 variant if you have INTEGER*8 variables in your code, and not to other variants. Unexpected program crashes are likely to occur if you link to the wrong version.

2.4 Library Version and Build Information

This document is applicable to version 19.2 of Arm Performance Libraries. The utility routine `armplversion()` can be called to get the major, minor, and patch version numbers of the installed Arm Performance Libraries.

The utility routine `armplinfo()` can be called to get information on the compiler that is used to build Arm Performance Libraries, the version of the compiler, and the options that are used for building the Library. This subroutine takes no arguments and prints the information to the current standard output.

2.4.1 Fortran specifications

SUBROUTINE: **ARMPLVERSION** *(MAJOR, MINOR, PATCH, BUILD)*

INTEGER: **MAJOR**, *MINOR, PATCH, BUILD*

SUBROUTINE: **ARMPLINFO** *()*

2.4.2 C specifications

function: *void* **armplversion** *(int *major, int *minor, int *patch, int *build)*;

function: *void* **armplinfo** *(void)*;

2.5 Example programs calling Arm Performance Libraries

The `examples` subdirectory in the Arm Performance Libraries installation directory contains example programs that show how to call Arm Performance Libraries. It also contains a `GNUmakefile` to build and run the example programs. The directory also includes examples of how to call Fortran and C interfaces. You can use these programs to test an Arm Performance Libraries installation.

You might need to modify some variables in the GNUmakefile before using it, depending on where your copy of the Arm Performance Libraries is installed, and depending on which compiler and flags you want to use.

If you need more example programs showing how to call LAPACK routines from Fortran,see the NAG double precision LAPACK driver routines web page. These examples work when linked with Arm Performance Libraries.

Note: In addition to the example programs, you must also download and compile a small amount of utility code used by the programs. See the web page for detailed instructions.

CHAPTER

THREE

BLAS BASIC LINEAR ALGEBRA SUBPROGRAMS

3.1 Overview

The BLAS are a set of well defined basic linear algebra operations ([1], [2], [3]). These operations are subdivided into three groups:

- Level 1: operations acting on vectors only (such as, dot product)
- Level 2: matrix-vector operations (such as, matrix-vector multiplication)
- Level 3: matrix-matrix operations (such as, matrix-matrix multiplication)

Efficient machine-specific implementations of the BLAS are available for many modern high-performance computers. The implementation of higher level linear algebra algorithms on these systems depends critically on the use of the BLAS as building blocks.

For any information relating to the standard BLAS Fortran interfaces please refer to the BLAS FAQ:

http://www.netlib.org/blas/faq.html

For C users, Arm Performance Libraries includes CBLAS, which are C interfaces to the Fortran BLAS. Names of the CBLAS routines are identical to the Fortran routines except that they are prefixed by the string `cblas_`. For example, the Fortran BLAS routine `dgemm` becomes `cblas_dgemm` in C. Other differences between Fortran BLAS and CBLAS interfaces:

- Scalar input arguments are passed by value in CBLAS interfaces. Fortran interfaces pass all arguments by reference (except for character string *length* arguments that are normally hidden from Fortran programmers).
- Unlike Fortran, C has no native *complex* data type. Arm Performance Libraries C routines, which operate on complex data, use the types `armpl_singlecomplex_t` and `armpl_doublecomplex_t` defined in `armpl.h` for single and double precision computations, respectively.
- As with Fortran, all CBLAS array arguments must be stored in contiguous memory. However, all Fortran BLAS routines which take one or more matrices (2D arrays) as arguments have an extra parameter in the CBLAS interface, which appears before all other parameters. This parameter is of the enum type `CBLAS_ORDER`, and it can take one of the values `CblasRowMajor` or `CblasColMajor`.

  The value `CblasColMajor` indicates that elements within any column of each array are contiguous in memory while elements within array rows are offset by a constant stride. This is the usual Fortran storage order. Such strides are given by "leading dimension" arguments (such as `LDA`) in the Fortran and C interfaces.

  The value `CblasRowMajor` indicates that elements within any row of each 2D array are contiguous in memory while elements within array columns are offset by a constant stride such as `LDA`.
- Fortran's `character` type arguments are converted into C enumerated types, as shown in the table below:

Table 1: Fortran and CBLAS interfaces

Fortran Interface		CBLAS Interface	
Character Argument	Value	enum type argument	Value
SIDE	'L' 'R'	CBLAS_SIDE	CblasLeft CblasRight
UPLO	'L' 'U'	CBLAS_UPLO	CblasLower CblasUpper
DIAG	'N' 'U'	CBLAS_DIAG	CblasNonUnit CblasUnit
TRANSPOSE	'T' 'C'	CBLAS_TRANSPOSE	CblasNoTrans CblasRTrans CblasConjTrans

See the `armpl.h` header file to find prototypes for all CBLAS functions.

Note: If you include `armpl.h`, the functions can also be called from a C++ program.

3.2 BLAS level 1

3.2.1 caxpy

`caxpy` performs the following vector update:

$$y \leftarrow \alpha x + y$$

Syntax

Fortran specification:

```
use armpl_library

subroutine caxpy(N, CA, CX, INCX, CY, INCY)
```

C specification:

```
#include "armpl.h"

void caxpy_(const armpl_int_t *n, const armpl_singlecomplex_t *alpha,
            const armpl_singlecomplex_t *x, const armpl_int_t *incx,
            armpl_singlecomplex_t *y, const armpl_int_t *incy);
```

Parameters

N Input parameter.

`N` is `INTEGER`

`N` is the number of elements in the input vectors `CX` and `CY`.

CA Input parameter.

`CA` is `COMPLEX`

`CA` specifies the scalar α.

CX Input parameter.

CX is COMPLEX

CX is the array x, dimension (1 + (N - 1)*abs(INCX)).

INCX Input parameter.

INCX is INTEGER

INCX is the storage spacing between elements of CX.

CY Input and output parameter.

CY is COMPLEX

CY is the array y, dimension (1 + (N - 1)*abs(INCY)).

INCY Input parameter.

INCY is INTEGER

INCY is the storage spacing between elements of CY.

Related Information

For this routine in other precisions, please see *daxpy*, *saxpy* and *zaxpy*. It also exists with a native C interface as *cblas_caxpy*.

3.2.2 ccopy

ccopy copies a vector x to a vector y.

Syntax

Fortran specification:

```
use armpl_library

subroutine ccopy(N, CX, INCX, CY, INCY)
```

C specification:

```
#include "armpl.h"

void ccopy_(const armpl_int_t *n, const armpl_singlecomplex_t *x,
            const armpl_int_t *incx, armpl_singlecomplex_t *y,
            const armpl_int_t *incy);
```

Parameters

N Input parameter.

N is INTEGER

N is the number of elements in the input vectors.

CX Input parameter.

CX is COMPLEX

CX is the array x, dimension (1 + (N - 1)*abs(INCX)).

INCX Input parameter.

INCX is INTEGER

INCX is the storage spacing between elements of CX.

CY Output parameter.

CY is COMPLEX

CY is the array y, dimension (1 + (N - 1)*abs(INCY)).

INCY Input parameter.

INCY is INTEGER

INCY is the storage spacing between elements of CY.

Related Information

For this routine in other precisions, please see *dcopy*, *scopy* and *zcopy*. It also exists with a native C interface as *cblas_ccopy*.

3.2.3 cdotc

cdotc forms the dot product of two complex vectors.

$$CDOTC = X^H \cdot Y$$

Syntax

Fortran specification:

```
use armpl_library

complex function cdotc(N, CX, INCX, CY, INCY)
```

C specification:

```
#include "armpl.h"

armpl_singlecomplex_t cdotc_(const armpl_int_t *n,
                             const armpl_singlecomplex_t *x,
                             const armpl_int_t *incx,
                             const armpl_singlecomplex_t *y,
                             const armpl_int_t *incy);
```

Returns

This returns the result of the dot product, CDOTC.

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

CX Input parameter.

CX is REAL

CX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of CX

CY Input parameter.

CY is REAL

CY is an array, dimension (1 + (N - 1)*abs(INCY))

INCY Input parameter.

INCY is INTEGER

storage spacing between elements of CY

Related Information

For this routine in other precisions, please see *zdotc*.

3.2.4 cdotu

cdotu forms the dot product of two complex vectors.

$$CDOTU = X^T \cdot Y$$

Syntax

Fortran specification:

```
use armpl_library

complex function cdotu(N, CX, INCX, CY, INCY)
```

C specification:

```
#include "armpl.h"

armpl_singlecomplex_t cdotu_(const armpl_int_t *n,
                             const armpl_singlecomplex_t *x,
                             const armpl_int_t *incx,
                             const armpl_singlecomplex_t *y,
                             const armpl_int_t *incy);
```

Returns

This returns the result of the dot product, CDOTU.

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

CX Input parameter.

CX is REAL

CX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of CX

CY Input parameter.

CY is REAL

CY is an array, dimension (1 + (N - 1)*abs(INCY))

INCY Input parameter.

INCY is INTEGER

storage spacing between elements of CY

Related Information

For this routine in other precisions, please see *zdotu*.

3.2.5 crot

crot applies a plane rotation, where the cos (C) is real and the sin (S) is complex, and the vectors CX and CY are complex.

Syntax

Fortran specification:

```
use armpl_library

subroutine crot(N, CX, INCX, CY, INCY, C, S)
```

C specification:

```
#include "armpl.h"

void crot_(const armpl_int_t *n, armpl_singlecomplex_t *cx,
           const armpl_int_t *incx, armpl_singlecomplex_t *cy,
           const armpl_int_t *incy, const float *c,
           const armpl_singlecomplex_t *s);
```

Parameters

N Input parameter.

N is INTEGER

The number of elements in the vectors CX and CY.

CX Input and output parameter.

CX is COMPLEX

CX is an array, dimension (N). On input, the vector X. On output, CX is overwritten with C*X + S*Y.

INCX Input parameter.

INCX is INTEGER

The increment between successive values of CY. INCX <> 0.

CY Input and output parameter.

CY is COMPLEX

CY is an array, dimension (N). On input, the vector Y. On output, CY is overwritten with -CONJG(S)*X + C*Y.

INCY Input parameter.

INCY is INTEGER

The increment between successive values of CY. INCX <> 0.

C Input parameter.

C is REAL

S Input parameter.

S is COMPLEX

C and S define a rotation [C S] [-conjg(S) C] where C* C + S*CONJG(S) = 1.0.

Related Information

For this routine in other precisions, please see *drot*, *srot* and *zrot*.

3.2.6 crotg

crotg determines a complex Givens rotation.

Syntax

Fortran specification:

```
use armpl_library

subroutine crotg(CA, CB, C, S)
```

C specification:

```
#include "armpl.h"

void crotg_(armpl_singlecomplex_t *ca, const armpl_singlecomplex_t *cb,
            float *c, armpl_singlecomplex_t *s);
```

Parameters

CA Input parameter.

CA is COMPLEX

CB Input parameter.

CB is COMPLEX

C Output parameter.

C is REAL

S Output parameter.

S is COMPLEX

Related Information

For this routine in other precisions, please see *drotg*, *srotg* and *zrotg*.

3.2.7 cscal

```
CSCAL scales a vector by a constant.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cscal(N, CA, CX, INCX)
```

C specification:

```
#include "armpl.h"

void cscal_(const armpl_int_t *n, const armpl_singlecomplex_t *alpha,
            armpl_singlecomplex_t *x, const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

CA Input parameter.

CA is COMPLEX

On entry, CA specifies the scalar alpha.

CX Input and output parameter.

CX is COMPLEX

CX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of CX

Related Information

For this routine in other precisions, please see *dscal*, *sscal* and *zscal*. It also exists with a native C interface as *cblas_cscal*.

3.2.8 csrot

csrot applies a plane rotation, where the cos and sin (c and s) are real and the vectors cx and cy are complex. jack dongarra, linpack, 3/11/78.

Syntax

Fortran specification:

```
use armpl_library

subroutine csrot(N, CX, INCX, CY, INCY, C, S)
```

C specification:

```
#include "armpl.h"

void csrot_(const armpl_int_t *n, armpl_singlecomplex_t *x,
            const armpl_int_t *incx, armpl_singlecomplex_t *y,
            const armpl_int_t *incy, const float *c, const float *s);
```

Parameters

N Input parameter.

N is INTEGER

On entry, N specifies the order of the vectors cx and cy. N must be at least zero.

CX Input and output parameter.

CX is COMPLEX

CX is an array, dimension at least. (1 + (N - 1)*abs(INCX)). Before entry, the incremented array CX must contain the n element vector cx. On exit, CX is overwritten by the updated vector cx.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of CX. INCX must not be zero.

CY Input and output parameter.

CY is COMPLEX

CY is an array, dimension at least. (1 + (N - 1)*abs(INCY)). Before entry, the incremented array CY must contain the n element vector cy. On exit, CY is overwritten by the updated vector cy.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of CY. INCY must not be zero.

C Input parameter.

C is REAL

On entry, C specifies the cosine, cos.

S Input parameter.

S is REAL

On entry, S specifies the sine, sin.

Related Information

3.2.9 csscal

CSSCAL scales a complex vector by a real constant.

Syntax

Fortran specification:

```
use armpl_library

subroutine csscal(N, SA, CX, INCX)
```

C specification:

```
#include "armpl.h"

void csscal_(const armpl_int_t *n, const float *alpha,
             armpl_singlecomplex_t *x, const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

SA Input parameter.

SA is REAL

On entry, SA specifies the scalar alpha.

CX Input and output parameter.

CX is COMPLEX

CX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of CX

Related Information

It also exists with a native C interface as *cblas_csscal*.

3.2.10 cswap

CSWAP interchanges two vectors.

Syntax

Fortran specification:

```
use armpl_library

subroutine cswap(N, CX, INCX, CY, INCY)
```

C specification:

```
#include "armpl.h"

void cswap_(const armpl_int_t *n, armpl_singlecomplex_t *x,
            const armpl_int_t *incx, armpl_singlecomplex_t *y,
            const armpl_int_t *incy);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

CX Input and output parameter.

CX is COMPLEX

CX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of CX

CY Input and output parameter.

CY is COMPLEX

CY is an array, dimension (1 + (N - 1)*abs(INCY))

INCY Input parameter.

INCY is INTEGER

storage spacing between elements of CY

Related Information

For this routine in other precisions, please see *dswap*, *sswap* and *zswap*. It also exists with a native C interface as *cblas_cswap*.

3.2.11 dasum

```
DASUM takes the sum of the absolute values.
```

Syntax

Fortran specification:

```
use armpl_library

double precision function dasum(N, DX, INCX)
```

C specification:

```
#include "armpl.h"

double dasum_(const armpl_int_t *n, const double *x,
              const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

DX Input parameter.

DX is DOUBLE PRECISION

DX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of DX

Related Information

For this routine in other precisions, please see *sasum*. It also exists with a native C interface as *cblas_dasum*.

3.2.12 daxpy

daxpy performs the following vector update:

$y \leftarrow \alpha x + y$

Syntax

Fortran specification:

```
use armpl_library

subroutine daxpy(N, DA, DX, INCX, DY, INCY)
```

C specification:

```
#include "armpl.h"

void daxpy_(const armpl_int_t *n, const double *alpha, const double *x,
            const armpl_int_t *incx, double *y, const armpl_int_t *incy);
```

Parameters

N Input parameter.

N is INTEGER

N is the number of elements in the input vectors DX and DY.

DA Input parameter.

DA is DOUBLE PRECISION

DA specifies the scalar α.

DX Input parameter.

DX is DOUBLE PRECISION

DX is the array x, dimension (1 + (N - 1)*abs(INCX)).

INCX Input parameter.

INCX is INTEGER

INCX is the storage spacing between elements of DX.

DY Input and output parameter.

DY is DOUBLE PRECISION

DY is the array y, dimension (1 + (N - 1)*abs(INCY)).

INCY Input parameter.

INCY is INTEGER

INCY is the storage spacing between elements of DY.

Related Information

For this routine in other precisions, please see *caxpy*, *saxpy* and *zaxpy*. It also exists with a native C interface as *cblas_daxpy*.

3.2.13 dcopy

dcopy copies a vector, x, to a vector, y.

Syntax

Fortran specification:

```
use armpl_library

subroutine dcopy(N, DX, INCX, DY, INCY)
```

C specification:

```
#include "armpl.h"

void dcopy_(const armpl_int_t *n, const double *x, const armpl_int_t *incx,
            double *y, const armpl_int_t *incy);
```

Parameters

N Input parameter.

N is INTEGER

N is the number of elements in input vectors.

DX Input parameter.

DX is DOUBLE PRECISION

DX is the array x, dimension (1 + (N - 1)*abs(INCX)).

INCX Input parameter.

INCX is INTEGER

INCX is the storage spacing between elements of DX.

DY Output parameter.

DY is DOUBLE PRECISION

DY is the array y, dimension (1 + (N - 1)*abs(INCY)).

INCY Input parameter.

INCY is INTEGER

INCY is the storage spacing between elements of DY.

Related Information

For this routine in other precisions, please see *ccopy*, *scopy* and *zcopy*. It also exists with a native C interface as *cblas_dcopy*.

3.2.14 ddot

ddot forms the dot product of two vectors.

$$ddot = X^T \cdot Y$$

Syntax

Fortran specification:

```
use armpl_library

double precision function ddot(N, DX, INCX, DY, INCY)
```

C specification:

```
#include "armpl.h"

double ddot_(const armpl_int_t *n, const double *x, const armpl_int_t *incx,
             const double *y, const armpl_int_t *incy);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

DX Input parameter.

DX is DOUBLE PRECISION

DX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of DX

DY Input parameter.

DY is DOUBLE PRECISION

DY is an array, dimension (1 + (N - 1)*abs(INCY))

INCY Input parameter.

INCY is INTEGER

storage spacing between elements of DY

Related Information

For this routine in other precisions, please see *sdot*. It also exists with a native C interface as *cblas_ddot*.

3.2.15 dnrm2

dnrm2 returns the euclidean norm of a vector via the function name, so that

```
DNRM2 := sqrt( x'*x )
```

Syntax

Fortran specification:

```
use armpl_library

double precision function dnrm2(N, X, INCX)
```

C specification:

```
#include "armpl.h"

double dnrm2_(const armpl_int_t *n, const double *x,
              const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of DX

Related Information

For this routine in other precisions, please see *snrm2*. It also exists with a native C interface as *cblas_dnrm2*.

3.2.16 drot

```
DROT applies a plane rotation.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine drot(N, DX, INCX, DY, INCY, C, S)
```

C specification:

```
#include "armpl.h"

void drot_(const armpl_int_t *n, double *x, const armpl_int_t *incx,
           double *y, const armpl_int_t *incy, const double *c,
           const double *s);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

DX Input and output parameter.

DX is DOUBLE PRECISION

DX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of DX

DY Input and output parameter.

DY is DOUBLE PRECISION

DY is an array, dimension (1 + (N - 1)*abs(INCY))

INCY Input parameter.

INCY is INTEGER

storage spacing between elements of DY

C Input parameter.

C is DOUBLE PRECISION

S Input parameter.

S is DOUBLE PRECISION

Related Information

For this routine in other precisions, please see *crot*, *srot* and *zrot*. It also exists with a native C interface as *cblas_drot*.

3.2.17 drotg

DROTG construct givens plane rotation.

Syntax

Fortran specification:

```
use armpl_library

subroutine drotg(DA, DB, C, S)
```

C specification:

```
#include "armpl.h"

void drotg_(double *a, double *b, double *c, double *s);
```

Parameters

DA Input parameter.

DA is DOUBLE PRECISION

DB Input parameter.

DB is DOUBLE PRECISION

C Output parameter.

C is DOUBLE PRECISION

S Output parameter.

S is DOUBLE PRECISION

Related Information

For this routine in other precisions, please see *crotg*, *srotg* and *zrotg*. It also exists with a native C interface as *cblas_drotg*.

3.2.18 drotm

```
APPLY THE MODIFIED GIVENS TRANSFORMATION, H, TO THE 2 BY N MATRIX

   (DX**T) , WHERE **T INDICATES TRANSPOSE. THE ELEMENTS OF DX ARE IN
   (DY**T)

   DX(LX+I*INCX), I = 0 TO N-1, WHERE LX = 1 IF INCX .GE. 0, ELSE
   LX = (-INCX)*N, AND SIMILARLY FOR SY USING LY AND INCY.
   WITH DPARAM(1)=DFLAG, H HAS ONE OF THE FOLLOWING FORMS..

   DFLAG=-1.D0     DFLAG=0.D0        DFLAG=1.D0     DFLAG=-2.D0

     (DH11  DH12)    (1.D0  DH12)    (DH11  1.D0)    (1.D0  0.D0)
   H=(          )    (          )    (          )    (          )
     (DH21  DH22),   (DH21  1.D0),   (-1.D0 DH22),   (0.D0  1.D0).
   SEE DROTMG FOR A DESCRIPTION OF DATA STORAGE IN DPARAM.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine drotm(N, DX, INCX, DY, INCY, DPARAM)
```

C specification:

```
#include "armpl.h"

void drotm_(const armpl_int_t *n, double *x, const armpl_int_t *incx,
            double *y, const armpl_int_t *incy, const double *param);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

DX Input and output parameter.

DX is DOUBLE PRECISION

DX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of DX

DY Input and output parameter.

DY is DOUBLE PRECISION

DY is an array, dimension (1 + (N - 1)*abs(INCY))

INCY Input parameter.

INCY is INTEGER

storage spacing between elements of DY

DPARAM Input parameter.

DPARAM is DOUBLE PRECISION

DPARAM is an array, dimension (5). DPARAM(1)=DFLAG DPARAM(2)=DH11 DPARAM(3)=DH21 DPARAM(4)=DH12 DPARAM(5)=DH22

Related Information

For this routine in other precisions, please see *srotm*. It also exists with a native C interface as *cblas_drotm*.

3.2.19 drotmg

```
CONSTRUCT THE MODIFIED GIVENS TRANSFORMATION MATRIX H WHICH ZEROS
   THE SECOND COMPONENT OF THE 2-VECTOR  (DSQRT(DD1)*DX1,DSQRT(DD2)*>     DY2)**T.
   WITH DPARAM(1)=DFLAG, H HAS ONE OF THE FOLLOWING FORMS..

   DFLAG=-1.D0     DFLAG=0.D0        DFLAG=1.D0     DFLAG=-2.D0

     (DH11  DH12)    (1.D0  DH12)    (DH11  1.D0)    (1.D0  0.D0)
   H=(          )    (          )    (          )    (          )
     (DH21  DH22),   (DH21  1.D0),   (-1.D0 DH22),   (0.D0  1.D0).
   LOCATIONS 2-4 OF DPARAM CONTAIN DH11, DH21, DH12, AND DH22
   RESPECTIVELY. (VALUES OF 1.D0, -1.D0, OR 0.D0 IMPLIED BY THE
   VALUE OF DPARAM(1) ARE NOT STORED IN DPARAM.)

   THE VALUES OF GAMSQ AND RGAMSQ SET IN THE DATA STATEMENT MAY BE
   INEXACT.  THIS IS OK AS THEY ARE ONLY USED FOR TESTING THE SIZE
   OF DD1 AND DD2.  ALL ACTUAL SCALING OF DATA IS DONE USING GAM.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine drotmg(DD1, DD2, DX1, DY1, DPARAM)
```

C specification:

```
#include "armpl.h"

void drotmg_(double *d1, double *d2, double *b1, const double *b2,
             double *param);
```

Parameters

DD1 Input and output parameter.

DD1 is DOUBLE PRECISION

DD2 Input and output parameter.

DD2 is DOUBLE PRECISION

DX1 Input and output parameter.

DX1 is DOUBLE PRECISION

DY1 Input parameter.

DY1 is DOUBLE PRECISION

DPARAM Output parameter.

DPARAM is DOUBLE PRECISION

DPARAM is an array, dimension (5). DPARAM(1)=DFLAG DPARAM(2)=DH11 DPARAM(3)=DH21 DPARAM(4)=DH12 DPARAM(5)=DH22

Related Information

For this routine in other precisions, please see *srotmg*. It also exists with a native C interface as *cblas_drotmg*.

3.2.20 dscal

```
DSCAL scales a vector by a constant.
   uses unrolled loops for increment equal to 1.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dscal(N, DA, DX, INCX)
```

C specification:

```
#include "armpl.h"

void dscal_(const armpl_int_t *n, const double *alpha, double *x,
            const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

DA Input parameter.

DA is DOUBLE PRECISION

On entry, DA specifies the scalar alpha.

DX Input and output parameter.

DX is DOUBLE PRECISION

DX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of DX

Related Information

For this routine in other precisions, please see *cscal*, *sscal* and *zscal*. It also exists with a native C interface as *cblas_dscal*.

3.2.21 dsdot

Compute the inner product of two vectors with extended precision accumulation and result.

Returns D.P. dot product accumulated in D.P., for S.P. SX and SY `dsdot` = sum for I = 0 to N-1 of SX(LX+I*INCX) * SY(LY+I*INCY), where LX = 1 if INCX .GE. 0, else LX = 1+(1-N)*INCX, and LY is defined in a similar way using INCY.

Syntax

Fortran specification:

```
use armpl_library

double precision function dsdot(N, SX, INCX, SY, INCY)
```

C specification:

```
#include "armpl.h"

double dsdot_(const armpl_int_t *n, const float *sx, const armpl_int_t *incx,
              const float *sy, const armpl_int_t *incy);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

SX Input parameter.

SX is REAL

SX is an array, dimension(N). single precision vector with N elements

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of SX

SY Input parameter.

SY is REAL

SY is an array, dimension(N). single precision vector with N elements

INCY Input parameter.

INCY is INTEGER

storage spacing between elements of SY

Related Information

It also exists with a native C interface as *cblas_dsdot*.

3.2.22 dswap

```
DSWAP interchanges two vectors.
   uses unrolled loops for increments equal to 1.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dswap(N, DX, INCX, DY, INCY)
```

C specification:

```
#include "armpl.h"

void dswap_(const armpl_int_t *n, double *x, const armpl_int_t *incx,
            double *y, const armpl_int_t *incy);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

DX Input and output parameter.

DX is DOUBLE PRECISION

DX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of DX

DY Input and output parameter.

DY is DOUBLE PRECISION

DY is an array, dimension (1 + (N - 1)*abs(INCY))

INCY Input parameter.

INCY is INTEGER

storage spacing between elements of DY

Related Information

For this routine in other precisions, please see *cswap*, *sswap* and *zswap*. It also exists with a native C interface as *cblas_dswap*.

3.2.23 dzasum

DZASUM takes the sum of the (|Re(.)| + |Im(.)|)'s of a complex vector and returns a single precision result.

Syntax

Fortran specification:

```
use armpl_library

double precision function dzasum(N, ZX, INCX)
```

C specification:

```
#include "armpl.h"

double dzasum_(const armpl_int_t *n, const armpl_doublecomplex_t *x,
               const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

ZX Input and output parameter.

ZX is COMPLEX*16

ZX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of ZX

Related Information

It also exists with a native C interface as *cblas_dzasum*.

3.2.24 dznrm2

dznrm2 returns the euclidean norm of a vector via the function name, so that

```
DZNRM2 := sqrt( x**H*x )
```

Syntax

Fortran specification:

```
use armpl_library

double precision function dznrm2(N, X, INCX)
```

C specification:

```
#include "armpl.h"

double dznrm2_(const armpl_int_t *n, const armpl_doublecomplex_t *x,
               const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

X Input parameter.

X is COMPLEX*16

X is an array, dimension (N). complex vector with N elements

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of X

Related Information

It also exists with a native C interface as *cblas_dznrm2*.

3.2.25 icamax

```
ICAMAX finds the index of the first element having maximum |Re(.)| + |Im(.)|
```

Syntax

Fortran specification:

```
use armpl_library

integer function icamax(N, CX, INCX)
```

C specification:

```
#include "armpl.h"

armpl_int_t icamax_(const armpl_int_t *n, const armpl_singlecomplex_t *x,
                    onst armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

CX Input parameter.

CX is COMPLEX

CX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of SX

Related Information

It also exists with a native C interface as *cblas_icamax*.

3.2.26 idamax

```
IDAMAX finds the index of the first element having maximum absolute value.
```

Syntax

Fortran specification:

```
use armpl_library

integer function idamax(N, DX, INCX)
```

C specification:

```
#include "armpl.h"

armpl_int_t idamax_(const armpl_int_t *n, const double *x,
                    onst armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

DX Input parameter.

DX is DOUBLE PRECISION

DX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of SX

Related Information

It also exists with a native C interface as *cblas_idamax*.

3.2.27 isamax

```
ISAMAX finds the index of the first element having maximum absolute value.
```

Syntax

Fortran specification:

```
use armpl_library

integer function isamax(N, SX, INCX)
```

C specification:

```
#include "armpl.h"

armpl_int_t isamax_(const armpl_int_t *n, const float *x,
                    onst armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

SX Input parameter.

SX is REAL

SX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of SX

Related Information

It also exists with a native C interface as *cblas_isamax*.

3.2.28 izamax

```
IZAMAX finds the index of the first element having maximum |Re(.)| + |Im(.)|
```

Syntax

Fortran specification:

```
use armpl_library

integer function izamax(N, ZX, INCX)
```

C specification:

```
#include "armpl.h"

armpl_int_t izamax_(const armpl_int_t *n, const armpl_doublecomplex_t *x,
                    onst armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

ZX Input parameter.

ZX is COMPLEX*16

ZX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of SX

Related Information

It also exists with a native C interface as *cblas_izamax*.

3.2.29 sasum

```
SASUM takes the sum of the absolute values.
   uses unrolled loops for increment equal to one.
```

Syntax

Fortran specification:

```
use armpl_library

real function sasum(N, SX, INCX)
```

C specification:

```
#include "armpl.h"

float sasum_(const armpl_int_t *n, const float *x, const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

SX Input parameter.

SX is REAL

SX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of SX

Related Information

For this routine in other precisions, please see *dasum*. It also exists with a native C interface as *cblas_sasum*.

3.2.30 saxpy

caxpy performs the following vector update:

$$y \leftarrow \alpha x + y$$

Syntax

Fortran specification:

```
use armpl_library

subroutine saxpy(N, SA, SX, INCX, SY, INCY)
```

C specification:

```
#include "armpl.h"

void saxpy_(const armpl_int_t *n, const float *alpha, const float *x,
            const armpl_int_t *incx, float *y, const armpl_int_t *incy);
```

Parameters

N Input parameter.

N is INTEGER

N is the number of elements in the input vectors SX and SY.

SA Input parameter.

SA is REAL

SA specifies the scalar $alpha$.

SX Input parameter.

SX is REAL

SX is the array x, dimension (1 + (N - 1)*abs(INCX)).

INCX Input parameter.

INCX is INTEGER

INCX is the storage spacing between elements of SX.

SY Input and output parameter.

SY is REAL

SY is the array y, dimension (1 + (N - 1)*abs(INCY)).

INCY Input parameter.

INCY is INTEGER

INCY is the storage spacing between elements of SY.

Related Information

For this routine in other precisions, please see *caxpy*, *daxpy* and *zaxpy*. It also exists with a native C interface as *cblas_saxpy*.

3.2.31 scasum

SCASUM takes the sum of the (|Re(.)| + |Im(.)|)'s of a complex vector and returns a single precision result.

Syntax

Fortran specification:

```
use armpl_library

real function scasum(N, CX, INCX)
```

C specification:

```
#include "armpl.h"

float scasum_(const armpl_int_t *n, const armpl_singlecomplex_t *x,
              const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

CX Input and output parameter.

CX is COMPLEX

CX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of SX

Related Information

It also exists with a native C interface as *cblas_scasum*.

3.2.32 scnrm2

scnrm2 returns the euclidean norm of a vector via the function name, so that

```
SCNRM2 := sqrt( x**H*x )
```

Syntax

Fortran specification:

```
use armpl_library

real function scnrm2(N, X, INCX)
```

C specification:

```
#include "armpl.h"

float scnrm2_(const armpl_int_t *n, const armpl_singlecomplex_t *x,
              const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

X Input parameter.

X is COMPLEX

X is an array, dimension (N). complex vector with N elements

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of X

Related Information

It also exists with a native C interface as *cblas_scnrm2*.

3.2.33 scopy

scopy copies a vector, x, to a vector, y.

Syntax

Fortran specification:

```
use armpl_library

subroutine scopy(N, SX, INCX, SY, INCY)
```

C specification:

```
#include "armpl.h"

void scopy_(const armpl_int_t *n, const float *x, const armpl_int_t *incx,
            float *y, const armpl_int_t *incy);
```

Parameters

N Input parameter.

N is INTEGER

N is the number of elements in input vectors.

SX Input parameter.

SX is REAL

SX is the array x, dimension (1 + (N - 1)*abs(INCX)).

INCX Input parameter.

INCX is INTEGER

INCX is the storage spacing between elements of SX.

SY Output parameter.

SY is REAL

SY is the array y, dimension (1 + (N - 1)*abs(INCY)).

INCY Input parameter.

INCY is INTEGER

INCY is the storage spacing between elements of SY.

Related Information

For this routine in other precisions, please see *ccopy*, *dcopy* and *zcopy*. It also exists with a native C interface as *cblas_scopy*.

3.2.34 sdot

sdot forms the dot product of two vectors.

$$SDOT = X^T \cdot Y$$

Syntax

Fortran specification:

```
use armpl_library

real function sdot(N, SX, INCX, SY, INCY)
```

C specification:

```
#include "armpl.h"

float sdot_(const armpl_int_t *n, const float *x, const armpl_int_t *incx,
            const float *y, const armpl_int_t *incy);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

SX Input parameter.

SX is REAL

SX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of SX

SY Input parameter.

SY is REAL

SY is an array, dimension (1 + (N - 1)*abs(INCY))

INCY Input parameter.

INCY is INTEGER

storage spacing between elements of SY

Related Information

For this routine in other precisions, please see *ddot*. It also exists with a native C interface as *cblas_sdot*.

3.2.35 sdsdot

Syntax

Fortran specification:

```
use armpl_library

real function sdsdot(N, SB, SX, INCX, SY, INCY)
```

C specification:

```
#include "armpl.h"

float sdsdot_(const armpl_int_t *n, const float *b, const float *x,
              const armpl_int_t *incx, const float *y,
              const armpl_int_t *incy);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

SB Input parameter.

SB is REAL

single precision scalar to be added to inner product

SX Input parameter.

SX is REAL

SX is an array, dimension (1 + (N - 1)*abs(INCX)). single precision vector with N elements

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of SX

SY Input parameter.

SY is REAL

SY is an array, dimension (1 + (N - 1)*abs(INCX)). single precision vector with N elements

INCY Input parameter.

INCY is INTEGER

storage spacing between elements of SY

Related Information

It also exists with a native C interface as *cblas_sdsdot*.

3.2.36 snrm2

snrm2 returns the euclidean norm of a vector via the function name, so that

```
SNRM2 := sqrt( x'*x ).
```

Syntax

Fortran specification:

```
use armpl_library

real function snrm2(N, X, INCX)
```

C specification:

```
#include "armpl.h"

float snrm2_(const armpl_int_t *n, const float *x, const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

X Input parameter.

X is REAL

X is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of SX

Related Information

For this routine in other precisions, please see *dnrm2*. It also exists with a native C interface as *cblas_snrm2*.

3.2.37 srot

applies a plane rotation.

Syntax

Fortran specification:

```
use armpl_library

subroutine srot(N, SX, INCX, SY, INCY, C, S)
```

C specification:

```
#include "armpl.h"

void srot_(const armpl_int_t *n, float *x, const armpl_int_t *incx, float *y,
           const armpl_int_t *incy, const float *c, const float *s);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

SX Input and output parameter.

SX is REAL

SX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of SX

SY Input and output parameter.

SY is REAL

SY is an array, dimension (1 + (N - 1)*abs(INCY))

INCY Input parameter.

INCY is INTEGER

storage spacing between elements of SY

C Input parameter.

C is REAL

S Input parameter.

S is REAL

Related Information

For this routine in other precisions, please see *crot*, *drot* and *zrot*. It also exists with a native C interface as *cblas_srot*.

3.2.38 srotg

SROTG construct givens plane rotation.

Syntax

Fortran specification:

```
use armpl_library

subroutine srotg(SA, SB, C, S)
```

C specification:

```
#include "armpl.h"

void srotg_(float *a, float *b, float *c, float *s);
```

Parameters

SA Input parameter.

SA is REAL

SB Input parameter.

SB is REAL

C Output parameter.

C is REAL

S Output parameter.

S is REAL

Related Information

For this routine in other precisions, please see *crotg*, *drotg* and *zrotg*. It also exists with a native C interface as *cblas_srotg*.

3.2.39 srotm

```
APPLY THE MODIFIED GIVENS TRANSFORMATION, H, TO THE 2 BY N MATRIX

   (SX**T) , WHERE **T INDICATES TRANSPOSE. THE ELEMENTS OF SX ARE IN
   (SX**T)

   SX(LX+I*INCX), I = 0 TO N-1, WHERE LX = 1 IF INCX .GE. 0, ELSE
   LX = (-INCX)*N, AND SIMILARLY FOR SY USING USING LY AND INCY.
   WITH SPARAM(1)=SFLAG, H HAS ONE OF THE FOLLOWING FORMS..

   SFLAG=-1.E0     SFLAG=0.E0         SFLAG=1.E0     SFLAG=-2.E0

     (SH11  SH12)    (1.E0  SH12)    (SH11  1.E0)    (1.E0  0.E0)
   H=(          )    (          )    (          )    (          )
     (SH21  SH22),   (SH21  1.E0),   (-1.E0 SH22),   (0.E0  1.E0).
   SEE  SROTMG FOR A DESCRIPTION OF DATA STORAGE IN SPARAM.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine srotm(N, SX, INCX, SY, INCY, SPARAM)
```

C specification:

```
#include "armpl.h"

void srotm_(const armpl_int_t *n, float *x, const armpl_int_t *incx, float *y,
            const armpl_int_t *incy, const float *param);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

SX Input and output parameter.

SX is REAL

SX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of SX

SY Input and output parameter.

SY is REAL

SY is an array, dimension (1 + (N - 1)*abs(INCY))

INCY Input parameter.

INCY is INTEGER

storage spacing between elements of SY

SPARAM Input parameter.

SPARAM is REAL

SPARAM is an array, dimension (5). SPARAM(1)=SFLAG SPARAM(2)=SH11 SPARAM(3)=SH21 SPARAM(4)=SH12 SPARAM(5)=SH22

Related Information

For this routine in other precisions, please see *drotm*. It also exists with a native C interface as *cblas_srotm*.

3.2.40 srotmg

```
CONSTRUCT THE MODIFIED GIVENS TRANSFORMATION MATRIX H WHICH ZEROS
   THE SECOND COMPONENT OF THE 2-VECTOR  (SQRT(SD1)*SX1,SQRT(SD2)*>     SY2)**T.
   WITH SPARAM(1)=SFLAG, H HAS ONE OF THE FOLLOWING FORMS..

   SFLAG=-1.E0     SFLAG=0.E0         SFLAG=1.E0     SFLAG=-2.E0

     (SH11  SH12)     (1.E0  SH12)     (SH11  1.E0)     (1.E0  0.E0)
   H=(          )     (          )     (          )     (          )
     (SH21  SH22),    (SH21  1.E0),    (-1.E0 SH22),    (0.E0  1.E0).
   LOCATIONS 2-4 OF SPARAM CONTAIN SH11,SH21,SH12, AND SH22
   RESPECTIVELY. (VALUES OF 1.E0, -1.E0, OR 0.E0 IMPLIED BY THE
   VALUE OF SPARAM(1) ARE NOT STORED IN SPARAM.)

   THE VALUES OF GAMSQ AND RGAMSQ SET IN THE DATA STATEMENT MAY BE
   INEXACT.  THIS IS OK AS THEY ARE ONLY USED FOR TESTING THE SIZE
   OF SD1 AND SD2.  ALL ACTUAL SCALING OF DATA IS DONE USING GAM.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine srotmg(SD1, SD2, SX1, SY1, SPARAM)
```

C specification:

```
#include "armpl.h"

void srotmg_(float *d1, float *d2, float *b1, const float *b2, float *param);
```

Parameters

SD1 Input and output parameter.

SD1 is REAL

SD2 Input and output parameter.

SD2 is REAL

SX1 Input and output parameter.

SX1 is REAL

SY1 Input parameter.

SY1 is REAL

SPARAM Output parameter.

SPARAM is REAL

SPARAM is an array, dimension (5). SPARAM(1)=SFLAG SPARAM(2)=SH11 SPARAM(3)=SH21 SPARAM(4)=SH12 SPARAM(5)=SH22

Related Information

For this routine in other precisions, please see *drotmg*. It also exists with a native C interface as *cblas_srotmg*.

3.2.41 sscal

```
SSCAL scales a vector by a constant.
   uses unrolled loops for increment equal to 1.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sscal(N, SA, SX, INCX)
```

C specification:

```
#include "armpl.h"

void sscal_(const armpl_int_t *n, const float *alpha, float *x,
            const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

SA Input parameter.

SA is REAL

On entry, SA specifies the scalar alpha.

SX Input and output parameter.

SX is REAL

SX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of SX

Related Information

For this routine in other precisions, please see *cscal*, *dscal* and *zscal*. It also exists with a native C interface as *cblas_sscal*.

3.2.42 sswap

```
SSWAP interchanges two vectors.
   uses unrolled loops for increments equal to 1.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sswap(N, SX, INCX, SY, INCY)
```

C specification:

```
#include "armpl.h"

void sswap_(const armpl_int_t *n, float *x, const armpl_int_t *incx, float *y,
            const armpl_int_t *incy);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

SX Input and output parameter.

SX is REAL

SX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of SX

SY Input and output parameter.

SY is REAL

SY is an array, dimension (1 + (N - 1)*abs(INCY))

INCY Input parameter.

INCY is INTEGER

storage spacing between elements of SY

Related Information

For this routine in other precisions, please see *cswap*, *dswap* and *zswap*. It also exists with a native C interface as *cblas_sswap*.

3.2.43 zaxpy

caxpy performs the following vector update:

$y \leftarrow \alpha x + y$

Syntax

Fortran specification:

```
use armpl_library

subroutine zaxpy(N, ZA, ZX, INCX, ZY, INCY)
```

C specification:

```
#include "armpl.h"

void zaxpy_(const armpl_int_t *n, const armpl_doublecomplex_t *alpha,
            const armpl_doublecomplex_t *x, const armpl_int_t *incx,
            armpl_doublecomplex_t *y, const armpl_int_t *incy);
```

Parameters

N Input parameter.

N is INTEGER

N is the number of elements in the input vectors ZX and ZY.

ZA Input parameter.

ZA is COMPLEX*16

ZA specifies the scalar α.

ZX Input parameter.

ZX is COMPLEX*16

ZX is the array x, dimension (1 + (N - 1)*abs(INCX)).

INCX Input parameter.

INCX is INTEGER

INCX is the storage spacing between elements of ZX.

ZY Input and output parameter.

ZY is COMPLEX*16

ZY is the array y, dimension (1 + (N - 1)*abs(INCY)).

INCY Input parameter.

INCY is INTEGER

INCY is the storage spacing between elements of ZY.

Related Information

For this routine in other precisions, please see *caxpy*, *daxpy* and *saxpy*. It also exists with a native C interface as *cblas_zaxpy*.

3.2.44 zcopy

zcopy copies a vector, x, to a vector, y.

Syntax

Fortran specification:

```
use armpl_library

subroutine zcopy(N, ZX, INCX, ZY, INCY)
```

C specification:

```
#include "armpl.h"

void zcopy_(const armpl_int_t *n, const armpl_doublecomplex_t *x,
            const armpl_int_t *incx, armpl_doublecomplex_t *y,
            const armpl_int_t *incy);
```

Parameters

N Input parameter.

N is INTEGER

N is the number of elements in input vectors.

ZX Input parameter.

ZX is COMPLEX*16

ZX is the array x, dimension (1 + (N - 1)*abs(INCX)).

INCX Input parameter.

INCX is INTEGER

INCX is the storage spacing between elements of ZX.

ZY Output parameter.

ZY is COMPLEX*16

ZY is the array y, dimension (1 + (N - 1)*abs(INCY)).

INCY Input parameter.

INCY is INTEGER

INCY is the storage spacing between elements of ZY.

Related Information

For this routine in other precisions, please see *ccopy*, *dcopy* and *scopy*. It also exists with a native C interface as *cblas_zcopy*.

3.2.45 zdotc

zdotc forms the dot product of two complex vectors.

$$ZDOTC = X^H \cdot Y$$

Syntax

Fortran specification:

```
use armpl_library

complex*16 function zdotc(N, ZX, INCX, ZY, INCY)
```

C specification:

```
#include "armpl.h"

DOUBLECOMPLEX_RET_VALUE zdotc_(const armpl_int_t *n,
                               const armpl_doublecomplex_t *x,
                               const armpl_int_t *incx,
                               const armpl_doublecomplex_t *y,
                               const armpl_int_t *incy);
```

Returns

This returns the result of the dot product, ZDOTC.

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

ZX Input parameter.

ZX is REAL

ZX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of ZX

ZY Input parameter.

ZY is REAL

ZY is an array, dimension (1 + (N - 1)*abs(INCY))

INCY Input parameter.

INCY is INTEGER

storage spacing between elements of ZY

Related Information

For this routine in other precisions, please see *cdotc*.

3.2.46 zdotu

zdotu forms the dot product of two complex vectors.

$$ZDOTU = X^T \cdot Y$$

Syntax

Fortran specification:

```
use armpl_library

complex*16 function zdotu(N, ZX, INCX, ZY, INCY)
```

C specification:

```
#include "armpl.h"

DOUBLECOMPLEX_RET_VALUE zdotu_(const armpl_int_t *n,
                               const armpl_doublecomplex_t *x,
                               const armpl_int_t *incx,
                               const armpl_doublecomplex_t *y,
                               const armpl_int_t *incy);
```

Returns

This returns the result of the dot product, ZDOTU.

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

ZX Input parameter.

ZX is REAL

ZX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of ZX

ZY Input parameter.

ZY is REAL

ZY is an array, dimension (1 + (N - 1)*abs(INCY))

INCY Input parameter.

INCY is INTEGER

storage spacing between elements of ZY

Related Information

For this routine in other precisions, please see *cdotu*.

3.2.47 zdrot

Applies a plane rotation, where the cos and sin (c and s) are real and the vectors cx and cy are complex. jack dongarra, linpack, 3/11/78.

Syntax

Fortran specification:

```
use armpl_library

subroutine zdrot(N, CX, INCX, CY, INCY, C, S)
```

C specification:

```
#include "armpl.h"

void zdrot_(const armpl_int_t *n, armpl_doublecomplex_t *x,
            const armpl_int_t *incx, armpl_doublecomplex_t *y,
            const armpl_int_t *incy, const double *c, const double *s);
```

Parameters

N Input parameter.

N is INTEGER

On entry, N specifies the order of the vectors cx and cy. N must be at least zero.

CX Input and output parameter.

CX is COMPLEX*16

CX is an array, dimension at least. (1 + (N - 1)*abs(INCX)). Before entry, the incremented array CX must contain the n element vector cx. On exit, CX is overwritten by the updated vector cx.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of CX. INCX must not be zero.

CY Input and output parameter.

CY is COMPLEX*16

CY is an array, dimension at least. (1 + (N - 1)*abs(INCY)). Before entry, the incremented array CY must contain the n element vector cy. On exit, CY is overwritten by the updated vector cy.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of CY. INCY must not be zero.

C Input parameter.

C is DOUBLE PRECISION

On entry, C specifies the cosine, cos.

S Input parameter.

S is DOUBLE PRECISION

On entry, S specifies the sine, sin.

Related Information

3.2.48 zdscal

ZDSCAL scales a vector by a constant.

Syntax

Fortran specification:

```
use armpl_library

subroutine zdscal(N, DA, ZX, INCX)
```

C specification:

```
#include "armpl.h"

void zdscal_(const armpl_int_t *n, const double *alpha,
             armpl_doublecomplex_t *x, const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

DA Input parameter.

DA is DOUBLE PRECISION

On entry, DA specifies the scalar alpha.

ZX Input and output parameter.

ZX is COMPLEX*16

ZX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of ZX

Related Information

It also exists with a native C interface as *cblas_zdscal*.

3.2.49 zrot

zrot applies a plane rotation, where the cos (C) is real and the sin (S) is complex, and the vectors CX and CY are complex.

Syntax

Fortran specification:

```
use armpl_library

subroutine zrot(N, CX, INCX, CY, INCY, C, S)
```

C specification:

```
#include "armpl.h"

void zrot_(const armpl_int_t *n, armpl_doublecomplex_t *cx,
           const armpl_int_t *incx, armpl_doublecomplex_t *cy,
           const armpl_int_t *incy, const double *c,
           const armpl_doublecomplex_t *s);
```

Parameters

N Input parameter.

N is INTEGER

The number of elements in the vectors CX and CY.

CX Input and output parameter.

CX is COMPLEX*16

CX is an array, dimension (N). On input, the vector X. On output, CX is overwritten with C*X + S*Y.

INCX Input parameter.

INCX is INTEGER

The increment between successive values of CY. INCX <> 0.

CY Input and output parameter.

CY is COMPLEX*16

CY is an array, dimension (N). On input, the vector Y. On output, CY is overwritten with -CONJG(S)*X + C*Y.

INCY Input parameter.

INCY is INTEGER

The increment between successive values of CY. INCX <> 0.

C Input parameter.

C is DOUBLE PRECISION

S Input parameter.

S is COMPLEX*16

C and S define a rotation [C S] [-conjg(S) C] where C* C + S*CONJG(S) = 1.0.

Related Information

For this routine in other precisions, please see *crot*, *drot* and *srot*.

3.2.50 zrotg

ZROTG determines a double complex Givens rotation.

Syntax

Fortran specification:

```
use armpl_library

subroutine zrotg(CA, CB, C, S)
```

C specification:

```
#include "armpl.h"

void zrotg_(armpl_doublecomplex_t *ca, const armpl_doublecomplex_t *cb,
            double *c, armpl_doublecomplex_t *s);
```

Parameters

CA Input parameter.

CA is COMPLEX*16

CB Input parameter.

CB is COMPLEX*16

C Output parameter.

C is DOUBLE PRECISION

S Output parameter.

S is COMPLEX*16

Related Information

For this routine in other precisions, please see *crotg*, *drotg* and *srotg*.

3.2.51 zscal

ZSCAL scales a vector by a constant.

Syntax

Fortran specification:

```
use armpl_library

subroutine zscal(N, ZA, ZX, INCX)
```

C specification:

```
#include "armpl.h"

void zscal_(const armpl_int_t *n, const armpl_doublecomplex_t *alpha,
            armpl_doublecomplex_t *x, const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

ZA Input parameter.

ZA is COMPLEX*16

On entry, ZA specifies the scalar alpha.

ZX Input and output parameter.

ZX is COMPLEX*16

ZX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of ZX

Related Information

For this routine in other precisions, please see *cscal*, *dscal* and *sscal*. It also exists with a native C interface as *cblas_zscal*.

3.2.52 zswap

```
ZSWAP interchanges two vectors.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zswap(N, ZX, INCX, ZY, INCY)
```

C specification:

```
#include "armpl.h"

void zswap_(const armpl_int_t *n, armpl_doublecomplex_t *x,
            const armpl_int_t *incx, armpl_doublecomplex_t *y,
            const armpl_int_t *incy);
```

Parameters

N Input parameter.

N is INTEGER

number of elements in input vector(s)

ZX Input and output parameter.

ZX is COMPLEX*16

ZX is an array, dimension (1 + (N - 1)*abs(INCX))

INCX Input parameter.

INCX is INTEGER

storage spacing between elements of ZX

ZY Input and output parameter.

ZY is COMPLEX*16

ZY is an array, dimension (1 + (N - 1)*abs(INCY))

INCY Input parameter.

INCY is INTEGER

storage spacing between elements of ZY

Related Information

For this routine in other precisions, please see *cswap*, *dswap* and *sswap*. It also exists with a native C interface as *cblas_zswap*.

Level 1 BLAS routines are memory bound. All functions are detailed in armpl.h.

3.3 BLAS level 2

3.3.1 cgbmv

cgbmv performs one of the matrix-vector operations

```
 y := alpha*A*x + beta*y,   or   y := alpha*A**T*x + beta*y,   or

y := alpha*A**H*x + beta*y,
```

where alpha and beta are scalars, x and y are vectors and A is an m by n band matrix, with kl sub-diagonals and ku super-diagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgbmv(TRANS, M, N, KL, KU, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void cgbmv_(const char *trans, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_int_t *kl, const armpl_int_t *ku,
            const armpl_singlecomplex_t *alpha,
            const armpl_singlecomplex_t *a, const armpl_int_t *lda,
            const armpl_singlecomplex_t *x, const armpl_int_t *incx,
            const armpl_singlecomplex_t *beta, armpl_singlecomplex_t *y,
            const armpl_int_t *incy, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' y := alpha*A*x + beta*y.

TRANS = 'T' or 't' y := alpha*A^T *x + beta*y.

TRANS = 'C' or 'c' y := alpha*A^H *x + beta*y.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero.

KL Input parameter.

KL is INTEGER

On entry, KL specifies the number of sub-diagonals of the matrix A. KL must satisfy 0 .le. KL.

KU Input parameter.

KU is INTEGER

On entry, KU specifies the number of super-diagonals of the matrix A. KU must satisfy 0 .le. KU.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). Before entry, the leading (kl + ku + 1) by n part of the array A must contain the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (ku + 1) of the array, the first super-diagonal starting at position 2 in row ku, the first sub-diagonal starting at position 1 in row (ku + 2), and so on. Elements in the array A that do not correspond to elements in the band matrix (such as the top left ku by ku triangle) are not referenced. The following program segment will transfer a band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      K = ``KU`` + 1 - J
      DO 10, I = MAX( 1, J - ``KU`` ), MIN( ``M``, J + ``KL`` )
         A( K + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (kl + ku + 1).

X Input parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)) when TRANS = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is COMPLEX

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input.

Y Input and output parameter.

Y is COMPLEX

Y is an array, dimension at least. (1 + (m - 1)*abs(INCY)) when TRANS = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *dgbmv*, *sgbmv* and *zgbmv*. It also exists with a native C interface as *cblas_cgbmv*.

3.3.2 cgemv

cgemv performs one of the matrix-vector operations

```
 y := alpha*A*x + beta*y,   or   y := alpha*A**T*x + beta*y,   or

y := alpha*A**H*x + beta*y,
```

where alpha and beta are scalars, x and y are vectors and A is an m by n matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgemv(TRANS, M, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void cgemv_(const char *trans, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_singlecomplex_t *alpha,
            const armpl_singlecomplex_t *a, const armpl_int_t *lda,
            const armpl_singlecomplex_t *x, const armpl_int_t *incx,
            const armpl_singlecomplex_t *beta, armpl_singlecomplex_t *y,
            const armpl_int_t *incy, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' y := alpha*A*x + beta*y.

TRANS = 'T' or 't' y := alpha*A^T *x + beta*y.

TRANS = 'C' or 'c' y := alpha*A^H *x + beta*y.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). Before entry, the leading m by n part of the array A must contain the matrix of coefficients.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, m).

X Input parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)) when TRANS = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is COMPLEX

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input.

Y Input and output parameter.

Y is COMPLEX

Y is an array, dimension at least. (1 + (m - 1)*abs(INCY)) when TRANS = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *dgemv*, *sgemv* and *zgemv*. It also exists with a native C interface as *cblas_cgemv*.

3.3.3 cgerc

cgerc performs the rank 1 operation

```
A := alpha*x*y**H + A,
```

where alpha is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgerc(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

C specification:

```
#include "armpl.h"

void cgerc_(const armpl_int_t *m, const armpl_int_t *n,
            const armpl_singlecomplex_t *alpha,
            const armpl_singlecomplex_t *x, const armpl_int_t *incx,
            const armpl_singlecomplex_t *y, const armpl_int_t *incy,
            armpl_singlecomplex_t *a, const armpl_int_t *lda);
```

Parameters

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (m - 1)*abs(INCX)). Before entry, the incremented array X must contain the m element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Y Input parameter.

Y is COMPLEX

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, m).

Related Information

For this routine in other precisions, please see *zgerc*. It also exists with a native C interface as *cblas_cgerc*.

3.3.4 cgeru

cgeru performs the rank 1 operation

```
A := alpha*x*y**T + A,
```

where alpha is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgeru(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

C specification:

```
#include "armpl.h"

void cgeru_(const armpl_int_t *m, const armpl_int_t *n,
            const armpl_singlecomplex_t *alpha,
            const armpl_singlecomplex_t *x, const armpl_int_t *incx,
            const armpl_singlecomplex_t *y, const armpl_int_t *incy,
            armpl_singlecomplex_t *a, const armpl_int_t *lda);
```

Parameters

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (m - 1)*abs(INCX)). Before entry, the incremented array X must contain the m element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Y Input parameter.

Y is COMPLEX

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, m).

Related Information

For this routine in other precisions, please see *zgeru*. It also exists with a native C interface as *cblas_cgeru*.

3.3.5 chbmv

chbmv performs the matrix-vector operation

```
y := alpha*A*x + beta*y,
```

where alpha and beta are scalars, x and y are n element vectors and A is an n by n hermitian band matrix, with k super-diagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine chbmv(UPLO, N, K, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void chbmv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *k,
            const armpl_singlecomplex_t *alpha,
            const armpl_singlecomplex_t *a, const armpl_int_t *lda,
            const armpl_singlecomplex_t *x, const armpl_int_t *incx,
            const armpl_singlecomplex_t *beta, armpl_singlecomplex_t *y,
            const armpl_int_t *incy, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the band matrix A is being supplied as follows:

UPLO = 'U' or 'u' The upper triangular part of A is being supplied.

UPLO = 'L' or 'l' The lower triangular part of A is being supplied.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

K Input parameter.

K is INTEGER

On entry, K specifies the number of super-diagonals of the matrix A. K must satisfy 0 .le. K.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the hermitian matrix, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer the upper triangular part of a hermitian band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = ``K`` + 1 - J
      DO 10, I = MAX( 1, J - ``K`` ), J
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the hermitian matrix, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer the lower triangular part of a hermitian band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = 1 - J
      DO 10, I = J, MIN( ``N``, J + ``K`` )
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (k + 1).

X Input parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is COMPLEX

On entry, BETA specifies the scalar beta.

Y Input and output parameter.

Y is COMPLEX

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *zhbmv*. It also exists with a native C interface as *cblas_chbmv*.

3.3.6 chemv

chemv performs the matrix-vector operation

```
y := alpha*A*x + beta*y,
```

where alpha and beta are scalars, x and y are n element vectors and A is an n by n hermitian matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine chemv(UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void chemv_(const char *uplo, const armpl_int_t *n,
            const armpl_singlecomplex_t *alpha,
            const armpl_singlecomplex_t *a, const armpl_int_t *lda,
            const armpl_singlecomplex_t *x, const armpl_int_t *incx,
            const armpl_singlecomplex_t *beta, armpl_singlecomplex_t *y,
            const armpl_int_t *incy, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

X Input parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is COMPLEX

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input.

Y Input and output parameter.

Y is COMPLEX

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *zhemv*. It also exists with a native C interface as *cblas_chemv*.

3.3.7 cher

`cher` performs the hermitian rank 1 operation

```
A := alpha*x*x**H + A,
```

where alpha is a real scalar, x is an n element vector and A is an n by n hermitian matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine cher(UPLO, N, ALPHA, X, INCX, A, LDA)
```

C specification:

```
#include "armpl.h"

void cher_(const char *uplo, const armpl_int_t *n, const float *alpha,
           const armpl_singlecomplex_t *x, const armpl_int_t *incx,
           armpl_singlecomplex_t *a, const armpl_int_t *lda, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

Related Information

For this routine in other precisions, please see *zher*. It also exists with a native C interface as *cblas_cher*.

3.3.8 cher2

cher2 performs the hermitian rank 2 operation

```
A := alpha*x*y**H + conjg( alpha )*y*x**H + A,
```

where alpha is a scalar, x and y are n element vectors and A is an n by n hermitian matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine cher2(UPLO, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

C specification:

```
#include "armpl.h"

void cher2_(const char *uplo, const armpl_int_t *n,
            const armpl_singlecomplex_t *alpha,
            const armpl_singlecomplex_t *x, const armpl_int_t *incx,
            const armpl_singlecomplex_t *y, const armpl_int_t *incy,
            armpl_singlecomplex_t *a, const armpl_int_t *lda, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Y Input parameter.

Y is COMPLEX

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

Related Information

For this routine in other precisions, please see *zher2*. It also exists with a native C interface as *cblas_cher2*.

3.3.9 chpmv

chpmv performs the matrix-vector operation

```
y := alpha*A*x + beta*y,
```

where alpha and beta are scalars, x and y are n element vectors and A is an n by n hermitian matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine chpmv(UPLO, N, ALPHA, AP, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void chpmv_(const char *uplo, const armpl_int_t *n,
            const armpl_singlecomplex_t *alpha,
            const armpl_singlecomplex_t *a, const armpl_singlecomplex_t *x,
            const armpl_int_t *incx, const armpl_singlecomplex_t *beta,
            armpl_singlecomplex_t *y, const armpl_int_t *incy, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array AP as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero.

X Input parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is COMPLEX

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input.

Y Input and output parameter.

Y is COMPLEX

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *zhpmv*. It also exists with a native C interface as *cblas_chpmv*.

3.3.10 chpr

chpr performs the hermitian rank 1 operation

```
A := alpha*x*x**H + A,
```

where alpha is a real scalar, x is an n element vector and A is an n by n hermitian matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine chpr(UPLO, N, ALPHA, X, INCX, AP)
```

C specification:

```
#include "armpl.h"

void chpr_(const char *uplo, const armpl_int_t *n, const float *alpha,
           const armpl_singlecomplex_t *x, const armpl_int_t *incx,
           armpl_singlecomplex_t *a, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array AP as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. On exit, the array AP is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. On exit, the array AP is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

Related Information

For this routine in other precisions, please see *zhpr*. It also exists with a native C interface as *cblas_chpr*.

3.3.11 chpr2

chpr2 performs the hermitian rank 2 operation

```
A := alpha*x*y**H + conjg( alpha )*y*x**H + A,
```

where alpha is a scalar, x and y are n element vectors and A is an n by n hermitian matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine chpr2(UPLO, N, ALPHA, X, INCX, Y, INCY, AP)
```

C specification:

```
#include "armpl.h"

void chpr2_(const char *uplo, const armpl_int_t *n,
            const armpl_singlecomplex_t *alpha,
            const armpl_singlecomplex_t *x, const armpl_int_t *incx,
            const armpl_singlecomplex_t *y, const armpl_int_t *incy,
            armpl_singlecomplex_t *a, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array AP as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Y Input parameter.

Y is COMPLEX

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. On exit, the array AP is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1)

respectively, and so on. On exit, the array AP is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

Related Information

For this routine in other precisions, please see *zhpr2*. It also exists with a native C interface as *cblas_chpr2*.

3.3.12 cspmv

cspmv performs the matrix-vector operation

```
y := alpha*A*x + beta*y,
```

where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine cspmv(UPLO, N, ALPHA, AP, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void cspmv_(const char *uplo, const armpl_int_t *n,
            const armpl_singlecomplex_t *alpha,
            const armpl_singlecomplex_t *ap, const armpl_singlecomplex_t *x,
            const armpl_int_t *incx, const armpl_singlecomplex_t *beta,
            armpl_singlecomplex_t *y, const armpl_int_t *incy, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array AP as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP.

Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension at least. ((N*(N + 1))/2). Before entry, with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry, with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. Unchanged on exit.

X Input parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (N - 1)*abs(INCX)). Before entry, the incremented array X must contain the N- element vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA Input parameter.

BETA is COMPLEX

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y Input and output parameter.

Y is COMPLEX

Y is an array, dimension at least. (1 + (N - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Related Information

For this routine in other precisions, please see *dspmv*, *sspmv* and *zspmv*.

3.3.13 cspr

cspr performs the symmetric rank 1 operation

```
A := alpha*x*x**H + A,
```

where alpha is a complex scalar, x is an n element vector and A is an n by n symmetric matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine cspr(UPLO, N, ALPHA, X, INCX, AP)
```

C specification:

```
#include "armpl.h"

void cspr_(const char *uplo, const armpl_int_t *n,
           const armpl_singlecomplex_t *alpha, const armpl_singlecomplex_t *x,
           const armpl_int_t *incx, armpl_singlecomplex_t *ap, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array AP as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP.

Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X Input parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (N - 1)*abs(INCX)). Before entry, the incremented array X must contain the N- element vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension at least. ((N*(N + 1))/2). Before entry, with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. On exit, the array AP is overwritten by the upper triangular part of the updated matrix. Before entry, with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. On exit, the array AP is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

Related Information

For this routine in other precisions, please see *dspr*, *sspr* and *zspr*.

3.3.14 csymv

csymv performs the matrix-vector operation

```
y := alpha*A*x + beta*y,
```

where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine csymv(UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void csymv_(const char *uplo, const armpl_int_t *n,
            const armpl_singlecomplex_t *alpha,
            const armpl_singlecomplex_t *a, const armpl_int_t *lda,
            const armpl_singlecomplex_t *x, const armpl_int_t *incx,
            const armpl_singlecomplex_t *beta, armpl_singlecomplex_t *y,
            const armpl_int_t *incy, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). Before entry, with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. Before entry, with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. Unchanged on exit.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, N). Unchanged on exit.

X Input parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (N - 1)*abs(INCX)). Before entry, the incremented array X must contain the N- element vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA Input parameter.

BETA is COMPLEX

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y Input and output parameter.

Y is COMPLEX

Y is an array, dimension at least. (1 + (N - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Related Information

For this routine in other precisions, please see *dsymv*, *ssymv* and *zsymv*.

3.3.15 csyr

csyr performs the symmetric rank 1 operation

```
A := alpha*x*x**H + A,
```

where alpha is a complex scalar, x is an n element vector and A is an n by n symmetric matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine csyr(UPLO, N, ALPHA, X, INCX, A, LDA)
```

C specification:

```
#include "armpl.h"

void csyr_(const char *uplo, const armpl_int_t *n,
           const armpl_singlecomplex_t *alpha, const armpl_singlecomplex_t *x,
           const armpl_int_t *incx, armpl_singlecomplex_t *a,
           const armpl_int_t *lda, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X Input parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (N - 1)*abs(INCX)). Before entry, the incremented array X must contain the N- element vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). Before entry, with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry, with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, N). Unchanged on exit.

Related Information

For this routine in other precisions, please see *dsyr*, *ssyr* and *zsyr*. It also exists with a native C interface as *LAPACKE_csyr*.

3.3.16 ctbmv

ctbmv performs one of the matrix-vector operations

```
x := A*x,   or   x := A**T*x,   or   x := A**H*x,
```

where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with (k + 1) diagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctbmv(UPLO, TRANS, DIAG, N, K, A, LDA, X, INCX)
```

C specification:

```
#include "armpl.h"

void ctbmv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const armpl_int_t *k,
            const armpl_singlecomplex_t *a, const armpl_int_t *lda,
            armpl_singlecomplex_t *x, const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' x := A*x.

TRANS = 'T' or 't' x := A^T *x.

TRANS = 'C' or 'c' x := A^H *x.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

K Input parameter.

K is INTEGER

On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K must satisfy 0 .le. K.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N).. Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

DO 20, J = 1, N M = K + 1 - J DO 10, I = MAX(1, J - K), J A(M + I, J) = matrix(I, J) 10 CONTINUE 20 CONTINUE

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

DO 20, J = 1, N M = 1 - J DO 10, I = J, MIN(N, J + K) A(M + I, J) = matrix(I, J) 10 CONTINUE 20 CONTINUE

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (k + 1).

X Input and output parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. On exit, X is overwritten with the transformed vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *dtbmv*, *stbmv* and *ztbmv*. It also exists with a native C interface as *cblas_ctbmv*.

3.3.17 ctbsv

ctbsv solves one of the systems of equations

```
A*x = b,   or   A**T*x = b,   or   A**H*x = b,
```

where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with (k + 1) diagonals.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctbsv(UPLO, TRANS, DIAG, N, K, A, LDA, X, INCX)
```

C specification:

```
#include "armpl.h"

void ctbsv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const armpl_int_t *k,
            const armpl_singlecomplex_t *a, const armpl_int_t *lda,
            armpl_singlecomplex_t *x, const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the equations to be solved as follows:

TRANS = 'N' or 'n' A*x = b.

TRANS = 'T' or 't' A^T *x = b.

TRANS = 'C' or 'c' A^H *x = b.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

K Input parameter.

K is INTEGER

On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K must satisfy 0 .le. K.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = ``K`` + 1 - J
      DO 10, I = MAX( 1, J - ``K`` ), J
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = 1 - J
      DO 10, I = J, MIN( ``N``, J + ``K`` )
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (k + 1).

X Input and output parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element right-hand side vector b. On exit, X is overwritten with the solution vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *dtbsv*, *stbsv* and *ztbsv*. It also exists with a native C interface as *cblas_ctbsv*.

3.3.18 ctpmv

ctpmv performs one of the matrix-vector operations

```
x := A*x,   or   x := A**T*x,   or   x := A**H*x,
```

where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctpmv(UPLO, TRANS, DIAG, N, AP, X, INCX)
```

C specification:

```
#include "armpl.h"

void ctpmv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const armpl_singlecomplex_t *ap,
            armpl_singlecomplex_t *x, const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' x := A*x.

TRANS = 'T' or 't' x := A^T *x.

TRANS = 'C' or 'c' x := A^H *x.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity.

X Input and output parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. On exit, X is overwritten with the transformed vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *dtpmv*, *stpmv* and *ztpmv*. It also exists with a native C interface as *cblas_ctpmv*.

3.3.19 ctpsv

ctpsv solves one of the systems of equations

```
A*x = b,   or   A**T*x = b,   or   A**H*x = b,
```

where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctpsv(UPLO, TRANS, DIAG, N, AP, X, INCX)
```

C specification:

```
#include "armpl.h"

void ctpsv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const armpl_singlecomplex_t *ap,
            armpl_singlecomplex_t *x, const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the equations to be solved as follows:

TRANS = 'N' or 'n' A*x = b.

TRANS = 'T' or 't' A^T *x = b.

TRANS = 'C' or 'c' A^H *x = b.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity.

X Input and output parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element right-hand side vector b. On exit, X is overwritten with the solution vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *dtpsv*, *stpsv* and *ztpsv*. It also exists with a native C interface as *cblas_ctpsv*.

3.3.20 ctrmv

ctrmv performs one of the matrix-vector operations

```
x := A*x,   or   x := A**T*x,   or   x := A**H*x,
```

where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctrmv(UPLO, TRANS, DIAG, N, A, LDA, X, INCX)
```

C specification:

```
#include "armpl.h"

void ctrmv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const armpl_singlecomplex_t *a,
            const armpl_int_t *lda, armpl_singlecomplex_t *x,
            const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' x := A*x.

TRANS = 'T' or 't' x := A^T *x.

TRANS = 'C' or 'c' x := A^H *x.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N).. Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

X Input and output parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. On exit, X is overwritten with the transformed vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *dtrmv*, *strmv* and *ztrmv*. It also exists with a native C interface as *cblas_ctrmv*.

3.3.21 ctrsv

ctrsv solves one of the systems of equations

```
A*x = b,   or   A**T*x = b,   or   A**H*x = b,
```

where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctrsv(UPLO, TRANS, DIAG, N, A, LDA, X, INCX)
```

C specification:

```
#include "armpl.h"

void ctrsv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const armpl_singlecomplex_t *a,
            const armpl_int_t *lda, armpl_singlecomplex_t *x,
            const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the equations to be solved as follows:

TRANS = 'N' or 'n' A*x = b.

TRANS = 'T' or 't' A^T *x = b.

TRANS = 'C' or 'c' A^H *x = b.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

X Input and output parameter.

X is COMPLEX

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element right-hand side vector b. On exit, X is overwritten with the solution vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *dtrsv*, *strsv* and *ztrsv*. It also exists with a native C interface as *cblas_ctrsv*.

3.3.22 dgbmv

dgbmv performs one of the matrix-vector operations

```
y := alpha*A*x + beta*y,   or   y := alpha*A**T*x + beta*y,
```

where alpha and beta are scalars, x and y are vectors and A is an m by n band matrix, with kl sub-diagonals and ku super-diagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgbmv(TRANS, M, N, KL, KU, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void dgbmv_(const char *trans, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_int_t *kl, const armpl_int_t *ku, const double *alpha,
            const double *a, const armpl_int_t *lda, const double *x,
            const armpl_int_t *incx, const double *beta, double *y,
            const armpl_int_t *incy, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' y := alpha*A*x + beta*y.

TRANS = 'T' or 't' y := alpha*A^T *x + beta*y.

TRANS = 'C' or 'c' y := alpha*A^T *x + beta*y.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero.

KL Input parameter.

KL is INTEGER

On entry, KL specifies the number of sub-diagonals of the matrix A. KL must satisfy 0 .le. KL.

KU Input parameter.

KU is INTEGER

On entry, KU specifies the number of super-diagonals of the matrix A. KU must satisfy 0 .le. KU.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION.

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). Before entry, the leading (kl + ku + 1) by n part of the array A must contain the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (ku + 1) of the array, the first super-diagonal starting at position 2 in row ku, the first sub-diagonal starting at position 1 in row (ku + 2), and so on. Elements in the array A that do not correspond to elements in the band matrix (such as the top left ku by ku triangle) are not referenced. The following program segment will transfer a band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      K = ``KU`` + 1 - J
      DO 10, I = MAX( 1, J - ``KU`` ), MIN( ``M``, J + ``KL`` )
         A( K + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (kl + ku + 1).

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)) when TRANS = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is DOUBLE PRECISION.

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension at least. (1 + (m - 1)*abs(INCY)) when TRANS = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *cgbmv*, *sgbmv* and *zgbmv*. It also exists with a native C interface as *cblas_dgbmv*.

3.3.23 dgemv

dgemv performs one of the matrix-vector operations

```
y := alpha*A*x + beta*y,   or   y := alpha*A**T*x + beta*y,
```

where alpha and beta are scalars, x and y are vectors and A is an m by n matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgemv(TRANS, M, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void dgemv_(const char *trans, const armpl_int_t *m, const armpl_int_t *n,
            const double *alpha, const double *a, const armpl_int_t *lda,
            const double *x, const armpl_int_t *incx, const double *beta,
            double *y, const armpl_int_t *incy, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' y := alpha*A*x + beta*y.

TRANS = 'T' or 't' y := alpha*A^T *x + beta*y.

TRANS = 'C' or 'c' y := alpha*A^T *x + beta*y.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION.

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). Before entry, the leading m by n part of the array A must contain the matrix of coefficients.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, m).

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)) when TRANS = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is DOUBLE PRECISION.

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension at least. (1 + (m - 1)*abs(INCY)) when TRANS = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *cgemv*, *sgemv* and *zgemv*. It also exists with a native C interface as *cblas_dgemv*.

3.3.24 dger

dger performs the rank 1 operation

```
A := alpha*x*y**T + A,
```

where alpha is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine dger(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

C specification:

```
#include "armpl.h"

void dger_(const armpl_int_t *m, const armpl_int_t *n, const double *alpha,
           const double *x, const armpl_int_t *incx, const double *y,
           const armpl_int_t *incy, double *a, const armpl_int_t *lda);
```

Parameters

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION.

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension at least. (1 + (m - 1)*abs(INCX)). Before entry, the incremented array X must contain the m element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Y Input parameter.

Y is DOUBLE PRECISION

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, m).

Related Information

For this routine in other precisions, please see *sger*. It also exists with a native C interface as *cblas_dger*.

3.3.25 dsbmv

dsbmv performs the matrix-vector operation

```
y := alpha*A*x + beta*y,
```

where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric band matrix, with k super-diagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsbmv(UPLO, N, K, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void dsbmv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *k,
            const double *alpha, const double *a, const armpl_int_t *lda,
            const double *x, const armpl_int_t *incx, const double *beta,
            double *y, const armpl_int_t *incy, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the band matrix A is being supplied as follows:

UPLO = 'U' or 'u' The upper triangular part of A is being supplied.

UPLO = 'L' or 'l' The lower triangular part of A is being supplied.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

K Input parameter.

K is INTEGER

On entry, K specifies the number of super-diagonals of the matrix A. K must satisfy 0 .le. K.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION.

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the symmetric matrix, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer the upper triangular part of a symmetric band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = ``K`` + 1 - J
      DO 10, I = MAX( 1, J - ``K`` ), J
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the symmetric matrix, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer the lower triangular part of a symmetric band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = 1 - J
      DO 10, I = J, MIN( ``N``, J + ``K`` )
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (k + 1).

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is DOUBLE PRECISION.

On entry, BETA specifies the scalar beta.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *ssbmv*. It also exists with a native C interface as *cblas_dsbmv*.

3.3.26 dspmv

dspmv performs the matrix-vector operation

```
y := alpha*A*x + beta*y,
```

where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine dspmv(UPLO, N, ALPHA, AP, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void dspmv_(const char *uplo, const armpl_int_t *n, const double *alpha,
            const double *ap, const double *x, const armpl_int_t *incx,
            const double *beta, double *y, const armpl_int_t *incy, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array AP as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION.

On entry, ALPHA specifies the scalar alpha.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the symmetric

matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on.

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is DOUBLE PRECISION.

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *cspmv*, *sspmv* and *zspmv*. It also exists with a native C interface as *cblas_dspmv*.

3.3.27 dspr

dspr performs the symmetric rank 1 operation

```
A := alpha*x*x**T + A,
```

where alpha is a real scalar, x is an n element vector and A is an n by n symmetric matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine dspr(UPLO, N, ALPHA, X, INCX, AP)
```

C specification:

```
#include "armpl.h"

void dspr_(const char *uplo, const armpl_int_t *n, const double *alpha,
           const double *x, const armpl_int_t *incx, double *ap, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array AP as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION.

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

AP Input and output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. On exit, the array AP is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. On exit, the array AP is overwritten by the lower triangular part of the updated matrix.

Related Information

For this routine in other precisions, please see *cspr*, *sspr* and *zspr*. It also exists with a native C interface as *cblas_dspr*.

3.3.28 dspr2

dspr2 performs the symmetric rank 2 operation

```
A := alpha*x*y**T + alpha*y*x**T + A,
```

where alpha is a scalar, x and y are n element vectors and A is an n by n symmetric matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine dspr2(UPLO, N, ALPHA, X, INCX, Y, INCY, AP)
```

C specification:

```
#include "armpl.h"

void dspr2_(const char *uplo, const armpl_int_t *n, const double *alpha,
            const double *x, const armpl_int_t *incx, const double *y,
            const armpl_int_t *incy, double *ap, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array AP as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION.

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Y Input parameter.

Y is DOUBLE PRECISION

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

AP Input and output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. On exit, the array AP is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. On exit, the array AP is overwritten by the lower triangular part of the updated matrix.

Related Information

For this routine in other precisions, please see *sspr2*. It also exists with a native C interface as *cblas_dspr2*.

3.3.29 dsymv

dsymv performs the matrix-vector operation

```
y := alpha*A*x + beta*y,
```

where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsymv(UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void dsymv_(const char *uplo, const armpl_int_t *n, const double *alpha,
            const double *a, const armpl_int_t *lda, const double *x,
            const armpl_int_t *incx, const double *beta, double *y,
            const armpl_int_t *incy, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION.

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is DOUBLE PRECISION.

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *csymv*, *ssymv* and *zsymv*. It also exists with a native C interface as *cblas_dsymv*.

3.3.30 dsyr

dsyr performs the symmetric rank 1 operation

```
A := alpha*x*x**T + A,
```

where alpha is a real scalar, x is an n element vector and A is an n by n symmetric matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsyr(UPLO, N, ALPHA, X, INCX, A, LDA)
```

C specification:

```
#include "armpl.h"

void dsyr_(const char *uplo, const armpl_int_t *n, const double *alpha,
           const double *x, const armpl_int_t *incx, double *a,
           const armpl_int_t *lda, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION.

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

Related Information

For this routine in other precisions, please see *csyr*, *ssyr* and *zsyr*. It also exists with a native C interface as *cblas_dsyr*.

3.3.31 dsyr2

dsyr2 performs the symmetric rank 2 operation

```
A := alpha*x*y**T + alpha*y*x**T + A,
```

where alpha is a scalar, x and y are n element vectors and A is an n by n symmetric matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsyr2(UPLO, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

C specification:

```
#include "armpl.h"

void dsyr2_(const char *uplo, const armpl_int_t *n, const double *alpha,
            const double *x, const armpl_int_t *incx, const double *y,
            const armpl_int_t *incy, double *a, const armpl_int_t *lda,
            ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION.

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Y Input parameter.

Y is DOUBLE PRECISION

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

Related Information

For this routine in other precisions, please see *ssyr2*. It also exists with a native C interface as *cblas_dsyr2*.

3.3.32 dtbmv

dtbmv performs one of the matrix-vector operations

```
x := A*x,   or   x := A**T*x,
```

where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with (k + 1) diagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtbmv(UPLO, TRANS, DIAG, N, K, A, LDA, X, INCX)
```

C specification:

```
#include "armpl.h"

void dtbmv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const armpl_int_t *k, const double *a,
            const armpl_int_t *lda, double *x, const armpl_int_t *incx,
            ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' x := A*x.

TRANS = 'T' or 't' x := A^T *x.

TRANS = 'C' or 'c' x := A^T *x.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

K Input parameter.

K is INTEGER

On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K must satisfy 0 .le. K.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = ``K`` + 1 - J
      DO 10, I = MAX( 1, J - ``K`` ), J
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

DO 20, J = 1, N M = 1 - J DO 10, I = J, MIN(N, J + K) A(M + I, J) = matrix(I, J) 10 CONTINUE 20 CONTINUE

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (k + 1).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. On exit, X is overwritten with the transformed vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *ctbmv*, *stbmv* and *ztbmv*. It also exists with a native C interface as *cblas_dtbmv*.

3.3.33 dtbsv

dtbsv solves one of the systems of equations

```
A*x = b,   or   A**T*x = b,
```

where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with (k + 1) diagonals.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtbsv(UPLO, TRANS, DIAG, N, K, A, LDA, X, INCX)
```

C specification:

```
#include "armpl.h"

void dtbsv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const armpl_int_t *k, const double *a,
            const armpl_int_t *lda, double *x, const armpl_int_t *incx,
            ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the equations to be solved as follows:

TRANS = 'N' or 'n' A*x = b.

TRANS = 'T' or 't' A^T *x = b.

TRANS = 'C' or 'c' A^T *x = b.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

K Input parameter.

K is INTEGER

On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K must satisfy 0 .le. K.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = ``K`` + 1 - J
      DO 10, I = MAX( 1, J - ``K`` ), J
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = 1 - J
      DO 10, I = J, MIN( ``N``, J + ``K`` )
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (k + 1).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element right-hand side vector b. On exit, X is overwritten with the solution vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *ctbsv*, *stbsv* and *ztbsv*. It also exists with a native C interface as *cblas_dtbsv*.

3.3.34 dtpmv

dtpmv performs one of the matrix-vector operations

```
x := A*x,   or   x := A**T*x,
```

where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtpmv(UPLO, TRANS, DIAG, N, AP, X, INCX)
```

C specification:

```
#include "armpl.h"

void dtpmv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const double *ap, double *x,
            const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' x := A*x.

TRANS = 'T' or 't' x := A^T *x.

TRANS = 'C' or 'c' x := A^T *x.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity.

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. On exit, X is overwritten with the transformed vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *ctpmv*, *stpmv* and *ztpmv*. It also exists with a native C interface as *cblas_dtpmv*.

3.3.35 dtpsv

dtpsv solves one of the systems of equations

```
A*x = b,   or   A**T*x = b,
```

where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtpsv(UPLO, TRANS, DIAG, N, AP, X, INCX)
```

C specification:

```
#include "armpl.h"

void dtpsv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const double *ap, double *x,
            const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the equations to be solved as follows:

TRANS = 'N' or 'n' A*x = b.

TRANS = 'T' or 't' A^T *x = b.

TRANS = 'C' or 'c' A^T *x = b.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity.

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element right-hand side vector b. On exit, X is overwritten with the solution vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *ctpsv*, *stpsv* and *ztpsv*. It also exists with a native C interface as *cblas_dtpsv*.

3.3.36 dtrmv

dtrmv performs one of the matrix-vector operations

```
x := A*x,   or   x := A**T*x,
```

where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtrmv(UPLO, TRANS, DIAG, N, A, LDA, X, INCX)
```

C specification:

```
#include "armpl.h"

void dtrmv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const double *a, const armpl_int_t *lda,
            double *x, const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' x := A*x.

TRANS = 'T' or 't' x := A^T *x.

TRANS = 'C' or 'c' x := A^T *x.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. On exit, X is overwritten with the transformed vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *ctrmv*, *strmv* and *ztrmv*. It also exists with a native C interface as *cblas_dtrmv*.

3.3.37 dtrsv

dtrsv solves one of the systems of equations

```
A*x = b,   or   A**T*x = b,
```

where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtrsv(UPLO, TRANS, DIAG, N, A, LDA, X, INCX)
```

C specification:

```
#include "armpl.h"

void dtrsv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const double *a, const armpl_int_t *lda,
            double *x, const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the equations to be solved as follows:

TRANS = 'N' or 'n' A*x = b.

TRANS = 'T' or 't' A^T *x = b.

TRANS = 'C' or 'c' A^T *x = b.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element right-hand side vector b. On exit, X is overwritten with the solution vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Level 2 Blas routine.

– Written on 22-October-1986. Jack Dongarra, Argonne National Lab. Jeremy Du Croz, Nag Central Office. Sven Hammarling, Nag Central Office. Richard Hanson, Sandia National Labs.

Related Information

For this routine in other precisions, please see *ctrsv*, *strsv* and *ztrsv*. It also exists with a native C interface as *cblas_dtrsv*.

3.3.38 sgbmv

sgbmv performs one of the matrix-vector operations

```
y := alpha*A*x + beta*y,   or   y := alpha*A**T*x + beta*y,
```

where alpha and beta are scalars, x and y are vectors and A is an m by n band matrix, with kl sub-diagonals and ku super-diagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgbmv(TRANS, M, N, KL, KU, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void sgbmv_(const char *trans, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_int_t *kl, const armpl_int_t *ku, const float *alpha,
            const float *a, const armpl_int_t *lda, const float *x,
            const armpl_int_t *incx, const float *beta, float *y,
            const armpl_int_t *incy, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' y := alpha*A*x + beta*y.

TRANS = 'T' or 't' y := alpha*A^T *x + beta*y.

TRANS = 'C' or 'c' y := alpha*A^T *x + beta*y.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero.

KL Input parameter.

KL is INTEGER

On entry, KL specifies the number of sub-diagonals of the matrix A. KL must satisfy 0 .le. KL.

KU Input parameter.

KU is INTEGER

On entry, KU specifies the number of super-diagonals of the matrix A. KU must satisfy 0 .le. KU.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). Before entry, the leading (kl + ku + 1) by n part of the array A must contain the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (ku + 1) of the array, the first super-diagonal starting at position 2 in row ku, the first sub-diagonal starting at position 1 in row (ku + 2), and so on. Elements in the array A that do not correspond to elements in the

band matrix (such as the top left ku by ku triangle) are not referenced. The following program segment will transfer a band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      K = ``KU`` + 1 - J
      DO 10, I = MAX( 1, J - ``KU`` ), MIN( ``M``, J + ``KL`` )
         A( K + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (kl + ku + 1).

X Input parameter.

X is REAL

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)) when TRANS = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is REAL

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input.

Y Input and output parameter.

Y is REAL

Y is an array, dimension at least. (1 + (m - 1)*abs(INCY)) when TRANS = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *cgbmv*, *dgbmv* and *zgbmv*. It also exists with a native C interface as *cblas_sgbmv*.

3.3.39 sgemv

sgemv performs one of the matrix-vector operations

```
y := alpha*A*x + beta*y,   or   y := alpha*A**T*x + beta*y,
```

where alpha and beta are scalars, x and y are vectors and A is an m by n matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgemv(TRANS, M, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void sgemv_(const char *trans, const armpl_int_t *m, const armpl_int_t *n,
            const float *alpha, const float *a, const armpl_int_t *lda,
            const float *x, const armpl_int_t *incx, const float *beta,
            float *y, const armpl_int_t *incy, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' y := alpha*A*x + beta*y.

TRANS = 'T' or 't' y := alpha*A^T *x + beta*y.

TRANS = 'C' or 'c' y := alpha*A^T *x + beta*y.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). Before entry, the leading m by n part of the array A must contain the matrix of coefficients.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, m).

X Input parameter.

X is REAL

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)) when TRANS = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is REAL

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input.

Y Input and output parameter.

Y is REAL

Y is an array, dimension at least. (1 + (m - 1)*abs(INCY)) when TRANS = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *cgemv*, *dgemv* and *zgemv*. It also exists with a native C interface as *cblas_sgemv*.

3.3.40 sger

sger performs the rank 1 operation

```
A := alpha*x*y**T + A,
```

where alpha is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine sger(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

C specification:

```
#include "armpl.h"

void sger_(const armpl_int_t *m, const armpl_int_t *n, const float *alpha,
           const float *x, const armpl_int_t *incx, const float *y,
           const armpl_int_t *incy, float *a, const armpl_int_t *lda);
```

Parameters

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is REAL

X is an array, dimension at least. (1 + (m - 1)*abs(INCX)). Before entry, the incremented array X must contain the m element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Y Input parameter.

Y is REAL

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, m).

Related Information

For this routine in other precisions, please see *dger*. It also exists with a native C interface as *cblas_sger*.

3.3.41 ssbmv

ssbmv performs the matrix-vector operation

```
y := alpha*A*x + beta*y,
```

where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric band matrix, with k super-diagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssbmv(UPLO, N, K, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void ssbmv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *k,
            const float *alpha, const float *a, const armpl_int_t *lda,
            const float *x, const armpl_int_t *incx, const float *beta,
            float *y, const armpl_int_t *incy, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the band matrix A is being supplied as follows:

UPLO = 'U' or 'u' The upper triangular part of A is being supplied.

UPLO = 'L' or 'l' The lower triangular part of A is being supplied.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

K Input parameter.

K is INTEGER

On entry, K specifies the number of super-diagonals of the matrix A. K must satisfy 0 .le. K.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the symmetric matrix, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer the upper triangular part of a symmetric band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      K = ``KU`` + 1 - J
      DO 10, I = MAX( 1, J - ``K`` ), J
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the symmetric matrix, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer the lower triangular part of a symmetric band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = 1 - J
      DO 10, I = J, MIN( ``N``, J + ``K`` )
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (k + 1).

X Input parameter.

X is REAL

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is REAL

On entry, BETA specifies the scalar beta.

Y Input and output parameter.

Y is REAL

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *dsbmv*. It also exists with a native C interface as *cblas_ssbmv*.

3.3.42 sspmv

sspmv performs the matrix-vector operation

```
y := alpha*A*x + beta*y,
```

where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine sspmv(UPLO, N, ALPHA, AP, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void sspmv_(const char *uplo, const armpl_int_t *n, const float *alpha,
            const float *ap, const float *x, const armpl_int_t *incx,
            const float *beta, float *y, const armpl_int_t *incy, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array AP as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha.

AP Input parameter.

AP is REAL

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on.

X Input parameter.

X is REAL

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is REAL

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input.

Y Input and output parameter.

Y is REAL

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *cspmv*, *dspmv* and *zspmv*. It also exists with a native C interface as *cblas_sspmv*.

3.3.43 sspr

sspr performs the symmetric rank 1 operation

```
A := alpha*x*x**T + A,
```

where alpha is a real scalar, x is an n element vector and A is an n by n symmetric matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine sspr(UPLO, N, ALPHA, X, INCX, AP)
```

C specification:

```
#include "armpl.h"

void sspr_(const char *uplo, const armpl_int_t *n, const float *alpha,
           const float *x, const armpl_int_t *incx, float *ap, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array AP as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is REAL

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

AP Input and output parameter.

AP is REAL

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. On exit, the array AP is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. On exit, the array AP is overwritten by the lower triangular part of the updated matrix.

Related Information

For this routine in other precisions, please see *cspr*, *dspr* and *zspr*. It also exists with a native C interface as *cblas_sspr*.

3.3.44 sspr2

sspr2 performs the symmetric rank 2 operation

```
A := alpha*x*y**T + alpha*y*x**T + A,
```

where alpha is a scalar, x and y are n element vectors and A is an n by n symmetric matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine sspr2(UPLO, N, ALPHA, X, INCX, Y, INCY, AP)
```

C specification:

```
#include "armpl.h"

void sspr2_(const char *uplo, const armpl_int_t *n, const float *alpha,
            const float *x, const armpl_int_t *incx, const float *y,
            const armpl_int_t *incy, float *ap, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array AP as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is REAL

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Y Input parameter.

Y is REAL

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

AP Input and output parameter.

AP is REAL

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. On exit, the array AP is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. On exit, the array AP is overwritten by the lower triangular part of the updated matrix.

Related Information

For this routine in other precisions, please see *dspr2*. It also exists with a native C interface as *cblas_sspr2*.

3.3.45 ssymv

ssymv performs the matrix-vector operation

```
y := alpha*A*x + beta*y,
```

where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssymv(UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void ssymv_(const char *uplo, const armpl_int_t *n, const float *alpha,
            const float *a, const armpl_int_t *lda, const float *x,
            const armpl_int_t *incx, const float *beta, float *y,
            const armpl_int_t *incy, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

X Input parameter.

X is REAL

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is REAL

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input.

Y Input and output parameter.

Y is REAL

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *csymv*, *dsymv* and *zsymv*. It also exists with a native C interface as *cblas_ssymv*.

3.3.46 ssyr

ssyr performs the symmetric rank 1 operation

```
A := alpha*x*x**T + A,
```

where alpha is a real scalar, x is an n element vector and A is an n by n symmetric matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssyr(UPLO, N, ALPHA, X, INCX, A, LDA)
```

C specification:

```
#include "armpl.h"

void ssyr_(const char *uplo, const armpl_int_t *n, const float *alpha,
           const float *x, const armpl_int_t *incx, float *a,
           const armpl_int_t *lda, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is REAL

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

Related Information

For this routine in other precisions, please see *csyr*, *dsyr* and *zsyr*. It also exists with a native C interface as *cblas_ssyr*.

3.3.47 ssyr2

ssyr2 performs the symmetric rank 2 operation

```
A := alpha*x*y**T + alpha*y*x**T + A,
```

where alpha is a scalar, x and y are n element vectors and A is an n by n symmetric matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssyr2(UPLO, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

C specification:

```
#include "armpl.h"

void ssyr2_(const char *uplo, const armpl_int_t *n, const float *alpha,
            const float *x, const armpl_int_t *incx, const float *y,
            const armpl_int_t *incy, float *a, const armpl_int_t *lda, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is REAL

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Y Input parameter.

Y is REAL

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

Related Information

For this routine in other precisions, please see *dsyr2*. It also exists with a native C interface as *cblas_ssyr2*.

3.3.48 stbmv

stbmv performs one of the matrix-vector operations

```
x := A*x,   or   x := A**T*x,
```

where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with (k + 1) diagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine stbmv(UPLO, TRANS, DIAG, N, K, A, LDA, X, INCX)
```

C specification:

```
#include "armpl.h"

void stbmv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const armpl_int_t *k, const float *a,
            const armpl_int_t *lda, float *x, const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' x := A*x.

TRANS = 'T' or 't' x := A^T *x.

TRANS = 'C' or 'c' x := A^T *x.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

K Input parameter.

K is INTEGER

On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K must satisfy 0 .le. K.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = ``K`` + 1 - J
      DO 10, I = MAX( 1, J - ``K`` ), J
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = 1 - J
      DO 10, I = J, MIN( ``N``, J + ``K`` )
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (k + 1).

X Input and output parameter.

X is REAL

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. On exit, X is overwritten with the transformed vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *ctbmv*, *dtbmv* and *ztbmv*. It also exists with a native C interface as *cblas_stbmv*.

3.3.49 stbsv

stbsv solves one of the systems of equations

```
A*x = b,   or   A**T*x = b,
```

where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with (k + 1) diagonals.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

Syntax

Fortran specification:

```
use armpl_library

subroutine stbsv(UPLO, TRANS, DIAG, N, K, A, LDA, X, INCX)
```

C specification:

```
#include "armpl.h"

void stbsv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const armpl_int_t *k, const float *a,
            const armpl_int_t *lda, float *x, const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the equations to be solved as follows:

TRANS = 'N' or 'n' A*x = b.

TRANS = 'T' or 't' A^T *x = b.

TRANS = 'C' or 'c' A^T *x = b.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

K Input parameter.

K is INTEGER

On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K must satisfy 0 .le. K.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = ``K`` + 1 - J
      DO 10, I = MAX( 1, J - ``K`` ), J
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = 1 - J
      DO 10, I = J, MIN( ``N``, J + ``K`` )
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (k + 1).

X Input and output parameter.

X is REAL

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element right-hand side vector b. On exit, X is overwritten with the solution vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *ctbsv*, *dtbsv* and *ztbsv*. It also exists with a native C interface as *cblas_stbsv*.

3.3.50 stpmv

stpmv performs one of the matrix-vector operations

```
x := A*x,   or   x := A**T*x,
```

where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine stpmv(UPLO, TRANS, DIAG, N, AP, X, INCX)
```

C specification:

```
#include "armpl.h"

void stpmv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const float *ap, float *x,
            const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' x := A*x.

TRANS = 'T' or 't' x := A^T *x.

TRANS = 'C' or 'c' x := A^T *x.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

AP Input parameter.

AP is REAL

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity.

X Input and output parameter.

X is REAL

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. On exit, X is overwritten with the transformed vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *ctpmv*, *dtpmv* and *ztpmv*. It also exists with a native C interface as *cblas_stpmv*.

3.3.51 stpsv

stpsv solves one of the systems of equations

```
A*x = b,   or   A**T*x = b,
```

where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

Syntax

Fortran specification:

```
use armpl_library

subroutine stpsv(UPLO, TRANS, DIAG, N, AP, X, INCX)
```

C specification:

```
#include "armpl.h"

void stpsv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const float *ap, float *x,
            const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the equations to be solved as follows:

TRANS = 'N' or 'n' A*x = b.

TRANS = 'T' or 't' A^T *x = b.

TRANS = 'C' or 'c' A^T *x = b.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

AP Input parameter.

AP is REAL

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity.

X Input and output parameter.

X is REAL

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element right-hand side vector b. On exit, X is overwritten with the solution vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *ctpsv*, *dtpsv* and *ztpsv*. It also exists with a native C interface as *cblas_stpsv*.

3.3.52 strmv

strmv performs one of the matrix-vector operations

```
x := A*x,   or   x := A**T*x,
```

where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine strmv(UPLO, TRANS, DIAG, N, A, LDA, X, INCX)
```

C specification:

```
#include "armpl.h"

void strmv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const float *a, const armpl_int_t *lda,
            float *x, const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' x := A*x.

TRANS = 'T' or 't' x := A^T *x.

TRANS = 'C' or 'c' x := A^T *x.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

X Input and output parameter.

X is REAL

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. On exit, X is overwritten with the transformed vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *ctrmv*, *dtrmv* and *ztrmv*. It also exists with a native C interface as *cblas_strmv*.

3.3.53 strsv

strsv solves one of the systems of equations

```
A*x = b,   or   A**T*x = b,
```

where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

Syntax

Fortran specification:

```
use armpl_library

subroutine strsv(UPLO, TRANS, DIAG, N, A, LDA, X, INCX)
```

C specification:

```
#include "armpl.h"

void strsv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const float *a, const armpl_int_t *lda,
            float *x, const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the equations to be solved as follows:

TRANS = 'N' or 'n' A*x = b.

TRANS = 'T' or 't' A^T *x = b.

TRANS = 'C' or 'c' A^T *x = b.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

X Input and output parameter.

X is REAL

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element right-hand side vector b. On exit, X is overwritten with the solution vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *ctrsv*, *dtrsv* and *ztrsv*. It also exists with a native C interface as *cblas_strsv*.

3.3.54 zgbmv

zgbmv performs one of the matrix-vector operations

```
 y := alpha*A*x + beta*y,   or   y := alpha*A**T*x + beta*y,   or

y := alpha*A**H*x + beta*y,
```

where alpha and beta are scalars, x and y are vectors and A is an m by n band matrix, with kl sub-diagonals and ku super-diagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgbmv(TRANS, M, N, KL, KU, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void zgbmv_(const char *trans, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_int_t *kl, const armpl_int_t *ku,
            const armpl_doublecomplex_t *alpha,
            const armpl_doublecomplex_t *a, const armpl_int_t *lda,
            const armpl_doublecomplex_t *x, const armpl_int_t *incx,
            const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *y,
            const armpl_int_t *incy, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' y := alpha*A*x + beta*y.

TRANS = 'T' or 't' y := alpha*A^T *x + beta*y.

TRANS = 'C' or 'c' y := alpha*A^H *x + beta*y.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero.

KL Input parameter.

KL is INTEGER

On entry, KL specifies the number of sub-diagonals of the matrix A. KL must satisfy 0 .le. KL.

KU Input parameter.

KU is INTEGER

On entry, KU specifies the number of super-diagonals of the matrix A. KU must satisfy 0 .le. KU.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). Before entry, the leading (kl + ku + 1) by n part of the array A must contain the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (ku + 1) of the array, the first super-diagonal starting at position 2 in row ku, the first sub-diagonal starting at position 1 in row (ku + 2), and so on. Elements in the array A that do not correspond to elements in the band matrix (such as the top left ku by ku triangle) are not referenced. The following program segment will transfer a band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      K = ``KU`` + 1 - J
      DO 10, I = MAX( 1, J - ``KU`` ), MIN( ``M``, J + ``KL`` )
         A( K + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (kl + ku + 1).

X Input parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)) when TRANS = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is COMPLEX*16

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input.

Y Input and output parameter.

Y is COMPLEX*16

Y is an array, dimension at least. (1 + (m - 1)*abs(INCY)) when TRANS = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *cgbmv*, *dgbmv* and *sgbmv*. It also exists with a native C interface as *cblas_zgbmv*.

3.3.55 zgemv

zgemv performs one of the matrix-vector operations

```
 y := alpha*A*x + beta*y,   or   y := alpha*A**T*x + beta*y,   or

y := alpha*A**H*x + beta*y,
```

where alpha and beta are scalars, x and y are vectors and A is an m by n matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgemv(TRANS, M, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void zgemv_(const char *trans, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_doublecomplex_t *alpha,
            const armpl_doublecomplex_t *a, const armpl_int_t *lda,
            const armpl_doublecomplex_t *x, const armpl_int_t *incx,
            const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *y,
            const armpl_int_t *incy, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' y := alpha*A*x + beta*y.

TRANS = 'T' or 't' y := alpha*A^T *x + beta*y.

TRANS = 'C' or 'c' y := alpha*A^H *x + beta*y.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). Before entry, the leading m by n part of the array A must contain the matrix of coefficients.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, m).

X Input parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)) when TRANS = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is COMPLEX*16

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input.

Y Input and output parameter.

Y is COMPLEX*16

Y is an array, dimension at least. (1 + (m - 1)*abs(INCY)) when TRANS = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *cgemv*, *dgemv* and *sgemv*. It also exists with a native C interface as *cblas_zgemv*.

3.3.56 zgerc

zgerc performs the rank 1 operation

```
A := alpha*x*y**H + A,
```

where alpha is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgerc(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

C specification:

```
#include "armpl.h"

void zgerc_(const armpl_int_t *m, const armpl_int_t *n,
            const armpl_doublecomplex_t *alpha,
            const armpl_doublecomplex_t *x, const armpl_int_t *incx,
            const armpl_doublecomplex_t *y, const armpl_int_t *incy,
            armpl_doublecomplex_t *a, const armpl_int_t *lda);
```

Parameters

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (m - 1)*abs(INCX)). Before entry, the incremented array X must contain the m element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Y Input parameter.

Y is COMPLEX*16

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, m).

Related Information

For this routine in other precisions, please see *cgerc*. It also exists with a native C interface as *cblas_zgerc*.

3.3.57 zgeru

zgeru performs the rank 1 operation

```
A := alpha*x*y**T + A,
```

where alpha is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgeru(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

C specification:

```
#include "armpl.h"

void zgeru_(const armpl_int_t *m, const armpl_int_t *n,
            const armpl_doublecomplex_t *alpha,
            const armpl_doublecomplex_t *x, const armpl_int_t *incx,
            const armpl_doublecomplex_t *y, const armpl_int_t *incy,
            armpl_doublecomplex_t *a, const armpl_int_t *lda);
```

Parameters

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (m - 1)*abs(INCX)). Before entry, the incremented array X must contain the m element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Y Input parameter.

Y is COMPLEX*16

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, m).

Related Information

For this routine in other precisions, please see *cgeru*. It also exists with a native C interface as *cblas_zgeru*.

3.3.58 zhbmv

zhbmv performs the matrix-vector operation

```
y := alpha*A*x + beta*y,
```

where alpha and beta are scalars, x and y are n element vectors and A is an n by n hermitian band matrix, with k super-diagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhbmv(UPLO, N, K, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void zhbmv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *k,
            const armpl_doublecomplex_t *alpha,
            const armpl_doublecomplex_t *a, const armpl_int_t *lda,
            const armpl_doublecomplex_t *x, const armpl_int_t *incx,
            const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *y,
            const armpl_int_t *incy, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the band matrix A is being supplied as follows:

UPLO = 'U' or 'u' The upper triangular part of A is being supplied.

UPLO = 'L' or 'l' The lower triangular part of A is being supplied.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

K Input parameter.

K is INTEGER

On entry, K specifies the number of super-diagonals of the matrix A. K must satisfy 0 .le. K.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the hermitian matrix, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer the upper triangular part of a hermitian band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = ``K`` + 1 - J
      DO 10, I = MAX( 1, J - ``K`` ), J
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the hermitian matrix, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer the lower triangular part of a hermitian band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = 1 - J
      DO 10, I = J, MIN( ``N``, J + ``K`` )
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (k + 1).

X Input parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is COMPLEX*16

On entry, BETA specifies the scalar beta.

Y Input and output parameter.

Y is COMPLEX*16

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *chbmv*. It also exists with a native C interface as *cblas_zhbmv*.

3.3.59 zhemv

zhemv performs the matrix-vector operation

```
y := alpha*A*x + beta*y,
```

where alpha and beta are scalars, x and y are n element vectors and A is an n by n hermitian matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhemv(UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void zhemv_(const char *uplo, const armpl_int_t *n,
            const armpl_doublecomplex_t *alpha,
            const armpl_doublecomplex_t *a, const armpl_int_t *lda,
            const armpl_doublecomplex_t *x, const armpl_int_t *incx,
            const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *y,
            const armpl_int_t *incy, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

X Input parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is COMPLEX*16

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input.

Y Input and output parameter.

Y is COMPLEX*16

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *chemv*. It also exists with a native C interface as *cblas_zhemv*.

3.3.60 zher

zher performs the hermitian rank 1 operation

```
A := alpha*x*x**H + A,
```

where alpha is a real scalar, x is an n element vector and A is an n by n hermitian matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine zher(UPLO, N, ALPHA, X, INCX, A, LDA)
```

C specification:

```
#include "armpl.h"

void zher_(const char *uplo, const armpl_int_t *n, const double *alpha,
           const armpl_doublecomplex_t *x, const armpl_int_t *incx,
           armpl_doublecomplex_t *a, const armpl_int_t *lda, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION.

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

Related Information

For this routine in other precisions, please see *cher*. It also exists with a native C interface as *cblas_zher*.

3.3.61 zher2

zher2 performs the hermitian rank 2 operation

```
A := alpha*x*y**H + conjg( alpha )*y*x**H + A,
```

where alpha is a scalar, x and y are n element vectors and A is an n by n hermitian matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine zher2(UPLO, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

C specification:

```
#include "armpl.h"

void zher2_(const char *uplo, const armpl_int_t *n,
            const armpl_doublecomplex_t *alpha,
            const armpl_doublecomplex_t *x, const armpl_int_t *incx,
            const armpl_doublecomplex_t *y, const armpl_int_t *incy,
            armpl_doublecomplex_t *a, const armpl_int_t *lda, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Y Input parameter.

Y is COMPLEX*16

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

Related Information

For this routine in other precisions, please see *cher2*. It also exists with a native C interface as *cblas_zher2*.

3.3.62 zhpmv

zhpmv performs the matrix-vector operation

```
y := alpha*A*x + beta*y,
```

where alpha and beta are scalars, x and y are n element vectors and A is an n by n hermitian matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhpmv(UPLO, N, ALPHA, AP, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void zhpmv_(const char *uplo, const armpl_int_t *n,
            const armpl_doublecomplex_t *alpha,
            const armpl_doublecomplex_t *a, const armpl_doublecomplex_t *x,
            const armpl_int_t *incx, const armpl_doublecomplex_t *beta,
            armpl_doublecomplex_t *y, const armpl_int_t *incy, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array AP as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero.

X Input parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

BETA Input parameter.

BETA is COMPLEX*16

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input.

Y Input and output parameter.

Y is COMPLEX*16

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

Related Information

For this routine in other precisions, please see *chpmv*. It also exists with a native C interface as *cblas_zhpmv*.

3.3.63 zhpr

zhpr performs the hermitian rank 1 operation

```
A := alpha*x*x**H + A,
```

where alpha is a real scalar, x is an n element vector and A is an n by n hermitian matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhpr(UPLO, N, ALPHA, X, INCX, AP)
```

C specification:

```
#include "armpl.h"

void zhpr_(const char *uplo, const armpl_int_t *n, const double *alpha,
           const armpl_doublecomplex_t *x, const armpl_int_t *incx,
           armpl_doublecomplex_t *a, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array AP as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION.

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. On exit, the array AP is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. On exit, the array AP is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

Related Information

For this routine in other precisions, please see *chpr*. It also exists with a native C interface as *cblas_zhpr*.

3.3.64 zhpr2

zhpr2 performs the hermitian rank 2 operation

```
A := alpha*x*y**H + conjg( alpha )*y*x**H + A,
```

where alpha is a scalar, x and y are n element vectors and A is an n by n hermitian matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhpr2(UPLO, N, ALPHA, X, INCX, Y, INCY, AP)
```

C specification:

```
#include "armpl.h"

void zhpr2_(const char *uplo, const armpl_int_t *n,
            const armpl_doublecomplex_t *alpha,
            const armpl_doublecomplex_t *x, const armpl_int_t *incx,
            const armpl_doublecomplex_t *y, const armpl_int_t *incy,
            armpl_doublecomplex_t *a, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array AP as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha.

X Input parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Y Input parameter.

Y is COMPLEX*16

Y is an array, dimension at least. (1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. On exit, the array AP is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. On exit, the array AP is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

Related Information

For this routine in other precisions, please see *chpr2*. It also exists with a native C interface as *cblas_zhpr2*.

3.3.65 zspmv

zspmv performs the matrix-vector operation

```
y := alpha*A*x + beta*y,
```

where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine zspmv(UPLO, N, ALPHA, AP, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void zspmv_(const char *uplo, const armpl_int_t *n,
            const armpl_doublecomplex_t *alpha,
            const armpl_doublecomplex_t *ap, const armpl_doublecomplex_t *x,
            const armpl_int_t *incx, const armpl_doublecomplex_t *beta,
            armpl_doublecomplex_t *y, const armpl_int_t *incy, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array AP as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP.

Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension at least. ((N*(N + 1))/2). Before entry, with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry, with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. Unchanged on exit.

X Input parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (N - 1)*abs(INCX)). Before entry, the incremented array X must contain the N- element vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA Input parameter.

BETA is COMPLEX*16

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y Input and output parameter.

Y is COMPLEX*16

Y is an array, dimension at least. (1 + (N - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Related Information

For this routine in other precisions, please see *cspmv*, *dspmv* and *sspmv*.

3.3.66 zspr

zspr performs the symmetric rank 1 operation

```
A := alpha*x*x**H + A,
```

where alpha is a complex scalar, x is an n element vector and A is an n by n symmetric matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine zspr(UPLO, N, ALPHA, X, INCX, AP)
```

C specification:

```
#include "armpl.h"

void zspr_(const char *uplo, const armpl_int_t *n,
           const armpl_doublecomplex_t *alpha, const armpl_doublecomplex_t *x,
           const armpl_int_t *incx, armpl_doublecomplex_t *ap, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array AP as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP.

Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X Input parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (N - 1)*abs(INCX)). Before entry, the incremented array X must contain the N- element vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension at least. ((N*(N + 1))/2). Before entry, with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. On exit, the array AP is overwritten by the upper triangular part of the updated matrix. Before entry, with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. On exit, the array AP is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

Related Information

For this routine in other precisions, please see *cspr*, *dspr* and *sspr*.

3.3.67 zsymv

zsymv performs the matrix-vector operation

```
y := alpha*A*x + beta*y,
```

where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsymv(UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void zsymv_(const char *uplo, const armpl_int_t *n,
            const armpl_doublecomplex_t *alpha,
            const armpl_doublecomplex_t *a, const armpl_int_t *lda,
            const armpl_doublecomplex_t *x, const armpl_int_t *incx,
            const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *y,
            const armpl_int_t *incy, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). Before entry, with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. Before entry, with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. Unchanged on exit.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, N). Unchanged on exit.

X Input parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (N - 1)*abs(INCX)). Before entry, the incremented array X must contain the N- element vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA Input parameter.

BETA is COMPLEX*16

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y Input and output parameter.

Y is COMPLEX*16

Y is an array, dimension at least. (1 + (N - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Related Information

For this routine in other precisions, please see *csymv*, *dsymv* and *ssymv*.

3.3.68 zsyr

zsyr performs the symmetric rank 1 operation

```
A := alpha*x*x**H + A,
```

where alpha is a complex scalar, x is an n element vector and A is an n by n symmetric matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsyr(UPLO, N, ALPHA, X, INCX, A, LDA)
```

C specification:

```
#include "armpl.h"

void zsyr_(const char *uplo, const armpl_int_t *n,
           const armpl_doublecomplex_t *alpha, const armpl_doublecomplex_t *x,
           const armpl_int_t *incx, armpl_doublecomplex_t *a,
           const armpl_int_t *lda, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X Input parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (N - 1)*abs(INCX)). Before entry, the incremented array X must contain the N- element vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). Before entry, with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry, with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, N). Unchanged on exit.

Related Information

For this routine in other precisions, please see *csyr*, *dsyr* and *ssyr*. It also exists with a native C interface as *LAPACKE_zsyr*.

3.3.69 ztbmv

ztbmv performs one of the matrix-vector operations

```
x := A*x,   or   x := A**T*x,   or   x := A**H*x,
```

where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with (k + 1) diagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztbmv(UPLO, TRANS, DIAG, N, K, A, LDA, X, INCX)
```

C specification:

```
#include "armpl.h"

void ztbmv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const armpl_int_t *k,
            const armpl_doublecomplex_t *a, const armpl_int_t *lda,
            armpl_doublecomplex_t *x, const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' x := A*x.

TRANS = 'T' or 't' x := A^T *x.

TRANS = 'C' or 'c' x := A^H *x.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

K Input parameter.

K is INTEGER

On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K must satisfy 0 .le. K.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N).. Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = ``K`` + 1 - J
      DO 10, I = MAX( 1, J - ``K`` ), J
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = 1 - J
      DO 10, I = J, MIN( ``N``, J + ``K`` )
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (k + 1).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. On exit, X is overwritten with the transformed vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *ctbmv*, *dtbmv* and *stbmv*. It also exists with a native C interface as *cblas_ztbmv*.

3.3.70 ztbsv

ztbsv solves one of the systems of equations

```
A*x = b,   or   A**T*x = b,   or   A**H*x = b,
```

where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with (k + 1) diagonals.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztbsv(UPLO, TRANS, DIAG, N, K, A, LDA, X, INCX)
```

C specification:

```
#include "armpl.h"

void ztbsv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const armpl_int_t *k,
            const armpl_doublecomplex_t *a, const armpl_int_t *lda,
            armpl_doublecomplex_t *x, const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the equations to be solved as follows:

TRANS = 'N' or 'n' A*x = b.

TRANS = 'T' or 't' A^T *x = b.

TRANS = 'C' or 'c' A^H *x = b.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

K Input parameter.

K is INTEGER

On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K must satisfy 0 .le. K.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column,

with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = ``K`` + 1 - J
      DO 10, I = MAX( 1, J - ``K`` ), J
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
      M = 1 - J
      DO 10, I = J, MIN( ``N``, J + ``K`` )
         A( M + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (k + 1).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element right-hand side vector b. On exit, X is overwritten with the solution vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *ctbsv*, *dtbsv* and *stbsv*. It also exists with a native C interface as *cblas_ztbsv*.

3.3.71 ztpmv

ztpmv performs one of the matrix-vector operations

```
x := A*x,   or   x := A**T*x,   or   x := A**H*x,
```

where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztpmv(UPLO, TRANS, DIAG, N, AP, X, INCX)
```

C specification:

```
#include "armpl.h"

void ztpmv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const armpl_doublecomplex_t *ap,
            armpl_doublecomplex_t *x, const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' x := A*x.

TRANS = 'T' or 't' x := A^T *x.

TRANS = 'C' or 'c' x := A^H *x.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity.

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. On exit, X is overwritten with the transformed vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *ctpmv*, *dtpmv* and *stpmv*. It also exists with a native C interface as *cblas_ztpmv*.

3.3.72 ztpsv

ztpsv solves one of the systems of equations

```
A*x = b,   or   A**T*x = b,   or   A**H*x = b,
```

where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztpsv(UPLO, TRANS, DIAG, N, AP, X, INCX)
```

C specification:

```
#include "armpl.h"

void ztpsv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const armpl_doublecomplex_t *ap,
            armpl_doublecomplex_t *x, const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the equations to be solved as follows:

TRANS = 'N' or 'n' A*x = b.

TRANS = 'T' or 't' A^T *x = b.

TRANS = 'C' or 'c' A^H *x = b.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension at least. ((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity.

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element right-hand side vector b. On exit, X is overwritten with the solution vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *ctpsv*, *dtpsv* and *stpsv*. It also exists with a native C interface as *cblas_ztpsv*.

3.3.73 ztrmv

ztrmv performs one of the matrix-vector operations

```
x := A*x,   or   x := A**T*x,   or   x := A**H*x,
```

where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztrmv(UPLO, TRANS, DIAG, N, A, LDA, X, INCX)
```

C specification:

```
#include "armpl.h"

void ztrmv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const armpl_doublecomplex_t *a,
            const armpl_int_t *lda, armpl_doublecomplex_t *x,
            const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' x := A*x.

TRANS = 'T' or 't' x := A^T *x.

TRANS = 'C' or 'c' x := A^H *x.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N).. Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. On exit, X is overwritten with the transformed vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *ctrmv*, *dtrmv* and *strmv*. It also exists with a native C interface as *cblas_ztrmv*.

3.3.74 ztrsv

ztrsv solves one of the systems of equations

```
A*x = b,   or   A**T*x = b,   or   A**H*x = b,
```

where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztrsv(UPLO, TRANS, DIAG, N, A, LDA, X, INCX)
```

C specification:

```
#include "armpl.h"

void ztrsv_(const char *uplo, const char *trans, const char *diag,
            const armpl_int_t *n, const armpl_doublecomplex_t *a,
            const armpl_int_t *lda, armpl_doublecomplex_t *x,
            const armpl_int_t *incx, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the equations to be solved as follows:

TRANS = 'N' or 'n' A*x = b.

TRANS = 'T' or 't' A^T *x = b.

TRANS = 'C' or 'c' A^H *x = b.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix A. N must be at least zero.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element right-hand side vector b. On exit, X is overwritten with the solution vector x.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

Related Information

For this routine in other precisions, please see *ctrsv*, *dtrsv* and *strsv*. It also exists with a native C interface as *cblas_ztrsv*.

Level 2 BLAS routines are typically memory-vector operations and are normally memory bound. All functions are detailed in armpl.h.

3.4 BLAS level 3

3.4.1 cgemm

cgemm performs one of the matrix-matrix operations

```
C := alpha*op( A )*op( B ) + beta*C,
```

where op(X) is one of

```
op( X ) = X   or   op( X ) = X**T   or   op( X ) = X**H,
```

alpha and beta are scalars, and A, B and C are matrices, with op(A) an m by k matrix, op(B) a k by n matrix and C an m by n matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgemm(TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB, BETA, C,
                 LDC)
```

C specification:

```
#include "armpl.h"

void cgemm_(const char *transa, const char *transb, const armpl_int_t *m,
            const armpl_int_t *n, const armpl_int_t *k,
            const armpl_singlecomplex_t *alpha,
            const armpl_singlecomplex_t *a, const armpl_int_t *lda,
            const armpl_singlecomplex_t *b, const armpl_int_t *ldb,
            const armpl_singlecomplex_t *beta, armpl_singlecomplex_t *c,
            const armpl_int_t *ldc, ... );
```

Parameters

TRANSA Input parameter.

TRANSA is CHARACTER*1

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n', op(A) = A.

TRANSA = 'T' or 't', op(A) = A^T .

TRANSA = 'C' or 'c', op(A) = A^H .

TRANSB Input parameter.

TRANSB is CHARACTER*1

On entry, TRANSB specifies the form of op(B) to be used in the matrix multiplication as follows:

TRANSB = 'N' or 'n', op(B) = B.

TRANSB = 'T' or 't', op(B) = B^T .

TRANSB = 'C' or 'c', op(B) = B^H .

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix op(A) and of the matrix C. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix op(B) and the number of columns of the matrix C. N must be at least zero.

K Input parameter.

K is INTEGER

On entry, K specifies the number of columns of the matrix op(A) and the number of rows of the matrix op(B). K must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, ka), where ka is. k when TRANSA = 'N' or 'n', and is m otherwise. Before entry with TRANSA = 'N' or 'n', the leading m by k part of the array A must contain the matrix A, otherwise the leading k by m part of the array A must contain the matrix A.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, m), otherwise LDA must be at least max(1, k).

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, kb), where kb is. n when TRANSB = 'N' or 'n', and is k otherwise. Before entry with TRANSB = 'N' or 'n', the leading k by n part of the array B must contain the matrix B, otherwise the leading n by k part of the array B must contain the matrix B.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSB = 'N' or 'n' then LDB must be at least max(1, k), otherwise LDB must be at least max(1, n).

BETA Input parameter.

BETA is COMPLEX

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n matrix (alpha*op(A)*op(B) + beta* C).

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, m).

Related Information

For this routine in other precisions, please see *dgemm*, *hgemm*, *sgemm* and *zgemm*. It also exists with a native C interface as *cblas_cgemm*.

3.4.2 chemm

chemm performs one of the matrix-matrix operations

```
C := alpha*A*B + beta*C,
```

or

```
C := alpha*B*A + beta*C,
```

where alpha and beta are scalars, A is an hermitian matrix and B and C are m by n matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine chemm(SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C, LDC)
```

C specification:

```
#include "armpl.h"

void chemm_(const char *side, const char *uplo, const armpl_int_t *m,
            const armpl_int_t *n, const armpl_singlecomplex_t *alpha,
            const armpl_singlecomplex_t *a, const armpl_int_t *lda,
            const armpl_singlecomplex_t *b, const armpl_int_t *ldb,
            const armpl_singlecomplex_t *beta, armpl_singlecomplex_t *c,
            const armpl_int_t *ldc, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

On entry, SIDE specifies whether the hermitian matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l' C := alpha*A* B + beta*C,

SIDE = 'R' or 'r' C := alpha*B* A + beta*C,

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the hermitian matrix A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of the hermitian matrix is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of the hermitian matrix is to be referenced.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix C. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix C. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, ka), where ka is. m when SIDE = 'L' or 'l' and is n otherwise. Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the hermitian matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the hermitian matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA must be at least max(1, m), otherwise LDA must be at least max(1, n).

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, N). Before entry, the leading m by n part of the array B must contain the matrix B.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m).

BETA Input parameter.

BETA is COMPLEX

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n updated matrix.

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, m).

Related Information

For this routine in other precisions, please see *zhemm*. It also exists with a native C interface as *cblas_chemm*.

3.4.3 cher2k

cher2k performs one of the hermitian rank 2k operations

```
C := alpha*A*B**H + conjg( alpha )*B*A**H + beta*C,
```

or

```
C := alpha*A**H*B + conjg( alpha )*B**H*A + beta*C,
```

where alpha and beta are scalars with beta real, C is an n by n hermitian matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

Syntax

Fortran specification:

```
use armpl_library

subroutine cher2k(UPLO, TRANS, N, K, ALPHA, A, LDA, B, LDB, BETA, C, LDC)
```

C specification:

```
#include "armpl.h"

void cher2k_(const char *uplo, const char *trans, const armpl_int_t *n,
             const armpl_int_t *k, const armpl_singlecomplex_t *alpha,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             const float *beta, armpl_singlecomplex_t *c,
             const armpl_int_t *ldc, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' C := alpha*A*B^H + conjg(alpha)*B*A^H + beta*C.

TRANS = 'C' or 'c' C := alpha*A^H * B + conjg(alpha)*B^H * A + beta*C.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix C. N must be at least zero.

K Input parameter.

K is INTEGER

On entry with TRANS = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANS = 'C' or 'c', K specifies the number of rows of the matrices A and B. K must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, ka), where ka is. k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k).

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, kb), where kb is. k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDB must be at least max(1, n), otherwise LDB must be at least max(1, k).

BETA Input parameter.

BETA is REAL

On entry, BETA specifies the scalar beta.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n).

Related Information

For this routine in other precisions, please see *zher2k*. It also exists with a native C interface as *cblas_cher2k*.

3.4.4 cherk

`cherk` performs one of the hermitian rank k operations

```
C := alpha*A*A**H + beta*C,
```

or

```
C := alpha*A**H*A + beta*C,
```

where alpha and beta are real scalars, C is an n by n hermitian matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

Syntax

Fortran specification:

```
use armpl_library

subroutine cherk(UPLO, TRANS, N, K, ALPHA, A, LDA, BETA, C, LDC)
```

C specification:

```
#include "armpl.h"

void cherk_(const char *uplo, const char *trans, const armpl_int_t *n,
            const armpl_int_t *k, const float *alpha,
            const armpl_singlecomplex_t *a, const armpl_int_t *lda,
            const float *beta, armpl_singlecomplex_t *c,
            const armpl_int_t *ldc, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

On entry, `UPLO` specifies whether the upper or lower triangular part of the array `C` is to be referenced as follows:

`UPLO` = 'U' or 'u' Only the upper triangular part of C is to be referenced.

`UPLO` = 'L' or 'l' Only the lower triangular part of C is to be referenced.

TRANS Input parameter.

`TRANS` is `CHARACTER*1`

On entry, `TRANS` specifies the operation to be performed as follows:

`TRANS` = 'N' or 'n' `C` := alpha*A*A^H + beta*C.

`TRANS` = 'C' or 'c' `C` := alpha*A^H * `A` + beta*C.

N Input parameter.

`N` is `INTEGER`

On entry, `N` specifies the order of the matrix `C`. `N` must be at least zero.

K Input parameter.

`K` is `INTEGER`

On entry with `TRANS` = 'N' or 'n', `K` specifies the number of columns of the matrix `A`, and on entry with `TRANS` = 'C' or 'c', `K` specifies the number of rows of the matrix `A`. `K` must be at least zero.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, ka), where ka is. k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k).

BETA Input parameter.

BETA is REAL

On entry, BETA specifies the scalar beta.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n).

Related Information

For this routine in other precisions, please see *zherk*. It also exists with a native C interface as *cblas_cherk*.

3.4.5 csymm

csymm performs one of the matrix-matrix operations

```
C := alpha*A*B + beta*C,
```

or

```
C := alpha*B*A + beta*C,
```

where alpha and beta are scalars, A is a symmetric matrix and B and C are m by n matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine csymm(SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C, LDC)
```

C specification:

```
#include "armpl.h"

void csymm_(const char *side, const char *uplo, const armpl_int_t *m,
            const armpl_int_t *n, const armpl_singlecomplex_t *alpha,
            const armpl_singlecomplex_t *a, const armpl_int_t *lda,
            const armpl_singlecomplex_t *b, const armpl_int_t *ldb,
            const armpl_singlecomplex_t *beta, armpl_singlecomplex_t *c,
            const armpl_int_t *ldc, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

On entry, SIDE specifies whether the symmetric matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l' C := alpha*A* B + beta*C,

SIDE = 'R' or 'r' C := alpha*B* A + beta*C,

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of the symmetric matrix is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of the symmetric matrix is to be referenced.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix C. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix C. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, ka), where ka is. m when SIDE = 'L' or 'l' and is n otherwise. Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO =

'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA must be at least max(1, m), otherwise LDA must be at least max(1, n).

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, N). Before entry, the leading m by n part of the array B must contain the matrix B.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m).

BETA Input parameter.

BETA is COMPLEX

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n updated matrix.

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, m).

Related Information

For this routine in other precisions, please see *dsymm*, *ssymm* and *zsymm*. It also exists with a native C interface as *cblas_csymm*.

3.4.6 csyr2k

csyr2k performs one of the symmetric rank 2k operations

```
C := alpha*A*B**T + alpha*B*A**T + beta*C,
```

or

```
C := alpha*A**T*B + alpha*B**T*A + beta*C,
```

where alpha and beta are scalars, C is an n by n symmetric matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

Syntax

Fortran specification:

```
use armpl_library

subroutine csyr2k(UPLO, TRANS, N, K, ALPHA, A, LDA, B, LDB, BETA, C, LDC)
```

C specification:

```
#include "armpl.h"

void csyr2k_(const char *uplo, const char *trans, const armpl_int_t *n,
             const armpl_int_t *k, const armpl_singlecomplex_t *alpha,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             const armpl_singlecomplex_t *beta, armpl_singlecomplex_t *c,
             const armpl_int_t *ldc, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' C := alpha*A*B^T + alpha*B*A^T + beta*C.

TRANS = 'T' or 't' C := alpha*A^T * B + alpha*B^T * A + beta*C.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix C. N must be at least zero.

K Input parameter.

K is INTEGER

On entry with TRANS = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANS = 'T' or 't', K specifies the number of rows of the matrices A and B. K must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, ka), where ka is. k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k).

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, kb), where kb is. k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDB must be at least max(1, n), otherwise LDB must be at least max(1, k).

BETA Input parameter.

BETA is COMPLEX

On entry, BETA specifies the scalar beta.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n).

Related Information

For this routine in other precisions, please see *dsyr2k*, *ssyr2k* and *zsyr2k*. It also exists with a native C interface as *cblas_csyr2k*.

3.4.7 csyrk

csyrk performs one of the symmetric rank k operations

```
C := alpha*A*A**T + beta*C,
```

or

```
C := alpha*A**T*A + beta*C,
```

where alpha and beta are scalars, C is an n by n symmetric matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

Syntax

Fortran specification:

```
use armpl_library

subroutine csyrk(UPLO, TRANS, N, K, ALPHA, A, LDA, BETA, C, LDC)
```

C specification:

```
#include "armpl.h"

void csyrk_(const char *uplo, const char *trans, const armpl_int_t *n,
            const armpl_int_t *k, const armpl_singlecomplex_t *alpha,
            const armpl_singlecomplex_t *a, const armpl_int_t *lda,
            const armpl_singlecomplex_t *beta, armpl_singlecomplex_t *c,
            const armpl_int_t *ldc, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' C := alpha*A*A^T + beta*C.

TRANS = 'T' or 't' C := alpha*A^T * A + beta*C.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix C. N must be at least zero.

K Input parameter.

K is INTEGER

On entry with TRANS = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANS = 'T' or 't', K specifies the number of rows of the matrix A. K must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, ka), where ka is. k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k).

BETA Input parameter.

BETA is COMPLEX

On entry, BETA specifies the scalar beta.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n).

Related Information

For this routine in other precisions, please see *dsyrk*, *ssyrk* and *zsyrk*. It also exists with a native C interface as *cblas_csyrk*.

3.4.8 ctrmm

ctrmm performs one of the matrix-matrix operations

```
B := alpha*op( A )*B,   or   B := alpha*B*op( A )
```

where alpha is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of

```
op( A ) = A   or   op( A ) = A**T   or   op( A ) = A**H.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine ctrmm(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B, LDB)
```

C specification:

```
#include "armpl.h"

void ctrmm_(const char *side, const char *uplo, const char *transa,
            const char *diag, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_singlecomplex_t *alpha,
            const armpl_singlecomplex_t *a, const armpl_int_t *lda,
            armpl_singlecomplex_t *b, const armpl_int_t *ldb, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

On entry, SIDE specifies whether op(A) multiplies B from the left or right as follows:

SIDE = 'L' or 'l' B := alpha*op(A)*B.

SIDE = 'R' or 'r' B := alpha*B*op(A).

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANSA Input parameter.

TRANSA is CHARACTER*1

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' op(A) = A.

TRANSA = 'T' or 't' op(A) = A^T .

TRANSA = 'C' or 'c' op(A) = A^H .

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of B. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of B. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, k), where k is m. when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'. Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA must be at least max(1, m), when SIDE = 'R' or 'r' then LDA must be at least max(1, n).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N).. Before entry, the leading m by n part of the array B must contain the matrix B, and on exit is overwritten by the transformed matrix.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m).

Related Information

For this routine in other precisions, please see *dtrmm*, *strmm* and *ztrmm*. It also exists with a native C interface as *cblas_ctrmm*.

3.4.9 ctrsm

ctrsm solves one of the matrix equations

```
op( A )*X = alpha*B,   or   X*op( A ) = alpha*B,
```

where alpha is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of

```
op( A ) = A   or   op( A ) = A**T   or   op( A ) = A**H.
```

The matrix X is overwritten on B.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctrsm(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B, LDB)
```

C specification:

```
#include "armpl.h"

void ctrsm_(const char *side, const char *uplo, const char *transa,
            const char *diag, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_singlecomplex_t *alpha,
            const armpl_singlecomplex_t *a, const armpl_int_t *lda,
            armpl_singlecomplex_t *b, const armpl_int_t *ldb, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

On entry, SIDE specifies whether op(A) appears on the left or right of X as follows:

SIDE = 'L' or 'l' op(A)*X = alpha*B.

SIDE = 'R' or 'r' X*op(A) = alpha*B.

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANSA Input parameter.

TRANSA is CHARACTER*1

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' op(A) = A.

TRANSA = 'T' or 't' op(A) = A^T .

TRANSA = 'C' or 'c' op(A) = A^H .

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of B. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of B. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, k),. where k is m when SIDE = 'L' or 'l' and k is n when SIDE = 'R' or 'r'. Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA must be at least max(1, m), when SIDE = 'R' or 'r' then LDA must be at least max(1, n).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). Before entry, the leading m by n part of the array B must contain the right-hand side matrix B, and on exit is overwritten by the solution matrix X.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m).

Related Information

For this routine in other precisions, please see *dtrsm*, *strsm* and *ztrsm*. It also exists with a native C interface as *cblas_ctrsm*.

3.4.10 dgemm

dgemm performs one of the matrix-matrix operations

```
C := alpha*op( A )*op( B ) + beta*C,
```

where op(X) is one of

```
op( X ) = X   or   op( X ) = X**T,
```

alpha and beta are scalars, and A, B and C are matrices, with op(A) an m by k matrix, op(B) a k by n matrix and C an m by n matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgemm(TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB, BETA, C,
                 LDC)
```

C specification:

```
#include "armpl.h"

void dgemm_(const char *transa, const char *transb, const armpl_int_t *m,
            const armpl_int_t *n, const armpl_int_t *k, const double *alpha,
            const double *a, const armpl_int_t *lda, const double *b,
            const armpl_int_t *ldb, const double *beta, double *c,
            const armpl_int_t *ldc, ... );
```

Parameters

TRANSA Input parameter.

TRANSA is CHARACTER*1

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n', op(A) = A.

TRANSA = 'T' or 't', op(A) = A^T .

TRANSA = 'C' or 'c', op(A) = A^T .

TRANSB Input parameter.

TRANSB is CHARACTER*1

On entry, TRANSB specifies the form of op(B) to be used in the matrix multiplication as follows:

TRANSB = 'N' or 'n', op(B) = B.

TRANSB = 'T' or 't', op(B) = B^T .

TRANSB = 'C' or 'c', op(B) = B^T .

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix op(A) and of the matrix C. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix op(B) and the number of columns of the matrix C. N must be at least zero.

K Input parameter.

K is INTEGER

On entry, K specifies the number of columns of the matrix op(A) and the number of rows of the matrix op(B). K must be at least zero.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION.

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, ka), where ka is. k when TRANSA = 'N' or 'n', and is m otherwise. Before entry with TRANSA = 'N' or 'n', the leading m by k part of the array A must contain the matrix A, otherwise the leading k by m part of the array A must contain the matrix A.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, m), otherwise LDA must be at least max(1, k).

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, kb), where kb is. n when TRANSB = 'N' or 'n', and is k otherwise. Before entry with TRANSB = 'N' or 'n', the leading k by n part of the array B must contain the matrix B, otherwise the leading n by k part of the array B must contain the matrix B.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSB = 'N' or 'n' then LDB must be at least max(1, k), otherwise LDB must be at least max(1, n).

BETA Input parameter.

BETA is DOUBLE PRECISION.

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n matrix (alpha*op(A)*op(B) + beta* C).

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, m).

Related Information

For this routine in other precisions, please see *cgemm*, *hgemm*, *sgemm* and *zgemm*. It also exists with a native C interface as *cblas_dgemm*.

3.4.11 dsymm

dsymm performs one of the matrix-matrix operations

```
C := alpha*A*B + beta*C,
```

or

```
C := alpha*B*A + beta*C,
```

where alpha and beta are scalars, A is a symmetric matrix and B and C are m by n matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsymm(SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C, LDC)
```

C specification:

```
#include "armpl.h"

void dsymm_(const char *side, const char *uplo, const armpl_int_t *m,
            const armpl_int_t *n, const double *alpha, const double *a,
            const armpl_int_t *lda, const double *b, const armpl_int_t *ldb,
            const double *beta, double *c, const armpl_int_t *ldc, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

On entry, SIDE specifies whether the symmetric matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l' C := alpha*A* B + beta*C,

SIDE = 'R' or 'r' C := alpha*B* A + beta*C,

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of the symmetric matrix is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of the symmetric matrix is to be referenced.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix C. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix C. N must be at least zero.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION.

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, ka), where ka is. m when SIDE = 'L' or 'l' and is n otherwise. Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l',

the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA must be at least max(1, m), otherwise LDA must be at least max(1, n).

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). Before entry, the leading m by n part of the array B must contain the matrix B.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m).

BETA Input parameter.

BETA is DOUBLE PRECISION.

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n updated matrix.

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, m).

Related Information

For this routine in other precisions, please see *csymm*, *ssymm* and *zsymm*. It also exists with a native C interface as *cblas_dsymm*.

3.4.12 dsyr2k

dsyr2k performs one of the symmetric rank 2k operations

```
C := alpha*A*B**T + alpha*B*A**T + beta*C,
```

or

```
C := alpha*A**T*B + alpha*B**T*A + beta*C,
```

where alpha and beta are scalars, C is an n by n symmetric matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsyr2k(UPLO, TRANS, N, K, ALPHA, A, LDA, B, LDB, BETA, C, LDC)
```

C specification:

```
#include "armpl.h"

void dsyr2k_(const char *uplo, const char *trans, const armpl_int_t *n,
             const armpl_int_t *k, const double *alpha, const double *a,
             const armpl_int_t *lda, const double *b, const armpl_int_t *ldb,
             const double *beta, double *c, const armpl_int_t *ldc, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' C := alpha*A*B^T + alpha*B*A^T + beta*C.

TRANS = 'T' or 't' C := alpha*A^T * B + alpha*B^T * A + beta*C.

TRANS = 'C' or 'c' C := alpha*A^T * B + alpha*B^T * A + beta*C.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix C. N must be at least zero.

K Input parameter.

K is INTEGER

On entry with TRANS = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANS = 'T' or 't' or 'C' or 'c', K specifies the number of rows of the matrices A and B. K must be at least zero.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION.

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, ka), where ka is. k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k).

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, kb), where kb is. k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDB must be at least max(1, n), otherwise LDB must be at least max(1, k).

BETA Input parameter.

BETA is DOUBLE PRECISION.

On entry, BETA specifies the scalar beta.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n).

Related Information

For this routine in other precisions, please see *csyr2k*, *ssyr2k* and *zsyr2k*. It also exists with a native C interface as *cblas_dsyr2k*.

3.4.13 dsyrk

dsyrk performs one of the symmetric rank k operations

```
C := alpha*A*A**T + beta*C,
```

or

```
C := alpha*A**T*A + beta*C,
```

where alpha and beta are scalars, C is an n by n symmetric matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsyrk(UPLO, TRANS, N, K, ALPHA, A, LDA, BETA, C, LDC)
```

C specification:

```
#include "armpl.h"

void dsyrk_(const char *uplo, const char *trans, const armpl_int_t *n,
            const armpl_int_t *k, const double *alpha, const double *a,
            const armpl_int_t *lda, const double *beta, double *c,
            const armpl_int_t *ldc, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' C := alpha*A*A^T + beta*C.

TRANS = 'T' or 't' C := alpha*A^T * A + beta*C.

TRANS = 'C' or 'c' C := alpha*A^T * A + beta*C.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix C. N must be at least zero.

K Input parameter.

K is INTEGER

On entry with TRANS = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANS = 'T' or 't' or 'C' or 'c', K specifies the number of rows of the matrix A. K must be at least zero.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION.

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, ka), where ka is. k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k).

BETA Input parameter.

BETA is DOUBLE PRECISION.

On entry, BETA specifies the scalar beta.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n).

Related Information

For this routine in other precisions, please see *csyrk*, *ssyrk* and *zsyrk*. It also exists with a native C interface as *cblas_dsyrk*.

3.4.14 dtrmm

dtrmm performs one of the matrix-matrix operations

```
B := alpha*op( A )*B,   or   B := alpha*B*op( A ),
```

where alpha is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of

```
op( A ) = A   or   op( A ) = A**T.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dtrmm(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B, LDB)
```

C specification:

```
#include "armpl.h"

void dtrmm_(const char *side, const char *uplo, const char *transa,
            const char *diag, const armpl_int_t *m, const armpl_int_t *n,
```

(continues on next page)

(continued from previous page)

```
            const double *alpha, const double *a, const armpl_int_t *lda,
            double *b, const armpl_int_t *ldb, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

On entry, SIDE specifies whether op(A) multiplies B from the left or right as follows:

SIDE = 'L' or 'l' B := alpha*op(A)*B.

SIDE = 'R' or 'r' B := alpha*B*op(A).

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANSA Input parameter.

TRANSA is CHARACTER*1

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' op(A) = A.

TRANSA = 'T' or 't' op(A) = A^T .

TRANSA = 'C' or 'c' op(A) = A^T .

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of B. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of B. N must be at least zero.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION.

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, k), where k is m. when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'. Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the

upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA must be at least max(1, m), when SIDE = 'R' or 'r' then LDA must be at least max(1, n).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). Before entry, the leading m by n part of the array B must contain the matrix B, and on exit is overwritten by the transformed matrix.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m).

Related Information

For this routine in other precisions, please see *ctrmm*, *strmm* and *ztrmm*. It also exists with a native C interface as *cblas_dtrmm*.

3.4.15 dtrsm

dtrsm solves one of the matrix equations

```
op( A )*X = alpha*B,   or   X*op( A ) = alpha*B,
```

where alpha is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of

```
op( A ) = A   or   op( A ) = A**T.
```

The matrix X is overwritten on B.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtrsm(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B, LDB)
```

C specification:

```
#include "armpl.h"

void dtrsm_(const char *side, const char *uplo, const char *transa,
            const char *diag, const armpl_int_t *m, const armpl_int_t *n,
            const double *alpha, const double *a, const armpl_int_t *lda,
            double *b, const armpl_int_t *ldb, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

On entry, SIDE specifies whether op(A) appears on the left or right of X as follows:

SIDE = 'L' or 'l' op(A)*X = alpha*B.

SIDE = 'R' or 'r' X*op(A) = alpha*B.

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANSA Input parameter.

TRANSA is CHARACTER*1

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' op(A) = A.

TRANSA = 'T' or 't' op(A) = A^T .

TRANSA = 'C' or 'c' op(A) = A^T .

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of B. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of B. N must be at least zero.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION.

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, k),. where k is m when SIDE = 'L' or 'l' and k is n when SIDE = 'R' or 'r'. Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA must be at least max(1, m), when SIDE = 'R' or 'r' then LDA must be at least max(1, n).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). Before entry, the leading m by n part of the array B must contain the right-hand side matrix B, and on exit is overwritten by the solution matrix X.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m).

Related Information

For this routine in other precisions, please see *ctrsm*, *strsm* and *ztrsm*. It also exists with a native C interface as *cblas_dtrsm*.

3.4.16 sgemm

sgemm performs one of the matrix-matrix operations

```
C := alpha*op( A )*op( B ) + beta*C,
```

where op(X) is one of

```
op( X ) = X   or   op( X ) = X**T,
```

alpha and beta are scalars, and A, B and C are matrices, with op(A) an m by k matrix, op(B) a k by n matrix and C an m by n matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgemm(TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB, BETA, C,
                 LDC)
```

C specification:

```
#include "armpl.h"

void sgemm_(const char *transa, const char *transb, const armpl_int_t *m,
            const armpl_int_t *n, const armpl_int_t *k, const float *alpha,
            const float *a, const armpl_int_t *lda, const float *b,
            const armpl_int_t *ldb, const float *beta, float *c,
            const armpl_int_t *ldc, ... );
```

Parameters

TRANSA Input parameter.

TRANSA is CHARACTER*1

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n', op(A) = A.

TRANSA = 'T' or 't', op(A) = A^T .

TRANSA = 'C' or 'c', op(A) = A^T .

TRANSB Input parameter.

TRANSB is CHARACTER*1

On entry, TRANSB specifies the form of op(B) to be used in the matrix multiplication as follows:

TRANSB = 'N' or 'n', op(B) = B.

TRANSB = 'T' or 't', op(B) = B^T .

TRANSB = 'C' or 'c', op(B) = B^T .

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix op(A) and of the matrix C. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix op(B) and the number of columns of the matrix C. N must be at least zero.

K Input parameter.

K is INTEGER

On entry, K specifies the number of columns of the matrix op(A) and the number of rows of the matrix op(B). K must be at least zero.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is REAL

A is an array, dimension (LDA, ka), where ka is. k when TRANSA = 'N' or 'n', and is m otherwise. Before entry with TRANSA = 'N' or 'n', the leading m by k part of the array A must contain the matrix A, otherwise the leading k by m part of the array A must contain the matrix A.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, m), otherwise LDA must be at least max(1, k).

B Input parameter.

B is REAL

B is an array, dimension (LDB, kb), where kb is. n when TRANSB = 'N' or 'n', and is k otherwise. Before entry with TRANSB = 'N' or 'n', the leading k by n part of the array B must contain the matrix B, otherwise the leading n by k part of the array B must contain the matrix B.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSB = 'N' or 'n' then LDB must be at least max(1, k), otherwise LDB must be at least max(1, n).

BETA Input parameter.

BETA is REAL

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n matrix (alpha*op(A)*op(B) + beta* C).

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, m).

Related Information

For this routine in other precisions, please see *cgemm*, *dgemm*, *hgemm*, and *zgemm*. It also exists with a native C interface as *cblas_sgemm*.

3.4.17 ssymm

ssymm performs one of the matrix-matrix operations

```
C := alpha*A*B + beta*C,
```

or

```
C := alpha*B*A + beta*C,
```

where alpha and beta are scalars, A is a symmetric matrix and B and C are m by n matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssymm(SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C, LDC)
```

C specification:

```
#include "armpl.h"

void ssymm_(const char *side, const char *uplo, const armpl_int_t *m,
            const armpl_int_t *n, const float *alpha, const float *a,
            const armpl_int_t *lda, const float *b, const armpl_int_t *ldb,
            const float *beta, float *c, const armpl_int_t *ldc, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

On entry, SIDE specifies whether the symmetric matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l' C := alpha*A* B + beta*C,

SIDE = 'R' or 'r' C := alpha*B* A + beta*C,

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of the symmetric matrix is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of the symmetric matrix is to be referenced.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix C. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix C. N must be at least zero.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is REAL

A is an array, dimension (LDA, ka), where ka is. m when SIDE = 'L' or 'l' and is n otherwise. Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA must be at least max(1, m), otherwise LDA must be at least max(1, n).

B Input parameter.

B is REAL

B is an array, dimension (LDB, N). Before entry, the leading m by n part of the array B must contain the matrix B.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m).

BETA Input parameter.

BETA is REAL

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n updated matrix.

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, m).

Related Information

For this routine in other precisions, please see *csymm*, *dsymm* and *zsymm*. It also exists with a native C interface as *cblas_ssymm*.

3.4.18 ssyr2k

ssyr2k performs one of the symmetric rank 2k operations

```
C := alpha*A*B**T + alpha*B*A**T + beta*C,
```

or

```
C := alpha*A**T*B + alpha*B**T*A + beta*C,
```

where alpha and beta are scalars, C is an n by n symmetric matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssyr2k(UPLO, TRANS, N, K, ALPHA, A, LDA, B, LDB, BETA, C, LDC)
```

C specification:

```
#include "armpl.h"

void ssyr2k_(const char *uplo, const char *trans, const armpl_int_t *n,
             const armpl_int_t *k, const float *alpha, const float *a,
             const armpl_int_t *lda, const float *b, const armpl_int_t *ldb,
             const float *beta, float *c, const armpl_int_t *ldc, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' C := alpha*A*B^T + alpha*B*A^T + beta*C.

TRANS = 'T' or 't' C := alpha*A^T * B + alpha*B^T * A + beta*C.

TRANS = 'C' or 'c' C := alpha*A^T * B + alpha*B^T * A + beta*C.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix C. N must be at least zero.

K Input parameter.

K is INTEGER

On entry with TRANS = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANS = 'T' or 't' or 'C' or 'c', K specifies the number of rows of the matrices A and B. K must be at least zero.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is REAL

A is an array, dimension (LDA, ka), where ka is. k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k).

B Input parameter.

B is REAL

B is an array, dimension (LDB, kb), where kb is. k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDB must be at least max(1, n), otherwise LDB must be at least max(1, k).

BETA Input parameter.

BETA is REAL

On entry, BETA specifies the scalar beta.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n).

Related Information

For this routine in other precisions, please see *csyr2k*, *dsyr2k* and *zsyr2k*. It also exists with a native C interface as *cblas_ssyr2k*.

3.4.19 ssyrk

ssyrk performs one of the symmetric rank k operations

```
C := alpha*A*A**T + beta*C,
```

or

```
C := alpha*A**T*A + beta*C,
```

where alpha and beta are scalars, C is an n by n symmetric matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssyrk(UPLO, TRANS, N, K, ALPHA, A, LDA, BETA, C, LDC)
```

C specification:

```
#include "armpl.h"

void ssyrk_(const char *uplo, const char *trans, const armpl_int_t *n,
            const armpl_int_t *k, const float *alpha, const float *a,
            const armpl_int_t *lda, const float *beta, float *c,
            const armpl_int_t *ldc, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' C := alpha*A*A^T + beta*C.

TRANS = 'T' or 't' C := alpha*A^T * A + beta*C.

TRANS = 'C' or 'c' C := alpha*A^T * A + beta*C.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix C. N must be at least zero.

K Input parameter.

K is INTEGER

On entry with TRANS = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANS = 'T' or 't' or 'C' or 'c', K specifies the number of rows of the matrix A. K must be at least zero.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is REAL

A is an array, dimension (LDA, ka), where ka is. k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k).

BETA Input parameter.

BETA is REAL

On entry, BETA specifies the scalar beta.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly

upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n).

Related Information

For this routine in other precisions, please see *csyrk*, *dsyrk* and *zsyrk*. It also exists with a native C interface as *cblas_ssyrk*.

3.4.20 strmm

strmm performs one of the matrix-matrix operations

```
B := alpha*op( A )*B,   or   B := alpha*B*op( A ),
```

where alpha is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of

```
op( A ) = A   or   op( A ) = A**T.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine strmm(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B, LDB)
```

C specification:

```
#include "armpl.h"

void strmm_(const char *side, const char *uplo, const char *transa,
            const char *diag, const armpl_int_t *m, const armpl_int_t *n,
            const float *alpha, const float *a, const armpl_int_t *lda,
            float *b, const armpl_int_t *ldb, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

On entry, SIDE specifies whether op(A) multiplies B from the left or right as follows:

SIDE = 'L' or 'l' B := alpha*op(A)*B.

SIDE = 'R' or 'r' B := alpha*B*op(A).

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANSA Input parameter.

TRANSA is CHARACTER*1

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' op(A) = A.

TRANSA = 'T' or 't' op(A) = A^T .

TRANSA = 'C' or 'c' op(A) = A^T .

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of B. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of B. N must be at least zero.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry.

A Input parameter.

A is REAL

A is an array, dimension (LDA, k), where k is m. when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'. Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA must be at least max(1, m), when SIDE = 'R' or 'r' then LDA must be at least max(1, n).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). Before entry, the leading m by n part of the array B must contain the matrix B, and on exit is overwritten by the transformed matrix.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m).

Related Information

For this routine in other precisions, please see *ctrmm*, *dtrmm* and *ztrmm*. It also exists with a native C interface as *cblas_strmm*.

3.4.21 strsm

strsm solves one of the matrix equations

```
op( A )*X = alpha*B,   or   X*op( A ) = alpha*B,
```

where alpha is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of

```
op( A ) = A   or   op( A ) = A**T.
```

The matrix X is overwritten on B.

Syntax

Fortran specification:

```
use armpl_library

subroutine strsm(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B, LDB)
```

C specification:

```
#include "armpl.h"

void strsm_(const char *side, const char *uplo, const char *transa,
            const char *diag, const armpl_int_t *m, const armpl_int_t *n,
            const float *alpha, const float *a, const armpl_int_t *lda,
            float *b, const armpl_int_t *ldb, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

On entry, SIDE specifies whether op(A) appears on the left or right of X as follows:

SIDE = 'L' or 'l' op(A)*X = alpha*B.

SIDE = 'R' or 'r' X*op(A) = alpha*B.

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANSA Input parameter.

TRANSA is CHARACTER*1

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' op(A) = A.

TRANSA = 'T' or 't' op(A) = A^T .

TRANSA = 'C' or 'c' op(A) = A^T .

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of B. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of B. N must be at least zero.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry.

A Input parameter.

A is REAL

A is an array, dimension (LDA, k),. where k is m when SIDE = 'L' or 'l' and k is n when SIDE = 'R' or 'r'. Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA must be at least max(1, m), when SIDE = 'R' or 'r' then LDA must be at least max(1, n).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). Before entry, the leading m by n part of the array B must contain the right-hand side matrix B, and on exit is overwritten by the solution matrix X.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m).

Related Information

For this routine in other precisions, please see *ctrsm*, *dtrsm* and *ztrsm*. It also exists with a native C interface as *cblas_strsm*.

3.4.22 zgemm

zgemm performs one of the matrix-matrix operations

```
C := alpha*op( A )*op( B ) + beta*C,
```

where op(X) is one of

```
op( X ) = X   or   op( X ) = X**T   or   op( X ) = X**H,
```

alpha and beta are scalars, and A, B and C are matrices, with op(A) an m by k matrix, op(B) a k by n matrix and C an m by n matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgemm(TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB, BETA, C,
                 LDC)
```

C specification:

```
#include "armpl.h"

void zgemm_(const char *transa, const char *transb, const armpl_int_t *m,
            const armpl_int_t *n, const armpl_int_t *k,
            const armpl_doublecomplex_t *alpha,
            const armpl_doublecomplex_t *a, const armpl_int_t *lda,
            const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
            const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *c,
            const armpl_int_t *ldc, ... );
```

Parameters

TRANSA Input parameter.

TRANSA is CHARACTER*1

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n', op(A) = A.

TRANSA = 'T' or 't', op(A) = A^T .

TRANSA = 'C' or 'c', op(A) = A^H .

TRANSB Input parameter.

TRANSB is CHARACTER*1

On entry, TRANSB specifies the form of op(B) to be used in the matrix multiplication as follows:

TRANSB = 'N' or 'n', op(B) = B.

TRANSB = 'T' or 't', op(B) = B^T .

TRANSB = 'C' or 'c', op(B) = B^H .

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix op(A) and of the matrix C. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix op(B) and the number of columns of the matrix C. N must be at least zero.

K Input parameter.

K is INTEGER

On entry, K specifies the number of columns of the matrix op(A) and the number of rows of the matrix op(B). K must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, ka), where ka is. k when TRANSA = 'N' or 'n', and is m otherwise. Before entry with TRANSA = 'N' or 'n', the leading m by k part of the array A must contain the matrix A, otherwise the leading k by m part of the array A must contain the matrix A.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, m), otherwise LDA must be at least max(1, k).

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, kb), where kb is. n when TRANSB = 'N' or 'n', and is k otherwise. Before entry with TRANSB = 'N' or 'n', the leading k by n part of the array B must contain the matrix B, otherwise the leading n by k part of the array B must contain the matrix B.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSB = 'N' or 'n' then LDB must be at least max(1, k), otherwise LDB must be at least max(1, n).

BETA Input parameter.

BETA is COMPLEX*16

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n matrix (alpha*op(A)*op(B) + beta* C).

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, m).

Related Information

For this routine in other precisions, please see *cgemm*, *dgemm*, *hgemm*, and *sgemm*. It also exists with a native C interface as *cblas_zgemm*.

3.4.23 zhemm

zhemm performs one of the matrix-matrix operations

```
C := alpha*A*B + beta*C,
```

or

```
C := alpha*B*A + beta*C,
```

where alpha and beta are scalars, A is an hermitian matrix and B and C are m by n matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhemm(SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C, LDC)
```

C specification:

```
#include "armpl.h"

void zhemm_(const char *side, const char *uplo, const armpl_int_t *m,
            const armpl_int_t *n, const armpl_doublecomplex_t *alpha,
            const armpl_doublecomplex_t *a, const armpl_int_t *lda,
            const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
            const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *c,
            const armpl_int_t *ldc, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

On entry, SIDE specifies whether the hermitian matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l' C := alpha*A* B + beta*C,

SIDE = 'R' or 'r' C := alpha*B* A + beta*C,

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the hermitian matrix A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of the hermitian matrix is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of the hermitian matrix is to be referenced.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix C. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix C. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, ka), where ka is. m when SIDE = 'L' or 'l' and is n otherwise. Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the hermitian matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the hermitian matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA must be at least max(1, m), otherwise LDA must be at least max(1, n).

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). Before entry, the leading m by n part of the array B must contain the matrix B.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m).

BETA Input parameter.

BETA is COMPLEX*16

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n updated matrix.

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, m).

Related Information

For this routine in other precisions, please see *chemm*. It also exists with a native C interface as *cblas_zhemm*.

3.4.24 zher2k

zher2k performs one of the hermitian rank 2k operations

```
C := alpha*A*B**H + conjg( alpha )*B*A**H + beta*C,
```

or

```
C := alpha*A**H*B + conjg( alpha )*B**H*A + beta*C,
```

where alpha and beta are scalars with beta real, C is an n by n hermitian matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

Syntax

Fortran specification:

```
use armpl_library

subroutine zher2k(UPLO, TRANS, N, K, ALPHA, A, LDA, B, LDB, BETA, C, LDC)
```

C specification:

```
#include "armpl.h"

void zher2k_(const char *uplo, const char *trans, const armpl_int_t *n,
             const armpl_int_t *k, const armpl_doublecomplex_t *alpha,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             const double *beta, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' C := alpha*A*B^H + conjg(alpha)*B*A^H + beta*C.

TRANS = 'C' or 'c' C := alpha*A^H * B + conjg(alpha)*B^H * A + beta*C.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix C. N must be at least zero.

K Input parameter.

K is INTEGER

On entry with TRANS = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANS = 'C' or 'c', K specifies the number of rows of the matrices A and B. K must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX*16 .

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, ka), where ka is. k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k).

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, kb), where kb is. k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDB must be at least max(1, n), otherwise LDB must be at least max(1, k). Unchanged on exit.

BETA Input parameter.

BETA is DOUBLE PRECISION .

On entry, BETA specifies the scalar beta.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the hermitian matrix and the strictly

upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n).

Related Information

For this routine in other precisions, please see *cher2k*. It also exists with a native C interface as *cblas_zher2k*.

3.4.25 zherk

zherk performs one of the hermitian rank k operations

```
C := alpha*A*A**H + beta*C,
```

or

```
C := alpha*A**H*A + beta*C,
```

where alpha and beta are real scalars, C is an n by n hermitian matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

Syntax

Fortran specification:

```
use armpl_library

subroutine zherk(UPLO, TRANS, N, K, ALPHA, A, LDA, BETA, C, LDC)
```

C specification:

```
#include "armpl.h"

void zherk_(const char *uplo, const char *trans, const armpl_int_t *n,
            const armpl_int_t *k, const double *alpha,
            const armpl_doublecomplex_t *a, const armpl_int_t *lda,
            const double *beta, armpl_doublecomplex_t *c,
            const armpl_int_t *ldc, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' C := alpha*A*A^H + beta*C.

TRANS = 'C' or 'c' C := alpha*A^H * A + beta*C.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix C. N must be at least zero.

K Input parameter.

K is INTEGER

On entry with TRANS = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANS = 'C' or 'c', K specifies the number of rows of the matrix A. K must be at least zero.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION .

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, ka), where ka is. k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k).

BETA Input parameter.

BETA is DOUBLE PRECISION.

On entry, BETA specifies the scalar beta.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n).

Related Information

For this routine in other precisions, please see *cherk*. It also exists with a native C interface as *cblas_zherk*.

3.4.26 zsymm

zsymm performs one of the matrix-matrix operations

```
C := alpha*A*B + beta*C,
```

or

```
C := alpha*B*A + beta*C,
```

where alpha and beta are scalars, A is a symmetric matrix and B and C are m by n matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsymm(SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C, LDC)
```

C specification:

```
#include "armpl.h"

void zsymm_(const char *side, const char *uplo, const armpl_int_t *m,
            const armpl_int_t *n, const armpl_doublecomplex_t *alpha,
            const armpl_doublecomplex_t *a, const armpl_int_t *lda,
            const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
            const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *c,
            const armpl_int_t *ldc, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

On entry, SIDE specifies whether the symmetric matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l' C := alpha*A* B + beta*C,

SIDE = 'R' or 'r' C := alpha*B* A + beta*C,

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of the symmetric matrix is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of the symmetric matrix is to be referenced.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix C. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix C. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, ka), where ka is. m when SIDE = 'L' or 'l' and is n otherwise. Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA must be at least max(1, m), otherwise LDA must be at least max(1, n).

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). Before entry, the leading m by n part of the array B must contain the matrix B.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m).

BETA Input parameter.

BETA is COMPLEX*16

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n updated matrix.

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, m).

Related Information

For this routine in other precisions, please see *csymm*, *dsymm* and *ssymm*. It also exists with a native C interface as *cblas_zsymm*.

3.4.27 zsyr2k

`zsyr2k` performs one of the symmetric rank 2k operations

```
C := alpha*A*B**T + alpha*B*A**T + beta*C,
```

or

```
C := alpha*A**T*B + alpha*B**T*A + beta*C,
```

where alpha and beta are scalars, C is an n by n symmetric matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsyr2k(UPLO, TRANS, N, K, ALPHA, A, LDA, B, LDB, BETA, C, LDC)
```

C specification:

```
#include "armpl.h"

void zsyr2k_(const char *uplo, const char *trans, const armpl_int_t *n,
             const armpl_int_t *k, const armpl_doublecomplex_t *alpha,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

On entry, `UPLO` specifies whether the upper or lower triangular part of the array `C` is to be referenced as follows:

`UPLO` = 'U' or 'u' Only the upper triangular part of C is to be referenced.

`UPLO` = 'L' or 'l' Only the lower triangular part of C is to be referenced.

TRANS Input parameter.

`TRANS` is `CHARACTER*1`

On entry, `TRANS` specifies the operation to be performed as follows:

`TRANS` = 'N' or 'n' `C` := alpha*A*B^T + alpha*B*A^T + beta*C.

`TRANS` = 'T' or 't' `C` := alpha*A^T * `B` + alpha*B^T * `A` + beta*C.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix C. N must be at least zero.

K Input parameter.

K is INTEGER

On entry with TRANS = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANS = 'T' or 't', K specifies the number of rows of the matrices A and B. K must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, ka), where ka is. k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k).

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, kb), where kb is. k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDB must be at least max(1, n), otherwise LDB must be at least max(1, k).

BETA Input parameter.

BETA is COMPLEX*16

On entry, BETA specifies the scalar beta.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n).

Related Information

For this routine in other precisions, please see *csyr2k*, *dsyr2k* and *ssyr2k*. It also exists with a native C interface as *cblas_zsyr2k*.

3.4.28 zsyrk

`zsyrk` performs one of the symmetric rank k operations

```
C := alpha*A*A**T + beta*C,
```

or

```
C := alpha*A**T*A + beta*C,
```

where alpha and beta are scalars, C is an n by n symmetric matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsyrk(UPLO, TRANS, N, K, ALPHA, A, LDA, BETA, C, LDC)
```

C specification:

```
#include "armpl.h"

void zsyrk_(const char *uplo, const char *trans, const armpl_int_t *n,
            const armpl_int_t *k, const armpl_doublecomplex_t *alpha,
            const armpl_doublecomplex_t *a, const armpl_int_t *lda,
            const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *c,
            const armpl_int_t *ldc, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

On entry, `UPLO` specifies whether the upper or lower triangular part of the array `C` is to be referenced as follows:

`UPLO` = '`U`' or '`u`' Only the upper triangular part of C is to be referenced.

`UPLO` = '`L`' or '`l`' Only the lower triangular part of C is to be referenced.

TRANS Input parameter.

`TRANS` is `CHARACTER*1`

On entry, `TRANS` specifies the operation to be performed as follows:

`TRANS` = '`N`' or '`n`' `C` := alpha*A*A^T + beta*C.

`TRANS` = '`T`' or '`t`' `C` := alpha*A^T * `A` + beta*C.

N Input parameter.

`N` is `INTEGER`

On entry, N specifies the order of the matrix C. N must be at least zero.

K Input parameter.

K is INTEGER

On entry with TRANS = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANS = 'T' or 't', K specifies the number of rows of the matrix A. K must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, ka), where ka is. k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k).

BETA Input parameter.

BETA is COMPLEX*16

On entry, BETA specifies the scalar beta.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n).

Related Information

For this routine in other precisions, please see *csyrk*, *dsyrk* and *ssyrk*. It also exists with a native C interface as *cblas_zsyrk*.

3.4.29 ztrmm

ztrmm performs one of the matrix-matrix operations

```
B := alpha*op( A )*B,   or   B := alpha*B*op( A )
```

where alpha is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of

```
op( A ) = A   or   op( A ) = A**T   or   op( A ) = A**H.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine ztrmm(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B, LDB)
```

C specification:

```
#include "armpl.h"

void ztrmm_(const char *side, const char *uplo, const char *transa,
            const char *diag, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_doublecomplex_t *alpha,
            const armpl_doublecomplex_t *a, const armpl_int_t *lda,
            armpl_doublecomplex_t *b, const armpl_int_t *ldb, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

On entry, SIDE specifies whether op(A) multiplies B from the left or right as follows:

SIDE = 'L' or 'l' B := alpha*op(A)*B.

SIDE = 'R' or 'r' B := alpha*B*op(A).

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANSA Input parameter.

TRANSA is CHARACTER*1

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' op(A) = A.

TRANSA = 'T' or 't' op(A) = A^T .

TRANSA = 'C' or 'c' op(A) = A^H .

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of B. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of B. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, k), where k is m. when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'. Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA must be at least max(1, m), when SIDE = 'R' or 'r' then LDA must be at least max(1, n).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N).. Before entry, the leading m by n part of the array B must contain the matrix B, and on exit is overwritten by the transformed matrix.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m).

Related Information

For this routine in other precisions, please see *ctrmm*, *dtrmm* and *strmm*. It also exists with a native C interface as *cblas_ztrmm*.

3.4.30 ztrsm

ztrsm solves one of the matrix equations

```
op( A )*X = alpha*B,   or   X*op( A ) = alpha*B,
```

where alpha is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of

```
op( A ) = A   or   op( A ) = A**T   or   op( A ) = A**H.
```

The matrix X is overwritten on B.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztrsm(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B, LDB)
```

C specification:

```
#include "armpl.h"

void ztrsm_(const char *side, const char *uplo, const char *transa,
            const char *diag, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_doublecomplex_t *alpha,
            const armpl_doublecomplex_t *a, const armpl_int_t *lda,
            armpl_doublecomplex_t *b, const armpl_int_t *ldb, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

On entry, SIDE specifies whether op(A) appears on the left or right of X as follows:

SIDE = 'L' or 'l' op(A)*X = alpha*B.

SIDE = 'R' or 'r' X*op(A) = alpha*B.

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

TRANSA Input parameter.

TRANSA is CHARACTER*1

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' op(A) = A.

TRANSA = 'T' or 't' op(A) = A^T .

TRANSA = 'C' or 'c' op(A) = A^H .

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of B. M must be at least zero.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of B. N must be at least zero.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, k),. where k is m when SIDE = 'L' or 'l' and k is n when SIDE = 'R' or 'r'. Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA must be at least max(1, m), when SIDE = 'R' or 'r' then LDA must be at least max(1, n).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). Before entry, the leading m by n part of the array B must contain the right-hand side matrix B, and on exit is overwritten by the solution matrix X.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m).

Related Information

For this routine in other precisions, please see *ctrsm*, *dtrsm* and *strsm*. It also exists with a native C interface as *cblas_ztrsm*.

Level 3 BLAS routines are the computationally intensive routines, normally working on multiple dense matrices. All functions are detailed in armpl.h.

3.5 CBLAS functions

3.5.1 cblas_caxpby

Syntax

```
#include "armpl.h"

void cblas_caxpby(armpl_int_t N, const armpl_singlecomplex_t *alpha,
                  const armpl_singlecomplex_t *X, armpl_int_t incX,
```

(continues on next page)

(continued from previous page)

```
                    const armpl_singlecomplex_t *beta,
                    armpl_singlecomplex_t *Y, armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_caxpby*, *cblas_saxpy* and *cblas_zaxpby*. It also exists with a native Fortran interface as *caxpby*.

3.5.2 cblas_caxpy

Syntax

```
#include "armpl.h"

void cblas_caxpy(const armpl_int_t N, const armpl_singlecomplex_t*alpha,
                 const armpl_singlecomplex_t*X, const armpl_int_t incX,
                 armpl_singlecomplex_t*Y, const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_daxpy*, *cblas_saxpy* and *cblas_zaxpy*. It also exists with a native Fortran interface as *caxpy*.

3.5.3 cblas_ccopy

Syntax

```
#include "armpl.h"

void cblas_ccopy(const armpl_int_t N, const armpl_singlecomplex_t*X,
                 const armpl_int_t incX, armpl_singlecomplex_t*Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dcopy*, *cblas_scopy* and *cblas_zcopy*. It also exists with a native Fortran interface as *ccopy*.

3.5.4 cblas_cgbmv

Syntax

```
#include "armpl.h"

void cblas_cgbmv(const enum CBLAS_ORDER order,
                 const enum CBLAS_TRANSPOSE TransA, const armpl_int_t M,
                 const armpl_int_t N, const armpl_int_t KL,
                 const armpl_int_t KU, const armpl_singlecomplex_t*alpha,
                 const armpl_singlecomplex_t*A, const armpl_int_t lda,
                 const armpl_singlecomplex_t*X, const armpl_int_t incX,
                 const armpl_singlecomplex_t*beta, armpl_singlecomplex_t*Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dgbmv*, *cblas_sgbmv* and *cblas_zgbmv*. It also exists with a native Fortran interface as *cgbmv*.

3.5.5 cblas_cgemm

Syntax

```
#include "armpl.h"

void cblas_cgemm(const enum CBLAS_ORDER Order,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_TRANSPOSE TransB, const armpl_int_t M,
                 const armpl_int_t N, const armpl_int_t K,
                 const armpl_singlecomplex_t*alpha,
                 const armpl_singlecomplex_t*A, const armpl_int_t lda,
                 const armpl_singlecomplex_t*B, const armpl_int_t ldb,
                 const armpl_singlecomplex_t*beta, armpl_singlecomplex_t*C,
                 const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dgemm*, *cblas_sgemm* and *cblas_zgemm*. It also exists with a native Fortran interface as *cgemm*.

3.5.6 cblas_cgemm3m

Syntax

```
#include "armpl.h"

void cblas_cgemm3m(const enum CBLAS_ORDER Order,
                   const enum CBLAS_TRANSPOSE TransA,
                   const enum CBLAS_TRANSPOSE TransB, const armpl_int_t M,
```

(continues on next page)

(continued from previous page)

```
                    const armpl_int_t N, const armpl_int_t K,
                    const armpl_singlecomplex_t *alpha,
                    const armpl_singlecomplex_t *A, const armpl_int_t lda,
                    const armpl_singlecomplex_t *B, const armpl_int_t ldb,
                    const armpl_singlecomplex_t *beta,
                    armpl_singlecomplex_t *C, const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zgemm3m*. It also exists with a native Fortran interface as *cgemm3m*.

3.5.7 cblas_cgemv

Syntax

```
#include "armpl.h"

void cblas_cgemv(const enum CBLAS_ORDER order,
                 const enum CBLAS_TRANSPOSE TransA, const armpl_int_t M,
                 const armpl_int_t N, const armpl_singlecomplex_t*alpha,
                 const armpl_singlecomplex_t*A, const armpl_int_t lda,
                 const armpl_singlecomplex_t*X, const armpl_int_t incX,
                 const armpl_singlecomplex_t*beta, armpl_singlecomplex_t*Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dgemv*, *cblas_sgemv* and *cblas_zgemv*. It also exists with a native Fortran interface as *cgemv*.

3.5.8 cblas_cgerc

Syntax

```
#include "armpl.h"

void cblas_cgerc(const enum CBLAS_ORDER order, const armpl_int_t M,
                 const armpl_int_t N, const armpl_singlecomplex_t*alpha,
                 const armpl_singlecomplex_t*X, const armpl_int_t incX,
                 const armpl_singlecomplex_t*Y, const armpl_int_t incY,
                 armpl_singlecomplex_t*A, const armpl_int_t lda);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zgerc*. It also exists with a native Fortran interface as *cgerc*.

3.5.9 cblas_cgeru

Syntax

```
#include "armpl.h"

void cblas_cgeru(const enum CBLAS_ORDER order, const armpl_int_t M,
                 const armpl_int_t N, const armpl_singlecomplex_t*alpha,
                 const armpl_singlecomplex_t*X, const armpl_int_t incX,
                 const armpl_singlecomplex_t*Y, const armpl_int_t incY,
                 armpl_singlecomplex_t*A, const armpl_int_t lda);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zgeru*. It also exists with a native Fortran interface as *cgeru*.

3.5.10 cblas_chbmv

Syntax

```
#include "armpl.h"

void cblas_chbmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const armpl_int_t N, const armpl_int_t K,
                 const armpl_singlecomplex_t*alpha,
                 const armpl_singlecomplex_t*A, const armpl_int_t lda,
                 const armpl_singlecomplex_t*X, const armpl_int_t incX,
                 const armpl_singlecomplex_t*beta, armpl_singlecomplex_t*Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zhbmv*. It also exists with a native Fortran interface as *chbmv*.

3.5.11 cblas_chemm

Syntax

```
#include "armpl.h"

void cblas_chemm(const enum CBLAS_ORDER Order, const enum CBLAS_SIDE Side,
                 const enum CBLAS_UPLO Uplo, const armpl_int_t M,
                 const armpl_int_t N, const armpl_singlecomplex_t*alpha,
                 const armpl_singlecomplex_t*A, const armpl_int_t lda,
```

(continues on next page)

(continued from previous page)

```
                const armpl_singlecomplex_t*B, const armpl_int_t ldb,
                const armpl_singlecomplex_t*beta, armpl_singlecomplex_t*C,
                const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zhemm*. It also exists with a native Fortran interface as *chemm*.

3.5.12 cblas_chemv

Syntax

```
#include "armpl.h"

void cblas_chemv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                const armpl_int_t N, const armpl_singlecomplex_t*alpha,
                const armpl_singlecomplex_t*A, const armpl_int_t lda,
                const armpl_singlecomplex_t*X, const armpl_int_t incX,
                const armpl_singlecomplex_t*beta, armpl_singlecomplex_t*Y,
                const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zhemv*. It also exists with a native Fortran interface as *chemv*.

3.5.13 cblas_cher

Syntax

```
#include "armpl.h"

void cblas_cher(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                const armpl_int_t N, const float alpha,
                const armpl_singlecomplex_t*X, const armpl_int_t incX,
                armpl_singlecomplex_t*A, const armpl_int_t lda);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zher*. It also exists with a native Fortran interface as *cher*.

3.5.14 cblas_cher2

Syntax

```
#include "armpl.h"

void cblas_cher2(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const armpl_int_t N, const armpl_singlecomplex_t*alpha,
                 const armpl_singlecomplex_t*X, const armpl_int_t incX,
                 const armpl_singlecomplex_t*Y, const armpl_int_t incY,
                 armpl_singlecomplex_t*A, const armpl_int_t lda);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zher2*. It also exists with a native Fortran interface as *cher2*.

3.5.15 cblas_cher2k

Syntax

```
#include "armpl.h"

void cblas_cher2k(const enum CBLAS_ORDER Order, const enum CBLAS_UPLO Uplo,
                  const enum CBLAS_TRANSPOSE Trans, const armpl_int_t N,
                  const armpl_int_t K, const armpl_singlecomplex_t*alpha,
                  const armpl_singlecomplex_t*A, const armpl_int_t lda,
                  const armpl_singlecomplex_t*B, const armpl_int_t ldb,
                  const float beta, armpl_singlecomplex_t*C,
                  const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zher2k*. It also exists with a native Fortran interface as *cher2k*.

3.5.16 cblas_cherk

Syntax

```
#include "armpl.h"

void cblas_cherk(const enum CBLAS_ORDER Order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE Trans, const armpl_int_t N,
                 const armpl_int_t K, const float alpha,
                 const armpl_singlecomplex_t*A, const armpl_int_t lda,
                 const float beta, armpl_singlecomplex_t*C,
                 const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zherk*. It also exists with a native Fortran interface as *cherk*.

3.5.17 cblas_chpmv

Syntax

```
#include "armpl.h"

void cblas_chpmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const armpl_int_t N, const armpl_singlecomplex_t*alpha,
                 const armpl_singlecomplex_t*Ap,
                 const armpl_singlecomplex_t*X, const armpl_int_t incX,
                 const armpl_singlecomplex_t*beta, armpl_singlecomplex_t*Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zhpmv*. It also exists with a native Fortran interface as *chpmv*.

3.5.18 cblas_chpr

Syntax

```
#include "armpl.h"

void cblas_chpr(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                const armpl_int_t N, const float alpha,
                const armpl_singlecomplex_t*X, const armpl_int_t incX,
                armpl_singlecomplex_t*A);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zhpr*. It also exists with a native Fortran interface as *chpr*.

3.5.19 cblas_chpr2

Syntax

```
#include "armpl.h"

void cblas_chpr2(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const armpl_int_t N, const armpl_singlecomplex_t*alpha,
                 const armpl_singlecomplex_t*X, const armpl_int_t incX,
                 const armpl_singlecomplex_t*Y, const armpl_int_t incY,
                 armpl_singlecomplex_t*Ap);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zhpr2*. It also exists with a native Fortran interface as *chpr2*.

3.5.20 cblas_cscal

Syntax

```
#include "armpl.h"

void cblas_cscal(const armpl_int_t N, const armpl_singlecomplex_t*alpha,
                 armpl_singlecomplex_t*X, const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dscal*, *cblas_sscal* and *cblas_zscal*. It also exists with a native Fortran interface as *cscal*.

3.5.21 cblas_csscal

Syntax

```
#include "armpl.h"

void cblas_csscal(const armpl_int_t N, const float alpha,
                  armpl_singlecomplex_t*X, const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

It also exists with a native Fortran interface as *csscal*.

3.5.22 cblas_cswap

Syntax

```
#include "armpl.h"

void cblas_cswap(const armpl_int_t N, armpl_singlecomplex_t*X,
                 const armpl_int_t incX, armpl_singlecomplex_t*Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dswap*, *cblas_sswap* and *cblas_zswap*. It also exists with a native Fortran interface as *cswap*.

3.5.23 cblas_csymm

Syntax

```
#include "armpl.h"

void cblas_csymm(const enum CBLAS_ORDER Order, const enum CBLAS_SIDE Side,
                 const enum CBLAS_UPLO Uplo, const armpl_int_t M,
                 const armpl_int_t N, const armpl_singlecomplex_t*alpha,
                 const armpl_singlecomplex_t*A, const armpl_int_t lda,
                 const armpl_singlecomplex_t*B, const armpl_int_t ldb,
                 const armpl_singlecomplex_t*beta, armpl_singlecomplex_t*C,
                 const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsymm*, *cblas_ssymm* and *cblas_zsymm*. It also exists with a native Fortran interface as *csymm*.

3.5.24 cblas_csyr2k

Syntax

```
#include "armpl.h"

void cblas_csyr2k(const enum CBLAS_ORDER Order, const enum CBLAS_UPLO Uplo,
                  const enum CBLAS_TRANSPOSE Trans, const armpl_int_t N,
                  const armpl_int_t K, const armpl_singlecomplex_t*alpha,
                  const armpl_singlecomplex_t*A, const armpl_int_t lda,
                  const armpl_singlecomplex_t*B, const armpl_int_t ldb,
                  const armpl_singlecomplex_t*beta, armpl_singlecomplex_t*C,
                  const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsyr2k*, *cblas_ssyr2k* and *cblas_zsyr2k*. It also exists with a native Fortran interface as *csyr2k*.

3.5.25 cblas_csyrk

Syntax

```
#include "armpl.h"

void cblas_csyrk(const enum CBLAS_ORDER Order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE Trans, const armpl_int_t N,
                 const armpl_int_t K, const armpl_singlecomplex_t*alpha,
                 const armpl_singlecomplex_t*A, const armpl_int_t lda,
                 const armpl_singlecomplex_t*beta, armpl_singlecomplex_t*C,
                 const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsyrk*, *cblas_ssyrk* and *cblas_zsyrk*. It also exists with a native Fortran interface as *csyrk*.

3.5.26 cblas_ctbmv

Syntax

```
#include "armpl.h"

void cblas_ctbmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const armpl_int_t K, const armpl_singlecomplex_t*A,
                 const armpl_int_t lda, armpl_singlecomplex_t*X,
                 const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtbmv*, *cblas_stbmv* and *cblas_ztbmv*. It also exists with a native Fortran interface as *ctbmv*.

3.5.27 cblas_ctbsv

Syntax

```
#include "armpl.h"

void cblas_ctbsv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const armpl_int_t K, const armpl_singlecomplex_t*A,
                 const armpl_int_t lda, armpl_singlecomplex_t*X,
                 const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtbsv*, *cblas_stbsv* and *cblas_ztbsv*. It also exists with a native Fortran interface as *ctbsv*.

3.5.28 cblas_ctpmv

Syntax

```
#include "armpl.h"

void cblas_ctpmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const armpl_singlecomplex_t*Ap, armpl_singlecomplex_t*X,
                 const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtpmv*, *cblas_stpmv* and *cblas_ztpmv*. It also exists with a native Fortran interface as *ctpmv*.

3.5.29 cblas_ctpsv

Syntax

```
#include "armpl.h"

void cblas_ctpsv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const armpl_singlecomplex_t*Ap, armpl_singlecomplex_t*X,
                 const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtpsv*, *cblas_stpsv* and *cblas_ztpsv*. It also exists with a native Fortran interface as *ctpsv*.

3.5.30 cblas_ctrmm

Syntax

```
#include "armpl.h"

void cblas_ctrmm(const enum CBLAS_ORDER Order, const enum CBLAS_SIDE Side,
                 const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t M,
                 const armpl_int_t N, const armpl_singlecomplex_t*alpha,
                 const armpl_singlecomplex_t*A, const armpl_int_t lda,
                 armpl_singlecomplex_t*B, const armpl_int_t ldb);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtrmm*, *cblas_strmm* and *cblas_ztrmm*. It also exists with a native Fortran interface as *ctrmm*.

3.5.31 cblas_ctrmv

Syntax

```
#include "armpl.h"

void cblas_ctrmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const armpl_singlecomplex_t*A, const armpl_int_t lda,
                 armpl_singlecomplex_t*X, const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtrmv*, *cblas_strmv* and *cblas_ztrmv*. It also exists with a native Fortran interface as *ctrmv*.

3.5.32 cblas_ctrsm

Syntax

```
#include "armpl.h"

void cblas_ctrsm(const enum CBLAS_ORDER Order, const enum CBLAS_SIDE Side,
                 const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t M,
                 const armpl_int_t N, const armpl_singlecomplex_t*alpha,
                 const armpl_singlecomplex_t*A, const armpl_int_t lda,
                 armpl_singlecomplex_t*B, const armpl_int_t ldb);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtrsm*, *cblas_strsm* and *cblas_ztrsm*. It also exists with a native Fortran interface as *ctrsm*.

3.5.33 cblas_ctrsv

Syntax

```
#include "armpl.h"

void cblas_ctrsv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const armpl_singlecomplex_t*A, const armpl_int_t lda,
                 armpl_singlecomplex_t*X, const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtrsv*, *cblas_strsv* and *cblas_ztrsv*. It also exists with a native Fortran interface as *ctrsv*.

3.5.34 cblas_cwaxpby

Syntax

```
#include "armpl.h"

void cblas_cwaxpby(armpl_int_t N, const armpl_singlecomplex_t *alpha,
                   const armpl_singlecomplex_t *X, armpl_int_t incX,
                   const armpl_singlecomplex_t *beta,
                   armpl_singlecomplex_t *Y, armpl_int_t incY,
                   armpl_singlecomplex_t *W, armpl_int_t incw);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dwaxpby*, *cblas_swaxpby* and *cblas_zwaxpby*. It also exists with a native Fortran interface as *cwaxpby*.

3.5.35 cblas_dasum

Syntax

```
#include "armpl.h"

double cblas_dasum(const armpl_int_t N, const double *X,
                   const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dasum* and *cblas_sasum*. It also exists with a native Fortran interface as *dasum*.

3.5.36 cblas_caxpby

Syntax

```
#include "armpl.h"

void cblas_daxpby(armpl_int_t N, const double *alpha,const double *X,
                  armpl_int_t incX, const double *beta, double *Y,
                  armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_caxpby*, *cblas_saxpby* and *cblas_zaxpby*. It also exists with a native Fortran interface as *daxpby*.

3.5.37 cblas_daxpy

Syntax

```
#include "armpl.h"

void cblas_daxpy(const armpl_int_t N, const double alpha, const double *X,
                 const armpl_int_t incX, double *Y, const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_daxpy*, *cblas_saxpy* and *cblas_zaxpy*. It also exists with a native Fortran interface as *daxpy*.

3.5.38 cblas_dcopy

Syntax

```
#include "armpl.h"

void cblas_dcopy(const armpl_int_t N, const double *X, const armpl_int_t incX,
                 double *Y, const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dcopy*, *cblas_scopy* and *cblas_zcopy*. It also exists with a native Fortran interface as *dcopy*.

3.5.39 cblas_ddot

Syntax

```
#include "armpl.h"

double cblas_ddot(const armpl_int_t N, const double *X,
                  const armpl_int_t incX, const double *Y,
                  const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_ddot* and *cblas_sdot*. It also exists with a native Fortran interface as *ddot*.

3.5.40 cblas_dgbmv

Syntax

```
#include "armpl.h"

void cblas_dgbmv(const enum CBLAS_ORDER order,
                 const enum CBLAS_TRANSPOSE TransA, const armpl_int_t M,
                 const armpl_int_t N, const armpl_int_t KL,
                 const armpl_int_t KU, const double alpha, const double *A,
                 const armpl_int_t lda, const double *X,
                 const armpl_int_t incX, const double beta, double *Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dgbmv*, *cblas_sgbmv* and *cblas_zgbmv*. It also exists with a native Fortran interface as *dgbmv*.

3.5.41 cblas_dgemm

Syntax

```
#include "armpl.h"

void cblas_dgemm(const enum CBLAS_ORDER Order,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_TRANSPOSE TransB, const armpl_int_t M,
                 const armpl_int_t N, const armpl_int_t K, const double alpha,
                 const double *A, const armpl_int_t lda, const double *B,
                 const armpl_int_t ldb, const double beta, double *C,
                 const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dgemm*, *cblas_sgemm* and *cblas_zgemm*. It also exists with a native Fortran interface as *dgemm*.

3.5.42 cblas_dgemv

Syntax

```
#include "armpl.h"

void cblas_dgemv(const enum CBLAS_ORDER order,
                 const enum CBLAS_TRANSPOSE TransA, const armpl_int_t M,
                 const armpl_int_t N, const double alpha, const double *A,
                 const armpl_int_t lda, const double *X,
                 const armpl_int_t incX, const double beta, double *Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dgemv*, *cblas_sgemv* and *cblas_zgemv*. It also exists with a native Fortran interface as *dgemv*.

3.5.43 cblas_dger

Syntax

```
#include "armpl.h"

void cblas_dger(const enum CBLAS_ORDER order, const armpl_int_t M,
                const armpl_int_t N, const double alpha, const double *X,
                const armpl_int_t incX, const double *Y,
                const armpl_int_t incY, double *A, const armpl_int_t lda);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dger* and *cblas_sger*. It also exists with a native Fortran interface as *dger*.

3.5.44 cblas_dnrm2

Syntax

```
#include "armpl.h"

double cblas_dnrm2(const armpl_int_t N, const double *X,
                   const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dnrm2* and *cblas_snrm2*. It also exists with a native Fortran interface as *dnrm2*.

3.5.45 cblas_drot

Syntax

```
#include "armpl.h"

void cblas_drot(const armpl_int_t N, double *X, const armpl_int_t incX,
                double *Y, const armpl_int_t incY, const double c,
                const double s);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_drot* and *cblas_srot*. It also exists with a native Fortran interface as *drot*.

3.5.46 cblas_drotg

Syntax

```
#include "armpl.h"

void cblas_drotg(double *a, double *b, double *c, double *s);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_drotg* and *cblas_srotg*. It also exists with a native Fortran interface as *drotg*.

3.5.47 cblas_drotm

Syntax

```
#include "armpl.h"

void cblas_drotm(const armpl_int_t N, double *X, const armpl_int_t incX,
                 double *Y, const armpl_int_t incY, const double *P);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_drotm* and *cblas_srotm*. It also exists with a native Fortran interface as *drotm*.

3.5.48 cblas_drotmg

Syntax

```
#include "armpl.h"

void cblas_drotmg(double *d1, double *d2, double *b1, const double b2,
                  double *P);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_drotmg* and *cblas_srotmg*. It also exists with a native Fortran interface as *drotmg*.

3.5.49 cblas_dsbmv

Syntax

```
#include "armpl.h"

void cblas_dsbmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const armpl_int_t N, const armpl_int_t K, const double alpha,
                 const double *A, const armpl_int_t lda, const double *X,
                 const armpl_int_t incX, const double beta, double *Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsbmv* and *cblas_ssbmv*. It also exists with a native Fortran interface as *dsbmv*.

3.5.50 cblas_dscal

Syntax

```
#include "armpl.h"

void cblas_dscal(const armpl_int_t N, const double alpha, double *X,
                 const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dscal*, *cblas_sscal* and *cblas_zscal*. It also exists with a native Fortran interface as *dscal*.

3.5.51 cblas_dsdot

Syntax

```
#include "armpl.h"

double cblas_dsdot(const armpl_int_t N, const float *X,
                   const armpl_int_t incX, const float *Y,
                   const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsdot*. It also exists with a native Fortran interface as *dsdot*.

3.5.52 cblas_dspmv

Syntax

```
#include "armpl.h"

void cblas_dspmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const armpl_int_t N, const double alpha, const double *Ap,
                 const double *X, const armpl_int_t incX, const double beta,
                 double *Y, const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dspmv* and *cblas_sspmv*. It also exists with a native Fortran interface as *dspmv*.

3.5.53 cblas_dspr

Syntax

```
#include "armpl.h"

void cblas_dspr(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                const armpl_int_t N, const double alpha, const double *X,
                const armpl_int_t incX, double *Ap);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dspr* and *cblas_sspr*. It also exists with a native Fortran interface as *dspr*.

3.5.54 cblas_dspr2

Syntax

```
#include "armpl.h"

void cblas_dspr2(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const armpl_int_t N, const double alpha, const double *X,
                 const armpl_int_t incX, const double *Y,
                 const armpl_int_t incY, double *A);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dspr2* and *cblas_sspr2*. It also exists with a native Fortran interface as *dspr2*.

3.5.55 cblas_dswap

Syntax

```
#include "armpl.h"

void cblas_dswap(const armpl_int_t N, double *X, const armpl_int_t incX,
                 double *Y, const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dswap*, *cblas_sswap* and *cblas_zswap*. It also exists with a native Fortran interface as *dswap*.

3.5.56 cblas_dsymm

Syntax

```
#include "armpl.h"

void cblas_dsymm(const enum CBLAS_ORDER Order, const enum CBLAS_SIDE Side,
                 const enum CBLAS_UPLO Uplo, const armpl_int_t M,
                 const armpl_int_t N, const double alpha, const double *A,
                 const armpl_int_t lda, const double *B,
                 const armpl_int_t ldb, const double beta, double *C,
                 const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsymm*, *cblas_ssymm* and *cblas_zsymm*. It also exists with a native Fortran interface as *dsymm*.

3.5.57 cblas_dsymv

Syntax

```
#include "armpl.h"

void cblas_dsymv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const armpl_int_t N, const double alpha, const double *A,
                 const armpl_int_t lda, const double *X,
                 const armpl_int_t incX, const double beta, double *Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsymv* and *cblas_ssymv*. It also exists with a native Fortran interface as *dsymv*.

3.5.58 cblas_dsyr

Syntax

```
#include "armpl.h"

void cblas_dsyr(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                const armpl_int_t N, const double alpha, const double *X,
                const armpl_int_t incX, double *A, const armpl_int_t lda);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsyr* and *cblas_ssyr*. It also exists with a native Fortran interface as *dsyr*.

3.5.59 cblas_dsyr2

Syntax

```
#include "armpl.h"

void cblas_dsyr2(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const armpl_int_t N, const double alpha, const double *X,
                 const armpl_int_t incX, const double *Y,
                 const armpl_int_t incY, double *A, const armpl_int_t lda);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsyr2* and *cblas_ssyr2*. It also exists with a native Fortran interface as *dsyr2*.

3.5.60 cblas_dsyr2k

Syntax

```
#include "armpl.h"

void cblas_dsyr2k(const enum CBLAS_ORDER Order, const enum CBLAS_UPLO Uplo,
                  const enum CBLAS_TRANSPOSE Trans, const armpl_int_t N,
                  const armpl_int_t K, const double alpha, const double *A,
                  const armpl_int_t lda, const double *B,
                  const armpl_int_t ldb, const double beta, double *C,
                  const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsyr2k*, *cblas_ssyr2k* and *cblas_zsyr2k*. It also exists with a native Fortran interface as *dsyr2k*.

3.5.61 cblas_dsyrk

Syntax

```
#include "armpl.h"

void cblas_dsyrk(const enum CBLAS_ORDER Order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE Trans, const armpl_int_t N,
                 const armpl_int_t K, const double alpha, const double *A,
                 const armpl_int_t lda, const double beta, double *C,
                 const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsyrk*, *cblas_ssyrk* and *cblas_zsyrk*. It also exists with a native Fortran interface as *dsyrk*.

3.5.62 cblas_dtbmv

Syntax

```
#include "armpl.h"

void cblas_dtbmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const armpl_int_t K, const double *A, const armpl_int_t lda,
                 double *X, const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtbmv*, *cblas_stbmv* and *cblas_ztbmv*. It also exists with a native Fortran interface as *dtbmv*.

3.5.63 cblas_dtbsv

Syntax

```
#include "armpl.h"

void cblas_dtbsv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const armpl_int_t K, const double *A, const armpl_int_t lda,
                 double *X, const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtbsv*, *cblas_stbsv* and *cblas_ztbsv*. It also exists with a native Fortran interface as *dtbsv*.

3.5.64 cblas_dtpmv

Syntax

```
#include "armpl.h"

void cblas_dtpmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const double *Ap, double *X, const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtpmv*, *cblas_stpmv* and *cblas_ztpmv*. It also exists with a native Fortran interface as *dtpmv*.

3.5.65 cblas_dtpsv

Syntax

```
#include "armpl.h"

void cblas_dtpsv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const double *Ap, double *X, const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

3.5.66 cblas_dtrmm

Syntax

```
#include "armpl.h"

void cblas_dtrmm(const enum CBLAS_ORDER Order, const enum CBLAS_SIDE Side,
                 const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t M,
                 const armpl_int_t N, const double alpha, const double *A,
                 const armpl_int_t lda, double *B, const armpl_int_t ldb);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtrmm*, *cblas_strmm* and *cblas_ztrmm*. It also exists with a native Fortran interface as *dtrmm*.

3.5.67 cblas_dtrmv

Syntax

```
#include "armpl.h"

void cblas_dtrmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const double *A, const armpl_int_t lda, double *X,
                 const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtrmv*, *cblas_strmv* and *cblas_ztrmv*. It also exists with a native Fortran interface as *dtrmv*.

3.5.68 cblas_dtrsm

Syntax

```
#include "armpl.h"

void cblas_dtrsm(const enum CBLAS_ORDER Order, const enum CBLAS_SIDE Side,
                 const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t M,
                 const armpl_int_t N, const double alpha, const double *A,
                 const armpl_int_t lda, double *B, const armpl_int_t ldb);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtrsm*, *cblas_strsm* and *cblas_ztrsm*. It also exists with a native Fortran interface as *dtrsm*.

3.5.69 cblas_dtrsv

Syntax

```
#include "armpl.h"

void cblas_dtrsv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const double *A, const armpl_int_t lda, double *X,
                 const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtrsv*, *cblas_strsv* and *cblas_ztrsv*. It also exists with a native Fortran interface as *dtrsv*.

3.5.70 cblas_dwaxpby

Syntax

```
#include "armpl.h"

void cblas_dwaxpby(armpl_int_t N, const double *alpha,
                   const double *X, armpl_int_t incX,
```

(continues on next page)

(continued from previous page)

```
                    const double *beta,
                    double *Y, armpl_int_t incY,
                    double *W, armpl_int_t incw);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_cwaxpby*, *cblas_swaxpby* and *cblas_zwaxpby*. It also exists with a native Fortran interface as *dwaxpby*.

3.5.71 cblas_dzasum

Syntax

```
#include "armpl.h"

double cblas_dzasum(const armpl_int_t N, const armpl_doublecomplex_t *X,
                    const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dzasum*. It also exists with a native Fortran interface as *dzasum*.

3.5.72 cblas_dznrm2

Syntax

```
#include "armpl.h"

double cblas_dznrm2(const armpl_int_t N, const armpl_doublecomplex_t *X,
                    const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dznrm2*. It also exists with a native Fortran interface as *dznrm2*.

3.5.73 cblas_icamax

Syntax

```
#include "armpl.h"

armpl_int_t cblas_icamax(const armpl_int_t N, const armpl_singlecomplex_t*X,
                         const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

It also exists with a native Fortran interface as *icamax*.

3.5.74 cblas_idamax

Syntax

```
#include "armpl.h"

armpl_int_t cblas_idamax(const armpl_int_t N, const double *X,
                         const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

It also exists with a native Fortran interface as *idamax*.

3.5.75 cblas_isamax

Syntax

```
#include "armpl.h"

armpl_int_t cblas_isamax(const armpl_int_t N, const float *X,
                         const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

It also exists with a native Fortran interface as *isamax*.

3.5.76 cblas_izamax

Syntax

```
#include "armpl.h"

armpl_int_t cblas_izamax(const armpl_int_t N, const armpl_doublecomplex_t *X,
                         const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

It also exists with a native Fortran interface as *izamax*.

3.5.77 cblas_sasum

Syntax

```
#include "armpl.h"

float cblas_sasum(const armpl_int_t N, const float *X,
                  const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dasum* and *cblas_sasum*. It also exists with a native Fortran interface as *sasum*.

3.5.78 cblas_saxpby

Syntax

```
#include "armpl.h"

void cblas_saxpby(armpl_int_t N, const float *alpha,const float *X,
                  armpl_int_t incX, const float *beta, float *Y,
                  armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_caxpby*, *cblas_caxpby* and *cblas_zaxpby*. It also exists with a native Fortran interface as *saxpby*.

3.5.79 cblas_saxpy

Syntax

```
#include "armpl.h"

void cblas_saxpy(const armpl_int_t N, const float alpha, const float *X,
                 const armpl_int_t incX, float *Y, const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_daxpy*, *cblas_saxpy* and *cblas_zaxpy*. It also exists with a native Fortran interface as *saxpy*.

3.5.80 cblas_scasum

Syntax

```
#include "armpl.h"

float cblas_scasum(const armpl_int_t N, const armpl_singlecomplex_t*X,
                   const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_scasum*. It also exists with a native Fortran interface as *scasum*.

3.5.81 cblas_scnrm2

Syntax

```
#include "armpl.h"

float cblas_scnrm2(const armpl_int_t N, const armpl_singlecomplex_t*X,
                   const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_scnrm2*. It also exists with a native Fortran interface as *scnrm2*.

3.5.82 cblas_scopy

Syntax

```
#include "armpl.h"

void cblas_scopy(const armpl_int_t N, const float *X, const armpl_int_t incX,
                 float *Y, const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dcopy*, *cblas_scopy* and *cblas_zcopy*. It also exists with a native Fortran interface as *scopy*.

3.5.83 cblas_sdot

Syntax

```
#include "armpl.h"

float cblas_sdot(const armpl_int_t N, const float *X, const armpl_int_t incX,
                 const float *Y, const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_ddot* and *cblas_sdot*. It also exists with a native Fortran interface as *sdot*.

3.5.84 cblas_sdsdot

Syntax

```
#include "armpl.h"

float cblas_sdsdot(const armpl_int_t N, const float alpha, const float *X,
                   const armpl_int_t incX, const float *Y,
                   const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_sdsdot*. It also exists with a native Fortran interface as *sdsdot*.

3.5.85 cblas_sgbmv

Syntax

```
#include "armpl.h"

void cblas_sgbmv(const enum CBLAS_ORDER order,
                 const enum CBLAS_TRANSPOSE TransA, const armpl_int_t M,
                 const armpl_int_t N, const armpl_int_t KL,
                 const armpl_int_t KU, const float alpha, const float *A,
                 const armpl_int_t lda, const float *X,
                 const armpl_int_t incX, const float beta, float *Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dgbmv*, *cblas_sgbmv* and *cblas_zgbmv*. It also exists with a native Fortran interface as *sgbmv*.

3.5.86 cblas_sgemm

Syntax

```
#include "armpl.h"

void cblas_sgemm(const enum CBLAS_ORDER Order,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_TRANSPOSE TransB, const armpl_int_t M,
                 const armpl_int_t N, const armpl_int_t K, const float alpha,
                 const float *A, const armpl_int_t lda, const float *B,
                 const armpl_int_t ldb, const float beta, float *C,
                 const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dgemm*, *cblas_sgemm* and *cblas_zgemm*. It also exists with a native Fortran interface as *sgemm*.

3.5.87 cblas_sgemv

Syntax

```
#include "armpl.h"

void cblas_sgemv(const enum CBLAS_ORDER order,
                 const enum CBLAS_TRANSPOSE TransA, const armpl_int_t M,
                 const armpl_int_t N, const float alpha, const float *A,
                 const armpl_int_t lda, const float *X,
                 const armpl_int_t incX, const float beta, float *Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dgemv*, *cblas_sgemv* and *cblas_zgemv*. It also exists with a native Fortran interface as *sgemv*.

3.5.88 cblas_sger

Syntax

```
#include "armpl.h"

void cblas_sger(const enum CBLAS_ORDER order, const armpl_int_t M,
                const armpl_int_t N, const float alpha, const float *X,
                const armpl_int_t incX, const float *Y,
                const armpl_int_t incY, float *A, const armpl_int_t lda);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dger* and *cblas_sger*. It also exists with a native Fortran interface as *sger*.

3.5.89 cblas_snrm2

Syntax

```
#include "armpl.h"

float cblas_snrm2(const armpl_int_t N, const float *X,
                  const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dnrm2* and *cblas_snrm2*. It also exists with a native Fortran interface as *snrm2*.

3.5.90 cblas_srot

Syntax

```
#include "armpl.h"

void cblas_srot(const armpl_int_t N, float *X, const armpl_int_t incX,
                float *Y, const armpl_int_t incY, const float c,
                const float s);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_drot* and *cblas_srot*. It also exists with a native Fortran interface as *srot*.

3.5.91 cblas_srotg

Syntax

```
#include "armpl.h"

void cblas_srotg(float *a, float *b, float *c, float *s);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_drotg* and *cblas_srotg*. It also exists with a native Fortran interface as *srotg*.

3.5.92 cblas_srotm

Syntax

```
#include "armpl.h"

void cblas_srotm(const armpl_int_t N, float *X, const armpl_int_t incX,
                 float *Y, const armpl_int_t incY, const float *P);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_drotm* and *cblas_srotm*. It also exists with a native Fortran interface as *srotm*.

3.5.93 cblas_srotmg

Syntax

```
#include "armpl.h"

void cblas_srotmg(float *d1, float *d2, float *b1, const float b2, float *P);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_drotmg* and *cblas_srotmg*. It also exists with a native Fortran interface as *srotmg*.

3.5.94 cblas_ssbmv

Syntax

```
#include "armpl.h"

void cblas_ssbmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const armpl_int_t N, const armpl_int_t K, const float alpha,
                 const float *A, const armpl_int_t lda, const float *X,
                 const armpl_int_t incX, const float beta, float *Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsbmv* and *cblas_ssbmv*. It also exists with a native Fortran interface as *ssbmv*.

3.5.95 cblas_sscal

Syntax

```
#include "armpl.h"

void cblas_sscal(const armpl_int_t N, const float alpha, float *X,
                 const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dscal*, *cblas_sscal* and *cblas_zscal*. It also exists with a native Fortran interface as *sscal*.

3.5.96 cblas_sspmv

Syntax

```
#include "armpl.h"

void cblas_sspmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const armpl_int_t N, const float alpha, const float *Ap,
                 const float *X, const armpl_int_t incX, const float beta,
                 float *Y, const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dspmv* and *cblas_sspmv*. It also exists with a native Fortran interface as *sspmv*.

3.5.97 cblas_sspr

Syntax

```
#include "armpl.h"

void cblas_sspr(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                const armpl_int_t N, const float alpha, const float *X,
                const armpl_int_t incX, float *Ap);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dspr* and *cblas_sspr*. It also exists with a native Fortran interface as *sspr*.

3.5.98 cblas_sspr2

Syntax

```
#include "armpl.h"

void cblas_sspr2(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const armpl_int_t N, const float alpha, const float *X,
                 const armpl_int_t incX, const float *Y,
                 const armpl_int_t incY, float *A);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dspr2* and *cblas_sspr2*. It also exists with a native Fortran interface as *sspr2*.

3.5.99 cblas_sswap

Syntax

```
#include "armpl.h"

void cblas_sswap(const armpl_int_t N, float *X, const armpl_int_t incX,
                 float *Y, const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dswap*, *cblas_sswap* and *cblas_zswap*. It also exists with a native Fortran interface as *sswap*.

3.5.100 cblas_ssymm

Syntax

```
#include "armpl.h"

void cblas_ssymm(const enum CBLAS_ORDER Order, const enum CBLAS_SIDE Side,
                 const enum CBLAS_UPLO Uplo, const armpl_int_t M,
                 const armpl_int_t N, const float alpha, const float *A,
                 const armpl_int_t lda, const float *B, const armpl_int_t ldb,
                 const float beta, float *C, const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsymm*, *cblas_ssymm* and *cblas_zsymm*. It also exists with a native Fortran interface as *ssymm*.

3.5.101 cblas_ssymv

Syntax

```
#include "armpl.h"

void cblas_ssymv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const armpl_int_t N, const float alpha, const float *A,
                 const armpl_int_t lda, const float *X,
                 const armpl_int_t incX, const float beta, float *Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsymv* and *cblas_ssymv*. It also exists with a native Fortran interface as *ssymv*.

3.5.102 cblas_ssyr

Syntax

```
#include "armpl.h"

void cblas_ssyr(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                const armpl_int_t N, const float alpha, const float *X,
                const armpl_int_t incX, float *A, const armpl_int_t lda);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsyr* and *cblas_ssyr*. It also exists with a native Fortran interface as *ssyr*.

3.5.103 cblas_ssyr2

Syntax

```
#include "armpl.h"

void cblas_ssyr2(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const armpl_int_t N, const float alpha, const float *X,
                 const armpl_int_t incX, const float *Y,
                 const armpl_int_t incY, float *A, const armpl_int_t lda);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsyr2* and *cblas_ssyr2*. It also exists with a native Fortran interface as *ssyr2*.

3.5.104 cblas_ssyr2k

Syntax

```
#include "armpl.h"

void cblas_ssyr2k(const enum CBLAS_ORDER Order, const enum CBLAS_UPLO Uplo,
                  const enum CBLAS_TRANSPOSE Trans, const armpl_int_t N,
                  const armpl_int_t K, const float alpha, const float *A,
                  const armpl_int_t lda, const float *B,
                  const armpl_int_t ldb, const float beta, float *C,
                  const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsyr2k*, *cblas_ssyr2k* and *cblas_zsyr2k*. It also exists with a native Fortran interface as *ssyr2k*.

3.5.105 cblas_ssyrk

Syntax

```
#include "armpl.h"

void cblas_ssyrk(const enum CBLAS_ORDER Order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE Trans, const armpl_int_t N,
                 const armpl_int_t K, const float alpha, const float *A,
                 const armpl_int_t lda, const float beta, float *C,
                 const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsyrk*, *cblas_ssyrk* and *cblas_zsyrk*. It also exists with a native Fortran interface as *ssyrk*.

3.5.106 cblas_stbmv

Syntax

```
#include "armpl.h"

void cblas_stbmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const armpl_int_t K, const float *A, const armpl_int_t lda,
                 float *X, const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtbmv*, *cblas_stbmv* and *cblas_ztbmv*. It also exists with a native Fortran interface as *stbmv*.

3.5.107 cblas_stbsv

Syntax

```
#include "armpl.h"

void cblas_stbsv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const armpl_int_t K, const float *A, const armpl_int_t lda,
                 float *X, const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtbsv*, *cblas_stbsv* and *cblas_ztbsv*. It also exists with a native Fortran interface as *stbsv*.

3.5.108 cblas_stpmv

Syntax

```
#include "armpl.h"

void cblas_stpmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
```

(continues on next page)

(continued from previous page)

```
                const enum CBLAS_DIAG Diag, const armpl_int_t N,
                const float *Ap, float *X, const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtpmv*, *cblas_stpmv* and *cblas_ztpmv*. It also exists with a native Fortran interface as *stpmv*.

3.5.109 cblas_stpsv

Syntax

```
#include "armpl.h"

void cblas_stpsv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const float *Ap, float *X, const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtpsv*, *cblas_stpsv* and *cblas_ztpsv*. It also exists with a native Fortran interface as *stpsv*.

3.5.110 cblas_strmm

Syntax

```
#include "armpl.h"

void cblas_strmm(const enum CBLAS_ORDER Order, const enum CBLAS_SIDE Side,
                 const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t M,
                 const armpl_int_t N, const float alpha, const float *A,
                 const armpl_int_t lda, float *B, const armpl_int_t ldb);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtrmm*, *cblas_strmm* and *cblas_ztrmm*. It also exists with a native Fortran interface as *strmm*.

3.5.111 cblas_strmv

Syntax

```
#include "armpl.h"

void cblas_strmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const float *A, const armpl_int_t lda, float *X,
                 const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtrmv*, *cblas_strmv* and *cblas_ztrmv*. It also exists with a native Fortran interface as *strmv*.

3.5.112 cblas_strsm

Syntax

```
#include "armpl.h"

void cblas_strsm(const enum CBLAS_ORDER Order, const enum CBLAS_SIDE Side,
                 const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t M,
                 const armpl_int_t N, const float alpha, const float *A,
                 const armpl_int_t lda, float *B, const armpl_int_t ldb);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtrsm*, *cblas_strsm* and *cblas_ztrsm*. It also exists with a native Fortran interface as *strsm*.

3.5.113 cblas_strsv

Syntax

```
#include "armpl.h"

void cblas_strsv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const float *A, const armpl_int_t lda, float *X,
                 const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtrsv*, *cblas_strsv* and *cblas_ztrsv*. It also exists with a native Fortran interface as *strsv*.

3.5.114 cblas_swaxpby

Syntax

```
#include "armpl.h"

void cblas_swaxpby(armpl_int_t N, const float *alpha,
                   const float *X, armpl_int_t incX,
                   const float *beta,
                   float *Y, armpl_int_t incY,
                   float *W, armpl_int_t incw);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_cwaxpby*, *cblas_dwaxpby* and *cblas_zwaxpby*. It also exists with a native Fortran interface as *swaxpby*.

3.5.115 cblas_xerbla

Syntax

```
#include "armpl.h"

void cblas_xerbla(armpl_int_t RowMajorStrg, armpl_int_t CBLAS_CallFromC,
                  armpl_int_t p, const char *rout, const char *form,
                  int enumval);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

It also exists with a native Fortran interface as *xerbla*.

3.5.116 cblas_zaxpby

Syntax

```
#include "armpl.h"

void cblas_zaxpby(armpl_int_t N, const armpl_doublecomplex_t *alpha,
                  const armpl_doublecomplex_t *X, armpl_int_t incX,
                  const armpl_doublecomplex_t *beta,
                  armpl_doublecomplex_t *Y, armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_caxpby*, *cblas_caxpby* and *cblas_saxpby*. It also exists with a native Fortran interface as *zaxpby*.

3.5.117 cblas_zaxpy

Syntax

```
#include "armpl.h"

void cblas_zaxpy(const armpl_int_t N, const armpl_doublecomplex_t *alpha,
                 const armpl_doublecomplex_t *X, const armpl_int_t incX,
                 armpl_doublecomplex_t *Y, const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_daxpy*, *cblas_saxpy* and *cblas_zaxpy*. It also exists with a native Fortran interface as *zaxpy*.

3.5.118 cblas_zcopy

Syntax

```
#include "armpl.h"

void cblas_zcopy(const armpl_int_t N, const armpl_doublecomplex_t *X,
                 const armpl_int_t incX, armpl_doublecomplex_t *Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dcopy*, *cblas_scopy* and *cblas_zcopy*. It also exists with a native Fortran interface as *zcopy*.

3.5.119 cblas_zdscal

Syntax

```
#include "armpl.h"

void cblas_zdscal(const armpl_int_t N, const double alpha,
                  armpl_doublecomplex_t *X, const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zdscal*. It also exists with a native Fortran interface as *zdscal*.

3.5.120 cblas_zgbmv

Syntax

```
#include "armpl.h"

void cblas_zgbmv(const enum CBLAS_ORDER order,
                 const enum CBLAS_TRANSPOSE TransA, const armpl_int_t M,
                 const armpl_int_t N, const armpl_int_t KL,
                 const armpl_int_t KU, const armpl_doublecomplex_t *alpha,
                 const armpl_doublecomplex_t *A, const armpl_int_t lda,
                 const armpl_doublecomplex_t *X, const armpl_int_t incX,
                 const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dgbmv*, *cblas_sgbmv* and *cblas_zgbmv*. It also exists with a native Fortran interface as *zgbmv*.

3.5.121 cblas_zgemm

Syntax

```
#include "armpl.h"

void cblas_zgemm(const enum CBLAS_ORDER Order,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_TRANSPOSE TransB, const armpl_int_t M,
                 const armpl_int_t N, const armpl_int_t K,
                 const armpl_doublecomplex_t *alpha,
                 const armpl_doublecomplex_t *A, const armpl_int_t lda,
                 const armpl_doublecomplex_t *B, const armpl_int_t ldb,
                 const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *C,
                 const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dgemm*, *cblas_sgemm* and *cblas_zgemm*. It also exists with a native Fortran interface as *zgemm*.

3.5.122 cblas_zgemm3m

Syntax

```
#include "armpl.h"

void cblas_zgemm3m(const enum CBLAS_ORDER Order,
                   const enum CBLAS_TRANSPOSE TransA,
                   const enum CBLAS_TRANSPOSE TransB, const armpl_int_t M,
                   const armpl_int_t N, const armpl_int_t K,
                   const armpl_doublecomplex_t *alpha,
                   const armpl_doublecomplex_t *A, const armpl_int_t lda,
                   const armpl_doublecomplex_t *B, const armpl_int_t ldb,
                   const armpl_doublecomplex_t *beta,
                   armpl_doublecomplex_t *C, const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_cgemm3m*. It also exists with a native Fortran interface as *zgemm3m*.

3.5.123 cblas_zgemv

Syntax

```
#include "armpl.h"

void cblas_zgemv(const enum CBLAS_ORDER order,
                 const enum CBLAS_TRANSPOSE TransA, const armpl_int_t M,
                 const armpl_int_t N, const armpl_doublecomplex_t *alpha,
                 const armpl_doublecomplex_t *A, const armpl_int_t lda,
                 const armpl_doublecomplex_t *X, const armpl_int_t incX,
                 const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dgemv*, *cblas_sgemv* and *cblas_zgemv*. It also exists with a native Fortran interface as *zgemv*.

3.5.124 cblas_zgerc

Syntax

```
#include "armpl.h"

void cblas_zgerc(const enum CBLAS_ORDER order, const armpl_int_t M,
                 const armpl_int_t N, const armpl_doublecomplex_t *alpha,
                 const armpl_doublecomplex_t *X, const armpl_int_t incX,
                 const armpl_doublecomplex_t *Y, const armpl_int_t incY,
                 armpl_doublecomplex_t *A, const armpl_int_t lda);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zgerc*. It also exists with a native Fortran interface as *zgerc*.

3.5.125 cblas_zgeru

Syntax

```
#include "armpl.h"

void cblas_zgeru(const enum CBLAS_ORDER order, const armpl_int_t M,
                 const armpl_int_t N, const armpl_doublecomplex_t *alpha,
                 const armpl_doublecomplex_t *X, const armpl_int_t incX,
                 const armpl_doublecomplex_t *Y, const armpl_int_t incY,
                 armpl_doublecomplex_t *A, const armpl_int_t lda);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zgeru*. It also exists with a native Fortran interface as *zgeru*.

3.5.126 cblas_zhbmv

Syntax

```
#include "armpl.h"

void cblas_zhbmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const armpl_int_t N, const armpl_int_t K,
                 const armpl_doublecomplex_t *alpha,
                 const armpl_doublecomplex_t *A, const armpl_int_t lda,
                 const armpl_doublecomplex_t *X, const armpl_int_t incX,
                 const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zhbmv*. It also exists with a native Fortran interface as *zhbmv*.

3.5.127 cblas_zhemm

Syntax

```
#include "armpl.h"

void cblas_zhemm(const enum CBLAS_ORDER Order, const enum CBLAS_SIDE Side,
                 const enum CBLAS_UPLO Uplo, const armpl_int_t M,
                 const armpl_int_t N, const armpl_doublecomplex_t *alpha,
                 const armpl_doublecomplex_t *A, const armpl_int_t lda,
                 const armpl_doublecomplex_t *B, const armpl_int_t ldb,
                 const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *C,
                 const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zhemm*. It also exists with a native Fortran interface as *zhemm*.

3.5.128 cblas_zhemv

Syntax

```
#include "armpl.h"

void cblas_zhemv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const armpl_int_t N, const armpl_doublecomplex_t *alpha,
                 const armpl_doublecomplex_t *A, const armpl_int_t lda,
                 const armpl_doublecomplex_t *X, const armpl_int_t incX,
                 const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zhemv*. It also exists with a native Fortran interface as *zhemv*.

3.5.129 cblas_zher

Syntax

```
#include "armpl.h"

void cblas_zher(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                const armpl_int_t N, const double alpha,
                const armpl_doublecomplex_t *X, const armpl_int_t incX,
                armpl_doublecomplex_t *A, const armpl_int_t lda);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zher*. It also exists with a native Fortran interface as *zher*.

3.5.130 cblas_zher2

Syntax

```
#include "armpl.h"

void cblas_zher2(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const armpl_int_t N, const armpl_doublecomplex_t *alpha,
                 const armpl_doublecomplex_t *X, const armpl_int_t incX,
                 const armpl_doublecomplex_t *Y, const armpl_int_t incY,
                 armpl_doublecomplex_t *A, const armpl_int_t lda);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zher2*. It also exists with a native Fortran interface as *zher2*.

3.5.131 cblas_zher2k

Syntax

```
#include "armpl.h"

void cblas_zher2k(const enum CBLAS_ORDER Order, const enum CBLAS_UPLO Uplo,
                  const enum CBLAS_TRANSPOSE Trans, const armpl_int_t N,
                  const armpl_int_t K, const armpl_doublecomplex_t *alpha,
                  const armpl_doublecomplex_t *A, const armpl_int_t lda,
                  const armpl_doublecomplex_t *B, const armpl_int_t ldb,
                  const double beta, armpl_doublecomplex_t *C,
                  const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zher2k*. It also exists with a native Fortran interface as *zher2k*.

3.5.132 cblas_zherk

Syntax

```
#include "armpl.h"

void cblas_zherk(const enum CBLAS_ORDER Order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE Trans, const armpl_int_t N,
                 const armpl_int_t K, const double alpha,
                 const armpl_doublecomplex_t *A, const armpl_int_t lda,
                 const double beta, armpl_doublecomplex_t *C,
                 const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zherk*. It also exists with a native Fortran interface as *zherk*.

3.5.133 cblas_zhpmv

Syntax

```
#include "armpl.h"

void cblas_zhpmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const armpl_int_t N, const armpl_doublecomplex_t *alpha,
                 const armpl_doublecomplex_t *Ap,
                 const armpl_doublecomplex_t *X, const armpl_int_t incX,
                 const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zhpmv*. It also exists with a native Fortran interface as *zhpmv*.

3.5.134 cblas_zhpr

Syntax

```
#include "armpl.h"

void cblas_zhpr(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                const armpl_int_t N, const double alpha,
                const armpl_doublecomplex_t *X, const armpl_int_t incX,
                armpl_doublecomplex_t *A);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zhpr*. It also exists with a native Fortran interface as *zhpr*.

3.5.135 cblas_zhpr2

Syntax

```
#include "armpl.h"

void cblas_zhpr2(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const armpl_int_t N, const armpl_doublecomplex_t *alpha,
                 const armpl_doublecomplex_t *X, const armpl_int_t incX,
                 const armpl_doublecomplex_t *Y, const armpl_int_t incY,
                 armpl_doublecomplex_t *Ap);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_zhpr2*. It also exists with a native Fortran interface as *zhpr2*.

3.5.136 cblas_zscal

Syntax

```
#include "armpl.h"

void cblas_zscal(const armpl_int_t N, const armpl_doublecomplex_t *alpha,
                 armpl_doublecomplex_t *X, const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dscal*, *cblas_sscal* and *cblas_zscal*. It also exists with a native Fortran interface as *zscal*.

3.5.137 cblas_zswap

Syntax

```
#include "armpl.h"

void cblas_zswap(const armpl_int_t N, armpl_doublecomplex_t *X,
                 const armpl_int_t incX, armpl_doublecomplex_t *Y,
                 const armpl_int_t incY);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dswap*, *cblas_sswap* and *cblas_zswap*. It also exists with a native Fortran interface as *zswap*.

3.5.138 cblas_zsymm

Syntax

```
#include "armpl.h"

void cblas_zsymm(const enum CBLAS_ORDER Order, const enum CBLAS_SIDE Side,
                 const enum CBLAS_UPLO Uplo, const armpl_int_t M,
                 const armpl_int_t N, const armpl_doublecomplex_t *alpha,
                 const armpl_doublecomplex_t *A, const armpl_int_t lda,
                 const armpl_doublecomplex_t *B, const armpl_int_t ldb,
                 const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *C,
                 const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsymm*, *cblas_ssymm* and *cblas_zsymm*. It also exists with a native Fortran interface as *zsymm*.

3.5.139 cblas_zsyr2k

Syntax

```
#include "armpl.h"

void cblas_zsyr2k(const enum CBLAS_ORDER Order, const enum CBLAS_UPLO Uplo,
                  const enum CBLAS_TRANSPOSE Trans, const armpl_int_t N,
                  const armpl_int_t K, const armpl_doublecomplex_t *alpha,
                  const armpl_doublecomplex_t *A, const armpl_int_t lda,
                  const armpl_doublecomplex_t *B, const armpl_int_t ldb,
                  const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *C,
                  const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsyr2k*, *cblas_ssyr2k* and *cblas_zsyr2k*. It also exists with a native Fortran interface as *zsyr2k*.

3.5.140 cblas_zsyrk

Syntax

```
#include "armpl.h"

void cblas_zsyrk(const enum CBLAS_ORDER Order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE Trans, const armpl_int_t N,
                 const armpl_int_t K, const armpl_doublecomplex_t *alpha,
                 const armpl_doublecomplex_t *A, const armpl_int_t lda,
                 const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *C,
                 const armpl_int_t ldc);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dsyrk*, *cblas_ssyrk* and *cblas_zsyrk*. It also exists with a native Fortran interface as *zsyrk*.

3.5.141 cblas_ztbmv

Syntax

```
#include "armpl.h"

void cblas_ztbmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const armpl_int_t K, const armpl_doublecomplex_t *A,
                 const armpl_int_t lda, armpl_doublecomplex_t *X,
                 const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtbmv*, *cblas_stbmv* and *cblas_ztbmv*. It also exists with a native Fortran interface as *ztbmv*.

3.5.142 cblas_ztbsv

Syntax

```
#include "armpl.h"

void cblas_ztbsv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const armpl_int_t K, const armpl_doublecomplex_t *A,
                 const armpl_int_t lda, armpl_doublecomplex_t *X,
                 const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtbsv*, *cblas_stbsv* and *cblas_ztbsv*. It also exists with a native Fortran interface as *ztbsv*.

3.5.143 cblas_ztpmv

Syntax

```
#include "armpl.h"

void cblas_ztpmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const armpl_doublecomplex_t *Ap, armpl_doublecomplex_t *X,
                 const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtpmv*, *cblas_stpmv* and *cblas_ztpmv*. It also exists with a native Fortran interface as *ztpmv*.

3.5.144 cblas_ztpsv

Syntax

```
#include "armpl.h"

void cblas_ztpsv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const armpl_doublecomplex_t *Ap, armpl_doublecomplex_t *X,
                 const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtpsv*, *cblas_stpsv* and *cblas_ztpsv*. It also exists with a native Fortran interface as *ztpsv*.

3.5.145 cblas_ztrmm

Syntax

```
#include "armpl.h"

void cblas_ztrmm(const enum CBLAS_ORDER Order, const enum CBLAS_SIDE Side,
                 const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t M,
                 const armpl_int_t N, const armpl_doublecomplex_t *alpha,
                 const armpl_doublecomplex_t *A, const armpl_int_t lda,
                 armpl_doublecomplex_t *B, const armpl_int_t ldb);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtrmm*, *cblas_strmm* and *cblas_ztrmm*. It also exists with a native Fortran interface as *ztrmm*.

3.5.146 cblas_ztrmv

Syntax

```
#include "armpl.h"

void cblas_ztrmv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const armpl_doublecomplex_t *A, const armpl_int_t lda,
                 armpl_doublecomplex_t *X, const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtrmv*, *cblas_strmv* and *cblas_ztrmv*. It also exists with a native Fortran interface as *ztrmv*.

3.5.147 cblas_ztrsm

Syntax

```
#include "armpl.h"

void cblas_ztrsm(const enum CBLAS_ORDER Order, const enum CBLAS_SIDE Side,
                 const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t M,
                 const armpl_int_t N, const armpl_doublecomplex_t *alpha,
                 const armpl_doublecomplex_t *A, const armpl_int_t lda,
                 armpl_doublecomplex_t *B, const armpl_int_t ldb);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtrsm*, *cblas_strsm* and *cblas_ztrsm*. It also exists with a native Fortran interface as *ztrsm*.

3.5.148 cblas_ztrsv

Syntax

```
#include "armpl.h"

void cblas_ztrsv(const enum CBLAS_ORDER order, const enum CBLAS_UPLO Uplo,
                 const enum CBLAS_TRANSPOSE TransA,
                 const enum CBLAS_DIAG Diag, const armpl_int_t N,
                 const armpl_doublecomplex_t *A, const armpl_int_t lda,
                 armpl_doublecomplex_t *X, const armpl_int_t incX);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

Related Information

For this routine in other precisions, please see *cblas_dtrsv*, *cblas_strsv* and *cblas_ztrsv*. It also exists with a native Fortran interface as *ztrsv*.

3.5.149 cblas_zwaxpby

Syntax

```
#include "armpl.h"

void cblas_zwaxpby(armpl_int_t N, const armpl_doublecomplex_t *alpha,
                   const armpl_doublecomplex_t *X, armpl_int_t incX,
                   const armpl_doublecomplex_t *beta,
                   armpl_doublecomplex_t *Y, armpl_int_t incY,
                   armpl_doublecomplex_t *W, armpl_int_t incw);
```

Parameters

CBLAS routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- All parameters marked `const CBLAS_LAYOUT` take a value of either `CblasRowMajor` or `CblasColMajor`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.
- All parameters marked `const CBLAS_TRANSPOSE` take a value of either `CblasNoTrans`, `CblasTrans` or `CblasConjTrans`, depending on whether the matrix in question in given in regular, transposed or conjugate form, respectively.

3.6 BLAS Extensions

3.6.1 caxpby

`caxpby` performs the following vector update:

$y_i \leftarrow ax_i + by_i$ for $i = 0, n-1$.

Syntax

Fortran specification:

```
use armpl_library

subroutine caxpby(N, A, X, INCX, B, Y, INCY)
```

C specification:

```
#include "armpl.h"

void caxpby_(const armpl_int_t *n, const armpl_singlecomplex_t *alpha,
             const armpl_singlecomplex_t *x, const armpl_int_t *incx,
             const armpl_singlecomplex_t *beta, armpl_singlecomplex_t *y,
             const armpl_int_t *incy);
```

Parameters

N Input parameter.

N is INTEGER

The length of the vectors $\underline{x}$ and $\underline{y}$.

A Input parameter.

A is COMPLEX

The scalar a.

X Input parameter.

X is COMPLEX

X is an array, dimension *(1+(N-1)*ABS(INCX))*

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in X(1+(I-1)*ABS(INCX)).

INCX Input parameter.

INCX is INTEGER

INCX is the increment used to store successive elements of the Vector in X.

B Input parameter.

B is COMPLEX

The scalar b.

Y Input and output parameter.

Y is COMPLEX

Y is an array, dimension *(1+(N-1)*ABS(INCX))*

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in X(1+(I-1)*ABS(INCX)).

INCY Input parameter.

INCY is INTEGER

INCY is the increment used to store successive elements of the Vector in Y.

Related Information

For this routine in other precisions, please see *daxpby*, *saxpby* and *zaxpby*. It also exists with a native C interface as *cblas_caxpby*.

3.6.2 cgemm3m

cgemm3m performs one of the following matrix-matrix operations:

$$C \leftarrow \alpha op(A) op(B) + \beta C$$

where $op(X)$ is defined as one of:

$op(X) = X$

$op(X) = X^T$ (matrix transpose)

$op(X) = X^H$ (matrix conjugate transpose)

and α and β are scalars, $op(A)$ is an m by k matrix, $op(B)$ a k by n matrix and C is an m by n matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgemm3m(TRANSA, TRANSB, M, N, K ALPHA, A, LDA, B, LDB, BETA, C,
                   LDC)
```

C specification:

```
#include "armpl.h"

void cgemm3m_(const char *transa, const char *transb, const armpl_int_t *m,
              const armpl_int_t *n, const armpl_int_t *k,
              const armpl_singlecomplex_t *alpha,
              const armpl_singlecomplex_t *a, const armpl_int_t *lda,
              const armpl_singlecomplex_t *b, const armpl_int_t *ldb,
              const armpl_singlecomplex_t *beta, armpl_singlecomplex_t *c,
              const armpl_int_t *ldc, ... );
```

Parameters

TRANSA Input parameter

TRANSA is CHARACTER*1

On input:

- If TRANSA = 'n' or 'N' $op(A) = A$;
- If TRANSA = 't' or 'T' $op(A) = A^T$;
- If TRANSA = 'c' or 'C' $op(A) = A^H$.

TRANSB Input parameter

TRANSB is CHARACTER*1

On input:

- If TRANSB = 'n' or 'N' $op(B) = B$;
- If TRANSB = 't' or 'T' $op(B) = B^T$;
- If TRANSB = 'c' or 'C' $op(B) = B^H$.

M Input parameter

M is INTEGER

The number of rows of the matrices $p(A)$ and C.

Constraint $M \geq 0$.

N Input parameter

N is INTEGER

On input: The number of columns of the matrices $op(B)$ and :math‘C‘.

Constraint $N \geq 0$.

K Input parameter

K is INTEGER

On input: The number of columns of the matrix $op(A)$ and rows of the matrix $op(B)$.

Constraint $K \geq 0$.

ALPHA Input parameter

ALPHA is COMPLEX

On input: The value of the scalar α.

A Input parameter

A is COMPLEX

On input: An array of dimension (LDA, KA) containing the matrix A, where if *TRANSA = ‘n’ or ‘N’* then KA = K* and the matrix is held in the leading M by K part of the array, otherwise *KA = M* and the matrix is held in the leading K by M part of the array.

LDA Input parameter

LDA is INTEGER **LDA**

On input: The leading dimension of the array *A* as declared in the calling subprogram.

Constraint If *TRANSA = ‘n’ or ‘N’* then $LDA \geq max(1, M)$, otherwise $LDA \geq max(1, K)$.

B Input parameter

B is COMPLEX

On input: An array of dimension (LDB, KB) containing the matrix B, where if *TRANSB = ‘n’ or ‘N’* then *KB = N* and the matrix is held in the leading K by N part of the array, otherwise *KB = K* and the matrix is held in the leading *N* by *K* part of the array.

LDB Input parameter

LDB is INTEGER

On input: The leading dimension of the array *B* as declared in the calling subprogram.

Constraint If *TRANSB = ‘n’ or ‘N’* then $LDB \geq max(1, K)$, otherwise $LDB \geq max(1, N)$.

BETA Input parameter

`BETA` is ``COMPLEX

On input: The value of the scalar β.

C Input and output parameter

C is COMPLEX

On input: An array of dimension (LDC, N) containing the matrix C, in the leading *M* by *N* part of the array. Note that if BETA = 0 then the matrix *C* need not be initialised on input.

On output: The array is overwritten with the result of the operation: $\alpha op(A) op(B) + \beta C$.

LDC Input parameter

LDC is INTEGER

On input: The leading dimension of the array C as declared in the calling subprogram.

Constraint $LDC \geq max(1, M)$.

Related Information

For this routine in other precisions, please see *zgemm3m*. It also exists with a native C interface as *cblas_cgemm3m*.

3.6.3 cwaxpby

cwaxpby performs the following vector operation:

$w_i \leftarrow ax_i + by_i$ for $i = 0, n - 1$.

Syntax

Fortran specification:

```
use armpl_library

subroutine cwaxpby(N, A, X, INCX, B, Y, INCY, W, INCW)
```

C specification:

```
#include "armpl.h"

void cwaxpby_(const armpl_int_t *n, const armpl_singlecomplex_t *alpha,
              const armpl_singlecomplex_t *x, const armpl_int_t *incx,
              const armpl_singlecomplex_t *beta, armpl_singlecomplex_t *y,
              const armpl_int_t *incy, armpl_singlecomplex_t *w,
              const armpl_int_t *incw);
```

Parameters

N Input parameter.

N is INTEGER

The length of the vectors $\underline{x}$ and $\underline{y}$.

A Input parameter.

A is COMPLEX

The scalar a.

X Input parameter.

X is COMPLEX

X is an array, dimension (1+(N-1)*ABS(INCX))

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in X(1+(I-1)*ABS(INCX)).

INCX Input parameter.

INCX is INTEGER

INCX is the increment used to store successive elements of the vector in X.

B Input parameter.

B is COMPLEX

The scalar b.

Y Input parameter.

Y is COMPLEX

Y is an array, dimension (1+(N-1)*ABS(INCX))

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in X(1+(I-1)*ABS(INCX)).

INCY Input parameter.

INCY is INTEGER

INCY is the increment used to store successive elements of the vector in Y.

W Output parameter.

W is COMPLEX

W is an array, dimension (1+(N-1)*ABS(INCX))

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in X(1+(I-1)*ABS(INCX)).

INCW Input parameter.

INCW is INTEGER

INCW is the increment used to store successive elements of the vector in W.

Related Information

For this routine in other precisions, please see *caxpby*, *saxpby* and *daxpby*. It also exists with a native C interface as *cblas_zaxpby*.

3.6.4 daxpby

daxpby performs the following vector update:

$y_i \leftarrow ax_i + by_i$ for $i = 0, n-1$.

Syntax

Fortran specification:

```
use armpl_library

subroutine daxpby(N, A, X, INCX, B, Y, INCY)
```

C specification:

```
#include "armpl.h"

void daxpby_(const armpl_int_t *n, const double *alpha,
             const double *x, const armpl_int_t *incx,
             const double *beta, double *y,
             const armpl_int_t *incy);
```

Parameters

N Input parameter.

N is INTEGER

The length of the vectors $\underline{x}$ and $\underline{y}$.

A Input parameter.

A is DOUBLE PRECISION

The scalar a.

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension *(1+(N-1)*ABS(INCX))*

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in X(1+(I-1)*ABS(INCX)).

INCX Input parameter.

INCX is INTEGER

INCX is the increment used to store successive elements of the Vector in X.

B Input parameter.

B is DOUBLE PRECISION

The scalar b.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension *(1+(N-1)*ABS(INCX))*

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in X(1+(I-1)*ABS(INCX)).

INCY Input parameter.

INCY is INTEGER

INCY is the increment used to store successive elements of the Vector in Y.

Related Information

For this routine in other precisions, please see *caxpby*, *saxpby* and *zaxpby*. It also exists with a native C interface as *cblas_caxpby*.

3.6.5 dwaxpby

dwaxpby performs the following vector operation:

$w_i \leftarrow ax_i + by_i$ for $i = 0, n - 1$.

Syntax

Fortran specification:

```
use armpl_library

subroutine dwaxpby(N, A, X, INCX, B, Y, INCY, W, INCW)
```

C specification:

```
#include "armpl.h"

void dwaxpby_(const armpl_int_t *n, const armpl_doublecomplex_t *alpha,
              const armpl_doublecomplex_t *x, const armpl_int_t *incx,
              const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *y,
              const armpl_int_t *incy, armpl_doublecomplex_t *w,
              const armpl_int_t *incw);
```

Parameters

N Input parameter.

N is INTEGER

The length of the vectors $\underline{x}$ and $\underline{y}$.

A Input parameter.

A is DOUBLE PRECISION

The scalar a.

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension (1+(N-1)*ABS(INCX))

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in X(1+(I-1)*ABS(INCX)).

INCX Input parameter.

INCX is INTEGER

INCX is the increment used to store successive elements of the vector in X.

B Input parameter.

B is DOUBLE PRECISION

The scalar b.

Y Input parameter.

Y is DOUBLE PRECISION

Y is an array, dimension (1+(N-1)*ABS(INCX))

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in X(1+(I-1)*ABS(INCX)).

INCY Input parameter.

INCY is INTEGER

INCY is the increment used to store successive elements of the vector in Y.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (1+(N-1)*ABS(INCX))

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in X(1+(I-1)*ABS(INCX)).

INCW Input parameter.

INCW is INTEGER

INCW is the increment used to store successive elements of the vector in W.

Related Information

For this routine in other precisions, please see *caxpby*, *saxpby* and *daxpby*. It also exists with a native C interface as *cblas_zaxpby*.

3.6.6 hgemm

`hgemm` performs one of the matrix-matrix operations

```
C := alpha*op( A )*op( B ) + beta*C,
```

where op(X) is one of

```
op( X ) = X   or   op( X ) = X**T,
```

alpha and beta are scalars, and A, B and C are matrices, with op(A) an m by k matrix, op(B) a k by n matrix and C an m by n matrix.

Syntax

C specification:

```
#include "armpl.h"

void hgemm_(const char *transa, const char *transb, const armpl_int_t *m,
            const armpl_int_t *n, const armpl_int_t *k, const __fp16 *alpha,
            const __fp16 *A, const armpl_int_t *lda, const __fp16 *B,
            const armpl_int_t *ldb, const __fp16 *beta, __fp16 *C,
            const armpl_int_t *ldc, ... );
```

Parameters

`transa` Input parameter.

`transa` is `const char *`

On entry, `transa` specifies the form of op(`A`) to be used in the matrix multiplication as follows:

`transa` = 'N' or 'n', op(`A`) = A.

`transa` = 'T' or 't', op(`A`) = A^T .

`transa` = 'C' or 'c', op(`A`) = A^T .

`transb` Input parameter.

`transb` is `const char *`

On entry, `transb` specifies the form of op(`B`) to be used in the matrix multiplication as follows:

`transb` = 'N' or 'n', op(`B`) = B.

`transb` = 'T' or 't', op(`B`) = B^T .

`transb` = 'C' or 'c', op(`B`) = B^T .

`m` Input parameter.

`m` is `armpl_int_t *`

On entry, `m` specifies the number of rows of the matrix op(`A`) and of the matrix `C`. `m` must be at least zero.

n Input parameter.

n is armpl_int_t *

On entry, n specifies the number of columns of the matrix op(B) and the number of columns of the matrix C. n must be at least zero.

k Input parameter.

k is armpl_int_t *

On entry, k specifies the number of columns of the matrix op(A) and the number of rows of the matrix op(B). k must be at least zero.

alpha Input parameter.

alpha is __fp16 *

On entry, alpha specifies the scalar alpha.

A Input parameter.

A is __fp16 *

A is an array, dimension (lda, ka), where ka is. k when transa = 'N' or 'n', and is m otherwise. Before entry with transa = 'N' or 'n', the leading m by k part of the array A must contain the matrix A, otherwise the leading k by m part of the array A must contain the matrix A.

lda Input parameter.

lda is armpl_int_t *

On entry, lda specifies the first dimension of A as declared in the calling (sub) program. When transa = 'N' or 'n' then lda must be at least max(1, m), otherwise lda must be at least max(1, k).

B Input parameter.

B is __fp16 *

B is an array, dimension (ldb, kb), where kb is. n when transb = 'N' or 'n', and is k otherwise. Before entry with transb = 'N' or 'n', the leading k by n part of the array B must contain the matrix B, otherwise the leading n by k part of the array B must contain the matrix B.

ldb Input parameter.

ldb is armpl_int_t *

On entry, ldb specifies the first dimension of B as declared in the calling (sub) program. When transb = 'N' or 'n' then ldb must be at least max(1, k), otherwise ldb must be at least max(1, n).

beta Input parameter.

beta is __fp16 *

On entry, beta specifies the scalar beta. When beta is supplied as zero then C need not be set on input.

C Input and output parameter.

C is __fp16 *

C is an array, dimension (ldc, N). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n matrix (alpha*op(A)*op(B) + beta* C).

ldc Input parameter.

ldc is armpl_int_t *

On entry, ldc specifies the first dimension of C as declared in the calling (sub) program. ldc must be at least max(1, m).

Related Information

For this routine in other precisions, please see *cgemm*, *dgemm*, *sgemm* and *zgemm*.

3.6.7 saxpby

saxpby performs the following vector update:

$y_i \leftarrow ax_i + by_i$ for $i = 0, n-1$.

Syntax

Fortran specification:

```
use armpl_library

subroutine saxpby(N, A, X, INCX, B, Y, INCY)
```

C specification:

```
#include "armpl.h"

void saxpby_(const armpl_int_t *n, const real *alpha,
             const real *x, const armpl_int_t *incx,
             const real *beta, real *y,
             const armpl_int_t *incy);
```

Parameters

N Input parameter.

N is INTEGER

The length of the vectors $\underline{x}$ and $\underline{y}$.

A Input parameter.

A is DOUBLE PRECISION

The scalar a.

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension *(1+(N-1)*ABS(INCX))*

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in X(1+(I-1)*ABS(INCX)).

INCX Input parameter.

INCX is INTEGER

INCX is the increment used to store successive elements of the Vector in X.

B Input parameter.

B is DOUBLE PRECISION

The scalar b.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension *(1+(N-1)*ABS(INCX))*

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in X(1+(I-1)*ABS(INCX)).

INCY Input parameter.

INCY is INTEGER

INCY is the increment used to store successive elements of the Vector in Y.

Related Information

For this routine in other precisions, please see *caxpby*, *daxpby* and *zaxpby*. It also exists with a native C interface as *cblas_saxpby*.

3.6.8 swaxpby

swaxpby performs the following vector operation:

$w_i \leftarrow ax_i + by_i$ for $i = 0, n-1$.

Syntax

Fortran specification:

```
use armpl_library

subroutine swaxpby(N, A, X, INCX, B, Y, INCY, W, INCW)
```

C specification:

```
#include "armpl.h"

void swaxpby_(const armpl_int_t *n, const armpl_doublecomplex_t *alpha,
              const armpl_doublecomplex_t *x, const armpl_int_t *incx,
              const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *y,
              const armpl_int_t *incy, armpl_doublecomplex_t *w,
              const armpl_int_t *incw);
```

Parameters

N Input parameter.

N is INTEGER

The length of the vectors $\underline{x}$ and $\underline{y}$.

A Input parameter.

A is REAL

The scalar a.

X Input parameter.

X is REAL

X is an array, dimension (1+(N-1)*ABS(INCX))

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in X(1+(I-1)*ABS(INCX)).

INCX Input parameter.

INCX is INTEGER

INCX is the increment used to store successive elements of the vector in X.

B Input parameter.

B is REAL

The scalar b.

Y Input parameter.

Y is REAL

Y is an array, dimension (1+(N-1)*ABS(INCX))

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in X(1+(I-1)*ABS(INCX)).

INCY Input parameter.

INCY is INTEGER

INCY is the increment used to store successive elements of the vector in Y.

W Output parameter.

W is REAL

W is an array, dimension (1+(N-1)*ABS(INCX))

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in X(1+(I-1)*ABS(INCX)).

INCW Input parameter.

INCW is INTEGER

INCW is the increment used to store successive elements of the vector in W.

Related Information

For this routine in other precisions, please see *caxpby*, *saxpby* and *daxpby*. It also exists with a native C interface as *cblas_zaxpby*.

3.6.9 zaxpby

zaxpby performs the following vector update:

$y_i \leftarrow ax_i + by_i$ for $i = 0, n - 1$.

Syntax

Fortran specification:

```
use armpl_library

subroutine zaxpby(N, A, X, INCX, B, Y, INCY)
```

C specification:

```
#include "armpl.h"

void zaxpby_(const armpl_int_t *n, const armpl_doublecomplex_t *alpha,
             const armpl_doublecomplex_t *x, const armpl_int_t *incx,
             const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *y,
             const armpl_int_t *incy);
```

Parameters

N Input parameter.

N is INTEGER

The length of the vectors $\underline{x}$ and $\underline{y}$.

A Input parameter.

A is COMPLEX*16

The scalar a.

X Input parameter.

X is COMPLEX*16

X is an array, dimension *(1+(N-1)*ABS(INCX))*

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in X(1+(I-1)*ABS(INCX)).

INCX Input parameter.

INCX is INTEGER

INCX is the increment used to store successive elements of the Vector in X.

B Input parameter.

B is COMPLEX*16

The scalar b.

Y Input and output parameter.

Y is COMPLEX*16

Y is an array, dimension *(1+(N-1)*ABS(INCX))*

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in X(1+(I-1)*ABS(INCX)).

INCY Input parameter.

INCY is INTEGER

INCY is the increment used to store successive elements of the Vector in Y.

Related Information

For this routine in other precisions, please see *caxpby*, *saxpby* and *daxpby*. It also exists with a native C interface as *cblas_zaxpby*.

3.6.10 zgemm3m

zgemm3m performs one of the following matrix-matrix operations:

$$C \leftarrow \alpha op(A) op(B) + \beta C$$

where $op(X)$ is defined as one of:

$op(X) = X$

$op(X) = X^T$ (matrix transpose)

$op(X) = X^H$ (matrix conjugate transpose)

and α and β are scalars, $op(A)$ is an m by k matrix, $op(B)$ a k by n matrix and C is an m by n matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgemm3m(TRANSA, TRANSB, M, N, K ALPHA, A, LDA, B, LDB, BETA, C,
                   LDC)
```

C specification:

```
#include "armpl.h"

void zgemm3m_(const char *transa, const char *transb, const armpl_int_t *m,
              const armpl_int_t *n, const armpl_int_t *k,
              const armpl_doublecomplex_t *alpha,
              const armpl_doublecomplex_t *a, const armpl_int_t *lda,
              const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
              const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *c,
              const armpl_int_t *ldc, ... );
```

Parameters

TRANSA Input parameter

TRANSA is CHARACTER*1

On input:

- If TRANSA = 'n' or 'N' $op(A) = A$;
- If TRANSA = 't' or 'T' $op(A) = A^T$;
- If TRANSA = 'c' or 'C' $op(A) = A^H$.

TRANSB Input parameter

TRANSB is CHARACTER*1

On input:

- If TRANSB = 'n' or 'N' $op(B) = B$;
- If TRANSB = 't' or 'T' $op(B) = B^T$;
- If TRANSB = 'c' or 'C' $op(B) = B^H$.

M Input parameter

M is INTEGER

The number of rows of the matrices $p(A)$ and C.

Constraint $M \geq 0$.

N Input parameter

N is INTEGER

On input: The number of columns of the matrices $op(B)$ and :math'C'.

Constraint $N \geq 0$.

K Input parameter

K is INTEGER

On input: The number of columns of the matrix $op(A)$ and rows of the matrix $op(B)$.

Constraint $K \geq 0$.

ALPHA Input parameter

ALPHA is COMPLEX*16

On input: The value of the scalar α.

A Input parameter

A is COMPLEX*16

On input: An array of dimension (LDA, KA) containing the matrix A, where if *TRANSA = 'n' or 'N'* then KA = K* and the matrix is held in the leading M by K part of the array, otherwise *KA = M* and the matrix is held in the leading K by M part of the array.

LDA Input parameter

LDA is INTEGER **LDA**

On input: The leading dimension of the array *A* as declared in the calling subprogram.

Constraint If *TRANSA = 'n' or 'N'* then $LDA \geq max(1, M)$, otherwise $LDA \geq max(1, K)$.

B Input parameter

B is COMPLEX*16

On input: An array of dimension (LDB, KB) containing the matrix B, where if *TRANSB = 'n' or 'N'* then *KB = N* and the matrix is held in the leading K by N part of the array, otherwise *KB = K* and the matrix is held in the leading *N* by *K* part of the array.

LDB Input parameter

LDB is INTEGER

On input: The leading dimension of the array *B* as declared in the calling subprogram.

Constraint If *TRANSB = 'n' or 'N'* then $LDB \geq max(1, K)$, otherwise $LDB \geq max(1, N)$.

BETA Input parameter

`BETA` is ``COMPLEX*16

On input: The value of the scalar β.

C Input and output parameter

C is COMPLEX*16

On input: An array of dimension (LDC, N) containing the matrix C, in the leading *M* by *N* part of the array. Note that if BETA = 0 then the matrix *C* need not be initialised on input.

On output: The array is overwritten with the result of the operation: $\alpha op(A) op(B) + \beta C$.

LDC Input parameter

LDC is INTEGER

On input: The leading dimension of the array C as declared in the calling subprogram.

Constraint $LDC \geq max(1, M)$.

3.6.11 zwaxpby

zwaxpby performs the following vector operation:

$w_i \leftarrow ax_i + by_i$ for $i = 0, n - 1$.

Syntax

Fortran specification:

```
use armpl_library

subroutine zwaxpby(N, A, X, INCX, B, Y, INCY, W, INCW)
```

C specification:

```
#include "armpl.h"

void zwaxpby_(const armpl_int_t *n, const armpl_doublecomplex_t *alpha,
              const armpl_doublecomplex_t *x, const armpl_int_t *incx,
              const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *y,
              const armpl_int_t *incy, armpl_doublecomplex_t *w,
              const armpl_int_t *incw);
```

Parameters

N Input parameter.

N is INTEGER

The length of the vectors $\underline{x}$ and $\underline{y}$.

A Input parameter.

A is COMPLEX*16

The scalar a.

X Input parameter.

X is COMPLEX*16

X is an array, dimension (1+(N-1)*ABS(INCX))

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in X(1+(I-1)*ABS(INCX)).

INCX Input parameter.

INCX is INTEGER

INCX is the increment used to store successive elements of the vector in X.

B Input parameter.

B is COMPLEX*16

The scalar b.

Y Input parameter.

Y is COMPLEX*16

Y is an array, dimension (1+(N-1)*ABS(INCX))

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in X(1+(I-1)*ABS(INCX)).

INCY Input parameter.

INCY is INTEGER

INCY is the increment used to store successive elements of the vector in Y.

W Output parameter.

W is COMPLEX*16

W is an array, dimension (1+(N-1)*ABS(INCX))

Contains the elements of the vector $\underline{x}$ with the I^{th} element stored in `X(1+(I-1)*ABS(INCX))`.

`INCW` Input parameter.

`INCW` is `INTEGER`

`INCW` is the increment used to store successive elements of the vector in `W`.

Related Information

For this routine in other precisions, please see *caxpby*, *saxpby* and *daxpby*. It also exists with a native C interface as *cblas_zaxpby*.

3.6.12 sgemm_batch

`sgemm_batch` computes a batch of `TOTAL_SIZE` *sgemm* problems which are split into `GROUP_COUNT` groups, where problems in a group share the same transpose options, problem dimensions, array leading dimensions and scalars α and β.

This routine implements the following operation:

```
   TOTAL_SIZE = 0
   PID = 1
   DO 10 J = 1, GROUP_COUNT
      DO 20 I = 1, GROUP_SIZE(J)
         CALL SGEMM(TRANSA(J),TRANSB(J),M(J),N(J),K(J),ALPHA(J),
  &                 A(PID),LDA(J),B(PID),LDB(J),BETA(J),C(PID),LDC(J))
         PID = PID + 1
20    CONTINUE
      TOTAL_SIZE = TOTAL_SIZE + GROUP_SIZE(J)
10 CONTINUE
```

Note that the above also defines the value of `TOTAL_SIZE`, which is not required as a routine argument, but is used in the documentation below; it is the sum of the `GROUP_SIZE` array.

sgemm is the standard BLAS single precision complex matrix-matrix multiplication routine, and users are referred to its own documentation.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgemm_batch(TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB, BETA,
                       C, LDC, GROUP_COUNT, GROUP_SIZE)
```

C specification:

```
#include "armpl.h"

void sgemm_batch_(const char *transa, const char *transb,
                  const armpl_int_t *m, const armpl_int_t *n,
                  const armpl_int_t *k, const float *alpha,
                  const float *const *a,
                  const armpl_int_t *lda,
                  const float *const *b,
                  const armpl_int_t *ldb, const float *beta,
                  float *const *c, const armpl_int_t *ldc,
                  const armpl_int_t *group_count,
                  const armpl_int_t *group_size, ... );
```

Parameters

TRANSA Input parameter.

TRANSA is CHARACTER*1

TRANSA is an array, dimension (GROUP_COUNT)

- If TRANSA(J) = 'n' or 'N' then for the J^{th} group, for all matrices A, $op(A) = A$;
- If TRANSA(J) = 't' or 'T' or 'c' or 'C'vthen for the J^{th} group, for all matrices A, $op(A) = A^T$ (matrix transpose).

TRANSB Input parameter.

TRANSB is CHARACTER*1

TRANSB is an array, dimension (GROUP_COUNT)

- If TRANSB(J) = 'n' or 'N' then for the J^{th} group, for all matrices B, $op(B) = B$;
- If TRANSB(J) = 't' or 'T' or 'c' or 'C' then for the J^{th} group, for all matrices B, $op(B) = B^T$ (matrix transpose).

M Input parameter.

M is INTEGER

M is an array, dimension (GROUP_COUNT)

For all matrices A in the J^{th} group, M(J) specifies the number of rows of $op(A)$ and C.

Constraint: M(J) ≥ 0 for J=1,GROUP_COUNT.

N Input parameter.

N is INTEGER

N is an array, dimension (GROUP_COUNT)

For all matrices B and C in the J^{th} group, N(J) specifies the number of columns of $op(B)$ and C.

Constraint: N(J) ≥ 0 for J=1,GROUP_COUNT.

K Input parameter.

K is INTEGER

K is an array, dimension (GROUP_COUNT)

For all matrices A and B in the J^{th} group, K(J) specifies the number of columns of op(A) ` and rows of op(B).

Constraint: $K(J) \geq 0$ for J=1,GROUP_COUNT.

ALPHA Input parameter.

ALPHA is REAL

ALPHA is an array, dimension (GROUP_COUNT)

ALPHA(J) gives the value of the scalar α for the J^{th} group.

A Input parameter.

A is REAL

A is an array, dimension (TOTAL_SIZE)

An array of pointers to TOTAL_SIZE input matrices A.

LDA Input parameter.

LDA is INTEGER

LDA is an array, dimension (GROUP_COUNT)

LDA(J) gives the leading dimension of all A matrices in the J^{th} group as declared in the calling subprogram.

Constraint: If TRANSA(J) = 'n' or 'N' then LDA(J) $\geq$ max(1,M(J)) , otherwise LDA(J) $\geq$ max(1, K(J)) for J=1,GROUP_COUNT.

B Input parameter.

B is REAL

B is an array, dimension (TOTAL_SIZE)

An array of pointers to TOTAL_SIZE input matrices *B*.

LDB Input parameter.

LDB is INTEGER

LDB is an array, dimension (GROUP_COUNT)

LDB(J) gives the leading dimension of all B matrices in the J^{th} group as declared in the calling subprogram.

Constraint: If TRANSB(J) = 'n' or 'N' then LDA(J) $\geq$ max(1,K(J)) , otherwise LDA(J) $\geq$ max(1, N(J)) for J=1,GROUP_COUNT.

BETA Input parameter.

BETA is REAL

BETA is an array, dimension (GROUP_COUNT)

BETA(J) gives the value of the scalar β for the J^{th} group.

C Input and output parameter.

C is REAL

C is an array, dimension (TOTAL_SIZE)

An array of pointers to TOTAL_SIZE input matrices C.

LDC Input parameter.

LDC is INTEGER

LDC is an array, dimension (GROUP_COUNT)

LDC(J) gives the leading dimension of all C matrices in the J^{th} group as declared in the calling subprogram.

Constraint: LDC(J) $\geq$ max(1,M(J)) for J=1,GROUP_COUNT.

GROUP_COUNT Input parameter.

GROUP_COUNT is INTEGER

Specifies the number of groups.

Constraint: GROUP_COUNT ≥ 0.

GROUP_SIZE Input parameter.

GROUP_SIZE is INTEGER

GROUP_SIZE is an array, dimension (GROUP_COUNT)

On input: GROUP_SIZE(J) specifies the number of *sgemm* problems in the J^{th} group.

Constraint: GROUP_SIZE(J) ≥ 0 for J=1,GROUP_COUNT.

3.6.13 dgemm_batch

dgemm_batch computes a batch of TOTAL_SIZE *dgemm* problems which are split into GROUP_COUNT groups, where problems in a group share the same transpose options, problem dimensions, array leading dimensions and scalars α and β.

This routine implements the following operation:

```
   TOTAL_SIZE = 0
   PID = 1
   DO 10 J = 1, GROUP_COUNT
      DO 20 I = 1, GROUP_SIZE(J)
         CALL DGEMM(TRANSA(J),TRANSB(J),M(J),N(J),K(J),ALPHA(J),
  &                  A(PID),LDA(J),B(PID),LDB(J),BETA(J),C(PID),LDC(J))
         PID = PID + 1
20    CONTINUE
      TOTAL_SIZE = TOTAL_SIZE + GROUP_SIZE(J)
10 CONTINUE
```

Note that the above also defines the value of TOTAL_SIZE, which is not required as a routine argument, but is used in the documentation below; it is the sum of the GROUP_SIZE array.

dgemm is the standard BLAS single precision complex matrix-matrix multiplication routine, and users are referred to its own documentation.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgemm_batch(TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB, BETA,
                       C, LDC, GROUP_COUNT, GROUP_SIZE)
```

C specification:

```
#include "armpl.h"

void dgemm_batch_(const char *transa, const char *transb,
                  const armpl_int_t *m, const armpl_int_t *n,
                  const armpl_int_t *k, const double *alpha,
                  const double *const *a,
                  const armpl_int_t *lda,
                  const double *const *b,
                  const armpl_int_t *ldb, const double *beta,
                  double *const *c, const armpl_int_t *ldc,
                  const armpl_int_t *group_count,
                  const armpl_int_t *group_size, ... );
```

Parameters

TRANSA Input parameter.

TRANSA is CHARACTER*1

TRANSA is an array, dimension (GROUP_COUNT)

- If TRANSA(J) = 'n' or 'N' then for the J^{th} group, for all matrices A, $op(A) = A$;
- If TRANSA(J) = 't' or 'T' or 'c' or 'C'vthen for the J^{th} group, for all matrices A, $op(A) = A^T$ (matrix transpose).

TRANSB Input parameter.

TRANSB is CHARACTER*1

TRANSB is an array, dimension (GROUP_COUNT)

DOUBLE PRECISION

- If TRANSB(J) = 'n' or 'N' then for the J^{th} group, for all matrices B, $op(B) = B$;
- If TRANSB(J) = 't' or 'T' or 'c' or 'C' then for the J^{th} group, for all matrices B, $op(B) = B^T$ (matrix transpose).

M Input parameter.

M is INTEGER

M is an array, dimension (GROUP_COUNT)

For all matrices A in the J^{th} group, M(J) specifies the number of rows of $op(A)$ and C.

Constraint: M(J) ≥ 0 for J=1,GROUP_COUNT.

N Input parameter.

N is INTEGER

N is an array, dimension (GROUP_COUNT)

For all matrices B and C in the J^{th} group, N(J) specifies the number of columns of $op(B)$ and C.

Constraint: N(J) ≥ 0 for J=1,GROUP_COUNT.

K Input parameter.

K is INTEGER

K is an array, dimension (GROUP_COUNT)

For all matrices A and B in the J^{th} group, K(J) specifies the number of columns of op(A)` and rows of op(B).

Constraint: $K(J) \geq 0$ for J=1,GROUP_COUNT.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION

ALPHA is an array, dimension (GROUP_COUNT)

ALPHA(J) gives the value of the scalar α for the J^{th} group.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (TOTAL_SIZE)

An array of pointers to TOTAL_SIZE input matrices *A*.

LDA Input parameter.

LDA is INTEGER

LDA is an array, dimension (GROUP_COUNT)

LDA(J) gives the leading dimension of all A matrices in the J^{th} group as declared in the calling subprogram.

Constraint: If TRANSA(J) = 'n' or 'N' then LDA(J) $\geq$ max(1,M(J)) , otherwise LDA(J) $\geq$ max(1, K(J)) for J=1,GROUP_COUNT.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (TOTAL_SIZE)

An array of pointers to TOTAL_SIZE input matrices *B*.

LDB Input parameter.

LDB is INTEGER

LDB is an array, dimension (GROUP_COUNT)

LDB(J) gives the leading dimension of all B matrices in the J^{th} group as declared in the calling subprogram.

Constraint: If TRANSB(J) = 'n' or 'N' then LDA(J) $\geq$ max(1,K(J)) , otherwise LDA(J) $\geq$ max(1, N(J)) for J=1,GROUP_COUNT.

BETA Input parameter.

BETA is DOUBLE PRECISION

BETA is an array, dimension (GROUP_COUNT)

BETA(J) gives the value of the scalar β for the J^{th} group.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (TOTAL_SIZE)

An array of pointers to TOTAL_SIZE input matrices C.

LDC Input parameter.

LDC is INTEGER

LDC is an array, dimension (GROUP_COUNT)

LDC(J) gives the leading dimension of all C matrices in the J^{th} group as declared in the calling subprogram.

Constraint: LDC(J) $\geq$ max(1,M(J)) for J=1,GROUP_COUNT.

GROUP_COUNT Input parameter.

GROUP_COUNT is INTEGER

Specifies the number of groups.

Constraint: GROUP_COUNT ≥ 0.

GROUP_SIZE Input parameter.

GROUP_SIZE is INTEGER

GROUP_SIZE is an array, dimension (GROUP_COUNT)

On input: GROUP_SIZE(J) specifies the number of *dgemm* problems in the J^{th} group.

Constraint: GROUP_SIZE(J) ≥ 0 for J=1,GROUP_COUNT.

3.6.14 cgemm_batch

cgemm_batch computes a batch of TOTAL_SIZE *cgemm* problems which are split into GROUP_COUNT groups, where problems in a group share the same transpose options, problem dimensions, array leading dimensions and scalars α and β.

This routine implements the following operation:

```
   TOTAL_SIZE = 0
   PID = 1
   DO 10 J = 1, GROUP_COUNT
      DO 20 I = 1, GROUP_SIZE(J)
         CALL CGEMM(TRANSA(J),TRANSB(J),M(J),N(J),K(J),ALPHA(J),
  &                 A(PID),LDA(J),B(PID),LDB(J),BETA(J),C(PID),LDC(J))
```

(continues on next page)

(continued from previous page)

```
        PID = PID + 1
20    CONTINUE
      TOTAL_SIZE = TOTAL_SIZE + GROUP_SIZE(J)
10 CONTINUE
```

Note that the above also defines the value of TOTAL_SIZE, which is not required as a routine argument, but is used in the documentation below; it is the sum of the GROUP_SIZE array.

cgemm is the standard BLAS single precision complex matrix-matrix multiplication routine, and users are referred to its own documentation.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgemm_batch(TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB, BETA,
                       C, LDC, GROUP_COUNT, GROUP_SIZE)
```

C specification:

```
#include "armpl.h"

void cgemm_batch_(const char *transa, const char *transb,
                  const armpl_int_t *m, const armpl_int_t *n,
                  const armpl_int_t *k, const armpl_singlecomplex_t *alpha,
                  const armpl_singlecomplex_t *const *a,
                  const armpl_int_t *lda,
                  const armpl_singlecomplex_t *const *b,
                  const armpl_int_t *ldb, const armpl_singlecomplex_t *beta,
                  armpl_singlecomplex_t *const *c, const armpl_int_t *ldc,
                  const armpl_int_t *group_count,
                  const armpl_int_t *group_size, ... );
```

Parameters

TRANSA Input parameter.

TRANSA is CHARACTER*1

TRANSA is an array, dimension (GROUP_COUNT)

- If TRANSA(J) = 'n' or 'N' then for the J^{th} group, for all matrices A, $op(A) = A$;
- If TRANSA(J) = 't' or 'T' then for the J^{th} group, for all matrices A, $op(A) = A^T$ (matrix transpose).
- If TRANSA(J) = 'c' or 'C' then for the J^{th} group, for all matrices A, $op(A) = A^H$ (matrix conjugate transpose).

TRANSB Input parameter.

TRANSB is CHARACTER*1

TRANSB is an array, dimension (GROUP_COUNT)

- If TRANSB(J) = 'n' or 'N' then for the J^{th} group, for all matrices B, $op(B) = B$;
- If TRANSB(J) = 't' or 'T' then for the J^{th} group, for all matrices B, $op(B) = B^T$ (matrix transpose).
- If TRANSB(J) = 'c' or 'C' then for the J^{th} group, for all matrices B, $op(B) = B^H$ (matrix conjugate transpose).

M Input parameter.

M is INTEGER

M is an array, dimension (GROUP_COUNT)

For all matrices A in the J^{th} group, M(J) specifies the number of rows of $op(A)$ and C.

Constraint: M(J) ≥ 0 for J=1,GROUP_COUNT.

N Input parameter.

N is INTEGER

N is an array, dimension (GROUP_COUNT)

For all matrices B and C in the J^{th} group, N(J) specifies the number of columns of $op(B)$ and C.

Constraint: N(J) ≥ 0 for J=1,GROUP_COUNT.

K Input parameter.

K is INTEGER

K is an array, dimension (GROUP_COUNT)

For all matrices A and B in the J^{th} group, K(J) specifies the number of columns of op(A)` and rows of op(B).

Constraint: $K(J) \geq 0$ for J=1,GROUP_COUNT.

ALPHA Input parameter.

ALPHA is COMPLEX

ALPHA is an array, dimension (GROUP_COUNT)

ALPHA(J) gives the value of the scalar α for the J^{th} group.

A Input parameter.

A is COMPLEX

A is an array, dimension (TOTAL_SIZE)

An array of pointers to TOTAL_SIZE input matrices *A*.

LDA Input parameter.

LDA is INTEGER

LDA is an array, dimension (GROUP_COUNT)

LDA(J) gives the leading dimension of all A matrices in the J^{th} group as declared in the calling subprogram.

Constraint: If TRANSA(J) = 'n' or 'N' then LDA(J) $\geq$ max(1,M(J)) , otherwise LDA(J) $\geq$ max(1, K(J)) for J=1,GROUP_COUNT.

B Input parameter.

B is COMPLEX

B is an array, dimension (TOTAL_SIZE)

An array of pointers to TOTAL_SIZE input matrices *B*.

LDB Input parameter.

LDB is INTEGER

LDB is an array, dimension (GROUP_COUNT)

LDB(J) gives the leading dimension of all B matrices in the J^{th} group as declared in the calling subprogram.

Constraint: If TRANSB(J) = 'n' or 'N' then LDA(J) $\geq$ max(1,K(J)) , otherwise LDA(J) $\geq$ max(1, N(J)) for J=1,GROUP_COUNT.

BETA Input parameter.

BETA is COMPLEX

BETA is an array, dimension (GROUP_COUNT)

BETA(J) gives the value of the scalar β for the J^{th} group.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (TOTAL_SIZE)

An array of pointers to TOTAL_SIZE input matrices C.

LDC Input parameter.

LDC is INTEGER

LDC is an array, dimension (GROUP_COUNT)

LDC(J) gives the leading dimension of all C matrices in the J^{th} group as declared in the calling subprogram.

Constraint: LDC(J) $\geq$ max(1,M(J)) for J=1,GROUP_COUNT.

GROUP_COUNT Input parameter.

GROUP_COUNT is INTEGER

Specifies the number of groups.

Constraint: GROUP_COUNT ≥ 0.

GROUP_SIZE Input parameter.

GROUP_SIZE is INTEGER

GROUP_SIZE is an array, dimension (GROUP_COUNT)

On input: GROUP_SIZE(J) specifies the number of *zgemm* problems in the J^{th} group.

Constraint: GROUP_SIZE(J) ≥ 0 for J=1,GROUP_COUNT.

3.6.15 zgemm_batch

zgemm_batch computes a batch of TOTAL_SIZE *zgemm* problems which are split into GROUP_COUNT groups, where problems in a group share the same transpose options, problem dimensions, array leading dimensions and scalars α and β.

This routine implements the following operation:

```
   TOTAL_SIZE = 0
   PID = 1
   DO 10 J = 1, GROUP_COUNT
      DO 20 I = 1, GROUP_SIZE(J)
         CALL ZGEMM(TRANSA(J),TRANSB(J),M(J),N(J),K(J),ALPHA(J),
  &                 A(PID),LDA(J),B(PID),LDB(J),BETA(J),C(PID),LDC(J))
         PID = PID + 1
20    CONTINUE
      TOTAL_SIZE = TOTAL_SIZE + GROUP_SIZE(J)
10 CONTINUE
```

Note that the above also defines the value of TOTAL_SIZE, which is not required as a routine argument, but is used in the documentation below; it is the sum of the GROUP_SIZE array.

zgemm is the standard BLAS single precision complex matrix-matrix multiplication routine, and users are referred to its own documentation.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgemm_batch(TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB, BETA,
                       C, LDC, GROUP_COUNT, GROUP_SIZE)
```

C specification:

```
#include "armpl.h"

void zgemm_batch_(const char *transa, const char *transb,
                  const armpl_int_t *m, const armpl_int_t *n,
                  const armpl_int_t *k, const armpl_doublecomplex_t *alpha,
                  const armpl_doublecomplex_t *const *a,
                  const armpl_int_t *lda,
                  const armpl_doublecomplex_t *const *b,
                  const armpl_int_t *ldb, const armpl_doublecomplex_t *beta,
                  armpl_doublecomplex_t *const *c, const armpl_int_t *ldc,
                  const armpl_int_t *group_count,
                  const armpl_int_t *group_size, ... );
```

Parameters

TRANSA Input parameter.

TRANSA is CHARACTER*1

TRANSA is an array, dimension (GROUP_COUNT)

- If TRANSA(J) = 'n' or 'N' then for the J^{th} group, for all matrices A, $op(A) = A$;
- If TRANSA(J) = 't' or 'T' then for the J^{th} group, for all matrices A, $op(A) = A^T$ (matrix transpose).
- If TRANSA(J) = 'c' or 'C' then for the J^{th} group, for all matrices A, $op(A) = A^H$ (matrix conjugate transpose).

TRANSB Input parameter.

TRANSB is CHARACTER*1

TRANSB is an array, dimension (GROUP_COUNT)

- If TRANSB(J) = 'n' or 'N' then for the J^{th} group, for all matrices B, $op(B) = B$;
- If TRANSB(J) = 't' or 'T' then for the J^{th} group, for all matrices B, $op(B) = B^T$ (matrix transpose).
- If TRANSB(J) = 'c' or 'C' then for the J^{th} group, for all matrices B, $op(B) = B^H$ (matrix conjugate transpose).

M Input parameter.

M is INTEGER

M is an array, dimension (GROUP_COUNT)

For all matrices A in the J^{th} group, M(J) specifies the number of rows of $op(A)$ and C.

Constraint: M(J) ≥ 0 for J=1,GROUP_COUNT.

N Input parameter.

N is INTEGER

N is an array, dimension (GROUP_COUNT)

For all matrices B and C in the J^{th} group, N(J) specifies the number of columns of $op(B)$ and C.

Constraint: `N(J)` ≥ 0 for `J=1,GROUP_COUNT`.

K Input parameter.

`K` is `INTEGER`

`K` is an array, dimension `(GROUP_COUNT)`

For all matrices `A` and `B` in the J^{th} group, `K(J)` specifies the number of columns of `op(A)` ` and rows of `op(B)`.

Constraint: $K(J) \geq 0$ for `J=1,GROUP_COUNT`.

ALPHA Input parameter.

`ALPHA` is `COMPLEX*16`

`ALPHA` is an array, dimension `(GROUP_COUNT)`

`ALPHA(J)` gives the value of the scalar α for the J^{th} group.

A Input parameter.

`A` is `COMPLEX*16`

`A` is an array, dimension `(TOTAL_SIZE)`

An array of pointers to `TOTAL_SIZE` input matrices *A*.

LDA Input parameter.

`LDA` is `INTEGER`

`LDA` is an array, dimension `(GROUP_COUNT)`

`LDA(J)` gives the leading dimension of all `A` matrices in the J^{th} group as declared in the calling subprogram.

Constraint: If `TRANSA(J)` = 'n' or 'N' then `LDA(J)` $\geq$ `max(1,M(J))` , otherwise `LDA(J)` $\geq$ `max(1, K(J))` for `J=1,GROUP_COUNT`.

B Input parameter.

`B` is `COMPLEX*16`

`B` is an array, dimension `(TOTAL_SIZE)`

An array of pointers to `TOTAL_SIZE` input matrices *B*.

LDB Input parameter.

`LDB` is `INTEGER`

`LDB` is an array, dimension `(GROUP_COUNT)`

`LDB(J)` gives the leading dimension of all `B` matrices in the J^{th} group as declared in the calling subprogram.

Constraint: If `TRANSB(J)` = 'n' or 'N' then `LDA(J)` $\geq$ `max(1,K(J))` , otherwise `LDA(J)` $\geq$ `max(1, N(J))` for `J=1,GROUP_COUNT`.

BETA Input parameter.

`BETA` is `COMPLEX*16`

`BETA` is an array, dimension `(GROUP_COUNT)`

`BETA(J)` gives the value of the scalar β for the J^{th} group.

C Input and output parameter.

`C` is `COMPLEX*16`

`C` is an array, dimension `(TOTAL_SIZE)`

An array of pointers to `TOTAL_SIZE` input matrices `C`.

LDC Input parameter.

LDC is INTEGER

LDC is an array, dimension (GROUP_COUNT)

LDC(J) gives the leading dimension of all C matrices in the J^{th} group as declared in the calling subprogram.

Constraint: LDC(J) $\geq$ max(1,M(J))` for J=1,GROUP_COUNT.

GROUP_COUNT Input parameter.

GROUP_COUNT is INTEGER

Specifies the number of groups.

Constraint: GROUP_COUNT ≥ 0.

GROUP_SIZE Input parameter.

GROUP_SIZE is INTEGER

GROUP_SIZE is an array, dimension (GROUP_COUNT)

On input: GROUP_SIZE(J) specifies the number of *zgemm* problems in the J^{th} group.

Constraint: GROUP_SIZE(J) ≥ 0 for J=1,GROUP_COUNT.

In addition to the standard BLAS interfaces, Arm Performance Libraries also supports some commonly used extensions. We document here the Fortran interfaces, but the equivalent CBLAS-like interfaces are supported and prototypes are provided in armpl.h.

CHAPTER

FOUR

LAPACK LINEAR ALGEBRA PACKAGE

4.1 Introduction to LAPACK

LAPACK ([4]) is a library of FORTRAN 77 subroutines for solving commonly occurring problems in numerical linear algebra. LAPACK components can solve systems of linear equations, linear least squares problems, eigenvalue problems and singular value problems. Dense and banded matrices are provided for, but not general sparse matrices. In all areas, similar functionality is provided for real and complex matrices.

LAPACK routines are written so that as much as possible of the computations is performed by calls to the BLAS. The efficiency of LAPACK routines depends, in large part, on the efficiency of the BLAS being called. Block algorithms are employed wherever possible to maximize the use of calls to level 3 BLAS, which generally run faster than lower level BLAS due to the high number of operations per memory access.

The performance of some of the LAPACK routines has been further improved by reworking the computational algorithms. Some of the LAPACK routines contained in Arm Performance Libraries are therefore based on code that is different from the LAPACK sources available in the public domain. In all these cases the algorithmic and numerical properties of the original LAPACK routines have been strictly preserved. Furthermore, key LAPACK routines have been treated using OpenMP to take advantage of multiple processors when running on SMP machines. Your application will automatically benefit when you link with the OpenMP versions of Arm Performance Libraries.

4.2 Reference sources for LAPACK

The LAPACK homepage can be accessed on the World Wide Web via the URL address:

http://www.netlib.org/lapack/

The on-line version of the Lapack User's Guide, Third Edition ([4]) is available from this homepage, or directly using the URL:

http://www.netlib.org/lapack/lug/index.html

The standard source code is available for download from netlib:

http://www.netlib.org/lapack/lapack.tgz

A list of known problems, bugs, and compiler errors for LAPACK, as well as an errata list for the LAPACK User's Guide ([4]), is maintained on netlib

http://www.netlib.org/lapack/release_notes

A LAPACK FAQ (Frequently Asked Questions) file can also be accessed via the LAPACK homepage

http://www.netlib.org/lapack/faq.html

For C users, Arm Performance Libraries includes the LAPACKE C interfaces to Fortran LAPACK. Names of these routines are similar to the Fortran routines except they are prefixed by the string `LAPACKE_`. For example, the Fortran LAPACK routine `dgetrf` becomes `LAPACKE_dgetrf` in C. Other differences between Fortran BLAS and CBLAS interfaces:

- Scalar input arguments are passed by value in LAPACKE interfaces. FORTRAN interfaces pass all arguments (except for character string *length* arguments that are normally hidden from FORTRAN programmers) by reference.
- Unlike FORTRAN, C has no native *complex* data type. Arm Performance Libraries C routines which operate on complex data use the types `armpl_singlecomplex_t` and `armpl_doublecomplex_t` defined in `armpl.h` for single and double precision computations respectively.
- As with Fortran, all LAPACKE array arguments are required to be stored in contiguous memory. However, all Fortran LAPACK routines which take one or more matrices (2D arrays) as arguments have an extra parameter in the LAPACKE interface, which appears before all other parameters. This parameter is of integer type and is named `matrix_order`, and it can take one of the values `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, where `LAPACK_ROW_MAJOR` and `LAPACK_COL_MAJOR` are integers defined in `armpl.h`

  The value `LAPACK_COL_MAJOR` indicates that elements within any column of each array are contiguous in memory while elements within array rows are offset by a constant stride. This is the usual Fortran storage order. Such strides are given by "leading dimension" arguments (such as `LDA`) in the Fortran and C interfaces.

  The value `LAPACK_ROW_MAJOR` indicates that elements within any row of each 2D array are contiguous in memory while elements within array columns are offset by a constant stride such as `LDA`.
- Fortran's `character` type arguments are passed as values of the C `char` type.
- In general, Fortran "workspace" type arguments (with names such as `WORK`, `RWORK` and `CWORK`) do not appear in the C interfaces - workspace memory is allocated internally. However, LAPACKE also includes variants which *do* have the workspace arguments - these variants have the string `_work` appended to the function name, for example `LAPACKE_dgetrf_work`.

See the `armpl.h` header file to find prototypes for all LAPACKE functions. Note that the functions may also be called from a C++ program if you include `armpl.h`.

4.3 LAPACK matrix factorization routines

4.3.1 cgbtrf

`cgbtrf` computes an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgbtrf(M, N, KL, KU, AB, LDAB, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void cgbtrf_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku,
             armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
             armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Output parameter.

IPIV is INTEGER array, dimension (min(M, N))

The pivot indices; for 1 <= i <= min(M, N), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = +i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *dgbtrf*, *sgbtrf* and *zgbtrf*. It also exists with a native C interface as *LAPACKE_cgbtrf*.

4.3.2 cgelq

cgelq computes a LQ factorization of an M-by-N matrix A.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgelq(M, N, A, LDA, T, TSIZE, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgelq_(const armpl_int_t *m, const armpl_int_t *n,
            armpl_singlecomplex_t *a, const armpl_int_t *lda,
            armpl_singlecomplex_t *t, const armpl_int_t *tsize,
            armpl_singlecomplex_t *work, const armpl_int_t *lwork,
            armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the M-by-min(M, N) lower trapezoidal matrix L (L is lower triangular if M <= N); the elements above the diagonal are used to store part of the data structure to represent Q.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is COMPLEX

T is an array, dimension (MAX(5, TSIZE)). On exit, if INFO = 0, T(1) returns optimal (or either minimal or optimal, if query is assumed) TSIZE. See TSIZE for details. Remaining T contains part of the data structure used to represent Q. If one wants to apply or construct Q, then one needs to keep T (in addition to A) and pass it to further subroutines.

TSIZE Input parameter.

TSIZE is INTEGER

If TSIZE >= 5, the dimension of the array T. If TSIZE = -1 or -2, then a workspace query is assumed. The routine only calculates the sizes of the T and WORK arrays, returns these values as the first entries of the T and WORK arrays, and no error message related to T or WORK is issued by XERBLA. If TSIZE = -1, the routine calculates optimal size of T for the optimum performance and returns this value in T(1). If TSIZE = -2, the routine calculates minimal size of T and returns this value in T(1).

WORK Output parameter.

(workspace) COMPLEX

(workspace) is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) contains optimal (or either minimal or optimal, if query was assumed) LWORK. See LWORK for details.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1 or -2, then a workspace query is assumed. The routine only calculates the sizes of the T and WORK arrays, returns these values as the first entries of the T and WORK arrays, and no error message related to T or WORK is issued by XERBLA. If LWORK = -1, the routine calculates optimal size of WORK for the optimal performance and returns this value in WORK(1). If LWORK = -2, the routine calculates minimal size of WORK and returns this value in WORK(1).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgelq*, *sgelq* and *zgelq*. It also exists with a native C interface as *LAPACKE_cgelq*.

4.3.3 cgelqf

cgelqf computes an LQ factorization of a complex M-by-N matrix A: A = L * Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgelqf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgelqf_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the m-by-min(m,n) lower trapezoidal matrix L (L is lower triangular if m <= n); the elements above the diagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgelqf*, *sgelqf* and *zgelqf*. It also exists with a native C interface as *LAPACKE_cgelqf*.

4.3.4 cgelqt

cgelqt computes a blocked LQ factorization of a complex M-by-N matrix A using the compact WY representation of Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgelqt(M, N, MB, A, LDA, T, LDT, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgelqt_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *mb, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *t,
             const armpl_int_t *ldt, armpl_singlecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

MB Input parameter.

MB is INTEGER

The block size to be used in the blocked QR. MIN(M, N) >= MB >= 1.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the M-by-MIN(M, N) lower trapezoidal matrix L (L is lower triangular if M <= N); the elements above the diagonal are the rows of V.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is COMPLEX

T is an array, dimension (LDT,MIN(M, N)). The upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MB*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgelqt*, *sgelqt* and *zgelqt*.

4.3.5 cgemlq

cgemlq overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H where Q is a complex unitary matrix defined as the product of blocked elementary reflectors computed by short wide LQ factorization (CGELQ)

Syntax

Fortran specification:

```
use armpl_library

subroutine cgemlq(SIDE, TRANS, M, N, K, A, LDA, T, TSIZE, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void cgemlq_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *t, const armpl_int_t *tsize,
             armpl_singlecomplex_t *c, const armpl_int_t *ldc,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >=0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' Part of the data structure to represent Q as returned by CGELQ.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

T Input parameter.

T is COMPLEX

T is an array, dimension (MAX(5, TSIZE)).. Part of the data structure to represent Q as returned by CGELQ.

TSIZE Input parameter.

TSIZE is INTEGER

The dimension of the array T. TSIZE >= 5.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

(workspace) COMPLEX

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1, then a workspace query is assumed. The routine only calculates the size of the WORK array, returns this value as WORK(1), and no error message related to WORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgemlq*, *sgemlq* and *zgemlq*. It also exists with a native C interface as *LAPACKE_cgemlq*.

4.3.6 cgemlqt

cgemlqt overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': Q C C Q TRANS = 'C': Q^H C C Q^H where Q is a complex orthogonal matrix defined as the product of K elementary reflectors: Q = H(1) H(2) . . . H(K) = I - V T V^H generated using the compact WY representation as returned by CGELQT. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgemlqt(SIDE, TRANS, M, N, K, MB, V, LDV, T, LDT, C, LDC, WORK,
                   INFO)
```

C specification:

```
#include "armpl.h"

void cgemlqt_(const char *side, const char *trans, const armpl_int_t *m,
              const armpl_int_t *n, const armpl_int_t *k,
              const armpl_int_t *mb, const armpl_singlecomplex_t *v,
              const armpl_int_t *ldv, const armpl_singlecomplex_t *t,
              const armpl_int_t *ldt, armpl_singlecomplex_t *c,
              const armpl_int_t *ldc, armpl_singlecomplex_t *work,
              armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

MB Input parameter.

MB is INTEGER

The block size used for the storage of T. K >= MB >= 1. This must be the same value of MB used to generate T in DGELQT.

V Input parameter.

V is COMPLEX

V is an array, dimension. (LDV, M) if SIDE = 'L', (LDV, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DGELQT in the first K rows of its array argument A.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, K).

T Input parameter.

T is COMPLEX

T is an array, dimension (LDT, K). The upper triangular factors of the block reflectors as returned by DGELQT, stored as a MB-by-K matrix.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q C, Q^H C, C Q^H or C Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX array. The dimension of

WORK is N* MB if SIDE = 'L', or M* MB if SIDE = 'R'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgemlqt*, *sgemlqt* and *zgemlqt*.

4.3.7 cgemqr

cgemqr overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': Q * C C * Q TRANS = 'T': Q^H * C C * Q^H where Q is a complex unitary matrix defined as the product of blocked elementary reflectors computed by tall skinny QR factorization (CGEQR)

Syntax

Fortran specification:

```
use armpl_library

subroutine cgemqr(SIDE, TRANS, M, N, K, A, LDA, T, TSIZE, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void cgemqr_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *t, const armpl_int_t *tsize,
             armpl_singlecomplex_t *c, const armpl_int_t *ldc,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >=0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, K). Part of the data structure to represent Q as returned by CGEQR.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

T Input parameter.

T is COMPLEX

T is an array, dimension (MAX(5, TSIZE)).. Part of the data structure to represent Q as returned by CGEQR.

TSIZE Input parameter.

TSIZE is INTEGER

The dimension of the array T. TSIZE >= 5.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

(workspace) COMPLEX

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1, then a workspace query is assumed. The routine only calculates the size of the WORK array, returns this value as WORK(1), and no error message related to WORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgemqr*, *sgemqr* and *zgemqr*. It also exists with a native C interface as *LAPACKE_cgemqr*.

4.3.8 cgemqrt

cgemqrt overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'      SIDE = 'R'
```

TRANS = 'N': Q C C Q TRANS = 'C': Q^H C C Q^H

where Q is a complex orthogonal matrix defined as the product of K elementary reflectors:

```
Q = H(1) H(2) . . . H(K) = I - V T V**H
```

generated using the compact WY representation as returned by CGEQRT.

Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgemqrt(SIDE, TRANS, M, N, K, NB, V, LDV, T, LDT, C, LDC, WORK,
                   INFO)
```

C specification:

```
#include "armpl.h"

void cgemqrt_(const char *side, const char *trans, const armpl_int_t *m,
              const armpl_int_t *n, const armpl_int_t *k,
              const armpl_int_t *nb, const armpl_singlecomplex_t *v,
              const armpl_int_t *ldv, const armpl_singlecomplex_t *t,
              const armpl_int_t *ldt, armpl_singlecomplex_t *c,
              const armpl_int_t *ldc, armpl_singlecomplex_t *work,
              armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

NB Input parameter.

NB is INTEGER

The block size used for the storage of T. K >= NB >= 1. This must be the same value of NB used to generate T in CGEQRT.

V Input parameter.

V is COMPLEX

V is an array, dimension (LDV, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGEQRT in the first K columns of its array argument A.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

T Input parameter.

T is COMPLEX

T is an array, dimension (LDT, K). The upper triangular factors of the block reflectors as returned by CGEQRT, stored as a NB-by-N matrix.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q C, Q^H C, C Q^H or C Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX array. The dimension of WORK is

N* NB if SIDE = 'L', or M* NB if SIDE = 'R'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgemqrt*, *sgemqrt* and *zgemqrt*. It also exists with a native C interface as *LAPACKE_cgemqrt*.

4.3.9 cgeqlf

cgeqlf computes a QL factorization of a complex M-by-N matrix A: A = Q * L.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgeqlf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgeqlf_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if m >= n, the lower triangle of the subarray A(m-n+1:m,1:n) contains the N-by-N lower triangular matrix L; if m <= n, the elements on and below the (n-m)-th superdiagonal contain the M-by-N lower trapezoidal matrix L; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgeqlf*, *sgeqlf* and *zgeqlf*. It also exists with a native C interface as *LAPACKE_cgeqlf*.

4.3.10 cgeqp3

cgeqp3 computes a QR factorization with column pivoting of a matrix A: A*P = Q*R using Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgeqp3(M, N, A, LDA, JPVT, TAU, WORK, LWORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgeqp3_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_int_t *jpvt, armpl_singlecomplex_t *tau,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             float *rwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the min(M, N)-by-N upper trapezoidal matrix R; the elements below the diagonal, together with the array TAU, represent the unitary matrix Q as a product of min(M, N) elementary reflectors.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

JPVT Input and output parameter.

JPVT is INTEGER array, dimension (N)

On entry, if JPVT(J).ne.0, the J-th column of A is permuted to the front of A*P (a leading column); if JPVT(J)=0, the J-th column of A is a free column. On exit, if JPVT(J)=K, then the J-th column of A*P was the the K-th column of A.

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO=0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= N+1. For optimal performance LWORK >= (N+1)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dgeqp3*, *sgeqp3* and *zgeqp3*. It also exists with a native C interface as *LAPACKE_cgeqp3*.

4.3.11 cgeqr

cgeqr computes a QR factorization of an M-by-N matrix A.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgeqr(M, N, A, LDA, T, TSIZE, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgeqr_(const armpl_int_t *m, const armpl_int_t *n,
            armpl_singlecomplex_t *a, const armpl_int_t *lda,
            armpl_singlecomplex_t *t, const armpl_int_t *tsize,
            armpl_singlecomplex_t *work, const armpl_int_t *lwork,
            armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix R (R is upper triangular if M >= N); the elements below the diagonal are used to store part of the data structure to represent Q.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is COMPLEX

T is an array, dimension (MAX(5, TSIZE)). On exit, if INFO = 0, T(1) returns optimal (or either minimal or optimal, if query is assumed) TSIZE. See TSIZE for details. Remaining T contains part of the data structure used to represent Q. If one wants to apply or construct Q, then one needs to keep T (in addition to A) and pass it to further subroutines.

TSIZE Input parameter.

TSIZE is INTEGER

If TSIZE >= 5, the dimension of the array T. If TSIZE = -1 or -2, then a workspace query is assumed. The routine only calculates the sizes of the T and WORK arrays, returns these values as the first entries of the T and WORK arrays, and no error message related to T or WORK is issued by XERBLA. If TSIZE = -1, the routine calculates optimal size of T for the optimum performance and returns this value in T(1). If TSIZE = -2, the routine calculates minimal size of T and returns this value in T(1).

WORK Output parameter.

(workspace) COMPLEX

(workspace) is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) contains optimal (or either minimal or optimal, if query was assumed) LWORK. See LWORK for details.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1 or -2, then a workspace query is assumed. The routine only calculates the sizes of the T and WORK arrays, returns these values as the first entries of the T and WORK arrays, and no error message related to T or WORK is issued by XERBLA. If LWORK = -1, the routine calculates optimal size of WORK for the optimal performance and returns this value in WORK(1). If LWORK = -2, the routine calculates minimal size of WORK and returns this value in WORK(1).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgeqr*, *sgeqr* and *zgeqr*. It also exists with a native C interface as *LAPACKE_cgeqr*.

4.3.12 cgeqrf

cgeqrf computes a QR factorization of a complex M-by-N matrix A: A = Q * R.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgeqrf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgeqrf_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix R (R is upper triangular if m >= n); the elements below the diagonal, with the array TAU, represent the unitary matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgeqrf*, *sgeqrf* and *zgeqrf*. It also exists with a native C interface as *LAPACKE_cgeqrf*.

4.3.13 cgeqrfp

cgeqrfp computes a QR factorization of a complex M-by-N matrix A: A = Q * R. The diagonal entries of R are real and nonnegative.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgeqrfp(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgeqrfp_(const armpl_int_t *m, const armpl_int_t *n,
              armpl_singlecomplex_t *a, const armpl_int_t *lda,
              armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
              const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix R (R is upper triangular if m >= n). The diagonal entries of R are real and nonnegative; the elements below the diagonal, with the array TAU, represent the unitary matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgeqrfp*, *sgeqrfp* and *zgeqrfp*. It also exists with a native C interface as *LAPACKE_cgeqrfp*.

4.3.14 cgeqrt

cgeqrt computes a blocked QR factorization of a complex M-by-N matrix A using the compact WY representation of Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgeqrt(M, N, NB, A, LDA, T, LDT, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgeqrt_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *nb, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *t,
             const armpl_int_t *ldt, armpl_singlecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The block size to be used in the blocked QR. MIN(M, N) >= NB >= 1.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix R (R is upper triangular if M >= N); the elements below the diagonal are the columns of V.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is COMPLEX

T is an array, dimension (LDT,MIN(M, N)). The upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (NB*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgeqrt*, *sgeqrt* and *zgeqrt*. It also exists with a native C interface as *LAPACKE_cgeqrt*.

4.3.15 cgerqf

cgerqf computes an RQ factorization of a complex M-by-N matrix A: A = R * Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgerqf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgerqf_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if m <= n, the upper triangle of the subarray A(1:m,n-m+1:n) contains the M-by-M upper triangular matrix R; if m >= n, the elements on and above the (m-n)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgerqf*, *sgerqf* and *zgerqf*. It also exists with a native C interface as *LAPACKE_cgerqf*.

4.3.16 cgetrf

cgetrf computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form

```
A = P * L * U
```

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the right-looking Level 3 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgetrf(M, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void cgetrf_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

IPIV Output parameter.

IPIV is INTEGER array, dimension (min(M, N))

The pivot indices; for 1 <= i <= min(M, N), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *dgetrf*, *sgetrf* and *zgetrf*. It also exists with a native C interface as *LAPACKE_cgetrf*.

4.3.17 cgetrf2

cgetrf2 computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form

```
A = P * L * U
```

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the recursive version of the algorithm. It divides the matrix into four submatrices:

```
    [  A11 | A12  ]  where A11 is n1 by n1 and A22 is n2 by n2
A = [ -----|----- ]  with n1 = min(m,n)/2
    [  A21 | A22  ]       n2 = n-n1

                                  [ A11 ]
```

The subroutine calls itself to factor [—],

```
                      [ A12 ]
[ A12 ]
```

do the swaps on [—], solve A12, update A22,

```
[ A22 ]
```

then calls itself to factor A22 and do the swaps on A21.

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine cgetrf2(M, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void cgetrf2_(const armpl_int_t *m, const armpl_int_t *n,
              armpl_singlecomplex_t *a, const armpl_int_t *lda,
              armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

IPIV Output parameter.

IPIV is INTEGER array, dimension (min(M, N))

The pivot indices; for 1 <= i <= min(M, N), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *dgetrf2*, *sgetrf2* and *zgetrf2*. It also exists with a native C interface as *LAPACKE_cgetrf2*.

4.3.18 cggqrf

cggqrf computes a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B:

```
A = Q*R,        B = Q*T*Z,
```

where Q is an N-by-N unitary matrix, Z is a P-by-P unitary matrix, and R and T assume one of the forms:

if N >= M, R = (R11) M , or if N < M, R = (R11 R12) N,

```
(  0  ) N-M                          N   M-N
   M
```

where R11 is upper triangular, and

if N <= P, T = (0 T12) N, or if N > P, T = (T11) N-P,

```
P-N  N                             ( T21 ) P
                                     P
```

where T12 or T21 is upper triangular.

In particular, if B is square and nonsingular, the GQR factorization of A and B implicitly gives the QR factorization of inv(B)*A:

```
inv(B)*A = Z**H * (inv(T)*R)
```

where inv(B) denotes the inverse of the matrix B, and Z' denotes the conjugate transpose of matrix Z.

Syntax

Fortran specification:

```
use armpl_library

subroutine cggqrf(N, M, P, A, LDA, TAUA, B, LDB, TAUB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cggqrf_(const armpl_int_t *n, const armpl_int_t *m, const armpl_int_t *p,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *taua, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *taub,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of rows of the matrices A and B. N >= 0.

M Input parameter.

M is INTEGER

The number of columns of the matrix A. M >= 0.

P Input parameter.

P is INTEGER

The number of columns of the matrix B. P >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, M). On entry, the N-by-M matrix A. On exit, the elements on and above the diagonal of the array contain the min(N, M)-by-M upper trapezoidal matrix R (R is upper triangular if N >= M); the elements below the diagonal, with the array TAUA, represent the unitary matrix Q as a product of min(N, M) elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAUA Output parameter.

TAUA is COMPLEX

TAUA is an array, dimension (min(N, M)). The scalar factors of the elementary reflectors which represent the unitary matrix Q (see Further Details).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, P). On entry, the N-by-P matrix B. On exit, if N <= P, the upper triangle of the subarray B(1:N,P-N+1:P) contains the N-by-N upper triangular matrix T; if N > P, the elements on and above the (N-P)-th subdiagonal contain the N-by-P upper trapezoidal matrix T; the remaining elements, with the array TAUB, represent the unitary matrix Z as a product of elementary reflectors (see Further Details).

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

TAUB Output parameter.

TAUB is COMPLEX

TAUB is an array, dimension (min(N, P)). The scalar factors of the elementary reflectors which represent the unitary matrix Z (see Further Details).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N, M, P). For optimum performance LWORK >= max(N, M, P)*max(NB1,NB2,NB3), where NB1 is the optimal blocksize for the QR factorization of an N-by-M matrix, NB2 is the optimal blocksize for the RQ factorization of an N-by-P matrix, and NB3 is the optimal blocksize for a call of CUNMQR.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dggqrf*, *sggqrf* and *zggqrf*. It also exists with a native C interface as *LAPACKE_cggqrf*.

4.3.19 cggrqf

cggrqf computes a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B:

```
A = R*Q,        B = Z*T*Q,
```

where Q is an N-by-N unitary matrix, Z is a P-by-P unitary matrix, and R and T assume one of the forms:

if M <= N, R = (0 R12) M, or if M > N, R = (R11) M-N,

```
N-M  M                            ( R21 ) N
                                    N
```

where R12 or R21 is upper triangular, and

if P >= N, T = (T11) N , or if P < N, T = (T11 T12) P,

```
(  0  ) P-N                         P   N-P
   N
```

where T11 is upper triangular.

In particular, if B is square and nonsingular, the GRQ factorization of A and B implicitly gives the RQ factorization of A*inv(B):

```
A*inv(B) = (R*inv(T))*Z**H
```

where inv(B) denotes the inverse of the matrix B, and Z^H denotes the conjugate transpose of the matrix Z.

Syntax

Fortran specification:

```
use armpl_library

subroutine cggrqf(M, P, N, A, LDA, TAUA, B, LDB, TAUB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cggrqf_(const armpl_int_t *m, const armpl_int_t *p, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *taua, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *taub,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. P >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if M <= N, the upper triangle of the subarray A(1:M,N-M+1:N) contains the M-by-M upper triangular matrix R; if M > N, the elements on and above the (M-N)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAUA, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAUA Output parameter.

TAUA is COMPLEX

TAUA is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the unitary matrix Q (see Further Details).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, the elements on and above the diagonal of the array contain the min(P, N)-by-N upper trapezoidal matrix T (T is upper triangular if P >= N); the elements below the diagonal, with the array TAUB, represent the unitary matrix Z as a product of elementary reflectors (see Further Details).

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

TAUB Output parameter.

TAUB is COMPLEX

TAUB is an array, dimension (min(P, N)). The scalar factors of the elementary reflectors which represent the unitary matrix Z (see Further Details).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N, M, P). For optimum performance LWORK >= max(N, M, P)*max(NB1,NB2,NB3), where NB1 is the optimal blocksize for the RQ factorization of an M-by-N matrix, NB2 is the optimal blocksize for the QR factorization of a P-by-N matrix, and NB3 is the optimal blocksize for a call of CUNMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO=-i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dggrqf*, *sggrqf* and *zggrqf*. It also exists with a native C interface as *LAPACKE_cggrqf*.

4.3.20 cgttrf

cgttrf computes an LU factorization of a complex tridiagonal matrix A using elimination with partial pivoting and row interchanges.

The factorization has the form

```
A = L * U
```

where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgttrf(N, DL, D, DU, DU2, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void cgttrf_(const armpl_int_t *n, armpl_singlecomplex_t *dl,
             armpl_singlecomplex_t *d, armpl_singlecomplex_t *du,
             armpl_singlecomplex_t *du2, armpl_int_t *ipiv,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A.

DL Input and output parameter.

DL is COMPLEX

DL is an array, dimension (N-1). On entry, DL must contain the (n-1) sub-diagonal elements of A.

On exit, DL is overwritten by the (n-1) multipliers that define the matrix L from the LU factorization of A.

D Input and output parameter.

D is COMPLEX

D is an array, dimension (N). On entry, D must contain the diagonal elements of A.

On exit, D is overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DU Input and output parameter.

DU is COMPLEX

DU is an array, dimension (N-1). On entry, DU must contain the (n-1) super-diagonal elements of A.

On exit, DU is overwritten by the (n-1) elements of the first super-diagonal of U.

DU2 Output parameter.

DU2 is COMPLEX

DU2 is an array, dimension (N-2). On exit, DU2 is overwritten by the (n-2) elements of the second super-diagonal of U.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *dgttrf*, *sgttrf* and *zgttrf*. It also exists with a native C interface as *LAPACKE_cgttrf*.

4.3.21 chetrf

chetrf computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

```
A = U*D*U**H  or  A = L*D*L**H
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetrf(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chetrf_(const char *uplo, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *ipiv,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >=1. For best performance LWORK >= N*NB, where NB is the block size returned by ILAENV.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *zhetrf*. It also exists with a native C interface as *LAPACKE_chetrf*.

4.3.22 chetrf_aa

CHETRF_AA computes the factorization of a complex hermitian matrix A using the Aasen's algorithm. The form of the factorization is

```
A = U*T*U**H  or  A = L*T*L**H
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is a hermitian tridiagonal matrix.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetrf_aa(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chetrf_aa_(const char *uplo, const armpl_int_t *n,
                armpl_singlecomplex_t *a, const armpl_int_t *lda,
                armpl_int_t *ipiv, armpl_singlecomplex_t *work,
                const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the tridiagonal matrix is stored in the diagonals and the subdiagonals of A just below (or above) the diagonals, and L is stored below (or above) the subdiaonals, when UPLO is 'L' (or 'U').

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= 2*N. For optimum performance LWORK >= N*(1+NB), where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *zhetrf_aa*. It also exists with a native C interface as *LAPACKE_chetrf_aa*.

4.3.23 chetrf_rk

CHETRF_RK computes the factorization of a complex Hermitian matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method:

```
A = P*U*D*(U**H)*(P**T) or A = P*L*D*(L**H)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^H (or L^H) is the conjugate of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS. For more information see Further Details section.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetrf_rk(UPLO, N, A, LDA, E, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chetrf_rk_(const char *uplo, const armpl_int_t *n,
                armpl_singlecomplex_t *a, const armpl_int_t *lda,
                armpl_singlecomplex_t *e, armpl_int_t *ipiv,
                armpl_singlecomplex_t *work, const armpl_int_t *lwork,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, contains: a) ONLY diagonal elements of the Hermitian block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is COMPLEX

E is an array, dimension (N). On exit, contains the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

IPIV describes the permutation matrix P in the factorization of matrix A as follows. The absolute value of IPIV(k) represents the index of row and column that were interchanged with the k-th row and column. The value of UPLO describes the order in which the interchanges were applied. Also, the sign of IPIV represents the block structure of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks which correspond to 1 or 2 interchanges at each factorization step. For more info see Further Details section.

If UPLO = 'U', (in factorization order, k decreases from N to 1): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N); If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k-1) < 0 means: D(k-1:k,k-1:k) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k-1) != k-1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k-1) = k-1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) <= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

If UPLO = 'L', (in factorization order, k increases from 1 to N): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N). If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k+1) < 0 means: D(k:k+1,k:k+1) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k+1) != k+1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k+1) = k+1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) >= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)).. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >=1. For best performance LWORK >= N*NB, where NB is the block size returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

Related Information

For this routine in other precisions, please see *zhetrf_rk*. It also exists with a native C interface as *LAPACKE_chetrf_rk*.

4.3.24 chetrf_rook

CHETRF_ROOK computes the factorization of a comlex Hermitian matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method. The form of the factorization is

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetrf_rook(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chetrf_rook_(const char *uplo, const armpl_int_t *n,
                  armpl_singlecomplex_t *a, const armpl_int_t *lda,
                  armpl_int_t *ipiv, armpl_singlecomplex_t *work,
                  const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': Only the last KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': Only the first KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)).. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >=1. For best performance LWORK >= N*NB, where NB is the block size returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *zhetrf_rook*. It also exists with a native C interface as *LAPACKE_chetrf_rook*.

4.3.25 chptrf

chptrf computes the factorization of a complex Hermitian packed matrix A using the Bunch-Kaufman diagonal pivoting method:

```
A = U*D*U**H  or  A = L*D*L**H
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

Syntax

Fortran specification:

```
use armpl_library

subroutine chptrf(UPLO, N, AP, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void chptrf_(const char *uplo, const armpl_int_t *n,
             armpl_singlecomplex_t *ap, armpl_int_t *ipiv, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L, stored as a packed triangular matrix overwriting A (see below for further details).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *zhptrf*. It also exists with a native C interface as *LAPACKE_chptrf*.

4.3.26 cpbtrf

cpbtrf computes the Cholesky factorization of a complex Hermitian positive definite band matrix A.

The factorization has the form

```
A = U**H * U,  if UPLO = 'U', or
A = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpbtrf(UPLO, N, KD, AB, LDAB, INFO)
```

C specification:

```
#include "armpl.h"

void cpbtrf_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the band matrix A, in the same storage format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *dpbtrf*, *spbtrf* and *zpbtrf*. It also exists with a native C interface as *LAPACKE_cpbtrf*.

4.3.27 cpftrf

cpftrf computes the Cholesky factorization of a complex Hermitian positive definite matrix A.

The factorization has the form

```
A = U**H * U,  if UPLO = 'U', or
A = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

This is the block version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpftrf(TRANSR, UPLO, N, A, INFO)
```

C specification:

```
#include "armpl.h"

void cpftrf_(const char *transr, const char *uplo, const armpl_int_t *n,
             armpl_singlecomplex_t *a, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal TRANSR of RFP A is stored; = 'C': The Conjugate-transpose TRANSR of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of RFP A is stored; = 'L': Lower triangle of RFP A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (N*(N+1)/2);. On entry, the Hermitian matrix A in RFP format. RFP format is described by TRANSR, UPLO, and N as follows: If TRANSR = 'N' then RFP A is (0:N,0:k-1) when N is even; k=N/2. RFP A is (0:N-1,0:k) when N is odd; k=N/2. IF TRANSR = 'C' then RFP is the Conjugate-transpose of RFP A as defined when TRANSR = 'N'. The contents of RFP A are defined by UPLO as follows: If UPLO = 'U' the RFP A contains the nt elements of upper packed A. If UPLO = 'L' the RFP A contains the elements of lower packed A. The LDA of RFP A is (N+1)/2 when TRANSR = 'C'. When TRANSR is 'N' the LDA is N+1 when N is even and N is odd. See the Note below for more details.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization RFP A = U^H *U or RFP A = L*L^H .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Further Notes on RFP Format:

We first consider Standard Packed Format when N is even. We give an example where N = 6.

AP is Upper AP is Lower

00 01 02 03 04 05 00 11 12 13 14 15 10 11 22 23 24 25 20 21 22 33 34 35 30 31 32 33 44 45 40 41 42 43 44 55 50 51 52 53 54 55

Let TRANSR = 'N'. RFP holds AP as follows: For UPLO = 'U' the upper trapezoid A(0:5,0:2) consists of the last three columns of AP upper. The lower triangle A(4:6,0:2) consists of conjugate-transpose of the first three columns of AP upper. For UPLO = 'L' the lower trapezoid A(1:6,0:2) consists of the first three columns of AP lower. The upper triangle A(0:2,0:2) consists of conjugate-transpose of the last three columns of AP lower. To denote conjugate we place – above the element. This covers the case N even and TRANSR = 'N'.

RFP A RFP A

– – – 03 04 05 33 43 53 – – 13 14 15 00 44 54 – 23 24 25 10 11 55

33 34 35 20 21 22 – 00 44 45 30 31 32 – – 01 11 55 40 41 42 – – – 02 12 22 50 51 52

Now let TRANSR = 'C'. RFP A in both UPLO cases is just the conjugate- transpose of RFP A above. One therefore gets:

RFP A RFP A

– – – – – – – – – – 03 13 23 33 00 01 02 33 00 10 20 30 40 50 – – – – – – – – – – 04 14 24 34 44 11 12 43 44 11 21 31 41 51 – – – – – – – – – – 05 15 25 35 45 55 22 53 54 55 22 32 42 52

We next consider Standard Packed Format when N is odd. We give an example where N = 5.

AP is Upper AP is Lower

00 01 02 03 04 00 11 12 13 14 10 11 22 23 24 20 21 22 33 34 30 31 32 33 44 40 41 42 43 44

Let TRANSR = 'N'. RFP holds AP as follows: For UPLO = 'U' the upper trapezoid A(0:4,0:2) consists of the last three columns of AP upper. The lower triangle A(3:4,0:1) consists of conjugate-transpose of the first two columns of AP upper. For UPLO = 'L' the lower trapezoid A(0:4,0:2) consists of the first three columns of AP lower. The upper triangle A(0:1,1:2) consists of conjugate-transpose of the last two columns of AP lower. To denote conjugate we place – above the element. This covers the case N odd and TRANSR = 'N'.

RFP A RFP A

– – 02 03 04 00 33 43 – 12 13 14 10 11 44

22 23 24 20 21 22 – 00 33 34 30 31 32 – – 01 11 44 40 41 42

Now let TRANSR = 'C'. RFP A in both UPLO cases is just the conjugate- transpose of RFP A above. One therefore gets:

RFP A RFP A

– – – – – – – – – 02 12 22 00 01 00 10 20 30 40 50 – – – – – – – – – 03 13 23 33 11 33 11 21 31 41 51 – – – – – – – – – – 04 14 24 34 44 43 44 22 32 42 52

Related Information

For this routine in other precisions, please see *dpftrf*, *spftrf* and *zpftrf*. It also exists with a native C interface as *LAPACKE_cpftrf*.

4.3.28 cpotrf

cpotrf computes the Cholesky factorization of a complex Hermitian positive definite matrix A.

The factorization has the form

```
A = U**H * U,  if UPLO = 'U', or
A = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

This is the block version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpotrf(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void cpotrf_(const char *uplo, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *dpotrf*, *spotrf* and *zpotrf*. It also exists with a native C interface as *LAPACKE_cpotrf*.

4.3.29 cpotrf2

`cpotrf2` computes the Cholesky factorization of a real symmetric positive definite matrix A using the recursive algorithm.

The factorization has the form

```
A = U**H * U,  if UPLO = 'U', or
A = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

This is the recursive version of the algorithm. It divides the matrix into four submatrices:

```
    [  A11 | A12  ]  where A11 is n1 by n1 and A22 is n2 by n2
A = [ -----|-----  ]  with n1 = n/2
    [  A21 | A22  ]       n2 = n-n1
```

The subroutine calls itself to factor A11. Update and scale A21 or A12, update A22 then calls itself to factor A22.

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine cpotrf2(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void cpotrf2_(const char *uplo, const armpl_int_t *n,
              armpl_singlecomplex_t *a, const armpl_int_t *lda,
              armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

= '`U`': Upper triangle of `A` is stored; = '`L`': Lower triangle of `A` is stored.

N Input parameter.

`N` is `INTEGER`

The order of the matrix `A`. `N` >= 0.

A Input and output parameter.

`A` is `COMPLEX`

`A` is an array, dimension (`LDA`, `N`). On entry, the symmetric matrix `A`. If `UPLO` = '`U`', the leading N-by-N upper triangular part of `A` contains the upper triangular part of the matrix `A`, and the strictly lower triangular part of `A` is not referenced. If `UPLO` = '`L`', the leading N-by-N lower triangular part of `A` contains the lower triangular part of the matrix `A`, and the strictly upper triangular part of `A` is not referenced.

On exit, if `INFO` = 0, the factor U or L from the Cholesky factorization `A` = U^H *U or `A` = L*L^H .

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *dpotrf2*, *spotrf2* and *zpotrf2*. It also exists with a native C interface as *LAPACKE_cpotrf2*.

4.3.30 cpptrf

cpptrf computes the Cholesky factorization of a complex Hermitian positive definite matrix A stored in packed format.

The factorization has the form

```
A = U**H * U,  if UPLO = 'U', or
A = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpptrf(UPLO, N, AP, INFO)
```

C specification:

```
#include "armpl.h"

void cpptrf_(const char *uplo, const armpl_int_t *n,
             armpl_singlecomplex_t *ap, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO =

'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , in the same storage format as A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *dpptrf*, *spptrf* and *zpptrf*. It also exists with a native C interface as *LAPACKE_cpptrf*.

4.3.31 cpstrf

cpstrf computes the Cholesky factorization with complete pivoting of a complex Hermitian positive semidefinite matrix A.

The factorization has the form

```
P**T * A * P = U**H * U ,  if UPLO = 'U',
P**T * A * P = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular, and P is stored as vector PIV.

This algorithm does not attempt to check that A is positive semidefinite. This version of the algorithm calls level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpstrf(UPLO, N, A, LDA, PIV, RANK, TOL, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cpstrf_(const char *uplo, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *piv, armpl_int_t *rank,
             const float *tol, float *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization as above.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

PIV Output parameter.

PIV is INTEGER array, dimension (N)

PIV is such that the nonzero entries are P(PIV(K), K) = 1.

RANK Output parameter.

RANK is INTEGER

The rank of A given by the number of steps the algorithm completed.

TOL Input parameter.

TOL is REAL

User defined tolerance. If TOL < 0, then N*U*MAX(A(K,K)) will be used. The algorithm terminates at the (K-1)st step if the pivot <= TOL.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (2*N). Work space.

INFO Output parameter.

INFO is INTEGER

< 0: If INFO = -K, the K-th argument had an illegal value, = 0: algorithm completed successfully, and > 0: the matrix A is either rank deficient with computed rank as returned in RANK, or is not positive semidefinite. See Section 7 of LAPACK Working Note #161 for further information.

Related Information

For this routine in other precisions, please see *dpstrf*, *spstrf* and *zpstrf*. It also exists with a native C interface as *LAPACKE_cpstrf*.

4.3.32 cpttrf

cpttrf computes the L*D*L^H factorization of a complex Hermitian positive definite tridiagonal matrix A. The factorization may also be regarded as having the form A = U^H *D*U.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpttrf(N, D, E, INFO)
```

C specification:

```
#include "armpl.h"

void cpttrf_(const armpl_int_t *n, float *d, armpl_singlecomplex_t *e,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the L*D*L^H factorization of A.

E Input and output parameter.

E is COMPLEX

E is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*D*L^H factorization of A. E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U^H *D*U factorization of A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, the leading minor of order k is not positive definite; if k < N, the factorization could not be completed, while if k = N, the factorization was completed, but D(N) <= 0.

Related Information

For this routine in other precisions, please see *dpttrf*, *spttrf* and *zpttrf*. It also exists with a native C interface as *LAPACKE_cpttrf*.

4.3.33 csptrf

csptrf computes the factorization of a complex symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method:

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

Syntax

Fortran specification:

```
use armpl_library

subroutine csptrf(UPLO, N, AP, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void csptrf_(const char *uplo, const armpl_int_t *n,
             armpl_singlecomplex_t *ap, armpl_int_t *ipiv, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L, stored as a packed triangular matrix overwriting A (see below for further details).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *dsptrf*, *ssptrf* and *zsptrf*. It also exists with a native C interface as *LAPACKE_csptrf*.

4.3.34 csytrf

csytrf computes the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytrf(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void csytrf_(const char *uplo, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *ipiv,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >=1. For best performance LWORK >= N*NB, where NB is the block size returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *dsytrf*, *ssytrf* and *zsytrf*. It also exists with a native C interface as *LAPACKE_csytrf*.

4.3.35 csytrf_aa

CSYTRF_AA computes the factorization of a complex symmetric matrix A using the Aasen's algorithm. The form of the factorization is

```
A = U*T*U**T  or  A = L*T*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is a complex symmetric tridiagonal matrix.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytrf_aa(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void csytrf_aa_(const char *uplo, const armpl_int_t *n,
                armpl_singlecomplex_t *a, const armpl_int_t *lda,
                armpl_int_t *ipiv, armpl_singlecomplex_t *work,
                const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the tridiagonal matrix is stored in the diagonals and the subdiagonals of A just below (or above) the diagonals, and L is stored below (or above) the subdiaonals, when UPLO is 'L' (or 'U').

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= MAX(1,2*N). For optimum performance LWORK >= N*(1+NB), where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dsytrf_aa*, *ssytrf_aa* and *zsytrf_aa*. It also exists with a native C interface as *LAPACKE_csytrf_aa*.

4.3.36 csytrf_rk

CSYTRF_RK computes the factorization of a complex symmetric matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS. For more information see Further Details section.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytrf_rk(UPLO, N, A, LDA, E, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void csytrf_rk_(const char *uplo, const armpl_int_t *n,
                armpl_singlecomplex_t *a, const armpl_int_t *lda,
                armpl_singlecomplex_t *e, armpl_int_t *ipiv,
                armpl_singlecomplex_t *work, const armpl_int_t *lwork,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, contains: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is COMPLEX

E is an array, dimension (N). On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

IPIV describes the permutation matrix P in the factorization of matrix A as follows. The absolute value of IPIV(k) represents the index of row and column that were interchanged with the k-th row and column. The value of UPLO describes the order in which the interchanges were applied. Also, the sign of IPIV represents the block structure of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks which correspond to 1 or 2 interchanges at each factorization step. For more info see Further Details section.

If UPLO = 'U', (in factorization order, k decreases from N to 1): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N); If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k-1) < 0 means: D(k-1:k,k-1:k) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k-1) != k-1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k-1) = k-1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) <= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

If UPLO = 'L', (in factorization order, k increases from 1 to N): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N). If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k+1) < 0 means: D(k:k+1,k:k+1) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k+1) != k+1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k+1) = k+1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) >= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)).. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >=1. For best performance LWORK >= N*NB, where NB is the block size returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

Related Information

For this routine in other precisions, please see *dsytrf_rk*, *ssytrf_rk* and *zsytrf_rk*. It also exists with a native C interface as *LAPACKE_csytrf_rk*.

4.3.37 csytrf_rook

CSYTRF_ROOK computes the factorization of a complex symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method. The form of the factorization is

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytrf_rook(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void csytrf_rook_(const char *uplo, const armpl_int_t *n,
                  armpl_singlecomplex_t *a, const armpl_int_t *lda,
                  armpl_int_t *ipiv, armpl_singlecomplex_t *work,
                  const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)).. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >=1. For best performance LWORK >= N*NB, where NB is the block size returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *dsytrf_rook*, *ssytrf_rook* and *zsytrf_rook*. It also exists with a native C interface as *LAPACKE_csytrf_rook*.

4.3.38 ctplqt

ctplqt computes a blocked LQ factorization of a complex "triangular-pentagonal" matrix C, which is composed of a triangular block A and pentagonal block B, using the compact WY representation for Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctplqt(M, N, L, MB, A, LDA, B, LDB, T, LDT, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void ctplqt_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *l,
             const armpl_int_t *mb, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *t,
             const armpl_int_t *ldt, armpl_singlecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix B, and the order of the triangular matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B. N >= 0.

L Input parameter.

L is INTEGER

The number of rows of the lower trapezoidal part of B. MIN(M, N) >= L >= 0. See Further Details.

MB Input parameter.

MB is INTEGER

The block size to be used in the blocked QR. M >= MB >= 1.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, M). On entry, the lower triangular M-by-M matrix A. On exit, the elements on and below the diagonal of the array contain the lower triangular matrix L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the pentagonal M-by-N matrix B. The first N-L columns are rectangular, and the last L columns are lower trapezoidal. On exit, B contains the pentagonal matrix V. See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

T Output parameter.

T is COMPLEX

T is an array, dimension (LDT, N). The lower triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See Further Details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MB*M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtplqt*, *stplqt* and *ztplqt*.

4.3.39 ctpmlqt

ctpmlqt applies a complex orthogonal matrix Q obtained from a "triangular-pentagonal" complex block reflector H to a general complex matrix C, which consists of two blocks A and B.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctpmlqt(SIDE, TRANS, M, N, K, L, MB, V, LDV, T, LDT, A, LDA, B,
                   LDB, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void ctpmlqt_(const char *side, const char *trans, const armpl_int_t *m,
              const armpl_int_t *n, const armpl_int_t *k,
              const armpl_int_t *l, const armpl_int_t *mb,
              const armpl_singlecomplex_t *v, const armpl_int_t *ldv,
              const armpl_singlecomplex_t *t, const armpl_int_t *ldt,
              armpl_singlecomplex_t *a, const armpl_int_t *lda,
              armpl_singlecomplex_t *b, const armpl_int_t *ldb,
              armpl_singlecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q.

L Input parameter.

L is INTEGER

The order of the trapezoidal part of V. K >= L >= 0. See Further Details.

MB Input parameter.

MB is INTEGER

The block size used for the storage of T. K >= MB >= 1. This must be the same value of MB used to generate T in DTPLQT.

V Input parameter.

V is COMPLEX

V is an array, dimension (LDA, K). The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by DTPLQT in B. See Further Details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If SIDE = 'L', LDV >= max(1, M); if SIDE = 'R', LDV >= max(1, N).

T Input parameter.

T is COMPLEX

T is an array, dimension (LDT, K). The upper triangular factors of the block reflectors as returned by DTPLQT, stored as a MB-by-K matrix.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

A Input and output parameter.

A is COMPLEX

A is an array, dimension. (LDA, N) if SIDE = 'L' or (LDA, K) if SIDE = 'R' On entry, the K-by-N or M-by-K matrix A. On exit, A is overwritten by the corresponding block of Q*C or Q^H *C or C*Q or C*Q^H . See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDC >= max(1, K); If SIDE = 'R', LDC >= max(1, M).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the M-by-N matrix B. On exit, B is overwritten by the corresponding block of Q*C or Q^H *C or C*Q or C*Q^H . See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

WORK Output parameter.

WORK is COMPLEX array. The dimension of WORK is

N* MB if SIDE = 'L', or M* MB if SIDE = 'R'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtpmlqt*, *stpmlqt* and *ztpmlqt*.

4.3.40 ctpmqrt

ctpmqrt applies a complex orthogonal matrix Q obtained from a "triangular-pentagonal" complex block reflector H to a general complex matrix C, which consists of two blocks A and B.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctpmqrt(SIDE, TRANS, M, N, K, L, NB, V, LDV, T, LDT, A, LDA, B,
                   LDB, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void ctpmqrt_(const char *side, const char *trans, const armpl_int_t *m,
              const armpl_int_t *n, const armpl_int_t *k,
              const armpl_int_t *l, const armpl_int_t *nb,
              const armpl_singlecomplex_t *v, const armpl_int_t *ldv,
              const armpl_singlecomplex_t *t, const armpl_int_t *ldt,
              armpl_singlecomplex_t *a, const armpl_int_t *lda,
              armpl_singlecomplex_t *b, const armpl_int_t *ldb,
              armpl_singlecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q.

L Input parameter.

L is INTEGER

The order of the trapezoidal part of V. K >= L >= 0. See Further Details.

NB Input parameter.

NB is INTEGER

The block size used for the storage of T. K >= NB >= 1. This must be the same value of NB used to generate T in CTPQRT.

V Input parameter.

V is COMPLEX

V is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CTPQRT in B. See Further Details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If SIDE = 'L', LDV >= max(1, M); if SIDE = 'R', LDV >= max(1, N).

T Input parameter.

T is COMPLEX

T is an array, dimension (LDT, K). The upper triangular factors of the block reflectors as returned by CTPQRT, stored as a NB-by-K matrix.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

A Input and output parameter.

A is COMPLEX

A is an array, dimension. (LDA, N) if SIDE = 'L' or (LDA, K) if SIDE = 'R' On entry, the K-by-N or M-by-K matrix A. On exit, A is overwritten by the corresponding block of Q*C or Q^H *C or C*Q or C*Q^H . See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDC >= max(1, K); If SIDE = 'R', LDC >= max(1, M).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the M-by-N matrix B. On exit, B is overwritten by the corresponding block of Q*C or Q^H *C or C*Q or C*Q^H . See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

WORK Output parameter.

WORK is COMPLEX array. The dimension of WORK is

N* NB if SIDE = 'L', or M* NB if SIDE = 'R'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtpmqrt*, *stpmqrt* and *ztpmqrt*. It also exists with a native C interface as *LAPACKE_ctpmqrt*.

4.3.41 ctpqrt

ctpqrt computes a blocked QR factorization of a complex "triangular-pentagonal" matrix C, which is composed of a triangular block A and pentagonal block B, using the compact WY representation for Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctpqrt(M, N, L, NB, A, LDA, B, LDB, T, LDT, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void ctpqrt_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *l,
             const armpl_int_t *nb, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *t,
             const armpl_int_t *ldt, armpl_singlecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B, and the order of the triangular matrix A. N >= 0.

L Input parameter.

L is INTEGER

The number of rows of the upper trapezoidal part of B. MIN(M, N) >= L >= 0. See Further Details.

NB Input parameter.

NB is INTEGER

The block size to be used in the blocked QR. N >= NB >= 1.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the upper triangular N-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the upper triangular matrix R.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the pentagonal M-by-N matrix B. The first M-L rows are rectangular, and the last L rows are upper trapezoidal. On exit, B contains the pentagonal matrix V. See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

T Output parameter.

T is COMPLEX

T is an array, dimension (LDT, N). The upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See Further Details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (NB*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtpqrt*, *stpqrt* and *ztpqrt*. It also exists with a native C interface as *LAPACKE_ctpqrt*.

4.3.42 ctzrzf

ctzrzf reduces the M-by-N (M<=N) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations.

The upper trapezoidal matrix A is factored as

```
A = ( R  0 ) * Z,
```

where Z is an N-by-N unitary matrix and R is an M-by-M upper triangular matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctzrzf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ctzrzf_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= M.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the unitary matrix Z as a product of M elementary reflectors.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (M). The scalar factors of the elementary reflectors.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtzrzf*, *stzrzf* and *ztzrzf*. It also exists with a native C interface as *LAPACKE_ctzrzf*.

4.3.43 cunglq

`cunglq` generates an M-by-N complex matrix Q with orthonormal rows, which is defined as the first M rows of a product of K elementary reflectors of order N

```
Q  =  H(k)**H . . . H(2)**H H(1)**H
```

as returned by CGELQF.

Syntax

Fortran specification:

```
use armpl_library

subroutine cunglq(M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cunglq_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. N >= M.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by CGELQF in the first k rows of its array argument A. On exit, the M-by-N matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGELQF.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit; < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *zunglq*. It also exists with a native C interface as *LAPACKE_cunglq*.

4.3.44 cungql

cungql generates an M-by-N complex matrix Q with orthonormal columns, which is defined as the last N columns of a product of K elementary reflectors of order M

```
Q  =  H(k) . . . H(2) H(1)
```

as returned by CGEQLF.

Syntax

Fortran specification:

```
use armpl_library

subroutine cungql(M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cungql_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGEQLF in the last k columns of its array argument A. On exit, the M-by-N matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQLF.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *zungql*. It also exists with a native C interface as *LAPACKE_cungql*.

4.3.45 cungqr

cungqr generates an M-by-N complex matrix Q with orthonormal columns, which is defined as the first N columns of a product of K elementary reflectors of order M

```
Q  =  H(1) H(2) . . . H(k)
```

as returned by CGEQRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine cungqr(M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cungqr_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by CGEQRF in the first k columns of its array argument A. On exit, the M-by-N matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQRF.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *zungqr*. It also exists with a native C interface as *LAPACKE_cungqr*.

4.3.46 cungrq

cungrq generates an M-by-N complex matrix Q with orthonormal rows, which is defined as the last M rows of a product of K elementary reflectors of order N

```
Q  =  H(1)**H H(2)**H . . . H(k)**H
```

as returned by CGERQF.

Syntax

Fortran specification:

```
use armpl_library

subroutine cungrq(M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cungrq_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. N >= M.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the (m-k+i)-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGERQF in the last k rows of its array argument A. On exit, the M-by-N matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGERQF.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *zungrq*. It also exists with a native C interface as *LAPACKE_cungrq*.

4.3.47 cunmlq

cunmlq overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H

where Q is a complex unitary matrix defined as the product of k elementary reflectors

```
Q = H(k)**H . . . H(2)**H H(1)**H
```

as returned by CGELQF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine cunmlq(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void cunmlq_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *c,
             const armpl_int_t *ldc, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Conjugate transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGELQF in the first k rows of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGELQF.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zunmlq*. It also exists with a native C interface as *LAPACKE_cunmlq*.

4.3.48 cunmql

cunmql overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H

where Q is a complex unitary matrix defined as the product of k elementary reflectors

```
Q = H(k) . . . H(2) H(1)
```

as returned by CGEQLF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine cunmql(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void cunmql_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *c,
             const armpl_int_t *ldc, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by CGEQLF in the last k columns of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQLF.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zunmql*. It also exists with a native C interface as *LAPACKE_cunmql*.

4.3.49 cunmqr

cunmqr overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H

where Q is a complex unitary matrix defined as the product of k elementary reflectors

```
Q = H(1) H(2) . . . H(k)
```

as returned by CGEQRF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine cunmqr(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void cunmqr_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *c,
             const armpl_int_t *ldc, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Conjugate transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGEQRF in the first k columns of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQRF.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zunmqr*. It also exists with a native C interface as *LAPACKE_cunmqr*.

4.3.50 cunmrq

cunmrq overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H

where Q is a complex unitary matrix defined as the product of k elementary reflectors

```
Q = H(1)**H H(2)**H . . . H(k)**H
```

as returned by CGERQF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine cunmrq(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void cunmrq_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *c,
             const armpl_int_t *ldc, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGERQF in the last k rows of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGERQF.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zunmrq*. It also exists with a native C interface as *LAPACKE_cunmrq*.

4.3.51 cunmrz

cunmrz overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H

where Q is a complex unitary matrix defined as the product of k elementary reflectors

```
Q = H(1) H(2) . . . H(k)
```

as returned by CTZRZF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine cunmrz(SIDE, TRANS, M, N, K, L, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void cunmrz_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const armpl_int_t *l,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *c,
             const armpl_int_t *ldc, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Conjugate transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

L Input parameter.

L is INTEGER

The number of columns of the matrix A containing the meaningful part of the Householder reflectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CTZRZF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CTZRZF.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zunmrz*. It also exists with a native C interface as *LAPACKE_cunmrz*.

4.3.52 dgbtrf

dgbtrf computes an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgbtrf(M, N, KL, KU, AB, LDAB, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void dgbtrf_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku, double *ab,
             const armpl_int_t *ldab, armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Output parameter.

IPIV is INTEGER array, dimension (min(M, N))

The pivot indices; for 1 <= i <= min(M, N), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = +i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *cgbtrf*, *sgbtrf* and *zgbtrf*. It also exists with a native C interface as *LAPACKE_dgbtrf*.

4.3.53 dgelq

`dgelq` computes a LQ factorization of an M-by-N matrix A.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgelq(M, N, A, LDA, T, TSIZE, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgelq_(const armpl_int_t *m, const armpl_int_t *n, double *a,
            const armpl_int_t *lda, double *t, const armpl_int_t *tsize,
            double *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix `A`. `M` >= 0.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix `A`. `N` >= 0.

A Input and output parameter.

`A` is `DOUBLE PRECISION`

`A` is an array, dimension (`LDA`, `N`). On entry, the M-by-N matrix `A`. On exit, the elements on and below the diagonal of the array contain the M-by-min(`M`, `N`) lower trapezoidal matrix L (L is lower triangular if `M` <= N); the elements above the diagonal are used to store part of the data structure to represent Q.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `M`).

T Output parameter.

`T` is `DOUBLE PRECISION`

`T` is an array, dimension (MAX(5, `TSIZE`)). On exit, if `INFO` = 0, T(1) returns optimal (or either minimal or optimal, if query is assumed) `TSIZE`. See `TSIZE` for details. Remaining `T` contains part of the data structure used to represent Q. If one wants to apply or construct Q, then one needs to keep `T` (in addition to A) and pass it to further subroutines.

TSIZE Input parameter.

TSIZE is INTEGER

If TSIZE >= 5, the dimension of the array T. If TSIZE = -1 or -2, then a workspace query is assumed. The routine only calculates the sizes of the T and WORK arrays, returns these values as the first entries of the T and WORK arrays, and no error message related to T or WORK is issued by XERBLA. If TSIZE = -1, the routine calculates optimal size of T for the optimum performance and returns this value in T(1). If TSIZE = -2, the routine calculates minimal size of T and returns this value in T(1).

WORK Output parameter.

(workspace) DOUBLE PRECISION

(workspace) is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) contains optimal (or either minimal or optimal, if query was assumed) LWORK. See LWORK for details.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1 or -2, then a workspace query is assumed. The routine only calculates the sizes of the T and WORK arrays, returns these values as the first entries of the T and WORK arrays, and no error message related to T or WORK is issued by XERBLA. If LWORK = -1, the routine calculates optimal size of WORK for the optimal performance and returns this value in WORK(1). If LWORK = -2, the routine calculates minimal size of WORK and returns this value in WORK(1).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgelq*, *sgelq* and *zgelq*. It also exists with a native C interface as *LAPACKE_dgelq*.

4.3.54 dgelqf

dgelqf computes an LQ factorization of a real M-by-N matrix A: A = L * Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgelqf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgelqf_(const armpl_int_t *m, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, double *tau, double *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the m-by-min(m,n) lower trapezoidal matrix L (L is lower triangular if m <= n); the elements above the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgelqf*, *sgelqf* and *zgelqf*. It also exists with a native C interface as *LAPACKE_dgelqf*.

4.3.55 dgelqt

dgelqt computes a blocked LQ factorization of a real M-by-N matrix A using the compact WY representation of Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgelqt(M, N, MB, A, LDA, T, LDT, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgelqt_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *mb, double *a, const armpl_int_t *lda,
             double *t, const armpl_int_t *ldt, double *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

MB Input parameter.

MB is INTEGER

The block size to be used in the blocked QR. MIN(M, N) >= MB >= 1.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the M-by-MIN(M, N) lower trapezoidal matrix L (L is lower triangular if M <= N); the elements above the diagonal are the rows of V.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT,MIN(M, N)). The upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MB*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgelqt*, *sgelqt* and *zgelqt*.

4.3.56 dgemlq

dgemlq overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T where Q is a real orthogonal matrix defined as the product of blocked elementary reflectors computed by short wide LQ factorization (DGELQ)

Syntax

Fortran specification:

```
use armpl_library

subroutine dgemlq(SIDE, TRANS, M, N, K, A, LDA, T, TSIZE, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dgemlq_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const double *a,
             const armpl_int_t *lda, const double *t,
             const armpl_int_t *tsize, double *c, const armpl_int_t *ldc,
             double *work, const armpl_int_t *lwork, armpl_int_t *info,
             ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >=0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' Part of the data structure to represent Q as returned by DGELQ.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

T Input parameter.

T is DOUBLE PRECISION

T is an array, dimension (MAX(5, TSIZE)).. Part of the data structure to represent Q as returned by DGELQ.

TSIZE Input parameter.

TSIZE is INTEGER

The dimension of the array T. TSIZE >= 5.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

(workspace) DOUBLE PRECISION

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1, then a workspace query is assumed. The routine only calculates the size of the WORK array, returns this value as WORK(1), and no error message related to WORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgemlq*, *sgemlq* and *zgemlq*. It also exists with a native C interface as *LAPACKE_dgemlq*.

4.3.57 dgemlqt

dgemlqt overwrites the general real M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q C C Q TRANS = 'T': Q^T C C Q^T

where Q is a real orthogonal matrix defined as the product of K elementary reflectors:

```
Q = H(1) H(2) . . . H(K) = I - V T V**T
```

generated using the compact WY representation as returned by DGELQT.

Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgemlqt(SIDE, TRANS, M, N, K, MB, V, LDV, T, LDT, C, LDC, WORK,
                   INFO)
```

C specification:

```
#include "armpl.h"

void dgemlqt_(const char *side, const char *trans, const armpl_int_t *m,
              const armpl_int_t *n, const armpl_int_t *k,
              const armpl_int_t *mb, const double *v, const armpl_int_t *ldv,
              const double *t, const armpl_int_t *ldt, double *c,
              const armpl_int_t *ldc, double *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

MB Input parameter.

MB is INTEGER

The block size used for the storage of T. K >= MB >= 1. This must be the same value of MB used to generate T in DGELQT.

V Input parameter.

V is DOUBLE PRECISION

V is an array, dimension. (LDV, M) if SIDE = 'L', (LDV, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DGELQT in the first K rows of its array argument A.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, K).

T Input parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, K). The upper triangular factors of the block reflectors as returned by DGELQT, stored as a MB-by-K matrix.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q C, Q^T C, C Q^T or C Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION array. The dimension of

WORK is N* MB if SIDE = 'L', or M* MB if SIDE = 'R'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgemlqt*, *sgemlqt* and *zgemlqt*.

4.3.58 dgemqr

dgemqr overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T where Q is a real orthogonal matrix defined as the product of blocked elementary reflectors computed by tall skinny QR factorization (DGEQR)

Syntax

Fortran specification:

```
use armpl_library

subroutine dgemqr(SIDE, TRANS, M, N, K, A, LDA, T, TSIZE, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dgemqr_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const double *a,
             const armpl_int_t *lda, const double *t,
             const armpl_int_t *tsize, double *c, const armpl_int_t *ldc,
             double *work, const armpl_int_t *lwork, armpl_int_t *info,
             ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >=0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, K). Part of the data structure to represent Q as returned by DGEQR.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

T Input parameter.

T is DOUBLE PRECISION

T is an array, dimension (MAX(5, TSIZE)).. Part of the data structure to represent Q as returned by DGEQR.

TSIZE Input parameter.

TSIZE is INTEGER

The dimension of the array T. TSIZE >= 5.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

(workspace) DOUBLE PRECISION

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1, then a workspace query is assumed. The routine only calculates the size of the WORK array, returns this value as WORK(1), and no error message related to WORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgemqr*, *sgemqr* and *zgemqr*. It also exists with a native C interface as *LAPACKE_dgemqr*.

4.3.59 dgemqrt

dgemqrt overwrites the general real M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q C C Q TRANS = 'T': Q^T C C Q^T

where Q is a real orthogonal matrix defined as the product of K elementary reflectors:

```
Q = H(1) H(2) . . . H(K) = I - V T V**T
```

generated using the compact WY representation as returned by DGEQRT.

Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgemqrt(SIDE, TRANS, M, N, K, NB, V, LDV, T, LDT, C, LDC, WORK,
                   INFO)
```

C specification:

```
#include "armpl.h"

void dgemqrt_(const char *side, const char *trans, const armpl_int_t *m,
              const armpl_int_t *n, const armpl_int_t *k,
              const armpl_int_t *nb, const double *v, const armpl_int_t *ldv,
              const double *t, const armpl_int_t *ldt, double *c,
              const armpl_int_t *ldc, double *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

NB Input parameter.

NB is INTEGER

The block size used for the storage of T. K >= NB >= 1. This must be the same value of NB used to generate T in CGEQRT.

V Input parameter.

V is DOUBLE PRECISION

V is an array, dimension (LDV, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by CGEQRT in the first K columns of its array argument A.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

T Input parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, K). The upper triangular factors of the block reflectors as returned by CGEQRT, stored as a NB-by-N matrix.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q C, Q^T C, C Q^T or C Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION array. The dimension of

WORK is N* NB if SIDE = 'L', or M* NB if SIDE = 'R'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgemqrt*, *sgemqrt* and *zgemqrt*. It also exists with a native C interface as *LAPACKE_dgemqrt*.

4.3.60 dgeqlf

dgeqlf computes a QL factorization of a real M-by-N matrix A: A = Q * L.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgeqlf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgeqlf_(const armpl_int_t *m, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, double *tau, double *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if m >= n, the lower triangle of the subarray A(m-n+1:m,1:n) contains the N-by-N lower triangular matrix L; if m <= n, the elements on and below the (n-m)-th superdiagonal contain the M-by-N lower trapezoidal matrix L; the remaining elements, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqlf*, *sgeqlf* and *zgeqlf*. It also exists with a native C interface as *LAPACKE_dgeqlf*.

4.3.61 dgeqp3

`dgeqp3` computes a QR factorization with column pivoting of a matrix A: A*P = Q*R using Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgeqp3(M, N, A, LDA, JPVT, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgeqp3_(const armpl_int_t *m, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, armpl_int_t *jpvt, double *tau,
             double *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the min(M, N)-by-N upper trapezoidal matrix R; the elements below the diagonal, together with the array TAU, represent the orthogonal matrix Q as a product of min(M, N) elementary reflectors.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

JPVT Input and output parameter.

JPVT is INTEGER array, dimension (N)

On entry, if JPVT(J).ne.0, the J-th column of A is permuted to the front of A*P (a leading column); if JPVT(J)=0, the J-th column of A is a free column. On exit, if JPVT(J)=K, then the J-th column of A*P was the the K-th column of A.

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO=0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 3*N+1. For optimal performance LWORK >= 2*N+(N+1)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgeqp3*, *sgeqp3* and *zgeqp3*. It also exists with a native C interface as *LAPACKE_dgeqp3*.

4.3.62 dgeqr

dgeqr computes a QR factorization of an M-by-N matrix A.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgeqr(M, N, A, LDA, T, TSIZE, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgeqr_(const armpl_int_t *m, const armpl_int_t *n, double *a,
            const armpl_int_t *lda, double *t, const armpl_int_t *tsize,
            double *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix R (R is upper triangular if M >= N); the elements below the diagonal are used to store part of the data structure to represent Q.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is DOUBLE PRECISION

T is an array, dimension (MAX(5, TSIZE)). On exit, if INFO = 0, T(1) returns optimal (or either minimal or optimal, if query is assumed) TSIZE. See TSIZE for details. Remaining T contains part of the data structure used to represent Q. If one wants to apply or construct Q, then one needs to keep T (in addition to A) and pass it to further subroutines.

TSIZE Input parameter.

TSIZE is INTEGER

If TSIZE >= 5, the dimension of the array T. If TSIZE = -1 or -2, then a workspace query is assumed. The routine only calculates the sizes of the T and WORK arrays, returns these values as the first entries of the T and WORK arrays, and no error message related to T or WORK is issued by XERBLA. If TSIZE = -1, the routine calculates optimal size of T for the optimum performance and returns this value in T(1). If TSIZE = -2, the routine calculates minimal size of T and returns this value in T(1).

WORK Output parameter.

(workspace) DOUBLE PRECISION

(workspace) is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) contains optimal (or either minimal or optimal, if query was assumed) LWORK. See LWORK for details.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1 or -2, then a workspace query is assumed. The routine only calculates the sizes of the T and WORK arrays, returns these values as the first entries of the T and WORK arrays, and no error message related to T or WORK is issued by XERBLA. If LWORK = -1, the routine calculates optimal size of WORK for the optimal performance and returns this value in WORK(1). If LWORK = -2, the routine calculates minimal size of WORK and returns this value in WORK(1).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqr*, *sgeqr* and *zgeqr*. It also exists with a native C interface as *LAPACKE_dgeqr*.

4.3.63 dgeqrf

`dgeqrf` computes a QR factorization of a real M-by-N matrix A: A = Q * R.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgeqrf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgeqrf_(const armpl_int_t *m, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, double *tau, double *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix R (R is upper triangular if m >= n); the elements below the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqrf*, *sgeqrf* and *zgeqrf*. It also exists with a native C interface as *LAPACKE_dgeqrf*.

4.3.64 dgeqrfp

dgeqrfp computes a QR factorization of a real M-by-N matrix A: A = Q * R. The diagonal entries of R are nonnegative.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgeqrfp(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgeqrfp_(const armpl_int_t *m, const armpl_int_t *n, double *a,
              const armpl_int_t *lda, double *tau, double *work,
              const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix R (R is upper triangular if m >= n). The diagonal entries of R are nonnegative; the elements below the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqrfp*, *sgeqrfp* and *zgeqrfp*. It also exists with a native C interface as *LAPACKE_dgeqrfp*.

4.3.65 dgeqrt

dgeqrt computes a blocked QR factorization of a real M-by-N matrix A using the compact WY representation of Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgeqrt(M, N, NB, A, LDA, T, LDT, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgeqrt_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *nb, double *a, const armpl_int_t *lda,
             double *t, const armpl_int_t *ldt, double *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The block size to be used in the blocked QR. MIN(M, N) >= NB >= 1.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix R (R is upper triangular if M >= N); the elements below the diagonal are the columns of V.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT,MIN(M, N)). The upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (NB*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqrt*, *sgeqrt* and *zgeqrt*. It also exists with a native C interface as *LAPACKE_dgeqrt*.

4.3.66 dgerqf

dgerqf computes an RQ factorization of a real M-by-N matrix A: A = R * Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgerqf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgerqf_(const armpl_int_t *m, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, double *tau, double *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if m <= n, the upper triangle of the subarray A(1:m,n-m+1:n) contains the M-by-M upper triangular matrix R; if m >= n, the elements on and above the (m-n)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the orthogonal matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgerqf*, *sgerqf* and *zgerqf*. It also exists with a native C interface as *LAPACKE_dgerqf*.

4.3.67 dgetrf

dgetrf computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form

```
A = P * L * U
```

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the right-looking Level 3 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgetrf(M, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void dgetrf_(const armpl_int_t *m, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

IPIV Output parameter.

IPIV is INTEGER array, dimension (min(M, N))

The pivot indices; for 1 <= i <= min(M, N), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *cgetrf*, *sgetrf* and *zgetrf*. It also exists with a native C interface as *LAPACKE_dgetrf*.

4.3.68 dgetrf2

dgetrf2 computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form

```
A = P * L * U
```

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the recursive version of the algorithm. It divides the matrix into four submatrices:

```
    [  A11 | A12  ]  where A11 is n1 by n1 and A22 is n2 by n2
A = [ -----|-----  ]  with n1 = min(m,n)/2
    [  A21 | A22  ]       n2 = n-n1

                                  [ A11 ]
```

The subroutine calls itself to factor [—],

```
                      [ A12 ]
[ A12 ]
```

do the swaps on [—], solve A12, update A22,

```
[ A22 ]
```

then calls itself to factor A22 and do the swaps on A21.

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine dgetrf2(M, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void dgetrf2_(const armpl_int_t *m, const armpl_int_t *n, double *a,
              const armpl_int_t *lda, armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

IPIV Output parameter.

IPIV is INTEGER array, dimension (min(M, N))

The pivot indices; for 1 <= i <= min(M, N), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *cgetrf2*, *sgetrf2* and *zgetrf2*. It also exists with a native C interface as *LAPACKE_dgetrf2*.

4.3.69 dggqrf

dggqrf computes a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B:

```
A = Q*R,        B = Q*T*Z,
```

where Q is an N-by-N orthogonal matrix, Z is a P-by-P orthogonal matrix, and R and T assume one of the forms:

if N >= M, R = (R11) M , or if N < M, R = (R11 R12) N,

```
(  0  ) N-M                          N   M-N
   M
```

where R11 is upper triangular, and

if N <= P, T = (0 T12) N, or if N > P, T = (T11) N-P,

```
P-N  N                                ( T21 ) P
                                        P
```

where T12 or T21 is upper triangular.

In particular, if B is square and nonsingular, the GQR factorization of A and B implicitly gives the QR factorization of inv(B)*A:

```
inv(B)*A = Z**T*(inv(T)*R)
```

where inv(B) denotes the inverse of the matrix B, and Z^T denotes the transpose of the matrix Z.

Syntax

Fortran specification:

```
use armpl_library

subroutine dggqrf(N, M, P, A, LDA, TAUA, B, LDB, TAUB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dggqrf_(const armpl_int_t *n, const armpl_int_t *m, const armpl_int_t *p,
             double *a, const armpl_int_t *lda, double *taua, double *b,
             const armpl_int_t *ldb, double *taub, double *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of rows of the matrices A and B. N >= 0.

M Input parameter.

M is INTEGER

The number of columns of the matrix A. M >= 0.

P Input parameter.

P is INTEGER

The number of columns of the matrix B. P >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, M). On entry, the N-by-M matrix A. On exit, the elements on and above the diagonal of the array contain the min(N, M)-by-M upper trapezoidal matrix R (R is upper triangular if N >= M); the elements below the diagonal, with the array TAUA, represent the orthogonal matrix Q as a product of min(N, M) elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAUA Output parameter.

TAUA is DOUBLE PRECISION

TAUA is an array, dimension (min(N, M)). The scalar factors of the elementary reflectors which represent the orthogonal matrix Q (see Further Details).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, P). On entry, the N-by-P matrix B. On exit, if N <= P, the upper triangle of the subarray B(1:N,P-N+1:P) contains the N-by-N upper triangular matrix T; if N > P, the elements on and above the (N-P)-th subdiagonal contain the N-by-P upper trapezoidal matrix T; the remaining elements, with the array TAUB, represent the orthogonal matrix Z as a product of elementary reflectors (see Further Details).

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

TAUB Output parameter.

TAUB is DOUBLE PRECISION

TAUB is an array, dimension (min(N, P)). The scalar factors of the elementary reflectors which represent the orthogonal matrix Z (see Further Details).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N, M, P). For optimum performance LWORK >= max(N, M, P)*max(NB1,NB2,NB3), where NB1 is the optimal blocksize for the QR factorization of an N-by-M matrix, NB2 is the optimal blocksize for the RQ factorization of an N-by-P matrix, and NB3 is the optimal blocksize for a call of DORMQR.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cggqrf*, *sggqrf* and *zggqrf*. It also exists with a native C interface as *LAPACKE_dggqrf*.

4.3.70 dggrqf

dggrqf computes a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B:

```
A = R*Q,        B = Z*T*Q,
```

where Q is an N-by-N orthogonal matrix, Z is a P-by-P orthogonal matrix, and R and T assume one of the forms:

if M <= N, R = (0 R12) M, or if M > N, R = (R11) M-N,

```
N-M  M                              ( R21 ) N
                                      N
```

where R12 or R21 is upper triangular, and

if P >= N, T = (T11) N , or if P < N, T = (T11 T12) P,

```
(  0  ) P-N                           P   N-P
  N
```

where T11 is upper triangular.

In particular, if B is square and nonsingular, the GRQ factorization of A and B implicitly gives the RQ factorization of A*inv(B):

```
A*inv(B) = (R*inv(T))*Z**T
```

where inv(B) denotes the inverse of the matrix B, and Z^T denotes the transpose of the matrix Z.

Syntax

Fortran specification:

```
use armpl_library

subroutine dggrqf(M, P, N, A, LDA, TAUA, B, LDB, TAUB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dggrqf_(const armpl_int_t *m, const armpl_int_t *p, const armpl_int_t *n,
             double *a, const armpl_int_t *lda, double *taua, double *b,
             const armpl_int_t *ldb, double *taub, double *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. P >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if M <= N, the upper triangle of the subarray A(1:M,N-M+1:N) contains the M-by-M upper triangular matrix R; if M > N, the elements on and above the (M-N)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAUA, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAUA Output parameter.

TAUA is DOUBLE PRECISION

TAUA is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the orthogonal matrix Q (see Further Details).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, the elements on and above the diagonal of the array contain the min(P, N)-by-N upper trapezoidal matrix T (T is upper triangular if P >= N); the elements below the diagonal, with the array TAUB, represent the orthogonal matrix Z as a product of elementary reflectors (see Further Details).

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

TAUB Output parameter.

TAUB is DOUBLE PRECISION

TAUB is an array, dimension (min(P, N)). The scalar factors of the elementary reflectors which represent the orthogonal matrix Z (see Further Details).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N, M, P). For optimum performance LWORK >= max(N, M, P)*max(NB1,NB2,NB3), where NB1 is the optimal blocksize for the RQ factorization of an M-by-N matrix, NB2 is the optimal blocksize for the QR factorization of a P-by-N matrix, and NB3 is the optimal blocksize for a call of DORMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INF0= -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cggrqf*, *sggrqf* and *zggrqf*. It also exists with a native C interface as *LAPACKE_dggrqf*.

4.3.71 dgttrf

dgttrf computes an LU factorization of a real tridiagonal matrix A using elimination with partial pivoting and row interchanges.

The factorization has the form

```
A = L * U
```

where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgttrf(N, DL, D, DU, DU2, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void dgttrf_(const armpl_int_t *n, double *dl, double *d, double *du,
             double *du2, armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A.

DL Input and output parameter.

DL is DOUBLE PRECISION

DL is an array, dimension (N-1). On entry, DL must contain the (n-1) sub-diagonal elements of A.

On exit, DL is overwritten by the (n-1) multipliers that define the matrix L from the LU factorization of A.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, D must contain the diagonal elements of A.

On exit, D is overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DU Input and output parameter.

DU is DOUBLE PRECISION

DU is an array, dimension (N-1). On entry, DU must contain the (n-1) super-diagonal elements of A.

On exit, DU is overwritten by the (n-1) elements of the first super-diagonal of U.

DU2 Output parameter.

DU2 is DOUBLE PRECISION

DU2 is an array, dimension (N-2). On exit, DU2 is overwritten by the (n-2) elements of the second super-diagonal of U.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *cgttrf*, *sgttrf* and *zgttrf*. It also exists with a native C interface as *LAPACKE_dgttrf*.

4.3.72 dorglq

dorglq generates an M-by-N real matrix Q with orthonormal rows, which is defined as the first M rows of a product of K elementary reflectors of order N

```
Q  =  H(k) . . . H(2) H(1)
```

as returned by DGELQF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dorglq(M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorglq_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             double *a, const armpl_int_t *lda, const double *tau,
             double *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. N >= M.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by DGELQF in the first k rows of its array argument A. On exit, the M-by-N matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DGELQF.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *sorglq*. It also exists with a native C interface as *LAPACKE_dorglq*.

4.3.73 dorgql

dorgql generates an M-by-N real matrix Q with orthonormal columns, which is defined as the last N columns of a product of K elementary reflectors of order M

```
Q  =  H(k) . . . H(2) H(1)
```

as returned by DGEQLF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dorgql(M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorgql_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             double *a, const armpl_int_t *lda, const double *tau,
             double *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DGEQLF in the last k columns of its array argument A. On exit, the M-by-N matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DGEQLF.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *sorgql*. It also exists with a native C interface as *LAPACKE_dorgql*.

4.3.74 dorgqr

dorgqr generates an M-by-N real matrix Q with orthonormal columns, which is defined as the first N columns of a product of K elementary reflectors of order M

```
Q  =  H(1) H(2) . . . H(k)
```

as returned by DGEQRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dorgqr(M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorgqr_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             double *a, const armpl_int_t *lda, const double *tau,
             double *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DGEQRF in the first k columns of its array argument A. On exit, the M-by-N matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DGEQRF.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *sorgqr*. It also exists with a native C interface as *LAPACKE_dorgqr*.

4.3.75 dorgrq

dorgrq generates an M-by-N real matrix Q with orthonormal rows, which is defined as the last M rows of a product of K elementary reflectors of order N

```
Q  =  H(1) H(2) . . . H(k)
```

as returned by DGERQF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dorgrq(M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorgrq_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             double *a, const armpl_int_t *lda, const double *tau,
             double *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. N >= M.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the (m-k+i)-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DGERQF in the last k rows of its array argument A. On exit, the M-by-N matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DGERQF.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

4.3.76 dormlq

dormlq overwrites the general real M-by-N matrix C with

```
SIDE = 'L'      SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

```
Q = H(k) . . . H(2) H(1)
```

as returned by DGELQF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine dormlq(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dormlq_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const double *a,
             const armpl_int_t *lda, const double *tau, double *c,
             const armpl_int_t *ldc, double *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DGELQF in the first k rows of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DGELQF.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sormlq*. It also exists with a native C interface as *LAPACKE_dormlq*.

4.3.77 dormql

`dormql` overwrites the general real M-by-N matrix C with

```
SIDE = 'L'      SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

```
Q = H(k) . . . H(2) H(1)
```

as returned by DGEQLF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine dormql(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dormql_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const double *a,
             const armpl_int_t *lda, const double *tau, double *c,
             const armpl_int_t *ldc, double *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DGEQLF in the last k columns of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DGEQLF.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sormql*. It also exists with a native C interface as *LAPACKE_dormql*.

4.3.78 dormqr

dormqr overwrites the general real M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

```
Q = H(1) H(2) . . . H(k)
```

as returned by DGEQRF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine dormqr(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dormqr_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const double *a,
             const armpl_int_t *lda, const double *tau, double *c,
             const armpl_int_t *ldc, double *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by DGEQRF in the first k columns of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DGEQRF.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sormqr*. It also exists with a native C interface as *LAPACKE_dormqr*.

4.3.79 dormrq

dormrq overwrites the general real M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

```
Q = H(1) H(2) . . . H(k)
```

as returned by DGERQF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine dormrq(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dormrq_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const double *a,
             const armpl_int_t *lda, const double *tau, double *c,
             const armpl_int_t *ldc, double *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DGERQF in the last k rows of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DGERQF.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sormrq*. It also exists with a native C interface as *LAPACKE_dormrq*.

4.3.80 dormrz

dormrz overwrites the general real M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

```
Q = H(1) H(2) . . . H(k)
```

as returned by DTZRZF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine dormrz(SIDE, TRANS, M, N, K, L, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dormrz_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const armpl_int_t *l,
             const double *a, const armpl_int_t *lda, const double *tau,
             double *c, const armpl_int_t *ldc, double *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

L Input parameter.

L is INTEGER

The number of columns of the matrix A containing the meaningful part of the Householder reflectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DTZRZF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DTZRZF.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sormrz*. It also exists with a native C interface as *LAPACKE_dormrz*.

4.3.81 dpbtrf

dpbtrf computes the Cholesky factorization of a real symmetric positive definite band matrix A.

The factorization has the form

```
A = U**T * U,  if UPLO = 'U', or
A = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpbtrf(UPLO, N, KD, AB, LDAB, INFO)
```

C specification:

```
#include "armpl.h"

void dpbtrf_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             double *ab, const armpl_int_t *ldab, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the band matrix A, in the same storage format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpbtrf*, *spbtrf* and *zpbtrf*. It also exists with a native C interface as *LAPACKE_dpbtrf*.

4.3.82 dpftrf

dpftrf computes the Cholesky factorization of a real symmetric positive definite matrix A.

The factorization has the form

```
A = U**T * U,  if UPLO = 'U', or
A = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

This is the block version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpftrf(TRANSR, UPLO, N, A, INFO)
```

C specification:

```
#include "armpl.h"

void dpftrf_(const char *transr, const char *uplo, const armpl_int_t *n,
             double *a, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal TRANSR of RFP A is stored; = 'T': The Transpose TRANSR of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of RFP A is stored; = 'L': Lower triangle of RFP A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (N*(N+1)/2);. On entry, the symmetric matrix A in RFP format. RFP format is described by TRANSR, UPLO, and N as follows: If TRANSR = 'N' then RFP A is (0:N,0:k-1) when N is even; k=N/2. RFP A is (0:N-1,0:k) when N is odd; k=N/2. IF TRANSR = 'T' then RFP is the transpose of RFP A as defined when TRANSR = 'N'. The contents of RFP A are defined by UPLO as follows: If UPLO = 'U' the RFP A contains the NT elements of upper packed A. If UPLO = 'L' the RFP A contains the elements of lower packed A. The LDA of RFP A is (N+1)/2 when TRANSR = 'T'. When TRANSR is 'N' the LDA is N+1 when N is even and N is odd. See the Note below for more details.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization RFP A = U^T *U or RFP A = L*L^T .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpftrf*, *spftrf* and *zpftrf*. It also exists with a native C interface as *LAPACKE_dpftrf*.

4.3.83 dpotrf

dpotrf computes the Cholesky factorization of a real symmetric positive definite matrix A.

The factorization has the form

```
A = U**T * U,  if UPLO = 'U', or
A = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

This is the block version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpotrf(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void dpotrf_(const char *uplo, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpotrf*, *spotrf* and *zpotrf*. It also exists with a native C interface as *LAPACKE_dpotrf*.

4.3.84 dpotrf2

dpotrf2 computes the Cholesky factorization of a real symmetric positive definite matrix A using the recursive algorithm.

The factorization has the form

```
A = U**T * U,  if UPLO = 'U', or
A = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

This is the recursive version of the algorithm. It divides the matrix into four submatrices:

```
    [  A11 | A12  ]  where A11 is n1 by n1 and A22 is n2 by n2
A = [ -----|-----  ]  with n1 = n/2
    [  A21 | A22  ]       n2 = n-n1
```

The subroutine calls itself to factor A11. Update and scale A21 or A12, update A22 then calls itself to factor A22.

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine dpotrf2(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void dpotrf2_(const char *uplo, const armpl_int_t *n, double *a,
              const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpotrf2*, *spotrf2* and *zpotrf2*. It also exists with a native C interface as *LAPACKE_dpotrf2*.

4.3.85 dpptrf

dpptrf computes the Cholesky factorization of a real symmetric positive definite matrix A stored in packed format.

The factorization has the form

```
A = U**T * U,  if UPLO = 'U', or
A = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpptrf(UPLO, N, AP, INFO)
```

C specification:

```
#include "armpl.h"

void dpptrf_(const char *uplo, const armpl_int_t *n, double *ap,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$, in the same storage format as A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpptrf*, *spptrf* and *zpptrf*. It also exists with a native C interface as *LAPACKE_dpptrf*.

4.3.86 dpstrf

dpstrf computes the Cholesky factorization with complete pivoting of a real symmetric positive semidefinite matrix A.

The factorization has the form

```
P**T * A * P = U**T * U ,  if UPLO = 'U',
P**T * A * P = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular, and P is stored as vector PIV.

This algorithm does not attempt to check that A is positive semidefinite. This version of the algorithm calls level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpstrf(UPLO, N, A, LDA, PIV, RANK, TOL, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dpstrf_(const char *uplo, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, armpl_int_t *piv, armpl_int_t *rank,
             const double *tol, double *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization as above.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

PIV Output parameter.

PIV is INTEGER array, dimension (N)

PIV is such that the nonzero entries are P(PIV(K), K) = 1.

RANK Output parameter.

RANK is INTEGER

The rank of A given by the number of steps the algorithm completed.

TOL Input parameter.

TOL is DOUBLE PRECISION

User defined tolerance. If TOL < 0, then N*U*MAX(A(K,K)) will be used. The algorithm terminates at the (K-1)st step if the pivot <= TOL.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N). Work space.

INFO Output parameter.

INFO is INTEGER

< 0: If INFO = -K, the K-th argument had an illegal value, = 0: algorithm completed successfully, and > 0: the matrix A is either rank deficient with computed rank as returned in RANK, or is not positive semidefinite. See Section 7 of LAPACK Working Note #161 for further information.

Related Information

For this routine in other precisions, please see *cpstrf*, *spstrf* and *zpstrf*. It also exists with a native C interface as *LAPACKE_dpstrf*.

4.3.87 dpttrf

`dpttrf` computes the L*D*L^T factorization of a real symmetric positive definite tridiagonal matrix A. The factorization may also be regarded as having the form A = U^T *D*U.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpttrf(N, D, E, INFO)
```

C specification:

```
#include "armpl.h"

void dpttrf_(const armpl_int_t *n, double *d, double *e, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the L*D*L^T factorization of A.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*D*L^T factorization of A. E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U^T *D*U factorization of A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, the leading minor of order k is not positive definite; if k < N, the factorization could not be completed, while if k = N, the factorization was completed, but D(N) <= 0.

Related Information

For this routine in other precisions, please see *cpttrf*, *spttrf* and *zpttrf*. It also exists with a native C interface as *LAPACKE_dpttrf*.

4.3.88 dsptrf

`dsptrf` computes the factorization of a real symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method:

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsptrf(UPLO, N, AP, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void dsptrf_(const char *uplo, const armpl_int_t *n, double *ap,
             armpl_int_t *ipiv, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0.

AP Input and output parameter.

`AP` is `DOUBLE PRECISION`

`AP` is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array `AP` as follows: if `UPLO` = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if `UPLO` = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L, stored as a packed triangular matrix overwriting A (see below for further details).

IPIV Output parameter.

`IPIV` is `INTEGER` array, dimension (`N`)

Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If `UPLO` = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If `UPLO` = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO Output parameter.

`INFO` is `INTEGER`

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *csptrf*, *ssptrf* and *zsptrf*. It also exists with a native C interface as *LAPACKE_dsptrf*.

4.3.89 dsytrf

dsytrf computes the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytrf(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsytrf_(const char *uplo, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, armpl_int_t *ipiv, double *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >=1. For best performance LWORK >= N*NB, where NB is the block size returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *csytrf*, *ssytrf* and *zsytrf*. It also exists with a native C interface as *LAPACKE_dsytrf*.

4.3.90 dsytrf_aa

DSYTRF_AA computes the factorization of a real symmetric matrix A using the Aasen's algorithm. The form of the factorization is

```
A = U*T*U**T  or  A = L*T*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is a symmetric tridiagonal matrix.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytrf_aa(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsytrf_aa_(const char *uplo, const armpl_int_t *n, double *a,
                const armpl_int_t *lda, armpl_int_t *ipiv, double *work,
                const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the tridiagonal matrix is stored in the diagonals and the subdiagonals of A just below (or above) the diagonals, and L is stored below (or above) the subdiaonals, when UPLO is 'L' (or 'U').

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= MAX(1,2*N). For optimum performance LWORK >= N*(1+NB), where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *csytrf_aa*, *ssytrf_aa* and *zsytrf_aa*. It also exists with a native C interface as *LAPACKE_dsytrf_aa*.

4.3.91 dsytrf_rk

DSYTRF_RK computes the factorization of a real symmetric matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS. For more information see Further Details section.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytrf_rk(UPLO, N, A, LDA, E, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsytrf_rk_(const char *uplo, const armpl_int_t *n, double *a,
                const armpl_int_t *lda, double *e, armpl_int_t *ipiv,
                double *work, const armpl_int_t *lwork, armpl_int_t *info,
                ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, contains: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

IPIV describes the permutation matrix P in the factorization of matrix A as follows. The absolute value of IPIV(k) represents the index of row and column that were interchanged with the k-th row and column. The value of UPLO describes the order in which the interchanges were applied. Also, the sign of IPIV represents the block structure of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks which correspond to 1 or 2 interchanges at each factorization step. For more info see Further Details section.

If UPLO = 'U', (in factorization order, k decreases from N to 1): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N); If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k-1) < 0 means: D(k-1:k,k-1:k) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k-1) != k-1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k-1) = k-1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) <= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

If UPLO = 'L', (in factorization order, k increases from 1 to N): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N). If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k+1) < 0 means: D(k:k+1,k:k+1) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k+1) != k+1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k+1) = k+1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) >= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)).. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >=1. For best performance LWORK >= N*NB, where NB is the block size returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

Related Information

For this routine in other precisions, please see *csytrf_rk*, *ssytrf_rk* and *zsytrf_rk*. It also exists with a native C interface as *LAPACKE_dsytrf_rk*.

4.3.92 dsytrf_rook

DSYTRF_ROOK computes the factorization of a real symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method. The form of the factorization is

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytrf_rook(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsytrf_rook_(const char *uplo, const armpl_int_t *n, double *a,
                  const armpl_int_t *lda, armpl_int_t *ipiv, double *work,
                  const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)).. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >=1. For best performance LWORK >= N*NB, where NB is the block size returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

4.3.93 dtplqt

dtplqt computes a blocked LQ factorization of a real "triangular-pentagonal" matrix C, which is composed of a triangular block A and pentagonal block B, using the compact WY representation for Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtplqt(M, N, L, MB, A, LDA, B, LDB, T, LDT, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtplqt_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *l,
             const armpl_int_t *mb, double *a, const armpl_int_t *lda,
             double *b, const armpl_int_t *ldb, double *t,
             const armpl_int_t *ldt, double *work, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix B, and the order of the triangular matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B. N >= 0.

L Input parameter.

L is INTEGER

The number of rows of the lower trapezoidal part of B. MIN(M, N) >= L >= 0. See Further Details.

MB Input parameter.

MB is INTEGER

The block size to be used in the blocked QR. M >= MB >= 1.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, M). On entry, the lower triangular M-by-M matrix A. On exit, the elements on and below the diagonal of the array contain the lower triangular matrix L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the pentagonal M-by-N matrix B. The first N-L columns are rectangular, and the last L columns are lower trapezoidal. On exit, B contains the pentagonal matrix V. See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

T Output parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, N). The lower triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See Further Details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MB*M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctplqt*, *stplqt* and *ztplqt*.

4.3.94 dtpmlqt

DTPMQRT applies a real orthogonal matrix Q obtained from a "triangular-pentagonal" real block reflector H to a general real matrix C, which consists of two blocks A and B.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtpmlqt(SIDE, TRANS, M, N, K, L, MB, V, LDV, T, LDT, A, LDA, B,
                   LDB, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtpmlqt_(const char *side, const char *trans, const armpl_int_t *m,
              const armpl_int_t *n, const armpl_int_t *k,
              const armpl_int_t *l, const armpl_int_t *mb, const double *v,
              const armpl_int_t *ldv, const double *t, const armpl_int_t *ldt,
              double *a, const armpl_int_t *lda, double *b,
              const armpl_int_t *ldb, double *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q.

L Input parameter.

L is INTEGER

The order of the trapezoidal part of V. K >= L >= 0. See Further Details.

MB Input parameter.

MB is INTEGER

The block size used for the storage of T. K >= MB >= 1. This must be the same value of MB used to generate T in DTPLQT.

V Input parameter.

V is DOUBLE PRECISION

V is an array, dimension (LDA, K). The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by DTPLQT in B. See Further Details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If SIDE = 'L', LDV >= max(1, M); if SIDE = 'R', LDV >= max(1, N).

T Input parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, K). The upper triangular factors of the block reflectors as returned by DTPLQT, stored as a MB-by-K matrix.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension. (LDA, N) if SIDE = 'L' or (LDA, K) if SIDE = 'R' On entry, the K-by-N or M-by-K matrix A. On exit, A is overwritten by the corresponding block of Q*C or Q^T *C or C*Q or C*Q^T . See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDC >= max(1, K); If SIDE = 'R', LDC >= max(1, M).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the M-by-N matrix B. On exit, B is overwritten by the corresponding block of Q*C or Q^T *C or C*Q or C*Q^T . See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION array. The dimension of WORK is

N* MB if SIDE = 'L', or M* MB if SIDE = 'R'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpmlqt*, *stpmlqt* and *ztpmlqt*.

4.3.95 dtpmqrt

dtpmqrt applies a real orthogonal matrix Q obtained from a "triangular-pentagonal" real block reflector H to a general real matrix C, which consists of two blocks A and B.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtpmqrt(SIDE, TRANS, M, N, K, L, NB, V, LDV, T, LDT, A, LDA, B,
                   LDB, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtpmqrt_(const char *side, const char *trans, const armpl_int_t *m,
              const armpl_int_t *n, const armpl_int_t *k,
              const armpl_int_t *l, const armpl_int_t *nb, const double *v,
              const armpl_int_t *ldv, const double *t, const armpl_int_t *ldt,
              double *a, const armpl_int_t *lda, double *b,
              const armpl_int_t *ldb, double *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q.

L Input parameter.

L is INTEGER

The order of the trapezoidal part of V. K >= L >= 0. See Further Details.

NB Input parameter.

NB is INTEGER

The block size used for the storage of T. K >= NB >= 1. This must be the same value of NB used to generate T in CTPQRT.

V Input parameter.

V is DOUBLE PRECISION

V is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by CTPQRT in B. See Further Details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If SIDE = 'L', LDV >= max(1, M); if SIDE = 'R', LDV >= max(1, N).

T Input parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, K). The upper triangular factors of the block reflectors as returned by CTPQRT, stored as a NB-by-K matrix.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension. (LDA, N) if SIDE = 'L' or (LDA, K) if SIDE = 'R' On entry, the K-by-N or M-by-K matrix A. On exit, A is overwritten by the corresponding block of Q*C or Q^T *C or C*Q or C*Q^T . See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDC >= max(1, K); If SIDE = 'R', LDC >= max(1, M).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the M-by-N matrix B. On exit, B is overwritten by the corresponding block of Q*C or Q^T *C or C*Q or C*Q^T . See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION array. The dimension of WORK is

N* NB if SIDE = 'L', or M* NB if SIDE = 'R'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpmqrt*, *stpmqrt* and *ztpmqrt*. It also exists with a native C interface as *LAPACKE_dtpmqrt*.

4.3.96 dtpqrt

dtpqrt computes a blocked QR factorization of a real "triangular-pentagonal" matrix C, which is composed of a triangular block A and pentagonal block B, using the compact WY representation for Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtpqrt(M, N, L, NB, A, LDA, B, LDB, T, LDT, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtpqrt_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *l,
             const armpl_int_t *nb, double *a, const armpl_int_t *lda,
             double *b, const armpl_int_t *ldb, double *t,
             const armpl_int_t *ldt, double *work, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B, and the order of the triangular matrix A. N >= 0.

L Input parameter.

L is INTEGER

The number of rows of the upper trapezoidal part of B. MIN(M, N) >= L >= 0. See Further Details.

NB Input parameter.

NB is INTEGER

The block size to be used in the blocked QR. N >= NB >= 1.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the upper triangular N-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the upper triangular matrix R.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the pentagonal M-by-N matrix B. The first M-L rows are rectangular, and the last L rows are upper trapezoidal. On exit, B contains the pentagonal matrix V. See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

T Output parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, N). The upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See Further Details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (NB*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpqrt*, *stpqrt* and *ztpqrt*. It also exists with a native C interface as *LAPACKE_dtpqrt*.

4.3.97 dtzrzf

dtzrzf reduces the M-by-N (M<=N) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations.

The upper trapezoidal matrix A is factored as

```
A = ( R  0 ) * Z,
```

where Z is an N-by-N orthogonal matrix and R is an M-by-M upper triangular matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtzrzf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtzrzf_(const armpl_int_t *m, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, double *tau, double *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= M.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the orthogonal matrix Z as a product of M elementary reflectors.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (M). The scalar factors of the elementary reflectors.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctzrzf*, *stzrzf* and *ztzrzf*. It also exists with a native C interface as *LAPACKE_dtzrzf*.

4.3.98 sgbtrf

sgbtrf computes an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgbtrf(M, N, KL, KU, AB, LDAB, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void sgbtrf_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku, float *ab,
             const armpl_int_t *ldab, armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Output parameter.

IPIV is INTEGER array, dimension (min(M, N))

The pivot indices; for 1 <= i <= min(M, N), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = +i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *cgbtrf*, *dgbtrf* and *zgbtrf*. It also exists with a native C interface as *LAPACKE_sgbtrf*.

4.3.99 sgelq

sgelq computes a LQ factorization of an M-by-N matrix A.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgelq(M, N, A, LDA, T, TSIZE, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgelq_(const armpl_int_t *m, const armpl_int_t *n, float *a,
            const armpl_int_t *lda, float *t, const armpl_int_t *tsize,
            float *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the M-by-min(M, N) lower trapezoidal matrix L (L is lower triangular if M <= N); the elements above the diagonal are used to store part of the data structure to represent Q.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is REAL

T is an array, dimension (MAX(5, TSIZE)). On exit, if INFO = 0, T(1) returns optimal (or either minimal or optimal, if query is assumed) TSIZE. See TSIZE for details. Remaining T contains part of the data structure used to represent Q. If one wants to apply or construct Q, then one needs to keep T (in addition to A) and pass it to further subroutines.

TSIZE Input parameter.

TSIZE is INTEGER

If TSIZE >= 5, the dimension of the array T. If TSIZE = -1 or -2, then a workspace query is assumed. The routine only calculates the sizes of the T and WORK arrays, returns these values as the first entries of the T and WORK arrays, and no error message related to T or WORK is issued by XERBLA. If TSIZE = -1, the routine calculates optimal size of T for the optimum performance and returns this value in T(1). If TSIZE = -2, the routine calculates minimal size of T and returns this value in T(1).

WORK Output parameter.

(workspace) REAL

(workspace) is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) contains optimal (or either minimal or optimal, if query was assumed) LWORK. See LWORK for details.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1 or -2, then a workspace query is assumed. The routine only calculates the sizes of the T and WORK arrays, returns these values as the first entries of the T and WORK arrays, and no error message related to T or WORK is issued by XERBLA. If LWORK = -1, the routine calculates optimal size of WORK for the optimal performance and returns this value in WORK(1). If LWORK = -2, the routine calculates minimal size of WORK and returns this value in WORK(1).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgelq*, *dgelq* and *zgelq*. It also exists with a native C interface as *LAPACKE_sgelq*.

4.3.100 sgelqf

sgelqf computes an LQ factorization of a real M-by-N matrix A: A = L * Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgelqf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgelqf_(const armpl_int_t *m, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, float *tau, float *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the m-by-min(m,n) lower trapezoidal matrix L (L is lower triangular if m <= n); the elements above the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgelqf*, *dgelqf* and *zgelqf*. It also exists with a native C interface as *LAPACKE_sgelqf*.

4.3.101 sgelqt

DGELQT computes a blocked LQ factorization of a real M-by-N matrix A using the compact WY representation of Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgelqt(M, N, MB, A, LDA, T, LDT, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgelqt_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *mb, float *a, const armpl_int_t *lda,
             float *t, const armpl_int_t *ldt, float *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

MB Input parameter.

MB is INTEGER

The block size to be used in the blocked QR. MIN(M, N) >= MB >= 1.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the M-by-MIN(M, N) lower trapezoidal matrix L (L is lower triangular if M <= N); the elements above the diagonal are the rows of V.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is REAL

T is an array, dimension (LDT,MIN(M, N)). The upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MB*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgelqt*, *dgelqt* and *zgelqt*.

4.3.102 sgemlq

sgemlq overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T where Q is a real orthogonal matrix defined as the product of blocked elementary reflectors computed by short wide LQ factorization (SGELQ)

Syntax

Fortran specification:

```
use armpl_library

subroutine sgemlq(SIDE, TRANS, M, N, K, A, LDA, T, TSIZE, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sgemlq_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const float *a,
             const armpl_int_t *lda, const float *t, const armpl_int_t *tsize,
             float *c, const armpl_int_t *ldc, float *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >=0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is REAL

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' Part of the data structure to represent Q as returned by DGELQ.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

T Input parameter.

T is REAL

T is an array, dimension (MAX(5, TSIZE)).. Part of the data structure to represent Q as returned by SGELQ.

TSIZE Input parameter.

TSIZE is INTEGER

The dimension of the array T. TSIZE >= 5.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

(workspace) REAL

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1, then a workspace query is assumed. The routine only calculates the size of the WORK array, returns this value as WORK(1), and no error message related to WORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgemlq*, *dgemlq* and *zgemlq*. It also exists with a native C interface as *LAPACKE_sgemlq*.

4.3.103 sgemlqt

DGEMLQT overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': Q C C Q TRANS = 'T': Q^T C C Q^T where Q is a real orthogonal matrix defined as the product of K elementary reflectors: Q = H(1) H(2) . . . H(K) = I - V T V^T generated using the compact WY representation as returned by DGELQT. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgemlqt(SIDE, TRANS, M, N, K, MB, V, LDV, T, LDT, C, LDC, WORK,
                   INFO)
```

C specification:

```
#include "armpl.h"

void sgemlqt_(const char *side, const char *trans, const armpl_int_t *m,
              const armpl_int_t *n, const armpl_int_t *k,
              const armpl_int_t *mb, const float *v, const armpl_int_t *ldv,
              const float *t, const armpl_int_t *ldt, float *c,
              const armpl_int_t *ldc, float *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

MB Input parameter.

MB is INTEGER

The block size used for the storage of T. K >= MB >= 1. This must be the same value of MB used to generate T in DGELQT.

V Input parameter.

V is REAL

V is an array, dimension. (LDV, M) if SIDE = 'L', (LDV, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DGELQT in the first K rows of its array argument A.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, K).

T Input parameter.

T is REAL

T is an array, dimension (LDT, K). The upper triangular factors of the block reflectors as returned by DGELQT, stored as a MB-by-K matrix.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q C, Q^T C, C Q^T or C Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is REAL array. The dimension of

WORK is N* MB if SIDE = 'L', or M* MB if SIDE = 'R'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgemlqt*, *dgemlqt* and *zgemlqt*.

4.3.104 sgemqr

sgemqr overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T where Q is a real orthogonal matrix defined as the product of blocked elementary reflectors computed by tall skinny QR factorization (SGEQR)

Syntax

Fortran specification:

```
use armpl_library

subroutine sgemqr(SIDE, TRANS, M, N, K, A, LDA, T, TSIZE, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sgemqr_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const float *a,
             const armpl_int_t *lda, const float *t, const armpl_int_t *tsize,
             float *c, const armpl_int_t *ldc, float *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >=0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, K). Part of the data structure to represent Q as returned by SGEQR.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

T Input parameter.

T is REAL

T is an array, dimension (MAX(5, TSIZE)).. Part of the data structure to represent Q as returned by SGEQR.

TSIZE Input parameter.

TSIZE is INTEGER

The dimension of the array T. TSIZE >= 5.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

(workspace) REAL

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1, then a workspace query is assumed. The routine only calculates the size of the WORK array, returns this value as WORK(1), and no error message related to WORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgemqr*, *dgemqr* and *zgemqr*. It also exists with a native C interface as *LAPACKE_sgemqr*.

4.3.105 sgemqrt

sgemqrt overwrites the general real M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q C C Q TRANS = 'T': Q^T C C Q^T

where Q is a real orthogonal matrix defined as the product of K elementary reflectors:

```
Q = H(1) H(2) . . . H(K) = I - V T V**T
```

generated using the compact WY representation as returned by SGEQRT.

Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgemqrt(SIDE, TRANS, M, N, K, NB, V, LDV, T, LDT, C, LDC, WORK,
                   INFO)
```

C specification:

```
#include "armpl.h"

void sgemqrt_(const char *side, const char *trans, const armpl_int_t *m,
              const armpl_int_t *n, const armpl_int_t *k,
              const armpl_int_t *nb, const float *v, const armpl_int_t *ldv,
              const float *t, const armpl_int_t *ldt, float *c,
              const armpl_int_t *ldc, float *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

NB Input parameter.

NB is INTEGER

The block size used for the storage of T. K >= NB >= 1. This must be the same value of NB used to generate T in CGEQRT.

V Input parameter.

V is REAL

V is an array, dimension (LDV, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by CGEQRT in the first K columns of its array argument A.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

T Input parameter.

T is REAL

T is an array, dimension (LDT, K). The upper triangular factors of the block reflectors as returned by CGEQRT, stored as a NB-by-N matrix.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q C, Q^T C, C Q^T or C Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is REAL array. The dimension of WORK is

N* NB if SIDE = 'L', or M* NB if SIDE = 'R'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgemqrt*, *dgemqrt* and *zgemqrt*. It also exists with a native C interface as *LAPACKE_sgemqrt*.

4.3.106 sgeqlf

sgeqlf computes a QL factorization of a real M-by-N matrix A: A = Q * L.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgeqlf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgeqlf_(const armpl_int_t *m, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, float *tau, float *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if m >= n, the lower triangle of the subarray A(m-n+1:m,1:n) contains the N-by-N lower triangular matrix L; if m <= n, the elements on and below the (n-m)-th superdiagonal contain the M-by-N lower trapezoidal matrix L; the remaining elements, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqlf*, *dgeqlf* and *zgeqlf*. It also exists with a native C interface as *LAPACKE_sgeqlf*.

4.3.107 sgeqp3

`sgeqp3` computes a QR factorization with column pivoting of a matrix A: A*P = Q*R using Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgeqp3(M, N, A, LDA, JPVT, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgeqp3_(const armpl_int_t *m, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, armpl_int_t *jpvt, float *tau,
             float *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix `A`. `M` >= 0.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix `A`. `N` >= 0.

A Input and output parameter.

`A` is `REAL`

`A` is an array, dimension (`LDA`, `N`). On entry, the M-by-N matrix `A`. On exit, the upper triangle of the array contains the min(`M`, `N`)-by-N upper trapezoidal matrix R; the elements below the diagonal, together with the array `TAU`, represent the orthogonal matrix Q as a product of min(`M`, `N`) elementary reflectors.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `M`).

JPVT Input and output parameter.

`JPVT` is `INTEGER` array, dimension (`N`)

On entry, if JPVT(J).ne.0, the J-th column of `A` is permuted to the front of `A`*P (a leading column); if JPVT(J)=0, the J-th column of `A` is a free column. On exit, if JPVT(J)=K, then the J-th column of `A`*P was the the K-th column of `A`.

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO=0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 3*N+1. For optimal performance LWORK >= 2*N+(N+1)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgeqp3*, *dgeqp3* and *zgeqp3*. It also exists with a native C interface as *LAPACKE_sgeqp3*.

4.3.108 sgeqr

sgeqr computes a QR factorization of an M-by-N matrix A.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgeqr(M, N, A, LDA, T, TSIZE, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgeqr_(const armpl_int_t *m, const armpl_int_t *n, float *a,
            const armpl_int_t *lda, float *t, const armpl_int_t *tsize,
            float *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix R (R is upper triangular if M >= N); the elements below the diagonal are used to store part of the data structure to represent Q.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is REAL

T is an array, dimension (MAX(5, TSIZE)). On exit, if INFO = 0, T(1) returns optimal (or either minimal or optimal, if query is assumed) TSIZE. See TSIZE for details. Remaining T contains part of the data structure used to represent Q. If one wants to apply or construct Q, then one needs to keep T (in addition to A) and pass it to further subroutines.

TSIZE Input parameter.

TSIZE is INTEGER

If TSIZE >= 5, the dimension of the array T. If TSIZE = -1 or -2, then a workspace query is assumed. The routine only calculates the sizes of the T and WORK arrays, returns these values as the first entries of the T and WORK arrays, and no error message related to T or WORK is issued by XERBLA. If TSIZE = -1, the routine calculates optimal size of T for the optimum performance and returns this value in T(1). If TSIZE = -2, the routine calculates minimal size of T and returns this value in T(1).

WORK Output parameter.

(workspace) REAL

(workspace) is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) contains optimal (or either minimal or optimal, if query was assumed) LWORK. See LWORK for details.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1 or -2, then a workspace query is assumed. The routine only calculates the sizes of the T and WORK arrays, returns these values as the first entries of the T and WORK arrays, and no error message related to T or WORK is issued by XERBLA. If LWORK = -1, the routine calculates optimal size of WORK for the optimal performance and returns this value in WORK(1). If LWORK = -2, the routine calculates minimal size of WORK and returns this value in WORK(1).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqr*, *dgeqr* and *zgeqr*. It also exists with a native C interface as *LAPACKE_sgeqr*.

4.3.109 sgeqrf

`sgeqrf` computes a QR factorization of a real M-by-N matrix A: A = Q * R.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgeqrf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgeqrf_(const armpl_int_t *m, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, float *tau, float *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix R (R is upper triangular if m >= n); the elements below the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqrf*, *dgeqrf* and *zgeqrf*. It also exists with a native C interface as *LAPACKE_sgeqrf*.

4.3.110 sgeqrfp

sgeqrfp computes a QR factorization of a real M-by-N matrix A: A = Q * R. The diagonal entries of R are nonnegative.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgeqrfp(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgeqrfp_(const armpl_int_t *m, const armpl_int_t *n, float *a,
              const armpl_int_t *lda, float *tau, float *work,
              const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix R (R is upper triangular if m >= n). The diagonal entries of R are nonnegative; the elements below the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqrfp*, *dgeqrfp* and *zgeqrfp*. It also exists with a native C interface as *LAPACKE_sgeqrfp*.

4.3.111 sgeqrt

sgeqrt computes a blocked QR factorization of a real M-by-N matrix A using the compact WY representation of Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgeqrt(M, N, NB, A, LDA, T, LDT, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgeqrt_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *nb, float *a, const armpl_int_t *lda,
             float *t, const armpl_int_t *ldt, float *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The block size to be used in the blocked QR. MIN(M, N) >= NB >= 1.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix R (R is upper triangular if M >= N); the elements below the diagonal are the columns of V.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is REAL

T is an array, dimension (LDT,MIN(M, N)). The upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (NB*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqrt*, *dgeqrt* and *zgeqrt*. It also exists with a native C interface as *LAPACKE_sgeqrt*.

4.3.112 sgerqf

sgerqf computes an RQ factorization of a real M-by-N matrix A: A = R * Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgerqf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgerqf_(const armpl_int_t *m, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, float *tau, float *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if m <= n, the upper triangle of the subarray A(1:m,n-m+1:n) contains the M-by-M upper triangular matrix R; if m >= n, the elements on and above the (m-n)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the orthogonal matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgerqf*, *dgerqf* and *zgerqf*. It also exists with a native C interface as *LAPACKE_sgerqf*.

4.3.113 sgetrf

sgetrf computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form

```
A = P * L * U
```

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the right-looking Level 3 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgetrf(M, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void sgetrf_(const armpl_int_t *m, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

IPIV Output parameter.

IPIV is INTEGER array, dimension (min(M, N))

The pivot indices; for 1 <= i <= min(M, N), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *cgetrf*, *dgetrf* and *zgetrf*. It also exists with a native C interface as *LAPACKE_sgetrf*.

4.3.114 sgetrf2

sgetrf2 computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form

```
A = P * L * U
```

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the recursive version of the algorithm. It divides the matrix into four submatrices:

```
    [  A11 | A12  ]  where A11 is n1 by n1 and A22 is n2 by n2
A = [ -----|-----  ]  with n1 = min(m,n)/2
    [  A21 | A22  ]       n2 = n-n1

                                  [ A11 ]
```

The subroutine calls itself to factor [—],

```
                      [ A12 ]
[ A12 ]
```

do the swaps on [—], solve A12, update A22,

```
[ A22 ]
```

then calls itself to factor A22 and do the swaps on A21.

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine sgetrf2(M, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void sgetrf2_(const armpl_int_t *m, const armpl_int_t *n, float *a,
              const armpl_int_t *lda, armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

IPIV Output parameter.

IPIV is INTEGER array, dimension (min(M, N))

The pivot indices; for 1 <= i <= min(M, N), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *cgetrf2*, *dgetrf2* and *zgetrf2*. It also exists with a native C interface as *LAPACKE_sgetrf2*.

4.3.115 sggqrf

sggqrf computes a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B:

```
A = Q*R,        B = Q*T*Z,
```

where Q is an N-by-N orthogonal matrix, Z is a P-by-P orthogonal matrix, and R and T assume one of the forms:

if N >= M, R = (R11) M , or if N < M, R = (R11 R12) N,

```
(  0  ) N-M                          N   M-N
  M
```

where R11 is upper triangular, and

if N <= P, T = (0 T12) N, or if N > P, T = (T11) N-P,

```
P-N  N                              ( T21 ) P
                                      P
```

where T12 or T21 is upper triangular.

In particular, if B is square and nonsingular, the GQR factorization of A and B implicitly gives the QR factorization of inv(B)*A:

```
inv(B)*A = Z**T*(inv(T)*R)
```

where inv(B) denotes the inverse of the matrix B, and Z^T denotes the transpose of the matrix Z.

Syntax

Fortran specification:

```
use armpl_library

subroutine sggqrf(N, M, P, A, LDA, TAUA, B, LDB, TAUB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sggqrf_(const armpl_int_t *n, const armpl_int_t *m, const armpl_int_t *p,
             float *a, const armpl_int_t *lda, float *taua, float *b,
             const armpl_int_t *ldb, float *taub, float *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of rows of the matrices A and B. N >= 0.

M Input parameter.

M is INTEGER

The number of columns of the matrix A. M >= 0.

P Input parameter.

P is INTEGER

The number of columns of the matrix B. P >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, M). On entry, the N-by-M matrix A. On exit, the elements on and above the diagonal of the array contain the min(N, M)-by-M upper trapezoidal matrix R (R is upper triangular if N >= M); the elements below the diagonal, with the array TAUA, represent the orthogonal matrix Q as a product of min(N, M) elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAUA Output parameter.

TAUA is REAL

TAUA is an array, dimension (min(N, M)). The scalar factors of the elementary reflectors which represent the orthogonal matrix Q (see Further Details).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, P). On entry, the N-by-P matrix B. On exit, if N <= P, the upper triangle of the subarray B(1:N,P-N+1:P) contains the N-by-N upper triangular matrix T; if N > P, the elements on and above the (N-P)-th subdiagonal contain the N-by-P upper trapezoidal matrix T; the remaining elements, with the array TAUB, represent the orthogonal matrix Z as a product of elementary reflectors (see Further Details).

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

TAUB Output parameter.

TAUB is REAL

TAUB is an array, dimension (min(N, P)). The scalar factors of the elementary reflectors which represent the orthogonal matrix Z (see Further Details).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N, M, P). For optimum performance LWORK >= max(N, M, P)*max(NB1,NB2,NB3), where NB1 is the optimal blocksize for the QR factorization of an N-by-M matrix, NB2 is the optimal blocksize for the RQ factorization of an N-by-P matrix, and NB3 is the optimal blocksize for a call of SORMQR.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cggqrf*, *dggqrf* and *zggqrf*. It also exists with a native C interface as *LAPACKE_sggqrf*.

4.3.116 sggrqf

sggrqf computes a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B:

```
A = R*Q,        B = Z*T*Q,
```

where Q is an N-by-N orthogonal matrix, Z is a P-by-P orthogonal matrix, and R and T assume one of the forms:

if M <= N, R = (0 R12) M, or if M > N, R = (R11) M-N,

```
N-M  M                              ( R21 ) N
                                      N
```

where R12 or R21 is upper triangular, and

if P >= N, T = (T11) N , or if P < N, T = (T11 T12) P,

```
(  0  ) P-N                          P   N-P
   N
```

where T11 is upper triangular.

In particular, if B is square and nonsingular, the GRQ factorization of A and B implicitly gives the RQ factorization of A*inv(B):

```
A*inv(B) = (R*inv(T))*Z**T
```

where inv(B) denotes the inverse of the matrix B, and Z^T denotes the transpose of the matrix Z.

Syntax

Fortran specification:

```
use armpl_library

subroutine sggrqf(M, P, N, A, LDA, TAUA, B, LDB, TAUB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sggrqf_(const armpl_int_t *m, const armpl_int_t *p, const armpl_int_t *n,
             float *a, const armpl_int_t *lda, float *taua, float *b,
             const armpl_int_t *ldb, float *taub, float *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. P >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if M <= N, the upper triangle of the subarray A(1:M,N-M+1:N) contains the M-by-M upper triangular matrix R; if M > N, the elements on and above the (M-N)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAUA, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAUA Output parameter.

TAUA is REAL

TAUA is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the orthogonal matrix Q (see Further Details).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, the elements on and above the diagonal of the array contain the min(P, N)-by-N upper trapezoidal matrix T (T is upper triangular if P >= N); the elements below the diagonal, with the array TAUB, represent the orthogonal matrix Z as a product of elementary reflectors (see Further Details).

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

TAUB Output parameter.

TAUB is REAL

TAUB is an array, dimension (min(P, N)). The scalar factors of the elementary reflectors which represent the orthogonal matrix Z (see Further Details).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N, M, P). For optimum performance LWORK >= max(N, M, P)*max(NB1,NB2,NB3), where NB1 is the optimal blocksize for the RQ factorization of an M-by-N matrix, NB2 is the optimal blocksize for the QR factorization of a P-by-N matrix, and NB3 is the optimal blocksize for a call of SORMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INF0= -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cggrqf*, *dggrqf* and *zggrqf*. It also exists with a native C interface as *LAPACKE_sggrqf*.

4.3.117 sgttrf

`sgttrf` computes an LU factorization of a real tridiagonal matrix A using elimination with partial pivoting and row interchanges.

The factorization has the form

```
A = L * U
```

where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgttrf(N, DL, D, DU, DU2, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void sgttrf_(const armpl_int_t *n, float *dl, float *d, float *du, float *du2,
             armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

N Input parameter.

`N` is `INTEGER`

The order of the matrix A.

DL Input and output parameter.

`DL` is `REAL`

`DL` is an array, dimension (N-1). On entry, `DL` must contain the (n-1) sub-diagonal elements of A.

On exit, `DL` is overwritten by the (n-1) multipliers that define the matrix L from the LU factorization of A.

D Input and output parameter.

`D` is `REAL`

`D` is an array, dimension (`N`). On entry, `D` must contain the diagonal elements of A.

On exit, `D` is overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DU Input and output parameter.

`DU` is `REAL`

`DU` is an array, dimension (N-1). On entry, `DU` must contain the (n-1) super-diagonal elements of A.

On exit, `DU` is overwritten by the (n-1) elements of the first super-diagonal of U.

DU2 Output parameter.

DU2 is REAL

DU2 is an array, dimension (N-2). On exit, DU2 is overwritten by the (n-2) elements of the second super-diagonal of U.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *cgttrf*, *dgttrf* and *zgttrf*. It also exists with a native C interface as *LAPACKE_sgttrf*.

4.3.118 sorglq

sorglq generates an M-by-N real matrix Q with orthonormal rows, which is defined as the first M rows of a product of K elementary reflectors of order N

```
Q  =  H(k) . . . H(2) H(1)
```

as returned by SGELQF.

Syntax

Fortran specification:

```
use armpl_library

subroutine sorglq(M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorglq_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             float *a, const armpl_int_t *lda, const float *tau, float *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. N >= M.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGELQF in the first k rows of its array argument A. On exit, the M-by-N matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGELQF.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *dorglq*. It also exists with a native C interface as *LAPACKE_sorglq*.

4.3.119 sorgql

sorgql generates an M-by-N real matrix Q with orthonormal columns, which is defined as the last N columns of a product of K elementary reflectors of order M

```
Q  =  H(k) . . . H(2) H(1)
```

as returned by SGEQLF.

Syntax

Fortran specification:

```
use armpl_library

subroutine sorgql(M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorgql_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             float *a, const armpl_int_t *lda, const float *tau, float *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGEQLF in the last k columns of its array argument A. On exit, the M-by-N matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQLF.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *dorgql*. It also exists with a native C interface as *LAPACKE_sorgql*.

4.3.120 sorgqr

sorgqr generates an M-by-N real matrix Q with orthonormal columns, which is defined as the first N columns of a product of K elementary reflectors of order M

```
Q  =  H(1) H(2) . . . H(k)
```

as returned by SGEQRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine sorgqr(M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorgqr_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             float *a, const armpl_int_t *lda, const float *tau, float *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by SGEQRF in the first k columns of its array argument A. On exit, the M-by-N matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQRF.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *dorgqr*. It also exists with a native C interface as *LAPACKE_sorgqr*.

4.3.121 sorgrq

sorgrq generates an M-by-N real matrix Q with orthonormal rows, which is defined as the last M rows of a product of K elementary reflectors of order N

```
Q  =  H(1) H(2) . . . H(k)
```

as returned by SGERQF.

Syntax

Fortran specification:

```
use armpl_library

subroutine sorgrq(M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorgrq_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             float *a, const armpl_int_t *lda, const float *tau, float *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. N >= M.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the (m-k+i)-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGERQF in the last k rows of its array argument A. On exit, the M-by-N matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGERQF.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *dorgrq*. It also exists with a native C interface as *LAPACKE_sorgrq*.

4.3.122 sormlq

sormlq overwrites the general real M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

```
Q = H(k) . . . H(2) H(1)
```

as returned by SGELQF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine sormlq(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sormlq_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const float *a,
             const armpl_int_t *lda, const float *tau, float *c,
             const armpl_int_t *ldc, float *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is REAL

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGELQF in the first k rows of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGELQF.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dormlq*. It also exists with a native C interface as *LAPACKE_sormlq*.

4.3.123 sormql

`sormql` overwrites the general real M-by-N matrix C with

```
SIDE = 'L'      SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

```
Q = H(k) . . . H(2) H(1)
```

as returned by SGEQLF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine sormql(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sormql_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const float *a,
             const armpl_int_t *lda, const float *tau, float *c,
             const armpl_int_t *ldc, float *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGEQLF in the last k columns of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQLF.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dormql*. It also exists with a native C interface as *LAPACKE_sormql*.

4.3.124 sormqr

sormqr overwrites the general real M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

```
Q = H(1) H(2) . . . H(k)
```

as returned by SGEQRF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine sormqr(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sormqr_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const float *a,
             const armpl_int_t *lda, const float *tau, float *c,
             const armpl_int_t *ldc, float *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by SGEQRF in the first k columns of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQRF.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dormqr*. It also exists with a native C interface as *LAPACKE_sormqr*.

4.3.125 sormrq

sormrq overwrites the general real M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

```
Q = H(1) H(2) . . . H(k)
```

as returned by SGERQF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine sormrq(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sormrq_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const float *a,
             const armpl_int_t *lda, const float *tau, float *c,
             const armpl_int_t *ldc, float *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is REAL

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGERQF in the last k rows of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGERQF.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dormrq*. It also exists with a native C interface as *LAPACKE_sormrq*.

4.3.126 sormrz

sormrz overwrites the general real M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

```
Q = H(1) H(2) . . . H(k)
```

as returned by STZRZF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine sormrz(SIDE, TRANS, M, N, K, L, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sormrz_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const armpl_int_t *l,
             const float *a, const armpl_int_t *lda, const float *tau,
             float *c, const armpl_int_t *ldc, float *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

L Input parameter.

L is INTEGER

The number of columns of the matrix A containing the meaningful part of the Householder reflectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

A Input parameter.

A is REAL

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by STZRZF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by STZRZF.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dormrz*. It also exists with a native C interface as *LAPACKE_sormrz*.

4.3.127 spbtrf

spbtrf computes the Cholesky factorization of a real symmetric positive definite band matrix A.

The factorization has the form

```
 A = U**T * U,  if UPLO = 'U', or
A = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine spbtrf(UPLO, N, KD, AB, LDAB, INFO)
```

C specification:

```
#include "armpl.h"

void spbtrf_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             float *ab, const armpl_int_t *ldab, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the band matrix A, in the same storage format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpbtrf*, *dpbtrf* and *zpbtrf*. It also exists with a native C interface as *LAPACKE_spbtrf*.

4.3.128 spftrf

spftrf computes the Cholesky factorization of a real symmetric positive definite matrix A.

The factorization has the form

```
A = U**T * U,  if UPLO = 'U', or
A = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

This is the block version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine spftrf(TRANSR, UPLO, N, A, INFO)
```

C specification:

```
#include "armpl.h"

void spftrf_(const char *transr, const char *uplo, const armpl_int_t *n,
             float *a, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal TRANSR of RFP A is stored; = 'T': The Transpose TRANSR of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of RFP A is stored; = 'L': Lower triangle of RFP A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (N*(N+1)/2);. On entry, the symmetric matrix A in RFP format. RFP format is described by TRANSR, UPLO, and N as follows: If TRANSR = 'N' then RFP A is (0:N,0:k-1) when N is even; k=N/2. RFP A is (0:N-1,0:k) when N is odd; k=N/2. IF TRANSR = 'T' then RFP is the transpose of RFP A as defined when TRANSR = 'N'. The contents of RFP A are defined by UPLO as follows: If UPLO = 'U' the RFP A contains the NT elements of upper packed A. If UPLO = 'L' the RFP A contains the elements of lower packed A. The LDA of RFP A is (N+1)/2 when TRANSR = 'T'. When TRANSR is 'N' the LDA is N+1 when N is even and N is odd. See the Note below for more details.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization RFP A = U^T *U or RFP A = L*L^T .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpftrf*, *dpftrf* and *zpftrf*. It also exists with a native C interface as *LAPACKE_spftrf*.

4.3.129 spotrf

spotrf computes the Cholesky factorization of a real symmetric positive definite matrix A.

The factorization has the form

```
A = U**T * U,  if UPLO = 'U', or
A = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

This is the block version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine spotrf(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void spotrf_(const char *uplo, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpotrf*, *dpotrf* and *zpotrf*. It also exists with a native C interface as *LAPACKE_spotrf*.

4.3.130 spotrf2

spotrf2 computes the Cholesky factorization of a real symmetric positive definite matrix A using the recursive algorithm.

The factorization has the form

```
A = U**T * U,  if UPLO = 'U', or
A = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

This is the recursive version of the algorithm. It divides the matrix into four submatrices:

```
    [  A11 | A12  ]  where A11 is n1 by n1 and A22 is n2 by n2
A = [ -----|----- ]  with n1 = n/2
    [  A21 | A22  ]       n2 = n-n1
```

The subroutine calls itself to factor A11. Update and scale A21 or A12, update A22 then call itself to factor A22.

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine spotrf2(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void spotrf2_(const char *uplo, const armpl_int_t *n, float *a,
              const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpotrf2*, *dpotrf2* and *zpotrf2*. It also exists with a native C interface as *LAPACKE_spotrf2*.

4.3.131 spptrf

spptrf computes the Cholesky factorization of a real symmetric positive definite matrix A stored in packed format.

The factorization has the form

```
A = U**T * U,  if UPLO = 'U', or
A = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine spptrf(UPLO, N, AP, INFO)
```

C specification:

```
#include "armpl.h"

void spptrf_(const char *uplo, const armpl_int_t *n, float *ap,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$, in the same storage format as A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpptrf*, *dpptrf* and *zpptrf*. It also exists with a native C interface as *LAPACKE_spptrf*.

4.3.132 spstrf

spstrf computes the Cholesky factorization with complete pivoting of a real symmetric positive semidefinite matrix A.

The factorization has the form

```
P**T * A * P = U**T * U ,  if UPLO = 'U',
P**T * A * P = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular, and P is stored as vector PIV.

This algorithm does not attempt to check that A is positive semidefinite. This version of the algorithm calls level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine spstrf(UPLO, N, A, LDA, PIV, RANK, TOL, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void spstrf_(const char *uplo, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, armpl_int_t *piv, armpl_int_t *rank,
             const float *tol, float *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization as above.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

PIV Output parameter.

PIV is INTEGER array, dimension (N)

PIV is such that the nonzero entries are P(PIV(K), K) = 1.

RANK Output parameter.

RANK is INTEGER

The rank of A given by the number of steps the algorithm completed.

TOL Input parameter.

TOL is REAL

User defined tolerance. If TOL < 0, then N*U*MAX(A(K,K)) will be used. The algorithm terminates at the (K-1)st step if the pivot <= TOL.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (2*N). Work space.

INFO Output parameter.

INFO is INTEGER

< 0: If INFO = -K, the K-th argument had an illegal value, = 0: algorithm completed successfully, and > 0: the matrix A is either rank deficient with computed rank as returned in RANK, or is not positive semidefinite. See Section 7 of LAPACK Working Note #161 for further information.

Related Information

For this routine in other precisions, please see *cpstrf*, *dpstrf* and *zpstrf*. It also exists with a native C interface as *LAPACKE_spstrf*.

4.3.133 spttrf

`spttrf` computes the L*D*L^T factorization of a real symmetric positive definite tridiagonal matrix A. The factorization may also be regarded as having the form A = U^T *D*U.

Syntax

Fortran specification:

```
use armpl_library

subroutine spttrf(N, D, E, INFO)
```

C specification:

```
#include "armpl.h"

void spttrf_(const armpl_int_t *n, float *d, float *e, armpl_int_t *info);
```

Parameters

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0.

D Input and output parameter.

`D` is `REAL`

`D` is an array, dimension (`N`). On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix `D` from the L*D*L^T factorization of A.

E Input and output parameter.

`E` is `REAL`

`E` is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*D*L^T factorization of A. `E` can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U^T *D*U factorization of A.

INFO Output parameter.

`INFO` is `INTEGER`

= 0: successful exit < 0: if `INFO` = -k, the k-th argument had an illegal value > 0: if `INFO` = k, the leading minor of order k is not positive definite; if k < `N`, the factorization could not be completed, while if k = `N`, the factorization was completed, but D(`N`) <= 0.

Related Information

For this routine in other precisions, please see *cpttrf*, *dpttrf* and *zpttrf*. It also exists with a native C interface as *LAPACKE_spttrf*.

4.3.134 ssptrf

ssptrf computes the factorization of a real symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method:

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssptrf(UPLO, N, AP, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void ssptrf_(const char *uplo, const armpl_int_t *n, float *ap,
             armpl_int_t *ipiv, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L, stored as a packed triangular matrix overwriting A (see below for further details).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *csptrf*, *dsptrf* and *zsptrf*. It also exists with a native C interface as *LAPACKE_ssptrf*.

4.3.135 ssytrf

ssytrf computes the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytrf(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssytrf_(const char *uplo, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, armpl_int_t *ipiv, float *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >=1. For best performance LWORK >= N*NB, where NB is the block size returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *csytrf*, *dsytrf* and *zsytrf*. It also exists with a native C interface as *LAPACKE_ssytrf*.

4.3.136 ssytrf_aa

SSYTRF_AA computes the factorization of a real symmetric matrix A using the Aasen's algorithm. The form of the factorization is

```
A = U*T*U**T  or  A = L*T*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is a symmetric tridiagonal matrix.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytrf_aa(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssytrf_aa_(const char *uplo, const armpl_int_t *n, float *a,
                const armpl_int_t *lda, armpl_int_t *ipiv, float *work,
                const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the tridiagonal matrix is stored in the diagonals and the subdiagonals of A just below (or above) the diagonals, and L is stored below (or above) the subdiaonals, when UPLO is 'L' (or 'U').

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= MAX(1,2*N). For optimum performance LWORK >= N*(1+NB), where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *csytrf_aa*, *dsytrf_aa* and *zsytrf_aa*. It also exists with a native C interface as *LAPACKE_ssytrf_aa*.

4.3.137 ssytrf_rk

SSYTRF_RK computes the factorization of a real symmetric matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS. For more information see Further Details section.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytrf_rk(UPLO, N, A, LDA, E, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssytrf_rk_(const char *uplo, const armpl_int_t *n, float *a,
                const armpl_int_t *lda, float *e, armpl_int_t *ipiv,
                float *work, const armpl_int_t *lwork, armpl_int_t *info,
                ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, contains: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is REAL

E is an array, dimension (N). On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

IPIV describes the permutation matrix P in the factorization of matrix A as follows. The absolute value of IPIV(k) represents the index of row and column that were interchanged with the k-th row and column. The value of UPLO describes the order in which the interchanges were applied. Also, the sign of IPIV represents the block structure of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks which correspond to 1 or 2 interchanges at each factorization step. For more info see Further Details section.

If UPLO = 'U', (in factorization order, k decreases from N to 1): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N); If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k-1) < 0 means: D(k-1:k,k-1:k) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k-1) != k-1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k-1) = k-1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) <= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

If UPLO = 'L', (in factorization order, k increases from 1 to N): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N). If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k+1) < 0 means: D(k:k+1,k:k+1) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k+1) != k+1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k+1) = k+1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) >= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)).. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >=1. For best performance LWORK >= N*NB, where NB is the block size returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

4.3.138 ssytrf_rook

SSYTRF_ROOK computes the factorization of a real symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method. The form of the factorization is

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytrf_rook(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssytrf_rook_(const char *uplo, const armpl_int_t *n, float *a,
                  const armpl_int_t *lda, armpl_int_t *ipiv, float *work,
                  const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)).. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >=1. For best performance LWORK >= N*NB, where NB is the block size returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

4.3.139 stplqt

DTPLQT computes a blocked LQ factorization of a real "triangular-pentagonal" matrix C, which is composed of a triangular block A and pentagonal block B, using the compact WY representation for Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine stplqt(M, N, L, MB, A, LDA, B, LDB, T, LDT, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void stplqt_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *l,
             const armpl_int_t *mb, float *a, const armpl_int_t *lda,
             float *b, const armpl_int_t *ldb, float *t,
             const armpl_int_t *ldt, float *work, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix B, and the order of the triangular matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B. N >= 0.

L Input parameter.

L is INTEGER

The number of rows of the lower trapezoidal part of B. MIN(M, N) >= L >= 0. See Further Details.

MB Input parameter.

MB is INTEGER

The block size to be used in the blocked QR. M >= MB >= 1.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, M). On entry, the lower triangular M-by-M matrix A. On exit, the elements on and below the diagonal of the array contain the lower triangular matrix L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the pentagonal M-by-N matrix B. The first N-L columns are rectangular, and the last L columns are lower trapezoidal. On exit, B contains the pentagonal matrix V. See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

T Output parameter.

T is REAL

T is an array, dimension (LDT, N). The lower triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See Further Details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MB*M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctplqt*, *dtplqt* and *ztplqt*.

4.3.140 stpmlqt

DTPMQRT applies a real orthogonal matrix Q obtained from a "triangular-pentagonal" real block reflector H to a general real matrix C, which consists of two blocks A and B.

Syntax

Fortran specification:

```
use armpl_library

subroutine stpmlqt(SIDE, TRANS, M, N, K, L, MB, V, LDV, T, LDT, A, LDA, B,
                   LDB, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void stpmlqt_(const char *side, const char *trans, const armpl_int_t *m,
              const armpl_int_t *n, const armpl_int_t *k,
              const armpl_int_t *l, const armpl_int_t *mb, const float *v,
              const armpl_int_t *ldv, const float *t, const armpl_int_t *ldt,
              float *a, const armpl_int_t *lda, float *b,
              const armpl_int_t *ldb, float *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q.

L Input parameter.

L is INTEGER

The order of the trapezoidal part of V. K >= L >= 0. See Further Details.

MB Input parameter.

MB is INTEGER

The block size used for the storage of T. K >= MB >= 1. This must be the same value of MB used to generate T in DTPLQT.

V Input parameter.

V is REAL

V is an array, dimension (LDA, K). The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by DTPLQT in B. See Further Details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If SIDE = 'L', LDV >= max(1, M); if SIDE = 'R', LDV >= max(1, N).

T Input parameter.

T is REAL

T is an array, dimension (LDT, K). The upper triangular factors of the block reflectors as returned by DTPLQT, stored as a MB-by-K matrix.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

A Input and output parameter.

A is REAL

A is an array, dimension. (LDA, N) if SIDE = 'L' or (LDA, K) if SIDE = 'R' On entry, the K-by-N or M-by-K matrix A. On exit, A is overwritten by the corresponding block of Q*C or Q^T *C or C*Q or C*Q^T . See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDC >= max(1, K); If SIDE = 'R', LDC >= max(1, M).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the M-by-N matrix B. On exit, B is overwritten by the corresponding block of Q*C or Q^T *C or C*Q or C*Q^T . See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

WORK Output parameter.

WORK is REAL array. The dimension of WORK is

N* MB if SIDE = 'L', or M* MB if SIDE = 'R'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpmlqt*, *dtpmlqt* and *ztpmlqt*.

4.3.141 stpmqrt

stpmqrt applies a real orthogonal matrix Q obtained from a "triangular-pentagonal" real block reflector H to a general real matrix C, which consists of two blocks A and B.

Syntax

Fortran specification:

```
use armpl_library

subroutine stpmqrt(SIDE, TRANS, M, N, K, L, NB, V, LDV, T, LDT, A, LDA, B,
                   LDB, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void stpmqrt_(const char *side, const char *trans, const armpl_int_t *m,
              const armpl_int_t *n, const armpl_int_t *k,
              const armpl_int_t *l, const armpl_int_t *nb, const float *v,
              const armpl_int_t *ldv, const float *t, const armpl_int_t *ldt,
              float *a, const armpl_int_t *lda, float *b,
              const armpl_int_t *ldb, float *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T.

M Input parameter.

M is INTEGER

The number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q.

L Input parameter.

L is INTEGER

The order of the trapezoidal part of V. K >= L >= 0. See Further Details.

NB Input parameter.

NB is INTEGER

The block size used for the storage of T. K >= NB >= 1. This must be the same value of NB used to generate T in CTPQRT.

V Input parameter.

V is REAL

V is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by CTPQRT in B. See Further Details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If SIDE = 'L', LDV >= max(1, M); if SIDE = 'R', LDV >= max(1, N).

T Input parameter.

T is REAL

T is an array, dimension (LDT, K). The upper triangular factors of the block reflectors as returned by CTPQRT, stored as a NB-by-K matrix.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

A Input and output parameter.

A is REAL

A is an array, dimension. (LDA, N) if SIDE = 'L' or (LDA, K) if SIDE = 'R' On entry, the K-by-N or M-by-K matrix A. On exit, A is overwritten by the corresponding block of Q*C or Q^T*C or C*Q or C*Q^T. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDC >= max(1, K); If SIDE = 'R', LDC >= max(1, M).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the M-by-N matrix B. On exit, B is overwritten by the corresponding block of Q*C or Q^T*C or C*Q or C*Q^T. See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

WORK Output parameter.

WORK is REAL array. The dimension of WORK is

N* NB if SIDE = 'L', or M* NB if SIDE = 'R'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpmqrt*, *dtpmqrt* and *ztpmqrt*. It also exists with a native C interface as *LAPACKE_stpmqrt*.

4.3.142 stpqrt

stpqrt computes a blocked QR factorization of a real "triangular-pentagonal" matrix C, which is composed of a triangular block A and pentagonal block B, using the compact WY representation for Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine stpqrt(M, N, L, NB, A, LDA, B, LDB, T, LDT, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void stpqrt_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *l,
             const armpl_int_t *nb, float *a, const armpl_int_t *lda,
             float *b, const armpl_int_t *ldb, float *t,
             const armpl_int_t *ldt, float *work, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B, and the order of the triangular matrix A. N >= 0.

L Input parameter.

L is INTEGER

The number of rows of the upper trapezoidal part of B. MIN(M, N) >= L >= 0. See Further Details.

NB Input parameter.

NB is INTEGER

The block size to be used in the blocked QR. N >= NB >= 1.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the upper triangular N-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the upper triangular matrix R.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the pentagonal M-by-N matrix B. The first M-L rows are rectangular, and the last L rows are upper trapezoidal. On exit, B contains the pentagonal matrix V. See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

T Output parameter.

T is REAL

T is an array, dimension (LDT, N). The upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See Further Details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (NB*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpqrt*, *dtpqrt* and *ztpqrt*. It also exists with a native C interface as *LAPACKE_stpqrt*.

4.3.143 stzrzf

stzrzf reduces the M-by-N (M<=N) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations.

The upper trapezoidal matrix A is factored as

```
A = ( R  0 ) * Z,
```

where Z is an N-by-N orthogonal matrix and R is an M-by-M upper triangular matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine stzrzf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void stzrzf_(const armpl_int_t *m, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, float *tau, float *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= M.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the orthogonal matrix Z as a product of M elementary reflectors.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (M). The scalar factors of the elementary reflectors.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctzrzf*, *dtzrzf* and *ztzrzf*. It also exists with a native C interface as *LAPACKE_stzrzf*.

4.3.144 zgbtrf

zgbtrf computes an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgbtrf(M, N, KL, KU, AB, LDAB, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void zgbtrf_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku,
             armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
             armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Output parameter.

IPIV is INTEGER array, dimension (min(M, N))

The pivot indices; for 1 <= i <= min(M, N), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = +i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *cgbtrf*, *dgbtrf* and *sgbtrf*. It also exists with a native C interface as *LAPACKE_zgbtrf*.

4.3.145 zgelq

zgelq computes a LQ factorization of an M-by-N matrix A.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgelq(M, N, A, LDA, T, TSIZE, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgelq_(const armpl_int_t *m, const armpl_int_t *n,
            armpl_doublecomplex_t *a, const armpl_int_t *lda,
            armpl_doublecomplex_t *t, const armpl_int_t *tsize,
            armpl_doublecomplex_t *work, const armpl_int_t *lwork,
            armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the M-by-min(M, N) lower trapezoidal matrix L (L is lower triangular if M <= N); the elements above the diagonal are used to store part of the data structure to represent Q.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is COMPLEX*16

T is an array, dimension (MAX(5, TSIZE)). On exit, if INFO = 0, T(1) returns optimal (or either minimal or optimal, if query is assumed) TSIZE. See TSIZE for details. Remaining T contains part of the data structure used to represent Q. If one wants to apply or construct Q, then one needs to keep T (in addition to A) and pass it to further subroutines.

TSIZE Input parameter.

TSIZE is INTEGER

If TSIZE >= 5, the dimension of the array T. If TSIZE = -1 or -2, then a workspace query is assumed. The routine only calculates the sizes of the T and WORK arrays, returns these values as the first entries of the T and WORK arrays, and no error message related to T or WORK is issued by XERBLA. If TSIZE = -1, the routine calculates optimal size of T for the optimum performance and returns this value in T(1). If TSIZE = -2, the routine calculates minimal size of T and returns this value in T(1).

WORK Output parameter.

(workspace) COMPLEX*16

(workspace) is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) contains optimal (or either minimal or optimal, if query was assumed) LWORK. See LWORK for details.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1 or -2, then a workspace query is assumed. The routine only calculates the sizes of the T and WORK arrays, returns these values as the first entries of the T and WORK arrays, and no error message related to T or WORK is issued by XERBLA. If LWORK = -1, the routine calculates optimal size of WORK for the optimal performance and returns this value in WORK(1). If LWORK = -2, the routine calculates minimal size of WORK and returns this value in WORK(1).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgelq*, *dgelq* and *sgelq*. It also exists with a native C interface as *LAPACKE_zgelq*.

4.3.146 zgelqf

zgelqf computes an LQ factorization of a complex M-by-N matrix A: A = L * Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgelqf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgelqf_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the m-by-min(m,n) lower trapezoidal matrix L (L is lower triangular if m <= n); the elements above the diagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgelqf*, *dgelqf* and *sgelqf*. It also exists with a native C interface as *LAPACKE_zgelqf*.

4.3.147 zgelqt

`zgelqt` computes a blocked LQ factorization of a complex M-by-N matrix A using the compact WY representation of Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgelqt(M, N, MB, A, LDA, T, LDT, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgelqt_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *mb, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *t,
             const armpl_int_t *ldt, armpl_doublecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix `A`. `M` >= 0.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix `A`. `N` >= 0.

MB Input parameter.

`MB` is `INTEGER`

The block size to be used in the blocked QR. MIN(`M`, `N`) >= `MB` >= 1.

A Input and output parameter.

`A` is `COMPLEX*16`

`A` is an array, dimension (`LDA`, `N`). On entry, the M-by-N matrix `A`. On exit, the elements on and below the diagonal of the array contain the M-by-MIN(`M`, `N`) lower trapezoidal matrix L (L is lower triangular if `M` <= N); the elements above the diagonal are the rows of V.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `M`).

T Output parameter.

T is COMPLEX*16

T is an array, dimension (LDT,MIN(M, N)). The upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MB*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgelqt*, *dgelqt* and *sgelqt*.

4.3.148 zgemlq

zgemlq overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H where Q is a complex unitary matrix defined as the product of blocked elementary reflectors computed by short wide LQ factorization (ZGELQ)

Syntax

Fortran specification:

```
use armpl_library

subroutine zgemlq(SIDE, TRANS, M, N, K, A, LDA, T, TSIZE, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zgemlq_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *t, const armpl_int_t *tsize,
             armpl_doublecomplex_t *c, const armpl_int_t *ldc,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >=0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' Part of the data structure to represent Q as returned by ZGELQ.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

T Input parameter.

T is COMPLEX*16

T is an array, dimension (MAX(5, TSIZE)).. Part of the data structure to represent Q as returned by ZGELQ.

TSIZE Input parameter.

TSIZE is INTEGER

The dimension of the array T. TSIZE >= 5.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

(workspace) COMPLEX*16

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1, then a workspace query is assumed. The routine only calculates the size of the WORK array, returns this value as WORK(1), and no error message related to WORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgemlq*, *dgemlq* and *sgemlq*. It also exists with a native C interface as *LAPACKE_zgemlq*.

4.3.149 zgemlqt

zgemlqt overwrites the general real M-by-N matrix C with

```
SIDE = 'L'      SIDE = 'R'
```

TRANS = 'N': Q C C Q TRANS = 'C': Q^H C C Q^H

where Q is a complex orthogonal matrix defined as the product of K elementary reflectors:

```
Q = H(1) H(2) . . . H(K) = I - V T V**H
```

generated using the compact WY representation as returned by ZGELQT.

Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgemlqt(SIDE, TRANS, M, N, K, MB, V, LDV, T, LDT, C, LDC, WORK,
                   INFO)
```

C specification:

```
#include "armpl.h"

void zgemlqt_(const char *side, const char *trans, const armpl_int_t *m,
              const armpl_int_t *n, const armpl_int_t *k,
              const armpl_int_t *mb, const armpl_doublecomplex_t *v,
              const armpl_int_t *ldv, const armpl_doublecomplex_t *t,
              const armpl_int_t *ldt, armpl_doublecomplex_t *c,
              const armpl_int_t *ldc, armpl_doublecomplex_t *work,
              armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

MB Input parameter.

MB is INTEGER

The block size used for the storage of T. K >= MB >= 1. This must be the same value of MB used to generate T in DGELQT.

V Input parameter.

V is COMPLEX*16

V is an array, dimension. (LDV, M) if SIDE = 'L', (LDV, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DGELQT in the first K rows of its array argument A.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, K).

T Input parameter.

T is COMPLEX*16

T is an array, dimension (LDT, K). The upper triangular factors of the block reflectors as returned by DGELQT, stored as a MB-by-K matrix.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q C, Q^H C, C Q^H or C Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16 array. The dimension of

WORK is N* MB if SIDE = 'L', or M* MB if SIDE = 'R'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgemlqt*, *dgemlqt* and *sgemlqt*.

4.3.150 zgemqr

zgemqr overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': Q * C C * Q TRANS = 'T': Q^H * C C * Q^H where Q is a complex unitary matrix defined as the product of blocked elementary reflectors computed by tall skinny QR factorization (ZGEQR)

Syntax

Fortran specification:

```
use armpl_library

subroutine zgemqr(SIDE, TRANS, M, N, K, A, LDA, T, TSIZE, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zgemqr_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *t, const armpl_int_t *tsize,
             armpl_doublecomplex_t *c, const armpl_int_t *ldc,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >=0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, K). Part of the data structure to represent Q as returned by ZGEQR.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

T Input parameter.

T is COMPLEX*16

T is an array, dimension (MAX(5, TSIZE)).. Part of the data structure to represent Q as returned by ZGEQR.

TSIZE Input parameter.

TSIZE is INTEGER

The dimension of the array T. TSIZE >= 5.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

(workspace) COMPLEX*16

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1, then a workspace query is assumed. The routine only calculates the size of the WORK array, returns this value as WORK(1), and no error message related to WORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgemqr*, *dgemqr* and *sgemqr*. It also exists with a native C interface as *LAPACKE_zgemqr*.

4.3.151 zgemqrt

`zgemqrt` overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q C C Q TRANS = 'C': Q^H C C Q^H

where Q is a complex orthogonal matrix defined as the product of K elementary reflectors:

```
Q = H(1) H(2) . . . H(K) = I - V T V**H
```

generated using the compact WY representation as returned by ZGEQRT.

Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgemqrt(SIDE, TRANS, M, N, K, NB, V, LDV, T, LDT, C, LDC, WORK,
                   INFO)
```

C specification:

```
#include "armpl.h"

void zgemqrt_(const char *side, const char *trans, const armpl_int_t *m,
              const armpl_int_t *n, const armpl_int_t *k,
              const armpl_int_t *nb, const armpl_doublecomplex_t *v,
              const armpl_int_t *ldv, const armpl_doublecomplex_t *t,
              const armpl_int_t *ldt, armpl_doublecomplex_t *c,
              const armpl_int_t *ldc, armpl_doublecomplex_t *work,
              armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

NB Input parameter.

NB is INTEGER

The block size used for the storage of T. K >= NB >= 1. This must be the same value of NB used to generate T in CGEQRT.

V Input parameter.

V is COMPLEX*16

V is an array, dimension (LDV, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGEQRT in the first K columns of its array argument A.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

T Input parameter.

T is COMPLEX*16

T is an array, dimension (LDT, K). The upper triangular factors of the block reflectors as returned by CGEQRT, stored as a NB-by-N matrix.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q C, Q^H C, C Q^H or C Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16 array. The dimension of WORK is

N* NB if SIDE = 'L', or M* NB if SIDE = 'R'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgemqrt*, *dgemqrt* and *sgemqrt*. It also exists with a native C interface as *LAPACKE_zgemqrt*.

4.3.152 zgeqlf

`zgeqlf` computes a QL factorization of a complex M-by-N matrix A: A = Q * L.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgeqlf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgeqlf_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix `A`. `M` >= 0.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix `A`. `N` >= 0.

A Input and output parameter.

`A` is `COMPLEX*16`

`A` is an array, dimension (`LDA`, `N`). On entry, the M-by-N matrix `A`. On exit, if m >= n, the lower triangle of the subarray A(m-n+1:m,1:n) contains the N-by-N lower triangular matrix L; if m <= n, the elements on and below the (n-m)-th superdiagonal contain the M-by-N lower trapezoidal matrix L; the remaining elements, with the array `TAU`, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `M`).

TAU Output parameter.

`TAU` is `COMPLEX*16`

`TAU` is an array, dimension (min(`M`, `N`)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

`WORK` is `COMPLEX*16`

`WORK` is an array, dimension (MAX(1, `LWORK`)). On exit, if `INFO` = 0, WORK(1) returns the optimal `LWORK`.

LWORK Input parameter.

`LWORK` is `INTEGER`

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqlf*, *dgeqlf* and *sgeqlf*. It also exists with a native C interface as *LAPACKE_zgeqlf*.

4.3.153 zgeqp3

zgeqp3 computes a QR factorization with column pivoting of a matrix A: A*P = Q*R using Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgeqp3(M, N, A, LDA, JPVT, TAU, WORK, LWORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgeqp3_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_int_t *jpvt, armpl_doublecomplex_t *tau,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             double *rwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the min(M, N)-by-N upper trapezoidal matrix R; the elements below the diagonal, together with the array TAU, represent the unitary matrix Q as a product of min(M, N) elementary reflectors.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

JPVT Input and output parameter.

JPVT is INTEGER array, dimension (N)

On entry, if JPVT(J).ne.0, the J-th column of A is permuted to the front of A*P (a leading column); if JPVT(J)=0, the J-th column of A is a free column. On exit, if JPVT(J)=K, then the J-th column of A*P was the the K-th column of A.

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO=0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= N+1. For optimal performance LWORK >= (N+1)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgeqp3*, *dgeqp3* and *sgeqp3*. It also exists with a native C interface as *LAPACKE_zgeqp3*.

4.3.154 zgeqr

zgeqr computes a QR factorization of an M-by-N matrix A.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgeqr(M, N, A, LDA, T, TSIZE, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgeqr_(const armpl_int_t *m, const armpl_int_t *n,
            armpl_doublecomplex_t *a, const armpl_int_t *lda,
            armpl_doublecomplex_t *t, const armpl_int_t *tsize,
            armpl_doublecomplex_t *work, const armpl_int_t *lwork,
            armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix R (R is upper triangular if M >= N); the elements below the diagonal are used to store part of the data structure to represent Q.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is COMPLEX*16

T is an array, dimension (MAX(5, TSIZE)). On exit, if INFO = 0, T(1) returns optimal (or either minimal or optimal, if query is assumed) TSIZE. See TSIZE for details. Remaining T contains part of the data structure used to represent Q. If one wants to apply or construct Q, then one needs to keep T (in addition to A) and pass it to further subroutines.

TSIZE Input parameter.

TSIZE is INTEGER

If TSIZE >= 5, the dimension of the array T. If TSIZE = -1 or -2, then a workspace query is assumed. The routine only calculates the sizes of the T and WORK arrays, returns these values as the first entries of the T and WORK arrays, and no error message related to T or WORK is issued by XERBLA. If TSIZE = -1, the routine calculates optimal size of T for the optimum performance and returns this value in T(1). If TSIZE = -2, the routine calculates minimal size of T and returns this value in T(1).

WORK Output parameter.

(workspace) COMPLEX*16

(workspace) is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) contains optimal (or either minimal or optimal, if query was assumed) LWORK. See LWORK for details.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1 or -2, then a workspace query is assumed. The routine only calculates the sizes of the T and WORK arrays, returns these values as the first entries of the T and

WORK arrays, and no error message related to T or WORK is issued by XERBLA. If LWORK = -1, the routine calculates optimal size of WORK for the optimal performance and returns this value in WORK(1). If LWORK = -2, the routine calculates minimal size of WORK and returns this value in WORK(1).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqr*, *dgeqr* and *sgeqr*. It also exists with a native C interface as *LAPACKE_zgeqr*.

4.3.155 zgeqrf

zgeqrf computes a QR factorization of a complex M-by-N matrix A: A = Q * R.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgeqrf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgeqrf_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix R (R is upper triangular if m >= n); the elements below the diagonal, with the array TAU, represent the unitary matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqrf*, *dgeqrf* and *sgeqrf*. It also exists with a native C interface as *LAPACKE_zgeqrf*.

4.3.156 zgeqrfp

zgeqrfp computes a QR factorization of a complex M-by-N matrix A: A = Q * R. The diagonal entries of R are real and nonnegative.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgeqrfp(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgeqrfp_(const armpl_int_t *m, const armpl_int_t *n,
              armpl_doublecomplex_t *a, const armpl_int_t *lda,
              armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
              const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix R (R is upper triangular if m >= n). The diagonal entries of R are real and nonnegative; The elements below the diagonal, with the array TAU, represent the unitary matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqrfp*, *dgeqrfp* and *sgeqrfp*. It also exists with a native C interface as *LAPACKE_zgeqrfp*.

4.3.157 zgeqrt

zgeqrt computes a blocked QR factorization of a complex M-by-N matrix A using the compact WY representation of Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgeqrt(M, N, NB, A, LDA, T, LDT, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgeqrt_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *nb, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *t,
             const armpl_int_t *ldt, armpl_doublecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The block size to be used in the blocked QR. MIN(M, N) >= NB >= 1.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix R (R is upper triangular if M >= N); the elements below the diagonal are the columns of V.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is COMPLEX*16

T is an array, dimension (LDT,MIN(M, N)). The upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (NB*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqrt*, *dgeqrt* and *sgeqrt*. It also exists with a native C interface as *LAPACKE_zgeqrt*.

4.3.158 zgerqf

zgerqf computes an RQ factorization of a complex M-by-N matrix A: A = R * Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgerqf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgerqf_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if m <= n, the upper triangle of the subarray A(1:m,n-m+1:n) contains the M-by-M upper triangular matrix R; if m >= n, the elements on and above the (m-n)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgerqf*, *dgerqf* and *sgerqf*. It also exists with a native C interface as *LAPACKE_zgerqf*.

4.3.159 zgetrf

zgetrf computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form

```
A = P * L * U
```

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the right-looking Level 3 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgetrf(M, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void zgetrf_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

IPIV Output parameter.

IPIV is INTEGER array, dimension (min(M, N))

The pivot indices; for 1 <= i <= min(M, N), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *cgetrf*, *dgetrf* and *sgetrf*. It also exists with a native C interface as *LAPACKE_zgetrf*.

4.3.160 zgetrf2

zgetrf2 computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form

```
A = P * L * U
```

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the recursive version of the algorithm. It divides the matrix into four submatrices:

```
    [  A11 | A12  ]  where A11 is n1 by n1 and A22 is n2 by n2
A = [ -----|----- ]  with n1 = min(m,n)/2
    [  A21 | A22  ]       n2 = n-n1

                                  [ A11 ]
```

The subroutine calls itself to factor [—],

```
                    [ A12 ]
[ A12 ]
```

do the swaps on [—], solve A12, update A22,

```
[ A22 ]
```

then calls itself to factor A22 and do the swaps on A21.

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine zgetrf2(M, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void zgetrf2_(const armpl_int_t *m, const armpl_int_t *n,
              armpl_doublecomplex_t *a, const armpl_int_t *lda,
              armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

IPIV Output parameter.

IPIV is INTEGER array, dimension (min(M, N))

The pivot indices; for 1 <= i <= min(M, N), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *cgetrf2*, *dgetrf2* and *sgetrf2*. It also exists with a native C interface as *LAPACKE_zgetrf2*.

4.3.161 zggqrf

`zggqrf` computes a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B:

```
A = Q*R,        B = Q*T*Z,
```

where Q is an N-by-N unitary matrix, Z is a P-by-P unitary matrix, and R and T assume one of the forms:

if N >= M, R = (R11) M , or if N < M, R = (R11 R12) N,

```
(  0  ) N-M                          N   M-N
   M
```

where R11 is upper triangular, and

if N <= P, T = (0 T12) N, or if N > P, T = (T11) N-P,

```
P-N  N                             ( T21 ) P
                                      P
```

where T12 or T21 is upper triangular.

In particular, if B is square and nonsingular, the GQR factorization of A and B implicitly gives the QR factorization of inv(B)*A:

```
inv(B)*A = Z**H * (inv(T)*R)
```

where inv(B) denotes the inverse of the matrix B, and Z^H denotes the conjugate transpose of matrix Z.

Syntax

Fortran specification:

```
use armpl_library

subroutine zggqrf(N, M, P, A, LDA, TAUA, B, LDB, TAUB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zggqrf_(const armpl_int_t *n, const armpl_int_t *m, const armpl_int_t *p,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *taua, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *taub,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

N Input parameter.

`N` is `INTEGER`

The number of rows of the matrices `A` and `B`. `N` >= 0.

M Input parameter.

M is INTEGER

The number of columns of the matrix A. M >= 0.

P Input parameter.

P is INTEGER

The number of columns of the matrix B. P >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, M). On entry, the N-by-M matrix A. On exit, the elements on and above the diagonal of the array contain the min(N, M)-by-M upper trapezoidal matrix R (R is upper triangular if N >= M); the elements below the diagonal, with the array TAUA, represent the unitary matrix Q as a product of min(N, M) elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAUA Output parameter.

TAUA is COMPLEX*16

TAUA is an array, dimension (min(N, M)). The scalar factors of the elementary reflectors which represent the unitary matrix Q (see Further Details).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, P). On entry, the N-by-P matrix B. On exit, if N <= P, the upper triangle of the subarray B(1:N,P-N+1:P) contains the N-by-N upper triangular matrix T; if N > P, the elements on and above the (N-P)-th subdiagonal contain the N-by-P upper trapezoidal matrix T; the remaining elements, with the array TAUB, represent the unitary matrix Z as a product of elementary reflectors (see Further Details).

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

TAUB Output parameter.

TAUB is COMPLEX*16

TAUB is an array, dimension (min(N, P)). The scalar factors of the elementary reflectors which represent the unitary matrix Z (see Further Details).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N, M, P). For optimum performance LWORK >= max(N, M, P)*max(NB1,NB2,NB3), where NB1 is the optimal blocksize for the QR factorization of an N-by-M matrix, NB2 is the optimal blocksize for the RQ factorization of an N-by-P matrix, and NB3 is the optimal blocksize for a call of ZUNMQR.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cggqrf*, *dggqrf* and *sggqrf*. It also exists with a native C interface as *LAPACKE_zggqrf*.

4.3.162 zggrqf

zggrqf computes a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B:

```
A = R*Q,        B = Z*T*Q,
```

where Q is an N-by-N unitary matrix, Z is a P-by-P unitary matrix, and R and T assume one of the forms:

if M <= N, R = (0 R12) M, or if M > N, R = (R11) M-N,

```
N-M  M                            ( R21 ) N
                                    N
```

where R12 or R21 is upper triangular, and

if P >= N, T = (T11) N , or if P < N, T = (T11 T12) P,

```
(  0  ) P-N                         P    N-P
   N
```

where T11 is upper triangular.

In particular, if B is square and nonsingular, the GRQ factorization of A and B implicitly gives the RQ factorization of A*inv(B):

```
A*inv(B) = (R*inv(T))*Z**H
```

where inv(B) denotes the inverse of the matrix B, and Z^H denotes the conjugate transpose of the matrix Z.

Syntax

Fortran specification:

```
use armpl_library

subroutine zggrqf(M, P, N, A, LDA, TAUA, B, LDB, TAUB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zggrqf_(const armpl_int_t *m, const armpl_int_t *p, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *taua, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *taub,
```

(continues on next page)

(continued from previous page)

```
            armpl_doublecomplex_t *work, const armpl_int_t *lwork,
            armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. P >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if M <= N, the upper triangle of the subarray A(1:M,N-M+1:N) contains the M-by-M upper triangular matrix R; if M > N, the elements on and above the (M-N)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAUA, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAUA Output parameter.

TAUA is COMPLEX*16

TAUA is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the unitary matrix Q (see Further Details).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, the elements on and above the diagonal of the array contain the min(P, N)-by-N upper trapezoidal matrix T (T is upper triangular if P >= N); the elements below the diagonal, with the array TAUB, represent the unitary matrix Z as a product of elementary reflectors (see Further Details).

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

TAUB Output parameter.

TAUB is COMPLEX*16

TAUB is an array, dimension (min(P, N)). The scalar factors of the elementary reflectors which represent the unitary matrix Z (see Further Details).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N, M, P). For optimum performance LWORK >= max(N, M, P)*max(NB1,NB2,NB3), where NB1 is the optimal blocksize for the RQ factorization of an M-by-N matrix, NB2 is the optimal blocksize for the QR factorization of a P-by-N matrix, and NB3 is the optimal blocksize for a call of ZUNMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO=-i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cggrqf*, *dggrqf* and *sggrqf*. It also exists with a native C interface as *LAPACKE_zggrqf*.

4.3.163 zgttrf

zgttrf computes an LU factorization of a complex tridiagonal matrix A using elimination with partial pivoting and row interchanges.

The factorization has the form

```
A = L * U
```

where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgttrf(N, DL, D, DU, DU2, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void zgttrf_(const armpl_int_t *n, armpl_doublecomplex_t *dl,
             armpl_doublecomplex_t *d, armpl_doublecomplex_t *du,
             armpl_doublecomplex_t *du2, armpl_int_t *ipiv,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A.

DL Input and output parameter.

DL is COMPLEX*16

DL is an array, dimension (N-1). On entry, DL must contain the (n-1) sub-diagonal elements of A.

On exit, DL is overwritten by the (n-1) multipliers that define the matrix L from the LU factorization of A.

D Input and output parameter.

D is COMPLEX*16

D is an array, dimension (N). On entry, D must contain the diagonal elements of A.

On exit, D is overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DU Input and output parameter.

DU is COMPLEX*16

DU is an array, dimension (N-1). On entry, DU must contain the (n-1) super-diagonal elements of A.

On exit, DU is overwritten by the (n-1) elements of the first super-diagonal of U.

DU2 Output parameter.

DU2 is COMPLEX*16

DU2 is an array, dimension (N-2). On exit, DU2 is overwritten by the (n-2) elements of the second super-diagonal of U.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

For this routine in other precisions, please see *cgttrf*, *dgttrf* and *sgttrf*. It also exists with a native C interface as *LAPACKE_zgttrf*.

4.3.164 zhetrf

zhetrf computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

```
A = U*D*U**H  or  A = L*D*L**H
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetrf(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhetrf_(const char *uplo, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *ipiv,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >=1. For best performance LWORK >= N*NB, where NB is the block size returned by ILAENV.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *chetrf*. It also exists with a native C interface as *LAPACKE_zhetrf*.

4.3.165 zhetrf_aa

ZHETRF_AA computes the factorization of a complex hermitian matrix A using the Aasen's algorithm. The form of the factorization is

```
A = U*T*U**H  or  A = L*T*L**H
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is a hermitian tridiagonal matrix.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetrf_aa(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhetrf_aa_(const char *uplo, const armpl_int_t *n,
                armpl_doublecomplex_t *a, const armpl_int_t *lda,
                armpl_int_t *ipiv, armpl_doublecomplex_t *work,
                const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the tridiagonal matrix is stored in the diagonals and the subdiagonals of A just below (or above) the diagonals, and L is stored below (or above) the subdiaonals, when UPLO is 'L' (or 'U').

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= MAX(1,2*N). For optimum performance LWORK >= N*(1+NB), where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *chetrf_aa*. It also exists with a native C interface as *LAPACKE_zhetrf_aa*.

4.3.166 zhetrf_rk

ZHETRF_RK computes the factorization of a complex Hermitian matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method:

```
A = P*U*D*(U**H)*(P**T) or A = P*L*D*(L**H)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^H (or L^H) is the conjugate of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS. For more information see Further Details section.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetrf_rk(UPLO, N, A, LDA, E, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhetrf_rk_(const char *uplo, const armpl_int_t *n,
                armpl_doublecomplex_t *a, const armpl_int_t *lda,
                armpl_doublecomplex_t *e, armpl_int_t *ipiv,
                armpl_doublecomplex_t *work, const armpl_int_t *lwork,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, contains: a) ONLY diagonal elements of the Hermitian block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is COMPLEX*16

E is an array, dimension (N). On exit, contains the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

IPIV describes the permutation matrix P in the factorization of matrix A as follows. The absolute value of IPIV(k) represents the index of row and column that were interchanged with the k-th row and column. The value of UPLO describes the order in which the interchanges were applied. Also, the sign of IPIV represents the block structure of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks which correspond to 1 or 2 interchanges at each factorization step. For more info see Further Details section.

If UPLO = 'U', (in factorization order, k decreases from N to 1): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N); If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k-1) < 0 means: D(k-1:k,k-1:k) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k-1) != k-1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k-1) = k-1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) <= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

If UPLO = 'L', (in factorization order, k increases from 1 to N): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N). If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k+1) < 0 means: D(k:k+1,k:k+1) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k+1) != k+1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k+1) = k+1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) >= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)).. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >=1. For best performance LWORK >= N*NB, where NB is the block size returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

Related Information

For this routine in other precisions, please see *chetrf_rk*. It also exists with a native C interface as *LAPACKE_zhetrf_rk*.

4.3.167 zhetrf_rook

ZHETRF_ROOK computes the factorization of a complex Hermitian matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method. The form of the factorization is

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetrf_rook(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhetrf_rook_(const char *uplo, const armpl_int_t *n,
                  armpl_doublecomplex_t *a, const armpl_int_t *lda,
                  armpl_int_t *ipiv, armpl_doublecomplex_t *work,
                  const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': Only the last KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': Only the first KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)).. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >=1. For best performance LWORK >= N*NB, where NB is the block size returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *chetrf_rook*. It also exists with a native C interface as *LAPACKE_zhetrf_rook*.

4.3.168 zhptrf

zhptrf computes the factorization of a complex Hermitian packed matrix A using the Bunch-Kaufman diagonal pivoting method:

```
A = U*D*U**H  or  A = L*D*L**H
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhptrf(UPLO, N, AP, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void zhptrf_(const char *uplo, const armpl_int_t *n,
             armpl_doublecomplex_t *ap, armpl_int_t *ipiv, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L, stored as a packed triangular matrix overwriting A (see below for further details).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *chptrf*. It also exists with a native C interface as *LAPACKE_zhptrf*.

4.3.169 zpbtrf

zpbtrf computes the Cholesky factorization of a complex Hermitian positive definite band matrix A.

The factorization has the form

```
A = U**H * U,  if UPLO = 'U', or
A = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpbtrf(UPLO, N, KD, AB, LDAB, INFO)
```

C specification:

```
#include "armpl.h"

void zpbtrf_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB

as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the band matrix A, in the same storage format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpbtrf*, *dpbtrf* and *spbtrf*. It also exists with a native C interface as *LAPACKE_zpbtrf*.

4.3.170 zpftrf

zpftrf computes the Cholesky factorization of a complex Hermitian positive definite matrix A.

The factorization has the form

```
A = U**H * U,  if UPLO = 'U', or
A = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

This is the block version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpftrf(TRANSR, UPLO, N, A, INFO)
```

C specification:

```
#include "armpl.h"

void zpftrf_(const char *transr, const char *uplo, const armpl_int_t *n,
             armpl_doublecomplex_t *a, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal TRANSR of RFP A is stored; = 'C': The Conjugate-transpose TRANSR of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of RFP A is stored; = 'L': Lower triangle of RFP A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (N*(N+1)/2);. On entry, the Hermitian matrix A in RFP format. RFP format is described by TRANSR, UPLO, and N as follows: If TRANSR = 'N' then RFP A is (0:N,0:k-1) when N is even; k=N/2. RFP A is (0:N-1,0:k) when N is odd; k=N/2. IF TRANSR = 'C' then RFP is the Conjugate-transpose of RFP A as defined when TRANSR = 'N'. The contents of RFP A are defined by UPLO as follows: If UPLO = 'U' the RFP A contains the nt elements of upper packed A. If UPLO = 'L' the RFP A contains the elements of lower packed A. The LDA of RFP A is (N+1)/2 when TRANSR = 'C'. When TRANSR is 'N' the LDA is N+1 when N is even and N is odd. See the Note below for more details.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization RFP A = U^H *U or RFP A = L*L^H .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Further Notes on RFP Format:

We first consider Standard Packed Format when N is even. We give an example where N = 6.

AP is Upper AP is Lower

00 01 02 03 04 05 00 11 12 13 14 15 10 11 22 23 24 25 20 21 22 33 34 35 30 31 32 33 44 45 40 41 42 43 44 55 50 51 52 53 54 55

Let TRANSR = 'N'. RFP holds AP as follows: For UPLO = 'U' the upper trapezoid A(0:5,0:2) consists of the last three columns of AP upper. The lower triangle A(4:6,0:2) consists of conjugate-transpose of the first three columns of AP upper. For UPLO = 'L' the lower trapezoid A(1:6,0:2) consists of the first three columns of AP lower. The upper triangle A(0:2,0:2) consists of conjugate-transpose of the last three columns of AP lower. To denote conjugate we place – above the element. This covers the case N even and TRANSR = 'N'.

RFP A RFP A

– – – 03 04 05 33 43 53 – – 13 14 15 00 44 54 – 23 24 25 10 11 55

33 34 35 20 21 22 – 00 44 45 30 31 32 – – 01 11 55 40 41 42 – – – 02 12 22 50 51 52

Now let TRANSR = 'C'. RFP A in both UPLO cases is just the conjugate- transpose of RFP A above. One therefore gets:

RFP A RFP A

– – – – – – – – – – 03 13 23 33 00 01 02 33 00 10 20 30 40 50 – – – – – – – – – – 04 14 24 34 44 11 12 43 44 11 21 31 41 51 – – – – – – – – – – 05 15 25 35 45 55 22 53 54 55 22 32 42 52

We next consider Standard Packed Format when N is odd. We give an example where N = 5.

AP is Upper AP is Lower

00 01 02 03 04 00 11 12 13 14 10 11 22 23 24 20 21 22 33 34 30 31 32 33 44 40 41 42 43 44

Let TRANSR = 'N'. RFP holds AP as follows: For UPLO = 'U' the upper trapezoid A(0:4,0:2) consists of the last three columns of AP upper. The lower triangle A(3:4,0:1) consists of conjugate-transpose of the first two columns of AP upper. For UPLO = 'L' the lower trapezoid A(0:4,0:2) consists of the first three columns of

AP lower. The upper triangle A(0:1,1:2) consists of conjugate-transpose of the last two columns of AP lower. To denote conjugate we place – above the element. This covers the case N odd and TRANSR = 'N'.

RFP A RFP A

– – 02 03 04 00 33 43 – 12 13 14 10 11 44

22 23 24 20 21 22 – 00 33 34 30 31 32 – – 01 11 44 40 41 42

Now let TRANSR = 'C'. RFP A in both UPLO cases is just the conjugate- transpose of RFP A above. One therefore gets:

RFP A RFP A

– – – – – – – – – 02 12 22 00 01 00 10 20 30 40 50 – – – – – – – – – 03 13 23 33 11 33 11 21 31 41 51 – – – – – – – – – – 04 14 24 34 44 43 44 22 32 42 52

For this routine in other precisions, please see *cpftrf*, *dpftrf* and *spftrf*. It also exists with a native C interface as *LAPACKE_zpftrf*.

4.3.171 zpotrf

zpotrf computes the Cholesky factorization of a complex Hermitian positive definite matrix A.

The factorization has the form

```
A = U**H * U,  if UPLO = 'U', or
A = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

This is the block version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpotrf(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void zpotrf_(const char *uplo, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpotrf*, *dpotrf* and *spotrf*. It also exists with a native C interface as *LAPACKE_zpotrf*.

4.3.172 zpotrf2

zpotrf2 computes the Cholesky factorization of a real symmetric positive definite matrix A using the recursive algorithm.

The factorization has the form

```
A = U**H * U,  if UPLO = 'U', or
A = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

This is the recursive version of the algorithm. It divides the matrix into four submatrices:

```
    [  A11 | A12  ]  where A11 is n1 by n1 and A22 is n2 by n2
A = [ -----|-----  ]  with n1 = n/2
    [  A21 | A22  ]       n2 = n-n1
```

The subroutine calls itself to factor A11. Update and scale A21 or A12, update A22 then call itself to factor A22.

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine zpotrf2(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void zpotrf2_(const char *uplo, const armpl_int_t *n,
              armpl_doublecomplex_t *a, const armpl_int_t *lda,
              armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpotrf2*, *dpotrf2* and *spotrf2*. It also exists with a native C interface as *LAPACKE_zpotrf2*.

4.3.173 zpptrf

zpptrf computes the Cholesky factorization of a complex Hermitian positive definite matrix A stored in packed format.

The factorization has the form

```
A = U**H * U,  if UPLO = 'U', or
A = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpptrf(UPLO, N, AP, INFO)
```

C specification:

```
#include "armpl.h"

void zpptrf_(const char *uplo, const armpl_int_t *n,
             armpl_doublecomplex_t *ap, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , in the same storage format as A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpptrf*, *dpptrf* and *spptrf*. It also exists with a native C interface as *LAPACKE_zpptrf*.

4.3.174 zpstrf

zpstrf computes the Cholesky factorization with complete pivoting of a complex Hermitian positive semidefinite matrix A.

The factorization has the form

```
P**T * A * P = U**H * U ,  if UPLO = 'U',
P**T * A * P = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular, and P is stored as vector PIV.

This algorithm does not attempt to check that A is positive semidefinite. This version of the algorithm calls level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpstrf(UPLO, N, A, LDA, PIV, RANK, TOL, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zpstrf_(const char *uplo, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *piv, armpl_int_t *rank,
             const double *tol, double *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization as above.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

PIV Output parameter.

PIV is INTEGER array, dimension (N)

PIV is such that the nonzero entries are P(PIV(K), K) = 1.

RANK Output parameter.

RANK is INTEGER

The rank of A given by the number of steps the algorithm completed.

TOL Input parameter.

TOL is DOUBLE PRECISION

User defined tolerance. If TOL < 0, then N*U*MAX(A(K,K)) will be used. The algorithm terminates at the (K-1)st step if the pivot <= TOL.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N). Work space.

INFO Output parameter.

INFO is INTEGER

< 0: If INFO = -K, the K-th argument had an illegal value, = 0: algorithm completed successfully, and > 0: the matrix A is either rank deficient with computed rank as returned in RANK, or is not positive semidefinite. See Section 7 of LAPACK Working Note #161 for further information.

Related Information

For this routine in other precisions, please see *cpstrf*, *dpstrf* and *spstrf*. It also exists with a native C interface as *LAPACKE_zpstrf*.

4.3.175 zpttrf

zpttrf computes the L*D*L^H factorization of a complex Hermitian positive definite tridiagonal matrix A. The factorization may also be regarded as having the form A = U^H *D*U.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpttrf(N, D, E, INFO)
```

C specification:

```
#include "armpl.h"

void zpttrf_(const armpl_int_t *n, double *d, armpl_doublecomplex_t *e,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the L*D*L^H factorization of A.

E Input and output parameter.

E is COMPLEX*16

E is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*D*L^H factorization of A. E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U^H *D*U factorization of A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, the leading minor of order k is not positive definite; if k < N, the factorization could not be completed, while if k = N, the factorization was completed, but D(N) <= 0.

Related Information

For this routine in other precisions, please see *cpttrf*, *dpttrf* and *spttrf*. It also exists with a native C interface as *LAPACKE_zpttrf*.

4.3.176 zsptrf

zsptrf computes the factorization of a complex symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method:

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsptrf(UPLO, N, AP, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void zsptrf_(const char *uplo, const armpl_int_t *n,
             armpl_doublecomplex_t *ap, armpl_int_t *ipiv, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L, stored as a packed triangular matrix overwriting A (see below for further details).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *csptrf*, *dsptrf* and *ssptrf*. It also exists with a native C interface as *LAPACKE_zsptrf*.

4.3.177 zsytrf

zsytrf computes the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytrf(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsytrf_(const char *uplo, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *ipiv,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >=1. For best performance LWORK >= N*NB, where NB is the block size returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *csytrf*, *dsytrf* and *ssytrf*. It also exists with a native C interface as *LAPACKE_zsytrf*.

4.3.178 zsytrf_aa

ZSYTRF_AA computes the factorization of a complex symmetric matrix A using the Aasen's algorithm. The form of the factorization is

```
A = U*T*U**T  or  A = L*T*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is a complex symmetric tridiagonal matrix.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytrf_aa(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsytrf_aa_(const char *uplo, const armpl_int_t *n,
                armpl_doublecomplex_t *a, const armpl_int_t *lda,
                armpl_int_t *ipiv, armpl_doublecomplex_t *work,
                const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the tridiagonal matrix is stored in the diagonals and the subdiagonals of A just below (or above) the diagonals, and L is stored below (or above) the subdiaonals, when UPLO is 'L' (or 'U').

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >=MAX(1,2*N). For optimum performance LWORK >= N*(1+NB), where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *csytrf_aa*, *dsytrf_aa* and *ssytrf_aa*. It also exists with a native C interface as *LAPACKE_zsytrf_aa*.

4.3.179 zsytrf_rk

ZSYTRF_RK computes the factorization of a complex symmetric matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS. For more information see Further Details section.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytrf_rk(UPLO, N, A, LDA, E, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsytrf_rk_(const char *uplo, const armpl_int_t *n,
                armpl_doublecomplex_t *a, const armpl_int_t *lda,
                armpl_doublecomplex_t *e, armpl_int_t *ipiv,
                armpl_doublecomplex_t *work, const armpl_int_t *lwork,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, contains: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is COMPLEX*16

E is an array, dimension (N). On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

IPIV describes the permutation matrix P in the factorization of matrix A as follows. The absolute value of IPIV(k) represents the index of row and column that were interchanged with the k-th row and column. The value of UPLO describes the order in which the interchanges were applied. Also, the sign of IPIV represents the block structure of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks which correspond to 1 or 2 interchanges at each factorization step. For more info see Further Details section.

If UPLO = 'U', (in factorization order, k decreases from N to 1): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N); If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k-1) < 0 means: D(k-1:k,k-1:k) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k-1) != k-1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k-1) = k-1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) <= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

If UPLO = 'L', (in factorization order, k increases from 1 to N): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N). If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k+1) < 0 means: D(k:k+1,k:k+1) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k+1) != k+1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k+1) = k+1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) >= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)).. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >=1. For best performance LWORK >= N*NB, where NB is the block size returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

Related Information

4.3.180 zsytrf_rook

ZSYTRF_ROOK computes the factorization of a complex symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method. The form of the factorization is

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytrf_rook(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsytrf_rook_(const char *uplo, const armpl_int_t *n,
                  armpl_doublecomplex_t *a, const armpl_int_t *lda,
                  armpl_int_t *ipiv, armpl_doublecomplex_t *work,
                  const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)).. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >=1. For best performance LWORK >= N*NB, where NB is the block size returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

For this routine in other precisions, please see *csytrf_rook*, *dsytrf_rook* and *ssytrf_rook*. It also exists with a native C interface as *LAPACKE_zsytrf_rook*.

4.3.181 ztplqt

DTPLQT computes a blocked LQ factorization of a complex "triangular-pentagonal" matrix C, which is composed of a triangular block A and pentagonal block B, using the compact WY representation for Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztplqt(M, N, L, MB, A, LDA, B, LDB, T, LDT, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void ztplqt_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *l,
             const armpl_int_t *mb, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *b,
```

(continues on next page)

(continued from previous page)

```
              const armpl_int_t *ldb, armpl_doublecomplex_t *t,
              const armpl_int_t *ldt, armpl_doublecomplex_t *work,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix B, and the order of the triangular matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B. N >= 0.

L Input parameter.

L is INTEGER

The number of rows of the lower trapezoidal part of B. MIN(M, N) >= L >= 0. See Further Details.

MB Input parameter.

MB is INTEGER

The block size to be used in the blocked QR. M >= MB >= 1.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, M). On entry, the lower triangular M-by-M matrix A. On exit, the elements on and below the diagonal of the array contain the lower triangular matrix L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the pentagonal M-by-N matrix B. The first N-L columns are rectangular, and the last L columns are lower trapezoidal. On exit, B contains the pentagonal matrix V. See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

T Output parameter.

T is COMPLEX*16

T is an array, dimension (LDT, N). The lower triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See Further Details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MB*M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctplqt*, *dtplqt* and *stplqt*.

4.3.182 ztpmlqt

ztpmlqt applies a complex orthogonal matrix Q obtained from a "triangular-pentagonal" complex block reflector H to a general complex matrix C, which consists of two blocks A and B.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztpmlqt(SIDE, TRANS, M, N, K, L, MB, V, LDV, T, LDT, A, LDA, B,
                   LDB, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void ztpmlqt_(const char *side, const char *trans, const armpl_int_t *m,
              const armpl_int_t *n, const armpl_int_t *k,
              const armpl_int_t *l, const armpl_int_t *mb,
              const armpl_doublecomplex_t *v, const armpl_int_t *ldv,
              const armpl_doublecomplex_t *t, const armpl_int_t *ldt,
              armpl_doublecomplex_t *a, const armpl_int_t *lda,
              armpl_doublecomplex_t *b, const armpl_int_t *ldb,
              armpl_doublecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q.

L Input parameter.

L is INTEGER

The order of the trapezoidal part of V. K >= L >= 0. See Further Details.

MB Input parameter.

MB is INTEGER

The block size used for the storage of T. K >= MB >= 1. This must be the same value of MB used to generate T in DTPLQT.

V Input parameter.

V is COMPLEX*16

V is an array, dimension (LDA, K). The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DTPLQT in B. See Further Details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If SIDE = 'L', LDV >= max(1, M); if SIDE = 'R', LDV >= max(1, N).

T Input parameter.

T is COMPLEX*16

T is an array, dimension (LDT, K). The upper triangular factors of the block reflectors as returned by DTPLQT, stored as a MB-by-K matrix.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension. (LDA, N) if SIDE = 'L' or (LDA, K) if SIDE = 'R' On entry, the K-by-N or M-by-K matrix A. On exit, A is overwritten by the corresponding block of Q*C or Q^H *C or C*Q or C*Q^H . See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDC >= max(1, K); If SIDE = 'R', LDC >= max(1, M).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the M-by-N matrix B. On exit, B is overwritten by the corresponding block of Q*C or Q^H *C or C*Q or C*Q^H . See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16 array. The dimension of WORK is

N* MB if SIDE = 'L', or M* MB if SIDE = 'R'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpmlqt*, *dtpmlqt* and *stpmlqt*.

4.3.183 ztpmqrt

ztpmqrt applies a complex orthogonal matrix Q obtained from a "triangular-pentagonal" complex block reflector H to a general complex matrix C, which consists of two blocks A and B.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztpmqrt(SIDE, TRANS, M, N, K, L, NB, V, LDV, T, LDT, A, LDA, B,
                   LDB, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void ztpmqrt_(const char *side, const char *trans, const armpl_int_t *m,
              const armpl_int_t *n, const armpl_int_t *k,
              const armpl_int_t *l, const armpl_int_t *nb,
              const armpl_doublecomplex_t *v, const armpl_int_t *ldv,
              const armpl_doublecomplex_t *t, const armpl_int_t *ldt,
              armpl_doublecomplex_t *a, const armpl_int_t *lda,
              armpl_doublecomplex_t *b, const armpl_int_t *ldb,
              armpl_doublecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q.

L Input parameter.

L is INTEGER

The order of the trapezoidal part of V. K >= L >= 0. See Further Details.

NB Input parameter.

NB is INTEGER

The block size used for the storage of T. K >= NB >= 1. This must be the same value of NB used to generate T in CTPQRT.

V Input parameter.

V is COMPLEX*16

V is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CTPQRT in B. See Further Details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If SIDE = 'L', LDV >= max(1, M); if SIDE = 'R', LDV >= max(1, N).

T Input parameter.

T is COMPLEX*16

T is an array, dimension (LDT, K). The upper triangular factors of the block reflectors as returned by CTPQRT, stored as a NB-by-K matrix.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension. (LDA, N) if SIDE = 'L' or (LDA, K) if SIDE = 'R' On entry, the K-by-N or M-by-K matrix A. On exit, A is overwritten by the corresponding block of Q*C or Q^H *C or C*Q or C*Q^H . See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDC >= max(1, K); If SIDE = 'R', LDC >= max(1, M).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the M-by-N matrix B. On exit, B is overwritten by the corresponding block of Q*C or Q^H *C or C*Q or C*Q^H . See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16 array. The dimension of WORK is

N* NB if SIDE = 'L', or M* NB if SIDE = 'R'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpmqrt*, *dtpmqrt* and *stpmqrt*. It also exists with a native C interface as *LAPACKE_ztpmqrt*.

4.3.184 ztpqrt

ztpqrt computes a blocked QR factorization of a complex "triangular-pentagonal" matrix C, which is composed of a triangular block A and pentagonal block B, using the compact WY representation for Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztpqrt(M, N, L, NB, A, LDA, B, LDB, T, LDT, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void ztpqrt_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *l,
             const armpl_int_t *nb, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *t,
             const armpl_int_t *ldt, armpl_doublecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B, and the order of the triangular matrix A. N >= 0.

L Input parameter.

L is INTEGER

The number of rows of the upper trapezoidal part of B. MIN(M, N) >= L >= 0. See Further Details.

NB Input parameter.

NB is INTEGER

The block size to be used in the blocked QR. N >= NB >= 1.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the upper triangular N-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the upper triangular matrix R.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the pentagonal M-by-N matrix B. The first M-L rows are rectangular, and the last L rows are upper trapezoidal. On exit, B contains the pentagonal matrix V. See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

T Output parameter.

T is COMPLEX*16

T is an array, dimension (LDT, N). The upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See Further Details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (NB*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpqrt*, *dtpqrt* and *stpqrt*. It also exists with a native C interface as *LAPACKE_ztpqrt*.

4.3.185 ztzrzf

`ztzrzf` reduces the M-by-N (M<=N) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations.

The upper trapezoidal matrix A is factored as

```
A = ( R  0 ) * Z,
```

where Z is an N-by-N unitary matrix and R is an M-by-M upper triangular matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztzrzf(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ztzrzf_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix `A`. `M` >= 0.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix `A`. `N` >= `M`.

A Input and output parameter.

`A` is `COMPLEX*16`

`A` is an array, dimension (`LDA`, `N`). On entry, the leading M-by-N upper trapezoidal part of the array `A` must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to `N` of the first `M` rows of `A`, with the array `TAU`, represent the unitary matrix Z as a product of `M` elementary reflectors.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `M`).

TAU Output parameter.

`TAU` is `COMPLEX*16`

`TAU` is an array, dimension (`M`). The scalar factors of the elementary reflectors.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctzrzf*, *dtzrzf* and *stzrzf*. It also exists with a native C interface as *LAPACKE_ztzrzf*.

4.3.186 zunglq

zunglq generates an M-by-N complex matrix Q with orthonormal rows, which is defined as the first M rows of a product of K elementary reflectors of order N

```
Q  =  H(k)**H . . . H(2)**H H(1)**H
```

as returned by ZGELQF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zunglq(M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zunglq_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. N >= M.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by ZGELQF in the first k rows of its array argument A. On exit, the M-by-N matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZGELQF.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit; < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *cunglq*. It also exists with a native C interface as *LAPACKE_zunglq*.

4.3.187 zungql

zungql generates an M-by-N complex matrix Q with orthonormal columns, which is defined as the last N columns of a product of K elementary reflectors of order M

```
Q  =  H(k) . . . H(2) H(1)
```

as returned by ZGEQLF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zungql(M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zungql_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by ZGEQLF in the last k columns of its array argument A. On exit, the M-by-N matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZGEQLF.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *cungql*. It also exists with a native C interface as *LAPACKE_zungql*.

4.3.188 zungqr

zungqr generates an M-by-N complex matrix Q with orthonormal columns, which is defined as the first N columns of a product of K elementary reflectors of order M

```
Q  =  H(1) H(2) . . . H(k)
```

as returned by ZGEQRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zungqr(M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zungqr_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by ZGEQRF in the first k columns of its array argument A. On exit, the M-by-N matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZGEQRF.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *cungqr*. It also exists with a native C interface as *LAPACKE_zungqr*.

4.3.189 zungrq

zungrq generates an M-by-N complex matrix Q with orthonormal rows, which is defined as the last M rows of a product of K elementary reflectors of order N

```
Q  =  H(1)**H H(2)**H . . . H(k)**H
```

as returned by ZGERQF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zungrq(M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zungrq_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. N >= M.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the (m-k+i)-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by ZGERQF in the last k rows of its array argument A. On exit, the M-by-N matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZGERQF.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *cungrq*. It also exists with a native C interface as *LAPACKE_zungrq*.

4.3.190 zunmlq

zunmlq overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'      SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H

where Q is a complex unitary matrix defined as the product of k elementary reflectors

```
Q = H(k)**H . . . H(2)**H H(1)**H
```

as returned by ZGELQF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine zunmlq(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zunmlq_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Conjugate transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by ZGELQF in the first k rows of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZGELQF.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cunmlq*. It also exists with a native C interface as *LAPACKE_zunmlq*.

4.3.191 zunmql

zunmql overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H

where Q is a complex unitary matrix defined as the product of k elementary reflectors

```
Q = H(k) . . . H(2) H(1)
```

as returned by ZGEQLF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine zunmql(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zunmql_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by ZGEQLF in the last k columns of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZGEQLF.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should genreally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cunmql*. It also exists with a native C interface as *LAPACKE_zunmql*.

4.3.192 zunmqr

zunmqr overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'      SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H

where Q is a complex unitary matrix defined as the product of k elementary reflectors

```
Q = H(1) H(2) . . . H(k)
```

as returned by ZGEQRF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine zunmqr(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zunmqr_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Conjugate transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by ZGEQRF in the first k columns of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZGEQRF.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cunmqr*. It also exists with a native C interface as *LAPACKE_zunmqr*.

4.3.193 zunmrq

zunmrq overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H

where Q is a complex unitary matrix defined as the product of k elementary reflectors

```
Q = H(1)**H H(2)**H . . . H(k)**H
```

as returned by ZGERQF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine zunmrq(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zunmrq_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by ZGERQF in the last k rows of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZGERQF.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cunmrq*. It also exists with a native C interface as *LAPACKE_zunmrq*.

4.3.194 zunmrz

zunmrz overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H

where Q is a complex unitary matrix defined as the product of k elementary reflectors

```
Q = H(1) H(2) . . . H(k)
```

as returned by ZTZRZF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine zunmrz(SIDE, TRANS, M, N, K, L, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zunmrz_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const armpl_int_t *l,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Conjugate transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

L Input parameter.

L is INTEGER

The number of columns of the matrix A containing the meaningful part of the Householder reflectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by ZTZRZF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZTZRZF.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cunmrz*. It also exists with a native C interface as *LAPACKE_zunmrz*.

4.4 LAPACK matrix inversion routines

4.4.1 cgetri

cgetri computes the inverse of a matrix using the LU factorization computed by CGETRF.

This method inverts U and then computes inv(A) by solving the system inv(A)*L = inv(U) for inv(A).

Syntax

Fortran specification:

```
use armpl_library

subroutine cgetri(N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgetri_(const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, const armpl_int_t *ipiv,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the factors L and U from the factorization A = P*L*U as computed by CGETRF. On exit, if INFO = 0, the inverse of the original matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from CGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO=0, then WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimal performance LWORK >= N*NB, where NB is the optimal blocksize returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *dgetri*, *sgetri* and *zgetri*. It also exists with a native C interface as *LAPACKE_cgetri*.

4.4.2 chetri

chetri computes the inverse of a complex Hermitian indefinite matrix A using the factorization A = U*D*U^H or A = L*D*L^H computed by CHETRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetri(UPLO, N, A, LDA, IPIV, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void chetri_(const char *uplo, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, const armpl_int_t *ipiv,
             armpl_singlecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

On exit, if INFO = 0, the (Hermitian) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHETRF.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *zhetri*. It also exists with a native C interface as *LAPACKE_chetri*.

4.4.3 chetri2

chetri2 computes the inverse of a COMPLEX hermitian indefinite matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by CHETRF. chetri2 set the LEADING DIMENSION of the workspace before calling ‘‘chetri2‘‘X that actually computes the inverse.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetri2(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chetri2_(const char *uplo, const armpl_int_t *n,
              armpl_singlecomplex_t *a, const armpl_int_t *lda,
              const armpl_int_t *ipiv, armpl_singlecomplex_t *work,
              const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = ‘U’: Upper triangular, form is A = U*D*U^T ; = ‘L’: Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the NB diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the NB structure of D as determined by CHETRF.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N+NB+1)*(NB+3) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. WORK is size >= (N+NB+1)*(NB+3) If LWORK = -1, then a workspace query is assumed; the routine calculates: - the optimal size of the WORK array, returns this value as the first entry of the WORK array, - and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *zhetri2*. It also exists with a native C interface as *LAPACKE_chetri2*.

4.4.4 chetri2x

CHETRI2X computes the inverse of a complex Hermitian indefinite matrix A using the factorization A = U*D*U^H or A = L*D*L^H computed by CHETRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetri2x(UPLO, N, A, LDA, IPIV, WORK, NB, INFO)
```

C specification:

```
#include "armpl.h"

void chetri2x_(const char *uplo, const armpl_int_t *n,
               armpl_singlecomplex_t *a, const armpl_int_t *lda,
               const armpl_int_t *ipiv, armpl_singlecomplex_t *work,
               const armpl_int_t *nb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the NNB diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the NNB structure of D as determined by CHETRF.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N+NB+1,NB+3) .

NB Input parameter.

NB is INTEGER

Block size

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *zhetri2x*. It also exists with a native C interface as *LAPACKE_chetri2x*.

4.4.5 chetri_3

CHETRI_3 computes the inverse of a complex Hermitian indefinite matrix A using the factorization computed by CHETRF_RK or CHETRF_BK:

```
A = P*U*D*(U**H)*(P**T) or A = P*L*D*(L**H)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^H (or L^H) is the conjugate of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

CHETRI_3 sets the leading dimension of the workspace before calling CHETRI_3X that actually computes the inverse. This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetri_3(UPLO, N, A, LDA, E, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chetri_3_(const char *uplo, const armpl_int_t *n,
               armpl_singlecomplex_t *a, const armpl_int_t *lda,
               const armpl_singlecomplex_t *e, const armpl_int_t *ipiv,
               armpl_singlecomplex_t *work, const armpl_int_t *lwork,
               armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, diagonal of the block diagonal matrix D and factors U or L as computed by CHETRF_RK and CHETRF_BK: a) ONLY diagonal elements of the Hermitian block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, if INFO = 0, the Hermitian inverse of the original matrix. If UPLO = 'U': the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; If UPLO = 'L': the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is COMPLEX

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHETRF_RK or CHETRF_BK.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N+NB+1)*(NB+3).. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= (N+NB+1)*(NB+3).

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *zhetri_3*. It also exists with a native C interface as *LAPACKE_chetri_3*.

4.4.6 chetri_rook

CHETRI_ROOK computes the inverse of a complex Hermitian indefinite matrix A using the factorization A = $U*D*U^H$ or A = $L*D*L^H$ computed by CHETRF_ROOK.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetri_rook(UPLO, N, A, LDA, IPIV, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void chetri_rook_(const char *uplo, const armpl_int_t *n,
                  armpl_singlecomplex_t *a, const armpl_int_t *lda,
                  const armpl_int_t *ipiv, armpl_singlecomplex_t *work,
                  armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF_ROOK.

On exit, if INFO = 0, the (Hermitian) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHETRF_ROOK.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *zhetri_rook*.

4.4.7 chptri

chptri computes the inverse of a complex Hermitian indefinite matrix A in packed storage using the factorization A = U*D*U^H or A = L*D*L^H computed by CHPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine chptri(UPLO, N, AP, IPIV, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void chptri_(const char *uplo, const armpl_int_t *n,
             armpl_singlecomplex_t *ap, const armpl_int_t *ipiv,
             armpl_singlecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (Hermitian) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of inv(A) is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = inv(A)(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = inv(A)(i,j) for j<=i<=n.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHPTRF.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *zhptri*. It also exists with a native C interface as *LAPACKE_chptri*.

4.4.8 cpftri

`cpftri` computes the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^H * U$ or $A = L * L^H$ computed by CPFTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpftri(TRANSR, UPLO, N, A, INFO)
```

C specification:

```
#include "armpl.h"

void cpftri_(const char *transr, const char *uplo, const armpl_int_t *n,
             armpl_singlecomplex_t *a, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal TRANSR of RFP A is stored; = 'C': The Conjugate-transpose TRANSR of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (N*(N+1)/2);. On entry, the Hermitian matrix A in RFP format. RFP format is described by TRANSR, UPLO, and N as follows: If TRANSR = 'N' then RFP A is (0:N,0:k-1) when N is even; k=N/2. RFP A is (0:N-1,0:k) when N is odd; k=N/2. IF TRANSR = 'C' then RFP is the Conjugate-transpose of RFP A as defined when TRANSR = 'N'. The contents of RFP A are defined by UPLO as follows: If UPLO = 'U' the RFP A contains the nt elements of upper packed A. If UPLO = 'L' the RFP A contains the elements of lower packed A. The LDA of RFP A is (N+1)/2 when TRANSR = 'C'. When TRANSR is 'N' the LDA is N+1 when N is even and N is odd. See the Note below for more details.

On exit, the Hermitian inverse of the original matrix, in the same storage format.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

Related Information

For this routine in other precisions, please see *dpftri*, *spftri* and *zpftri*. It also exists with a native C interface as *LAPACKE_cpftri*.

4.4.9 cpotri

`cpotri` computes the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization A = U^H *U or A = L*L^H computed by CPOTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpotri(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void cpotri_(const char *uplo, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , as computed by CPOTRF. On exit, the upper or lower triangle of the (Hermitian) inverse of A, overwriting the input factor U or L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

Related Information

For this routine in other precisions, please see *dpotri*, *spotri* and *zpotri*. It also exists with a native C interface as *LAPACKE_cpotri*.

4.4.10 cpptri

`cpptri` computes the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^H * U$ or $A = L * L^H$ computed by CPPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpptri(UPLO, N, AP, INFO)
```

C specification:

```
#include "armpl.h"

void cpptri_(const char *uplo, const armpl_int_t *n,
             armpl_singlecomplex_t *ap, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

= 'U': Upper triangular factor is stored in AP; = 'L': Lower triangular factor is stored in `AP`.

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0.

AP Input and output parameter.

`AP` is `COMPLEX`

`AP` is an array, dimension (N*(N+1)/2). On entry, the triangular factor U or L from the Cholesky factorization $A = U^H * U$ or $A = L * L^H$, packed columnwise as a linear array. The j-th column of U or L is stored in the array `AP` as follows: if `UPLO` = 'U', AP(i + (j-1)*j/2) = U(i,j) for 1<=i<=j; if `UPLO` = 'L', AP(i + (j-1)*(2n-j)/2) = L(i,j) for j<=i<=n.

On exit, the upper or lower triangle of the (Hermitian) inverse of A, overwriting the input factor U or L.

INFO Output parameter.

`INFO` is `INTEGER`

= 0: successful exit < 0: if `INFO` = -i, the i-th argument had an illegal value > 0: if `INFO` = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

Related Information

For this routine in other precisions, please see *dpptri*, *spptri* and *zpptri*. It also exists with a native C interface as *LAPACKE_cpptri*.

4.4.11 csptri

csptri computes the inverse of a complex symmetric indefinite matrix A in packed storage using the factorization A = U*D*U^T or A = L*D*L^T computed by CSPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine csptri(UPLO, N, AP, IPIV, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void csptri_(const char *uplo, const armpl_int_t *n,
             armpl_singlecomplex_t *ap, const armpl_int_t *ipiv,
             armpl_singlecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of inv(A) is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = inv(A)(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = inv(A)(i,j) for j<=i<=n.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSPTRF.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *dsptri*, *ssptri* and *zsptri*. It also exists with a native C interface as *LAPACKE_csptri*.

4.4.12 csytri

`csytri` computes the inverse of a complex symmetric indefinite matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by CSYTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytri(UPLO, N, A, LDA, IPIV, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void csytri_(const char *uplo, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, const armpl_int_t *ipiv,
             armpl_singlecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSYTRF.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *dsytri*, *ssytri* and *zsytri*. It also exists with a native C interface as *LAPACKE_csytri*.

4.4.13 csytri2

csytri2 computes the inverse of a COMPLEX symmetric indefinite matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by CSYTRF. csytri2 sets the LEADING DIMENSION of the workspace before calling ‘‘csytri2‘‘X that actually computes the inverse.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytri2(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void csytri2_(const char *uplo, const armpl_int_t *n,
              armpl_singlecomplex_t *a, const armpl_int_t *lda,
              const armpl_int_t *ipiv, armpl_singlecomplex_t *work,
              const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = ‘U’: Upper triangular, form is A = U*D*U^T ; = ‘L’: Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the NB diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the NB structure of D as determined by CSYTRF.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N+NB+1)*(NB+3) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. WORK is size >= (N+NB+1)*(NB+3) If LDWORK = -1, then a workspace query is assumed; the routine calculates: - the optimal size of the WORK array, returns this value as the first entry of the WORK array, - and no error message related to LDWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *dsytri2*, *ssytri2* and *zsytri2*. It also exists with a native C interface as *LAPACKE_csytri2*.

4.4.14 csytri2x

CSYTRI2X computes the inverse of a real symmetric indefinite matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by CSYTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytri2x(UPLO, N, A, LDA, IPIV, WORK, NB, INFO)
```

C specification:

```
#include "armpl.h"

void csytri2x_(const char *uplo, const armpl_int_t *n,
               armpl_singlecomplex_t *a, const armpl_int_t *lda,
               const armpl_int_t *ipiv, armpl_singlecomplex_t *work,
               const armpl_int_t *nb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the NNB diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the NNB structure of D as determined by CSYTRF.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N+NB+1,NB+3) .

NB Input parameter.

NB is INTEGER

Block size

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *dsytri2x*, *ssytri2x* and *zsytri2x*. It also exists with a native C interface as *LAPACKE_csytri2x*.

4.4.15 csytri_3

CSYTRI_3 computes the inverse of a complex symmetric indefinite matrix A using the factorization computed by CSYTRF_RK or CSYTRF_BK:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

CSYTRI_3 sets the leading dimension of the workspace before calling CSYTRI_3X that actually computes the inverse. This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytri_3(UPLO, N, A, LDA, E, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void csytri_3_(const char *uplo, const armpl_int_t *n,
               armpl_singlecomplex_t *a, const armpl_int_t *lda,
               const armpl_singlecomplex_t *e, const armpl_int_t *ipiv,
               armpl_singlecomplex_t *work, const armpl_int_t *lwork,
               armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, diagonal of the block diagonal matrix D and factors U or L as computed by CSYTRF_RK and CSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, if INFO = 0, the symmetric inverse of the original matrix. If UPLO = 'U': the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; If UPLO = 'L': the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is COMPLEX

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSYTRF_RK or CSYTRF_BK.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N+NB+1)*(NB+3).. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= (N+NB+1)*(NB+3).

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *dsytri_3*, *ssytri_3* and *zsytri_3*. It also exists with a native C interface as *LAPACKE_csytri_3*.

4.4.16 csytri_rook

CSYTRI_ROOK computes the inverse of a complex symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by CSYTRF_ROOK.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytri_rook(UPLO, N, A, LDA, IPIV, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void csytri_rook_(const char *uplo, const armpl_int_t *n,
                  armpl_singlecomplex_t *a, const armpl_int_t *lda,
                  const armpl_int_t *ipiv, armpl_singlecomplex_t *work,
                  armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF_ROOK.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSYTRF_ROOK.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *dsytri_rook*, *ssytri_rook* and *zsytri_rook*.

4.4.17 ctftri

ctftri computes the inverse of a triangular matrix A stored in RFP format.

This is a Level 3 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctftri(TRANSR, UPLO, DIAG, N, A, INFO)
```

C specification:

```
#include "armpl.h"

void ctftri_(const char *transr, const char *uplo, const char *diag,
             const armpl_int_t *n, armpl_singlecomplex_t *a,
             armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal TRANSR of RFP A is stored; = 'C': The Conjugate-transpose TRANSR of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (N*(N+1)/2);. On entry, the triangular matrix A in RFP format. RFP format is described by TRANSR, UPLO, and N as follows: If TRANSR = 'N' then RFP A is (0:N,0:k-1) when N is even; k=N/2. RFP A is (0:N-1,0:k) when N is odd; k=N/2. IF TRANSR = 'C' then RFP is the Conjugate-transpose of RFP A as defined when TRANSR = 'N'. The contents of RFP A are defined by UPLO as follows: If UPLO = 'U' the RFP A contains the nt elements of upper packed A; If UPLO = 'L' the RFP A contains the nt elements of lower packed A. The LDA of RFP A is (N+1)/2 when TRANSR = 'C'. When TRANSR is 'N' the LDA is N+1 when N is even and N is odd. See the Note below for more details.

On exit, the (triangular) inverse of the original matrix, in the same storage format.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, A(i,i) is exactly zero. The triangular matrix is singular and its inverse can not be computed.

Related Information

For this routine in other precisions, please see *dtftri*, *stftri* and *ztftri*. It also exists with a native C interface as *LAPACKE_ctftri*.

4.4.18 ctptri

`ctptri` computes the inverse of a complex upper or lower triangular matrix A stored in packed format.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctptri(UPLO, DIAG, N, AP, INFO)
```

C specification:

```
#include "armpl.h"

void ctptri_(const char *uplo, const char *diag, const armpl_int_t *n,
             armpl_singlecomplex_t *ap, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

`DIAG` is `CHARACTER*1`

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0.

AP Input and output parameter.

`AP` is `COMPLEX`

`AP` is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangular matrix A, stored columnwise in a linear array. The j-th column of A is stored in the array `AP` as follows: if `UPLO` = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if `UPLO` = 'L', AP(i + (j-1)*((2*n-j)/2) = A(i,j) for j<=i<=n. See below for further details. On exit, the (triangular) inverse of the original matrix, in the same packed storage format.

INFO Output parameter.

`INFO` is `INTEGER`

= 0: successful exit < 0: if `INFO` = -i, the i-th argument had an illegal value > 0: if `INFO` = i, A(i,i) is exactly zero. The triangular matrix is singular and its inverse can not be computed.

Related Information

For this routine in other precisions, please see *dtptri*, *stptri* and *ztptri*. It also exists with a native C interface as *LAPACKE_ctptri*.

4.4.19 ctrtri

`ctrtri` computes the inverse of a complex upper or lower triangular matrix A.

This is the Level 3 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctrtri(UPLO, DIAG, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void ctrtri_(const char *uplo, const char *diag, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1. On exit, the (triangular) inverse of the original matrix, in the same storage format.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, A(i,i) is exactly zero. The triangular matrix is singular and its inverse can not be computed.

Related Information

For this routine in other precisions, please see *dtrtri*, *strtri* and *ztrtri*. It also exists with a native C interface as *LAPACKE_ctrtri*.

4.4.20 dgetri

`dgetri` computes the inverse of a matrix using the LU factorization computed by DGETRF.

This method inverts U and then computes inv(A) by solving the system inv(A)*L = inv(U) for inv(A).

Syntax

Fortran specification:

```
use armpl_library

subroutine dgetri(N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgetri_(const armpl_int_t *n, double *a, const armpl_int_t *lda,
             const armpl_int_t *ipiv, double *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

N Input parameter.

`N` is `INTEGER`

The order of the matrix `A`. `N` >= 0.

A Input and output parameter.

`A` is `DOUBLE PRECISION`

`A` is an array, dimension (`LDA`, `N`). On entry, the factors L and U from the factorization `A` = P*L*U as computed by DGETRF. On exit, if `INFO` = 0, the inverse of the original matrix `A`.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `N`).

IPIV Input parameter.

`IPIV` is `INTEGER` array, dimension (`N`)

The pivot indices from DGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

WORK Output parameter.

`WORK` is `DOUBLE PRECISION`

`WORK` is an array, dimension (MAX(1, `LWORK`)). On exit, if INFO=0, then WORK(1) returns the optimal `LWORK`.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimal performance LWORK >= N*NB, where NB is the optimal blocksize returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *cgetri*, *sgetri* and *zgetri*. It also exists with a native C interface as *LAPACKE_dgetri*.

4.4.21 dpftri

dpftri computes the inverse of a (real) symmetric positive definite matrix A using the Cholesky factorization A = U^T *U or A = L*L^T computed by DPFTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpftri(TRANSR, UPLO, N, A, INFO)
```

C specification:

```
#include "armpl.h"

void dpftri_(const char *transr, const char *uplo, const armpl_int_t *n,
             double *a, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal TRANSR of RFP A is stored; = 'T': The Transpose TRANSR of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (N*(N+1)/2). On entry, the symmetric matrix A in RFP format. RFP format is described by TRANSR, UPLO, and N as follows: If TRANSR = 'N' then RFP A is (0:N,0:k-1) when N is even; k=N/2. RFP A is (0:N-1,0:k) when N is odd; k=N/2. IF TRANSR = 'T' then RFP is the transpose of RFP A as defined when TRANSR = 'N'. The contents of RFP A are defined by UPLO as follows: If UPLO = 'U' the RFP A contains the nt elements of upper packed A. If UPLO = 'L' the RFP A contains the elements of lower packed A. The LDA of RFP A is (N+1)/2 when TRANSR = 'T'. When TRANSR is 'N' the LDA is N+1 when N is even and N is odd. See the Note below for more details.

On exit, the symmetric inverse of the original matrix, in the same storage format.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

Related Information

For this routine in other precisions, please see *cpftri*, *spftri* and *zpftri*. It also exists with a native C interface as *LAPACKE_dpftri*.

4.4.22 dpotri

dpotri computes the inverse of a real symmetric positive definite matrix A using the Cholesky factorization A = U^T *U or A = L*L^T computed by DPOTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpotri(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void dpotri_(const char *uplo, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by DPOTRF. On exit, the upper or lower triangle of the (symmetric) inverse of A, overwriting the input factor U or L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

Related Information

For this routine in other precisions, please see *cpotri*, *spotri* and *zpotri*. It also exists with a native C interface as *LAPACKE_dpotri*.

4.4.23 dpptri

dpptri computes the inverse of a real symmetric positive definite matrix A using the Cholesky factorization A = U^T *U or A = L*L^T computed by DPPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpptri(UPLO, N, AP, INFO)
```

C specification:

```
#include "armpl.h"

void dpptri_(const char *uplo, const armpl_int_t *n, double *ap,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular factor is stored in AP; = 'L': Lower triangular factor is stored in AP.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). On entry, the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , packed columnwise as a linear array. The j-th column of U or L is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = U(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = L(i,j) for j<=i<=n.

On exit, the upper or lower triangle of the (symmetric) inverse of A, overwriting the input factor U or L.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

Related Information

For this routine in other precisions, please see *cpptri*, *spptri* and *zpptri*. It also exists with a native C interface as *LAPACKE_dpptri*.

4.4.24 dsptri

dsptri computes the inverse of a real symmetric indefinite matrix A in packed storage using the factorization A = U*D*U^T or A = L*D*L^T computed by DSPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsptri(UPLO, N, AP, IPIV, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsptri_(const char *uplo, const armpl_int_t *n, double *ap,
             const armpl_int_t *ipiv, double *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of inv(A) is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = inv(A)(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = inv(A)(i,j) for j<=i<=n.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSPTRF.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csptri*, *ssptri* and *zsptri*. It also exists with a native C interface as *LAPACKE_dsptri*.

4.4.25 dsytri

dsytri computes the inverse of a real symmetric indefinite matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by DSYTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytri(UPLO, N, A, LDA, IPIV, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsytri_(const char *uplo, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, const armpl_int_t *ipiv, double *work,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSYTRF.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csytri*, *ssytri* and *zsytri*. It also exists with a native C interface as *LAPACKE_dsytri*.

4.4.26 dsytri2

dsytri2 computes the inverse of a DOUBLE PRECISION symmetric indefinite matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by DSYTRF. dsytri2 sets the LEADING DIMENSION of the workspace before calling ‘‘dsytri2‘‘X that actually computes the inverse.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytri2(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsytri2_(const char *uplo, const armpl_int_t *n, double *a,
              const armpl_int_t *lda, const armpl_int_t *ipiv, double *work,
              const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the NB diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the NB structure of D as determined by DSYTRF.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N+NB+1)*(NB+3) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. WORK is size >= (N+NB+1)*(NB+3) If LDWORK = -1, then a workspace query is assumed; the routine calculates: - the optimal size of the WORK array, returns this value as the first entry of the WORK array, - and no error message related to LDWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csytri2*, *ssytri2* and *zsytri2*. It also exists with a native C interface as *LAPACKE_dsytri2*.

4.4.27 dsytri2x

DSYTRI2X computes the inverse of a real symmetric indefinite matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by DSYTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytri2x(UPLO, N, A, LDA, IPIV, WORK, NB, INFO)
```

C specification:

```
#include "armpl.h"

void dsytri2x_(const char *uplo, const armpl_int_t *n, double *a,
               const armpl_int_t *lda, const armpl_int_t *ipiv, double *work,
               const armpl_int_t *nb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the NNB diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the NNB structure of D as determined by DSYTRF.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N+NB+1,NB+3) .

NB Input parameter.

NB is INTEGER

Block size

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csytri2x*, *ssytri2x* and *zsytri2x*. It also exists with a native C interface as *LAPACKE_dsytri2x*.

4.4.28 dsytri_3

DSYTRI_3 computes the inverse of a real symmetric indefinite matrix A using the factorization computed by DSYTRF_RK or DSYTRF_BK:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

DSYTRI_3 sets the leading dimension of the workspace before calling DSYTRI_3X that actually computes the inverse. This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytri_3(UPLO, N, A, LDA, E, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsytri_3_(const char *uplo, const armpl_int_t *n, double *a,
               const armpl_int_t *lda, const double *e,
               const armpl_int_t *ipiv, double *work,
               const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, diagonal of the block diagonal matrix D and factors U or L as computed by DSYTRF_RK and DSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, if INFO = 0, the symmetric inverse of the original matrix. If UPLO = 'U': the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; If UPLO = 'L': the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSYTRF_RK or DSYTRF_BK.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N+NB+1)*(NB+3).. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= (N+NB+1)*(NB+3).

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csytri_3*, *ssytri_3* and *zsytri_3*. It also exists with a native C interface as *LAPACKE_dsytri_3*.

4.4.29 dsytri_rook

DSYTRI_ROOK computes the inverse of a real symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by DSYTRF_ROOK.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytri_rook(UPLO, N, A, LDA, IPIV, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsytri_rook_(const char *uplo, const armpl_int_t *n, double *a,
                  const armpl_int_t *lda, const armpl_int_t *ipiv,
                  double *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSYTRF_ROOK.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSYTRF_ROOK.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csytri_rook*, *ssytri_rook* and *zsytri_rook*.

4.4.30 dtftri

dtftri computes the inverse of a triangular matrix A stored in RFP format.

This is a Level 3 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtftri(TRANSR, UPLO, DIAG, N, A, INFO)
```

C specification:

```
#include "armpl.h"

void dtftri_(const char *transr, const char *uplo, const char *diag,
             const armpl_int_t *n, double *a, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal TRANSR of RFP A is stored; = 'T': The Transpose TRANSR of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (0:nt-1);. nt=N*(N+1)/2. On entry, the triangular factor of a Hermitian Positive Definite matrix A in RFP format. RFP format is described by TRANSR, UPLO, and N as follows: If TRANSR = 'N' then RFP A is (0:N,0:k-1) when N is even; k=N/2. RFP A is (0:N-1,0:k) when N is odd; k=N/2. IF TRANSR = 'T' then RFP is the transpose of RFP A as defined when TRANSR = 'N'. The contents of RFP A are defined by UPLO as follows: If UPLO = 'U' the RFP A contains the nt elements of upper packed A; If UPLO = 'L' the RFP A contains the nt elements of lower packed A. The LDA of RFP A is (N+1)/2 when TRANSR = 'T'. When TRANSR is 'N' the LDA is N+1 when N is even and N is odd. See the Note below for more details.

On exit, the (triangular) inverse of the original matrix, in the same storage format.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, A(i,i) is exactly zero. The triangular matrix is singular and its inverse can not be computed.

Related Information

For this routine in other precisions, please see *ctftri*, *stftri* and *ztftri*. It also exists with a native C interface as *LAPACKE_dtftri*.

4.4.31 dtptri

dtptri computes the inverse of a real upper or lower triangular matrix A stored in packed format.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtptri(UPLO, DIAG, N, AP, INFO)
```

C specification:

```
#include "armpl.h"

void dtptri_(const char *uplo, const char *diag, const armpl_int_t *n,
             double *ap, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangular matrix A, stored columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*((2*n-j)/2) = A(i,j) for j<=i<=n. See below for further details. On exit, the (triangular) inverse of the original matrix, in the same packed storage format.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, A(i,i) is exactly zero. The triangular matrix is singular and its inverse can not be computed.

Related Information

For this routine in other precisions, please see *ctptri*, *stptri* and *ztptri*. It also exists with a native C interface as *LAPACKE_dtptri*.

4.4.32 dtrtri

dtrtri computes the inverse of a real upper or lower triangular matrix A.

This is the Level 3 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtrtri(UPLO, DIAG, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void dtrtri_(const char *uplo, const char *diag, const armpl_int_t *n,
             double *a, const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1. On exit, the (triangular) inverse of the original matrix, in the same storage format.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, A(i,i) is exactly zero. The triangular matrix is singular and its inverse can not be computed.

Related Information

For this routine in other precisions, please see *ctrtri*, *strtri* and *ztrtri*. It also exists with a native C interface as *LAPACKE_dtrtri*.

4.4.33 sgetri

`sgetri` computes the inverse of a matrix using the LU factorization computed by SGETRF.

This method inverts U and then computes inv(A) by solving the system inv(A)*L = inv(U) for inv(A).

Syntax

Fortran specification:

```
use armpl_library

subroutine sgetri(N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgetri_(const armpl_int_t *n, float *a, const armpl_int_t *lda,
             const armpl_int_t *ipiv, float *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the factors L and U from the factorization A = P*L*U as computed by SGETRF. On exit, if INFO = 0, the inverse of the original matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from SGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO=0, then WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimal performance LWORK >= N*NB, where NB is the optimal blocksize returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *cgetri*, *dgetri* and *zgetri*. It also exists with a native C interface as *LAPACKE_sgetri*.

4.4.34 spftri

spftri computes the inverse of a real (symmetric) positive definite matrix A using the Cholesky factorization A = U^T *U or A = L*L^T computed by SPFTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine spftri(TRANSR, UPLO, N, A, INFO)
```

C specification:

```
#include "armpl.h"

void spftri_(const char *transr, const char *uplo, const armpl_int_t *n,
             float *a, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal TRANSR of RFP A is stored; = 'T': The Transpose TRANSR of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (N*(N+1)/2). On entry, the symmetric matrix A in RFP format. RFP format is described by TRANSR, UPLO, and N as follows: If TRANSR = 'N' then RFP A is (0:N,0:k-1) when N is even; k=N/2. RFP A is (0:N-1,0:k) when N is odd; k=N/2. IF TRANSR = 'T' then RFP is the transpose of RFP A as defined when TRANSR = 'N'. The contents of RFP A are defined by UPLO as follows: If UPLO = 'U' the RFP A contains the nt elements of upper packed A. If UPLO = 'L' the RFP A contains the elements of lower packed A. The LDA of RFP A is (N+1)/2 when TRANSR = 'T'. When TRANSR is 'N' the LDA is N+1 when N is even and N is odd. See the Note below for more details.

On exit, the symmetric inverse of the original matrix, in the same storage format.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

Related Information

For this routine in other precisions, please see *cpftri*, *dpftri* and *zpftri*. It also exists with a native C interface as *LAPACKE_spftri*.

4.4.35 spotri

spotri computes the inverse of a real symmetric positive definite matrix A using the Cholesky factorization A = U^T *U or A = L*L^T computed by SPOTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine spotri(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void spotri_(const char *uplo, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by SPOTRF. On exit, the upper or lower triangle of the (symmetric) inverse of A, overwriting the input factor U or L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

Related Information

For this routine in other precisions, please see *cpotri*, *dpotri* and *zpotri*. It also exists with a native C interface as *LAPACKE_spotri*.

4.4.36 spptri

spptri computes the inverse of a real symmetric positive definite matrix A using the Cholesky factorization A = U^T *U or A = L*L^T computed by SPPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine spptri(UPLO, N, AP, INFO)
```

C specification:

```
#include "armpl.h"

void spptri_(const char *uplo, const armpl_int_t *n, float *ap,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular factor is stored in AP; = 'L': Lower triangular factor is stored in AP.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). On entry, the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , packed columnwise as a linear array. The j-th column of U or L is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = U(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = L(i,j) for j<=i<=n.

On exit, the upper or lower triangle of the (symmetric) inverse of A, overwriting the input factor U or L.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

Related Information

For this routine in other precisions, please see *cpptri*, *dpptri* and *zpptri*. It also exists with a native C interface as *LAPACKE_spptri*.

4.4.37 ssptri

ssptri computes the inverse of a real symmetric indefinite matrix A in packed storage using the factorization A = U*D*U^T or A = L*D*L^T computed by SSPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssptri(UPLO, N, AP, IPIV, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssptri_(const char *uplo, const armpl_int_t *n, float *ap,
             const armpl_int_t *ipiv, float *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of inv(A) is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = inv(A)(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = inv(A)(i,j) for j<=i<=n.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSPTRF.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csptri*, *dsptri* and *zsptri*. It also exists with a native C interface as *LAPACKE_ssptri*.

4.4.38 ssytri

ssytri computes the inverse of a real symmetric indefinite matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by SSYTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytri(UPLO, N, A, LDA, IPIV, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssytri_(const char *uplo, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, const armpl_int_t *ipiv, float *work,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSYTRF.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csytri*, *dsytri* and *zsytri*. It also exists with a native C interface as *LAPACKE_ssytri*.

4.4.39 ssytri2

`ssytri2` computes the inverse of a REAL symmetric indefinite matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by SSYTRF. `ssytri2` sets the LEADING DIMENSION of the workspace before calling ‘‘ssytri2‘‘X that actually computes the inverse.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytri2(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssytri2_(const char *uplo, const armpl_int_t *n, float *a,
              const armpl_int_t *lda, const armpl_int_t *ipiv, float *work,
              const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = ‘U’: Upper triangular, form is A = U*D*U^T ; = ‘L’: Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the NB diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = ‘U’, the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = ‘L’ the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the NB structure of D as determined by SSYTRF.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N+NB+1)*(NB+3) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. WORK is size >= (N+NB+1)*(NB+3) If LDWORK = -1, then a workspace query is assumed; the routine calculates: - the optimal size of the WORK array, returns this value as the first entry of the WORK array, - and no error message related to LDWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csytri2*, *dsytri2* and *zsytri2*. It also exists with a native C interface as *LAPACKE_ssytri2*.

4.4.40 ssytri2x

SSYTRI2X computes the inverse of a real symmetric indefinite matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by SSYTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytri2x(UPLO, N, A, LDA, IPIV, WORK, NB, INFO)
```

C specification:

```
#include "armpl.h"

void ssytri2x_(const char *uplo, const armpl_int_t *n, float *a,
               const armpl_int_t *lda, const armpl_int_t *ipiv, float *work,
               const armpl_int_t *nb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the NNB diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the NNB structure of D as determined by SSYTRF.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N+NB+1,NB+3) .

NB Input parameter.

NB is INTEGER

Block size

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csytri2x*, *dsytri2x* and *zsytri2x*. It also exists with a native C interface as *LAPACKE_ssytri2x*.

4.4.41 ssytri_3

SSYTRI_3 computes the inverse of a real symmetric indefinite matrix A using the factorization computed by SSYTRF_RK or SSYTRF_BK:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

SSYTRI_3 sets the leading dimension of the workspace before calling SSYTRI_3X that actually computes the inverse. This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytri_3(UPLO, N, A, LDA, E, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssytri_3_(const char *uplo, const armpl_int_t *n, float *a,
               const armpl_int_t *lda, const float *e,
               const armpl_int_t *ipiv, float *work, const armpl_int_t *lwork,
               armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, diagonal of the block diagonal matrix D and factors U or L as computed by SSYTRF_RK and SSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, if INFO = 0, the symmetric inverse of the original matrix. If UPLO = 'U': the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; If UPLO = 'L': the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is REAL

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSYTRF_RK or SSYTRF_BK.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N+NB+1)*(NB+3).. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= (N+NB+1)*(NB+3).

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csytri_3*, *dsytri_3* and *zsytri_3*. It also exists with a native C interface as *LAPACKE_ssytri_3*.

4.4.42 ssytri_rook

SSYTRI_ROOK computes the inverse of a real symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by SSYTRF_ROOK.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytri_rook(UPLO, N, A, LDA, IPIV, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssytri_rook_(const char *uplo, const armpl_int_t *n, float *a,
                  const armpl_int_t *lda, const armpl_int_t *ipiv,
                  float *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF_ROOK.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSYTRF_ROOK.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csytri_rook*, *dsytri_rook* and *zsytri_rook*.

4.4.43 stftri

stftri computes the inverse of a triangular matrix A stored in RFP format.

This is a Level 3 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine stftri(TRANSR, UPLO, DIAG, N, A, INFO)
```

C specification:

```
#include "armpl.h"

void stftri_(const char *transr, const char *uplo, const char *diag,
             const armpl_int_t *n, float *a, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal TRANSR of RFP A is stored; = 'T': The Transpose TRANSR of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (NT);. NT=N*(N+1)/2. On entry, the triangular factor of a Hermitian Positive Definite matrix A in RFP format. RFP format is described by TRANSR, UPLO, and N as follows: If TRANSR = 'N' then RFP A is (0:N,0:k-1) when N is even; k=N/2. RFP A is (0:N-1,0:k) when N is odd; k=N/2. IF TRANSR = 'T' then RFP is the transpose of RFP A as defined when TRANSR = 'N'. The contents of RFP A are defined by UPLO as follows: If UPLO = 'U' the RFP A contains the nt elements of upper packed A; If UPLO = 'L' the RFP A contains the nt elements of lower packed A. The LDA of RFP A is (N+1)/2 when TRANSR = 'T'. When TRANSR is 'N' the LDA is N+1 when N is even and N is odd. See the Note below for more details.

On exit, the (triangular) inverse of the original matrix, in the same storage format.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, A(i,i) is exactly zero. The triangular matrix is singular and its inverse can not be computed.

Related Information

For this routine in other precisions, please see *ctftri*, *dtftri* and *ztftri*. It also exists with a native C interface as *LAPACKE_stftri*.

4.4.44 stptri

stptri computes the inverse of a real upper or lower triangular matrix A stored in packed format.

Syntax

Fortran specification:

```
use armpl_library

subroutine stptri(UPLO, DIAG, N, AP, INFO)
```

C specification:

```
#include "armpl.h"

void stptri_(const char *uplo, const char *diag, const armpl_int_t *n,
             float *ap, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangular matrix A, stored columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*((2*n-j)/2) = A(i,j) for j<=i<=n. See below for further details. On exit, the (triangular) inverse of the original matrix, in the same packed storage format.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, A(i,i) is exactly zero. The triangular matrix is singular and its inverse can not be computed.

Related Information

For this routine in other precisions, please see *ctptri*, *dtptri* and *ztptri*. It also exists with a native C interface as *LAPACKE_stptri*.

4.4.45 strtri

strtri computes the inverse of a real upper or lower triangular matrix A.

This is the Level 3 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine strtri(UPLO, DIAG, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void strtri_(const char *uplo, const char *diag, const armpl_int_t *n,
             float *a, const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1. On exit, the (triangular) inverse of the original matrix, in the same storage format.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, A(i,i) is exactly zero. The triangular matrix is singular and its inverse can not be computed.

Related Information

For this routine in other precisions, please see *ctrtri*, *dtrtri* and *ztrtri*. It also exists with a native C interface as *LAPACKE_strtri*.

4.4.46 zgetri

zgetri computes the inverse of a matrix using the LU factorization computed by ZGETRF.

This method inverts U and then computes inv(A) by solving the system inv(A)*L = inv(U) for inv(A).

Syntax

Fortran specification:

```
use armpl_library

subroutine zgetri(N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgetri_(const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, const armpl_int_t *ipiv,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the factors L and U from the factorization A = P*L*U as computed by ZGETRF. On exit, if INFO = 0, the inverse of the original matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from ZGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO=0, then WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). For optimal performance LWORK >= N*NB, where NB is the optimal blocksize returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *cgetri*, *dgetri* and *sgetri*. It also exists with a native C interface as *LAPACKE_zgetri*.

4.4.47 zhetri

`zhetri` computes the inverse of a complex Hermitian indefinite matrix A using the factorization A = U*D*U^H or A = L*D*L^H computed by ZHETRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetri(UPLO, N, A, LDA, IPIV, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhetri_(const char *uplo, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, const armpl_int_t *ipiv,
             armpl_doublecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHETRF.

On exit, if INFO = 0, the (Hermitian) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZHETRF.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *chetri*. It also exists with a native C interface as *LAPACKE_zhetri*.

4.4.48 zhetri2

zhetri2 computes the inverse of a COMPLEX*16 hermitian indefinite matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by ZHETRF. zhetri2 set the LEADING DIMENSION of the workspace before calling ‘‘zhetri2‘‘X that actually computes the inverse.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetri2(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhetri2_(const char *uplo, const armpl_int_t *n,
              armpl_doublecomplex_t *a, const armpl_int_t *lda,
              const armpl_int_t *ipiv, armpl_doublecomplex_t *work,
              const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = ‘U’: Upper triangular, form is A = U*D*U^T ; = ‘L’: Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the NB diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHETRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the NB structure of D as determined by ZHETRF.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N+NB+1)*(NB+3) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. WORK is size >= (N+NB+1)*(NB+3) If LWORK = -1, then a workspace query is assumed; the routine calculates: - the optimal size of the WORK array, returns this value as the first entry of the WORK array, - and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *chetri2*. It also exists with a native C interface as *LAPACKE_zhetri2*.

4.4.49 zhetri2x

ZHETRI2X computes the inverse of a COMPLEX*16 Hermitian indefinite matrix A using the factorization A = U*D*U^H or A = L*D*L^H computed by ZHETRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetri2x(UPLO, N, A, LDA, IPIV, WORK, NB, INFO)
```

C specification:

```
#include "armpl.h"

void zhetri2x_(const char *uplo, const armpl_int_t *n,
               armpl_doublecomplex_t *a, const armpl_int_t *lda,
               const armpl_int_t *ipiv, armpl_doublecomplex_t *work,
               const armpl_int_t *nb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the NNB diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHETRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the NNB structure of D as determined by ZHETRF.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N+NB+1,NB+3) .

NB Input parameter.

NB is INTEGER

Block size

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *chetri2x*. It also exists with a native C interface as *LAPACKE_zhetri2x*.

4.4.50 zhetri_3

ZHETRI_3 computes the inverse of a complex Hermitian indefinite matrix A using the factorization computed by ZHETRF_RK or ZHETRF_BK:

```
A = P*U*D*(U**H)*(P**T) or A = P*L*D*(L**H)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^H (or L^H) is the conjugate of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ZHETRI_3 sets the leading dimension of the workspace before calling ZHETRI_3X that actually computes the inverse. This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetri_3(UPLO, N, A, LDA, E, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhetri_3_(const char *uplo, const armpl_int_t *n,
               armpl_doublecomplex_t *a, const armpl_int_t *lda,
               const armpl_doublecomplex_t *e, const armpl_int_t *ipiv,
               armpl_doublecomplex_t *work, const armpl_int_t *lwork,
               armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, diagonal of the block diagonal matrix D and factors U or L as computed by ZHETRF_RK and ZHETRF_BK: a) ONLY diagonal elements of the Hermitian block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, if INFO = 0, the Hermitian inverse of the original matrix. If UPLO = 'U': the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; If UPLO = 'L': the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is COMPLEX*16

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZHETRF_RK or ZHETRF_BK.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N+NB+1)*(NB+3).. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= (N+NB+1)*(NB+3).

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *chetri_3*. It also exists with a native C interface as *LAPACKE_zhetri_3*.

4.4.51 zhetri_rook

ZHETRI_ROOK computes the inverse of a complex Hermitian indefinite matrix A using the factorization A = $U*D*U^H$ or A = $L*D*L^H$ computed by ZHETRF_ROOK.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetri_rook(UPLO, N, A, LDA, IPIV, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhetri_rook_(const char *uplo, const armpl_int_t *n,
                  armpl_doublecomplex_t *a, const armpl_int_t *lda,
                  const armpl_int_t *ipiv, armpl_doublecomplex_t *work,
                  armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHETRF_ROOK.

On exit, if INFO = 0, the (Hermitian) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZHETRF_ROOK.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *chetri_rook*.

4.4.52 zhptri

zhptri computes the inverse of a complex Hermitian indefinite matrix A in packed storage using the factorization A = U*D*U^H or A = L*D*L^H computed by ZHPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhptri(UPLO, N, AP, IPIV, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhptri_(const char *uplo, const armpl_int_t *n,
             armpl_doublecomplex_t *ap, const armpl_int_t *ipiv,
             armpl_doublecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (Hermitian) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of inv(A) is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = inv(A)(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = inv(A)(i,j) for j<=i<=n.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZHPTRF.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *chptri*. It also exists with a native C interface as *LAPACKE_zhptri*.

4.4.53 zpftri

zpftri computes the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization A = U^H *U or A = L*L^H computed by ZPFTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpftri(TRANSR, UPLO, N, A, INFO)
```

C specification:

```
#include "armpl.h"

void zpftri_(const char *transr, const char *uplo, const armpl_int_t *n,
             armpl_doublecomplex_t *a, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal TRANSR of RFP A is stored; = 'C': The Conjugate-transpose TRANSR of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (N*(N+1)/2);. On entry, the Hermitian matrix A in RFP format. RFP format is described by TRANSR, UPLO, and N as follows: If TRANSR = 'N' then RFP A is (0:N,0:k-1) when N is even; k=N/2. RFP A is (0:N-1,0:k) when N is odd; k=N/2. IF TRANSR = 'C' then RFP is the Conjugate-transpose of RFP A as defined when TRANSR = 'N'. The contents of RFP A are defined by UPLO as follows: If UPLO = 'U' the RFP A contains the nt elements of upper packed A. If UPLO = 'L' the RFP A contains the elements of lower packed A. The LDA of RFP A is (N+1)/2 when TRANSR = 'C'. When TRANSR is 'N' the LDA is N+1 when N is even and N is odd. See the Note below for more details.

On exit, the Hermitian inverse of the original matrix, in the same storage format.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

Related Information

For this routine in other precisions, please see *cpftri*, *dpftri* and *spftri*. It also exists with a native C interface as *LAPACKE_zpftri*.

4.4.54 zpotri

zpotri computes the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization A = U^H *U or A = L*L^H computed by ZPOTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpotri(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void zpotri_(const char *uplo, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , as computed by ZPOTRF. On exit, the upper or lower triangle of the (Hermitian) inverse of A, overwriting the input factor U or L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

Related Information

For this routine in other precisions, please see *cpotri*, *dpotri* and *spotri*. It also exists with a native C interface as *LAPACKE_zpotri*.

4.4.55 zpptri

zpptri computes the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^H * U$ or $A = L * L^H$ computed by ZPPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpptri(UPLO, N, AP, INFO)
```

C specification:

```
#include "armpl.h"

void zpptri_(const char *uplo, const armpl_int_t *n,
             armpl_doublecomplex_t *ap, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular factor is stored in AP; = 'L': Lower triangular factor is stored in AP.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). On entry, the triangular factor U or L from the Cholesky factorization $A = U^H * U$ or $A = L * L^H$, packed columnwise as a linear array. The j-th column of U or L is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = U(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = L(i,j) for j<=i<=n.

On exit, the upper or lower triangle of the (Hermitian) inverse of A, overwriting the input factor U or L.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

Related Information

For this routine in other precisions, please see *cpptri*, *dpptri* and *spptri*. It also exists with a native C interface as *LAPACKE_zpptri*.

4.4.56 zsptri

zsptri computes the inverse of a complex symmetric indefinite matrix A in packed storage using the factorization $A = U * D * U^T$ or $A = L * D * L^T$ computed by ZSPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsptri(UPLO, N, AP, IPIV, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsptri_(const char *uplo, const armpl_int_t *n,
             armpl_doublecomplex_t *ap, const armpl_int_t *ipiv,
             armpl_doublecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of inv(A) is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = inv(A)(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = inv(A)(i,j) for j<=i<=n.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSPTRF.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csptri*, *dsptri* and *ssptri*. It also exists with a native C interface as *LAPACKE_zsptri*.

4.4.57 zsytri

`zsytri` computes the inverse of a complex symmetric indefinite matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by ZSYTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytri(UPLO, N, A, LDA, IPIV, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsytri_(const char *uplo, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, const armpl_int_t *ipiv,
             armpl_doublecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSYTRF.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csytri*, *dsytri* and *ssytri*. It also exists with a native C interface as *LAPACKE_zsytri*.

4.4.58 zsytri2

zsytri2 computes the inverse of a COMPLEX*16 symmetric indefinite matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by ZSYTRF. zsytri2 sets the LEADING DIMENSION of the workspace before calling ‘‘zsytri2‘‘X that actually computes the inverse.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytri2(UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsytri2_(const char *uplo, const armpl_int_t *n,
              armpl_doublecomplex_t *a, const armpl_int_t *lda,
              const armpl_int_t *ipiv, armpl_doublecomplex_t *work,
              const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = ‘U’: Upper triangular, form is A = U*D*U^T ; = ‘L’: Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the NB diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = ‘U’, the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = ‘L’ the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the NB structure of D as determined by ZSYTRF.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N+NB+1)*(NB+3) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. WORK is size >= (N+NB+1)*(NB+3) If LDWORK = -1, then a workspace query is assumed; the routine calculates: - the optimal size of the WORK array, returns this value as the first entry of the WORK array, - and no error message related to LDWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csytri2*, *dsytri2* and *ssytri2*. It also exists with a native C interface as *LAPACKE_zsytri2*.

4.4.59 zsytri2x

ZSYTRI2X computes the inverse of a complex symmetric indefinite matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by ZSYTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytri2x(UPLO, N, A, LDA, IPIV, WORK, NB, INFO)
```

C specification:

```
#include "armpl.h"

void zsytri2x_(const char *uplo, const armpl_int_t *n,
               armpl_doublecomplex_t *a, const armpl_int_t *lda,
               const armpl_int_t *ipiv, armpl_doublecomplex_t *work,
               const armpl_int_t *nb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the NNB diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the NNB structure of D as determined by ZSYTRF.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N+NB+1,NB+3) .

NB Input parameter.

NB is INTEGER

Block size

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csytri2x*, *dsytri2x* and *ssytri2x*. It also exists with a native C interface as *LAPACKE_zsytri2x*.

4.4.60 zsytri_3

ZSYTRI_3 computes the inverse of a complex symmetric indefinite matrix A using the factorization computed by ZSYTRF_RK or ZSYTRF_BK:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ZSYTRI_3 sets the leading dimension of the workspace before calling ZSYTRI_3X that actually computes the inverse. This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytri_3(UPLO, N, A, LDA, E, IPIV, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsytri_3_(const char *uplo, const armpl_int_t *n,
               armpl_doublecomplex_t *a, const armpl_int_t *lda,
               const armpl_doublecomplex_t *e, const armpl_int_t *ipiv,
               armpl_doublecomplex_t *work, const armpl_int_t *lwork,
               armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, diagonal of the block diagonal matrix D and factors U or L as computed by ZSYTRF_RK and ZSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, if INFO = 0, the symmetric inverse of the original matrix. If UPLO = 'U': the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; If UPLO = 'L': the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is COMPLEX*16

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSYTRF_RK or ZSYTRF_BK.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N+NB+1)*(NB+3).. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= (N+NB+1)*(NB+3).

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csytri_3*, *dsytri_3* and *ssytri_3*. It also exists with a native C interface as *LAPACKE_zsytri_3*.

4.4.61 zsytri_rook

ZSYTRI_ROOK computes the inverse of a complex symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by ZSYTRF_ROOK.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytri_rook(UPLO, N, A, LDA, IPIV, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsytri_rook_(const char *uplo, const armpl_int_t *n,
                  armpl_doublecomplex_t *a, const armpl_int_t *lda,
                  const armpl_int_t *ipiv, armpl_doublecomplex_t *work,
                  armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSYTRF_ROOK.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSYTRF_ROOK.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csytri_rook*, *dsytri_rook* and *ssytri_rook*.

4.4.62 ztftri

ztftri computes the inverse of a triangular matrix A stored in RFP format.

This is a Level 3 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztftri(TRANSR, UPLO, DIAG, N, A, INFO)
```

C specification:

```
#include "armpl.h"

void ztftri_(const char *transr, const char *uplo, const char *diag,
             const armpl_int_t *n, armpl_doublecomplex_t *a,
             armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal TRANSR of RFP A is stored; = 'C': The Conjugate-transpose TRANSR of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (N*(N+1)/2);. On entry, the triangular matrix A in RFP format. RFP format is described by TRANSR, UPLO, and N as follows: If TRANSR = 'N' then RFP A is (0:N,0:k-1) when N is even; k=N/2. RFP A is (0:N-1,0:k) when N is odd; k=N/2. IF TRANSR = 'C' then RFP is the Conjugate-transpose of RFP A as defined when TRANSR = 'N'. The contents of RFP A are defined by UPLO as follows: If UPLO = 'U' the RFP A contains the nt elements of upper packed A; If UPLO = 'L' the RFP A contains the nt elements of lower packed A. The LDA of RFP A is (N+1)/2 when TRANSR = 'C'. When TRANSR is 'N' the LDA is N+1 when N is even and N is odd. See the Note below for more details.

On exit, the (triangular) inverse of the original matrix, in the same storage format.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, A(i,i) is exactly zero. The triangular matrix is singular and its inverse can not be computed.

Related Information

For this routine in other precisions, please see *ctftri*, *dtftri* and *stftri*. It also exists with a native C interface as *LAPACKE_ztftri*.

4.4.63 ztptri

`ztptri` computes the inverse of a complex upper or lower triangular matrix A stored in packed format.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztptri(UPLO, DIAG, N, AP, INFO)
```

C specification:

```
#include "armpl.h"

void ztptri_(const char *uplo, const char *diag, const armpl_int_t *n,
             armpl_doublecomplex_t *ap, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

`DIAG` is `CHARACTER*1`

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0.

AP Input and output parameter.

`AP` is `COMPLEX*16`

`AP` is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangular matrix A, stored columnwise in a linear array. The j-th column of A is stored in the array `AP` as follows: if `UPLO` = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if `UPLO` = 'L', AP(i + (j-1)*((2*n-j)/2) = A(i,j) for j<=i<=n. See below for further details. On exit, the (triangular) inverse of the original matrix, in the same packed storage format.

INFO Output parameter.

`INFO` is `INTEGER`

= 0: successful exit < 0: if `INFO` = -i, the i-th argument had an illegal value > 0: if `INFO` = i, A(i,i) is exactly zero. The triangular matrix is singular and its inverse can not be computed.

Related Information

For this routine in other precisions, please see *ctptri*, *dtptri* and *stptri*. It also exists with a native C interface as *LAPACKE_ztptri*.

4.4.64 ztrtri

`ztrtri` computes the inverse of a complex upper or lower triangular matrix A.

This is the Level 3 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztrtri(UPLO, DIAG, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void ztrtri_(const char *uplo, const char *diag, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1. On exit, the (triangular) inverse of the original matrix, in the same storage format.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, A(i,i) is exactly zero. The triangular matrix is singular and its inverse can not be computed.

Related Information

For this routine in other precisions, please see *ctrtri*, *dtrtri* and *strtri*. It also exists with a native C interface as *LAPACKE_ztrtri*.

4.5 LAPACK least squares routines

4.5.1 cgels

`cgels` solves overdetermined or underdetermined complex linear systems involving an M-by-N matrix A, or its conjugate-transpose, using a QR or LQ factorization of A. It is assumed that A has full rank.

The following options are provided:

1. If TRANS = '`N`' and m >= n: find the least squares solution of

```
an overdetermined system, i.e., solve the least squares problem
            minimize || B - A*X ||.
```

2. If TRANS = '`N`' and m < n: find the minimum norm solution of

```
an underdetermined system A * X = B.
```

3. If TRANS = '`C`' and m >= n: find the minimum norm solution of

```
an underdetermined system A**H * X = B.
```

4. If TRANS = '`C`' and m < n: find the least squares solution of

```
an overdetermined system, i.e., solve the least squares problem
            minimize || B - A**H * X ||.
```

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgels(TRANS, M, N, NRHS, A, LDA, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgels_(const char *trans, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_int_t *nrhs, armpl_singlecomplex_t *a,
            const armpl_int_t *lda, armpl_singlecomplex_t *b,
            const armpl_int_t *ldb, armpl_singlecomplex_t *work,
            const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

`TRANS` Input parameter.

`TRANS` is `CHARACTER*1`

= 'N': the linear system involves A; = 'C': the linear system involves A^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. if M >= N, A is overwritten by details of its QR factorization as returned by CGEQRF; if M < N, A is overwritten by details of its LQ factorization as returned by CGELQF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the matrix B of right hand side vectors, stored columnwise; B is M-by-NRHS if TRANS = 'N', or N-by-NRHS if TRANS = 'C'. On exit, if INFO = 0, B is overwritten by the solution vectors, stored columnwise: if TRANS = 'N' and m >= n, rows 1 to n of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of the modulus of elements N+1 to M in that column; if TRANS = 'N' and m < n, rows 1 to N of B contain the minimum norm solution vectors; if TRANS = 'C' and m >= n, rows 1 to M of B contain the minimum norm solution vectors; if TRANS = 'C' and m < n, rows 1 to M of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of the modulus of elements M+1 to N in that column.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= MAX(1, M, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, MN + max(MN, NRHS)). For optimal performance, LWORK >= max(1, MN + max(MN, NRHS)*NB). where MN = min(M, N) and NB is the optimum block size.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of the triangular factor of A is zero, so that A does not have full rank; the least squares solution could not be computed.

Related Information

For this routine in other precisions, please see *dgels*, *sgels* and *zgels*. It also exists with a native C interface as *LAPACKE_cgels*.

4.5.2 cgelsd

cgelsd computes the minimum-norm solution to a real linear least squares problem:

```
minimize 2-norm(| b - A*x |)
```

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The problem is solved in three steps: (1) Reduce the coefficient matrix A to bidiagonal form with

```
Householder transformations, reducing the original problem
into a "bidiagonal least squares problem" (BLS)
```

(2) Solve the BLS using a divide and conquer approach.

(3) Apply back all the Householder transformations to solve

```
the original least squares problem.
```

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgelsd(M, N, NRHS, A, LDA, B, LDB, S, RCOND, RANK, WORK, LWORK,
                  RWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A has been destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If m >= n and RANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of the modulus of elements n+1:m in that column.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M, N).

S Output parameter.

S is REAL

S is an array, dimension (min(M, N)). The singular values of A in decreasing order. The condition number of A in the 2-norm = S(1)/S(min(m,n)).

RCOND Input parameter.

RCOND is REAL

RCOND is used to determine the effective rank of A. Singular values S(i) <= RCOND*S(1) are treated as zero. If RCOND < 0, machine precision is used instead.

RANK Output parameter.

RANK is INTEGER

The effective rank of A, i.e., the number of singular values which are greater than RCOND*S(1).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK must be at least 1. The exact minimum amount of workspace needed depends on M, N and NRHS. As long as LWORK is at least 2 * N + N * NRHS if M is greater than or equal to N or 2 * M + M * NRHS if M is less than N, the code will execute correctly. For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the array WORK and the minimum sizes of the arrays RWORK and IWORK, and returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (MAX(1,LRWORK)). LRWORK >= 10* N + 2*N*SMLSIZ + 8*N*NLVL + 3*SMLSIZ* NRHS + MAX((SMLSIZ+1)**2, N*(1+NRHS) + 2* NRHS) if M is greater than or equal to N or 10* M + 2*M*SMLSIZ + 8*M*NLVL + 3*SMLSIZ* NRHS + MAX((SMLSIZ+1)**2, N*(1+NRHS) + 2* NRHS) if M is less than N, the code will execute correctly. SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25), and NLVL = MAX(0, INT(LOG_2(MIN(M,N)/(SMLSIZ+1))) + 1) On exit, if INFO = 0, RWORK(1) returns the minimum LRWORK.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1,LIWORK))

LIWORK >= max(1, 3*MINMN*NLVL + 11*MINMN), where MINMN = MIN(M,N). On exit, if INFO = 0, IWORK(1) returns the minimum LIWORK.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *dgelsd*, *sgelsd* and *zgelsd*. It also exists with a native C interface as *LAPACKE_cgelsd*.

4.5.3 cgelss

cgelss computes the minimum norm solution to a complex linear least squares problem:

Minimize 2-norm(| b - A*x |).

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgelss(M, N, NRHS, A, LDA, B, LDB, S, RCOND, RANK, WORK, LWORK,
                  RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgelss_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *nrhs, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, float *s, const float *rcond,
             armpl_int_t *rank, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, float *rwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the first min(m,n) rows of A are overwritten with its right singular vectors, stored rowwise.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If m >= n and RANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of the modulus of elements n+1:m in that column.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M, N).

S Output parameter.

S is REAL

S is an array, dimension (min(M, N)). The singular values of A in decreasing order. The condition number of A in the 2-norm = S(1)/S(min(m,n)).

RCOND Input parameter.

RCOND is REAL

RCOND is used to determine the effective rank of A. Singular values S(i) <= RCOND*S(1) are treated as zero. If RCOND < 0, machine precision is used instead.

RANK Output parameter.

RANK is INTEGER

The effective rank of A, i.e., the number of singular values which are greater than RCOND*S(1).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 1, and also: LWORK >= 2*min(M, N) + max(M, N, NRHS) For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (5*min(M, N)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *dgelss*, *sgelss* and *zgelss*. It also exists with a native C interface as *LAPACKE_cgelss*.

4.5.4 cgelsy

cgelsy computes the minimum-norm solution to a complex linear least squares problem:

```
minimize || A * X - B ||
```

using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting:

```
A * P = Q * [ R11 R12 ]
            [  0  R22 ]
```

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by unitary transformations from the right, arriving at the complete orthogonal factorization:

```
A * P = Q * [ T11 0 ] * Z
            [  0  0 ]
```

The minimum-norm solution is then

```
X = P * Z**H [ inv(T11)*Q1**H*B ]
             [         0        ]
```

where Q1 consists of the first RANK columns of Q.

This routine is basically identical to the original xGELSX except three differences:

```
o The permutation of matrix B (the right hand side) is faster and
  more simple.
o The call to the subroutine xGEQPF has been substituted by the
  the call to the subroutine xGEQP3. This subroutine is a Blas-3
  version of the QR factorization with column pivoting.
o Matrix B (the right hand side) is updated with Blas-3.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cgelsy(M, N, NRHS, A, LDA, B, LDB, JPVT, RCOND, RANK, WORK, LWORK,
                  RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgelsy_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *nrhs, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *jpvt, const float *rcond,
             armpl_int_t *rank, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, float *rwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M, N).

JPVT Input and output parameter.

JPVT is INTEGER array, dimension (N)

On entry, if JPVT(i) .ne. 0, the i-th column of A is permuted to the front of AP, otherwise column i is a free column. On exit, if JPVT(i) = k, then the i-th column of A*P was the k-th column of A.

RCOND Input parameter.

RCOND is REAL

RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number < 1/RCOND.

RANK Output parameter.

RANK is INTEGER

The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. The unblocked strategy requires that: LWORK >= MN + MAX(2*MN, N+1, MN+NRHS) where MN = min(M, N). The block algorithm requires that: LWORK >= MN + MAX(2*MN, NB*(N+1), MN+MN*NB, MN+NB* NRHS) where NB is an upper bound on the blocksize returned by ILAENV for the routines CGEQP3, CTZRZF, CTZRQF, CUNMQR, and CUNMRZ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgelsy*, *sgelsy* and *zgelsy*. It also exists with a native C interface as *LAPACKE_cgelsy*.

4.5.5 cggglm

cggglm solves a general Gauss-Markov linear model (GLM) problem:

```
minimize || y ||_2   subject to   d = A*x + B*y
   x
```

where A is an N-by-M matrix, B is an N-by-P matrix, and d is a given N-vector. It is assumed that M <= N <= M+P, and

```
rank(A) = M    and    rank( A B ) = N.
```

Under these assumptions, the constrained equation is always consistent, and there is a unique solution x and a minimal 2-norm solution y, which is obtained using a generalized QR factorization of the matrices (A, B) given by

```
A = Q*(R),    B = Q*T*Z.
      (0)
```

In particular, if matrix B is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

```
minimize || inv(B)*(d-A*x) ||_2
   x
```

where inv(B) denotes the inverse of B.

Syntax

Fortran specification:

```
use armpl_library

subroutine cggglm(N, M, P, A, LDA, B, LDB, D, X, Y, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cggglm_(const armpl_int_t *n, const armpl_int_t *m, const armpl_int_t *p,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_singlecomplex_t *d, armpl_singlecomplex_t *x,
             armpl_singlecomplex_t *y, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of rows of the matrices A and B. N >= 0.

M Input parameter.

M is INTEGER

The number of columns of the matrix A. 0 <= M <= N.

P Input parameter.

P is INTEGER

The number of columns of the matrix B. P >= N-M.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, M). On entry, the N-by-M matrix A. On exit, the upper triangular part of the array A contains the M-by-M upper triangular matrix R.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, P). On entry, the N-by-P matrix B. On exit, if N <= P, the upper triangle of the subarray B(1:N,P-N+1:P) contains the N-by-N upper triangular matrix T; if N > P, the elements on and above the (N-P)th subdiagonal contain the N-by-P upper trapezoidal matrix T.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

D Input and output parameter.

D is COMPLEX

D is an array, dimension (N). On entry, D is the left hand side of the GLM equation. On exit, D is destroyed.

X Output parameter.

X is COMPLEX

X is an array, dimension (M) .

Y Output parameter.

Y is COMPLEX

Y is an array, dimension (P). On exit, X and Y are the solutions of the GLM problem.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,N+M+P). For optimum performance, LWORK >= M+min(N, P)+max(N, P)*NB, where NB is an upper bound for the optimal blocksizes for CGEQRF, CGERQF, CUNMQR and CUNMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. = 1: the upper triangular factor R associated with A in the generalized QR factorization of the pair (A, B) is singular, so that rank(A) < M; the least squares solution could not be computed. = 2: the bottom (N-M) by (N-M) part of the upper trapezoidal factor T associated with B in the generalized QR factorization of the pair (A, B) is singular, so that rank(A B) < N; the least squares solution could not be computed.

Related Information

For this routine in other precisions, please see *dggglm*, *sggglm* and *zggglm*. It also exists with a native C interface as *LAPACKE_cggglm*.

4.5.6 cgglse

cgglse solves the linear equality-constrained least squares (LSE) problem:

```
minimize || c - A*x ||_2   subject to   B*x = d
```

where A is an M-by-N matrix, B is a P-by-N matrix, c is a given M-vector, and d is a given P-vector. It is assumed that P <= N <= M+P, and

```
rank(B) = P and  rank( (A) ) = N.
                      ( (B) )
```

These conditions ensure that the LSE problem has a unique solution, which is obtained using a generalized RQ factorization of the matrices (B, A) given by

```
B = (0 R)*Q,    A = Z*T*Q.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cgglse(M, N, P, A, LDA, B, LDB, C, D, X, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgglse_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *p,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_singlecomplex_t *c, armpl_singlecomplex_t *d,
```

(continues on next page)

(continued from previous page)

```
            armpl_singlecomplex_t *x, armpl_singlecomplex_t *work,
            const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. 0 <= P <= N <= M+P.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix T.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, the upper triangle of the subarray B(1:P,N-P+1:N) contains the P-by-P upper triangular matrix R.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

C Input and output parameter.

C is COMPLEX

C is an array, dimension (M). On entry, C contains the right hand side vector for the least squares part of the LSE problem. On exit, the residual sum of squares for the solution is given by the sum of squares of elements N-P+1 to M of vector C.

D Input and output parameter.

D is COMPLEX

D is an array, dimension (P). On entry, D contains the right hand side vector for the constrained equation. On exit, D is destroyed.

X Output parameter.

X is COMPLEX

X is an array, dimension (N). On exit, X is the solution of the LSE problem.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,M+N+P). For optimum performance LWORK >= P+min(M, N)+max(M, N)*NB, where NB is an upper bound for the optimal blocksizes for CGEQRF, CGERQF, CUNMQR and CUNMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. = 1: the upper triangular factor R associated with B in the generalized RQ factorization of the pair (B, A) is singular, so that rank(B) < P; the least squares solution could not be computed. = 2: the (N-P) by (N-P) part of the upper trapezoidal factor T associated with A in the generalized RQ factorization of the pair (B, A) is singular, so that rank((A)) < N; the least squares solution could not ((B)) be computed.

Related Information

For this routine in other precisions, please see *dgglse*, *sgglse* and *zgglse*. It also exists with a native C interface as *LAPACKE_cgglse*.

4.5.7 dgels

dgels solves overdetermined or underdetermined real linear systems involving an M-by-N matrix A, or its transpose, using a QR or LQ factorization of A. It is assumed that A has full rank.

The following options are provided:

1. If TRANS = 'N' and m >= n: find the least squares solution of

```
an overdetermined system, i.e., solve the least squares problem
            minimize || B - A*X ||.
```

2. If TRANS = 'N' and m < n: find the minimum norm solution of

```
an underdetermined system A * X = B.
```

3. If TRANS = 'T' and m >= n: find the minimum norm solution of

```
an underdetermined system A**T * X = B.
```

4. If TRANS = 'T' and m < n: find the least squares solution of

```
an overdetermined system, i.e., solve the least squares problem
            minimize || B - A**T * X ||.
```

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgels(TRANS, M, N, NRHS, A, LDA, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgels_(const char *trans, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_int_t *nrhs, double *a, const armpl_int_t *lda,
            double *b, const armpl_int_t *ldb, double *work,
            const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': the linear system involves A; = 'T': the linear system involves A^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >=0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if M >= N, A is overwritten by details of its QR factorization as returned by DGEQRF; if M < N, A is overwritten by details of its LQ factorization as returned by DGELQF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the matrix B of right hand side vectors, stored columnwise; B is M-by-NRHS if TRANS = 'N', or N-by-NRHS if TRANS = 'T'. On exit, if INFO = 0, B is overwritten by the solution vectors, stored columnwise: if TRANS = 'N' and m >= n, rows 1 to n of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements N+1 to M in that column; if TRANS = 'N' and m < n, rows 1 to N of B contain the minimum norm solution vectors; if TRANS = 'T' and m >= n, rows 1 to M of B contain the minimum norm solution vectors; if TRANS = 'T' and m < n, rows 1 to M of B contain the least squares solution vectors; the

residual sum of squares for the solution in each column is given by the sum of squares of elements M+1 to N in that column.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= MAX(1, M, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, MN + max(MN, NRHS)). For optimal performance, LWORK >= max(1, MN + max(MN, NRHS)*NB). where MN = min(M, N) and NB is the optimum block size.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of the triangular factor of A is zero, so that A does not have full rank; the least squares solution could not be computed.

Related Information

For this routine in other precisions, please see *cgels*, *sgels* and *zgels*. It also exists with a native C interface as *LAPACKE_dgels*.

4.5.8 dgelsd

dgelsd computes the minimum-norm solution to a real linear least squares problem:

```
minimize 2-norm(| b - A*x |)
```

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The problem is solved in three steps: (1) Reduce the coefficient matrix A to bidiagonal form with

```
Householder transformations, reducing the original problem
into a "bidiagonal least squares problem" (BLS)
```

(2) Solve the BLS using a divide and conquer approach.

(3) Apply back all the Householder transformations to solve

```
the original least squares problem.
```

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgelsd(M, N, NRHS, A, LDA, B, LDB, S, RCOND, RANK, WORK, LWORK,
                  IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgelsd_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *nrhs, const double *a, const armpl_int_t *lda,
             double *b, const armpl_int_t *ldb, double *s,
             const double *rcond, armpl_int_t *rank, double *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A has been destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If m >= n and RANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements n+1:m in that column.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1,max(M, N)).

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (min(M, N)). The singular values of A in decreasing order. The condition number of A in the 2-norm = S(1)/S(min(m,n)).

RCOND Input parameter.

RCOND is DOUBLE PRECISION

RCOND is used to determine the effective rank of A. Singular values S(i) <= RCOND*S(1) are treated as zero. If RCOND < 0, machine precision is used instead.

RANK Output parameter.

RANK is INTEGER

The effective rank of A, i.e., the number of singular values which are greater than RCOND*S(1).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK must be at least 1. The exact minimum amount of workspace needed depends on M, N and NRHS. As long as LWORK is at least 12* N + 2*N*SMLSIZ + 8*N*NLVL + N* NRHS + (SMLSIZ+1)**2, if M is greater than or equal to N or 12* M + 2*M*SMLSIZ + 8*M*NLVL + M* NRHS + (SMLSIZ+1)**2, if M is less than N, the code will execute correctly. SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25), and NLVL = MAX(0, INT(LOG_2(MIN(M,N)/(SMLSIZ+1))) + 1) For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1,LIWORK))

LIWORK >= max(1, 3 * MINMN * NLVL + 11 * MINMN), where MINMN = MIN(M,N). On exit, if INFO = 0, IWORK(1) returns the minimum LIWORK.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *cgelsd*, *sgelsd* and *zgelsd*. It also exists with a native C interface as *LAPACKE_dgelsd*.

4.5.9 dgelss

`dgelss` computes the minimum norm solution to a real linear least squares problem:

Minimize 2-norm(| b - A*x |).

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgelss(M, N, NRHS, A, LDA, B, LDB, S, RCOND, RANK, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dgelss_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *nrhs, double *a, const armpl_int_t *lda,
             double *b, const armpl_int_t *ldb, double *s,
             const double *rcond, armpl_int_t *rank, double *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix `A`. `M` >= 0.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix `A`. `N` >= 0.

NRHS Input parameter.

`NRHS` is `INTEGER`

The number of right hand sides, i.e., the number of columns of the matrices `B` and X. `NRHS` >= 0.

A Input and output parameter.

`A` is `DOUBLE PRECISION`

`A` is an array, dimension (`LDA`, `N`). On entry, the M-by-N matrix `A`. On exit, the first min(m,n) rows of `A` are overwritten with its right singular vectors, stored rowwise.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `M`).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If m >= n and RANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements n+1:m in that column.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1,max(M, N)).

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (min(M, N)). The singular values of A in decreasing order. The condition number of A in the 2-norm = S(1)/S(min(m,n)).

RCOND Input parameter.

RCOND is DOUBLE PRECISION

RCOND is used to determine the effective rank of A. Singular values S(i) <= RCOND*S(1) are treated as zero. If RCOND < 0, machine precision is used instead.

RANK Output parameter.

RANK is INTEGER

The effective rank of A, i.e., the number of singular values which are greater than RCOND*S(1).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 1, and also: LWORK >= 3*min(M, N) + max(2*min(M, N), max(M, N), NRHS) For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *cgelss*, *sgelss* and *zgelss*. It also exists with a native C interface as *LAPACKE_dgelss*.

4.5.10 dgelsy

`dgelsy` computes the minimum-norm solution to a real linear least squares problem:

```
minimize || A * X - B ||
```

using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting:

```
A * P = Q * [ R11 R12 ]
            [  0  R22 ]
```

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by orthogonal transformations from the right, arriving at the complete orthogonal factorization:

```
A * P = Q * [ T11 0 ] * Z
            [  0  0 ]
```

The minimum-norm solution is then

```
X = P * Z**T [ inv(T11)*Q1**T*B ]
             [         0        ]
```

where Q1 consists of the first RANK columns of Q.

This routine is basically identical to the original xGELSX except three differences:

```
o The call to the subroutine xGEQPF has been substituted by the
  the call to the subroutine xGEQP3. This subroutine is a Blas-3
  version of the QR factorization with column pivoting.
o Matrix B (the right hand side) is updated with Blas-3.
o The permutation of matrix B (the right hand side) is faster and
  more simple.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dgelsy(M, N, NRHS, A, LDA, B, LDB, JPVT, RCOND, RANK, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dgelsy_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *nrhs, double *a, const armpl_int_t *lda,
             double *b, const armpl_int_t *ldb, armpl_int_t *jpvt,
             const double *rcond, armpl_int_t *rank, double *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of matrices B and X. NRHS >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M, N).

JPVT Input and output parameter.

JPVT is INTEGER array, dimension (N)

On entry, if JPVT(i) .ne. 0, the i-th column of A is permuted to the front of AP, otherwise column i is a free column. On exit, if JPVT(i) = k, then the i-th column of AP was the k-th column of A.

RCOND Input parameter.

RCOND is DOUBLE PRECISION

RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number < 1/RCOND.

RANK Output parameter.

RANK is INTEGER

The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. The unblocked strategy requires that: LWORK >= MAX(MN+3*N+1, 2*MN+NRHS), where MN = min(M, N). The block algorithm requires that: LWORK >= MAX(MN+2*N+NB*(N+1), 2*MN+NB* NRHS), where NB is an upper bound on the blocksize returned by ILAENV for the routines DGEQP3, DTZRZF, STZRQF, DORMQR, and DORMRZ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: If INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgelsy*, *sgelsy* and *zgelsy*. It also exists with a native C interface as *LAPACKE_dgelsy*.

4.5.11 dggglm

dggglm solves a general Gauss-Markov linear model (GLM) problem:

```
minimize || y ||_2   subject to   d = A*x + B*y
   x
```

where A is an N-by-M matrix, B is an N-by-P matrix, and d is a given N-vector. It is assumed that M <= N <= M+P, and

```
rank(A) = M    and    rank( A B ) = N.
```

Under these assumptions, the constrained equation is always consistent, and there is a unique solution x and a minimal 2-norm solution y, which is obtained using a generalized QR factorization of the matrices (A, B) given by

```
A = Q*(R),   B = Q*T*Z.
      (0)
```

In particular, if matrix B is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

```
minimize || inv(B)*(d-A*x) ||_2
   x
```

where inv(B) denotes the inverse of B.

Syntax

Fortran specification:

```
use armpl_library

subroutine dggglm(N, M, P, A, LDA, B, LDB, D, X, Y, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dggglm_(const armpl_int_t *n, const armpl_int_t *m, const armpl_int_t *p,
             double *a, const armpl_int_t *lda, double *b,
             const armpl_int_t *ldb, double *d, double *x, double *y,
             double *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of rows of the matrices A and B. N >= 0.

M Input parameter.

M is INTEGER

The number of columns of the matrix A. 0 <= M <= N.

P Input parameter.

P is INTEGER

The number of columns of the matrix B. P >= N-M.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, M). On entry, the N-by-M matrix A. On exit, the upper triangular part of the array A contains the M-by-M upper triangular matrix R.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, P). On entry, the N-by-P matrix B. On exit, if N <= P, the upper triangle of the subarray B(1:N,P-N+1:P) contains the N-by-N upper triangular matrix T; if N > P, the elements on and above the (N-P)th subdiagonal contain the N-by-P upper trapezoidal matrix T.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, D is the left hand side of the GLM equation. On exit, D is destroyed.

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (M) .

Y Output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension (P). On exit, X and Y are the solutions of the GLM problem.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,N+M+P). For optimum performance, LWORK >= M+min(N, P)+max(N, P)*NB, where NB is an upper bound for the optimal blocksizes for DGEQRF, SGERQF, DORMQR and SORMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. = 1: the upper triangular factor R associated with A in the generalized QR factorization of the pair (A, B) is singular, so that rank(A) < M; the least squares solution could not be computed. = 2: the bottom (N-M) by (N-M) part of the upper trapezoidal factor T associated with B in the generalized QR factorization of the pair (A, B) is singular, so that rank(A B) < N; the least squares solution could not be computed.

Related Information

For this routine in other precisions, please see *cggglm*, *sggglm* and *zggglm*. It also exists with a native C interface as *LAPACKE_dggglm*.

4.5.12 dgglse

dgglse solves the linear equality-constrained least squares (LSE) problem:

```
minimize || c - A*x ||_2   subject to   B*x = d
```

where A is an M-by-N matrix, B is a P-by-N matrix, c is a given M-vector, and d is a given P-vector. It is assumed that P <= N <= M+P, and

```
rank(B) = P and  rank( (A) ) = N.
                       ( (B) )
```

These conditions ensure that the LSE problem has a unique solution, which is obtained using a generalized RQ factorization of the matrices (B, A) given by

```
B = (0 R)*Q,    A = Z*T*Q.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dgglse(M, N, P, A, LDA, B, LDB, C, D, X, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgglse_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *p,
             double *a, const armpl_int_t *lda, double *b,
             const armpl_int_t *ldb, double *c, double *d, double *x,
             double *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. 0 <= P <= N <= M+P.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix T.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, the upper triangle of the subarray B(1:P,N-P+1:N) contains the P-by-P upper triangular matrix R.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (M). On entry, C contains the right hand side vector for the least squares part of the LSE problem. On exit, the residual sum of squares for the solution is given by the sum of squares of elements N-P+1 to M of vector C.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (P). On entry, D contains the right hand side vector for the constrained equation. On exit, D is destroyed.

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (N). On exit, X is the solution of the LSE problem.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,M+N+P). For optimum performance LWORK >= P+min(M, N)+max(M, N)*NB, where NB is an upper bound for the optimal blocksizes for DGEQRF, SGERQF, DORMQR and SORMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. = 1: the upper triangular factor R associated with B in the generalized RQ factorization of the pair (B, A) is singular, so that rank(B) < P; the least squares solution could not be computed. = 2: the (N-P) by (N-P) part of the upper trapezoidal factor T associated with A in the generalized RQ factorization of the pair (B, A) is singular, so that rank((A)) < N; the least squares solution could not ((B)) be computed.

Related Information

For this routine in other precisions, please see *cgglse*, *sgglse* and *zgglse*. It also exists with a native C interface as *LAPACKE_dgglse*.

4.5.13 sgels

sgels solves overdetermined or underdetermined real linear systems involving an M-by-N matrix A, or its transpose, using a QR or LQ factorization of A. It is assumed that A has full rank.

The following options are provided:

1. If TRANS = 'N' and m >= n: find the least squares solution of

```
an overdetermined system, i.e., solve the least squares problem
            minimize || B - A*X ||.
```

2. If TRANS = 'N' and m < n: find the minimum norm solution of

```
an underdetermined system A * X = B.
```

3. If TRANS = 'T' and m >= n: find the minimum norm solution of

```
an underdetermined system A**T * X = B.
```

4. If TRANS = 'T' and m < n: find the least squares solution of

```
an overdetermined system, i.e., solve the least squares problem
            minimize || B - A**T * X ||.
```

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgels(TRANS, M, N, NRHS, A, LDA, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgels_(const char *trans, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_int_t *nrhs, float *a, const armpl_int_t *lda,
            float *b, const armpl_int_t *ldb, float *work,
            const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': the linear system involves A; = 'T': the linear system involves A^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >=0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if M >= N, A is overwritten by details of its QR factorization as returned by SGEQRF; if M < N, A is overwritten by details of its LQ factorization as returned by SGELQF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the matrix B of right hand side vectors, stored columnwise; B is M-by-NRHS if TRANS = 'N', or N-by-NRHS if TRANS = 'T'. On exit, if INFO = 0, B is overwritten by the solution vectors, stored columnwise: if TRANS = 'N' and m >= n, rows 1 to n of B contain the least

squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements N+1 to M in that column; if TRANS = 'N' and m < n, rows 1 to N of B contain the minimum norm solution vectors; if TRANS = 'T' and m >= n, rows 1 to M of B contain the minimum norm solution vectors; if TRANS = 'T' and m < n, rows 1 to M of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements M+1 to N in that column.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= MAX(1, M, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, MN + max(MN, NRHS)). For optimal performance, LWORK >= max(1, MN + max(MN, NRHS)*NB). where MN = min(M, N) and NB is the optimum block size.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of the triangular factor of A is zero, so that A does not have full rank; the least squares solution could not be computed.

Related Information

For this routine in other precisions, please see *cgels*, *dgels* and *zgels*. It also exists with a native C interface as *LAPACKE_sgels*.

4.5.14 sgelsd

sgelsd computes the minimum-norm solution to a real linear least squares problem:

```
minimize 2-norm(| b - A*x |)
```

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The problem is solved in three steps: (1) Reduce the coefficient matrix A to bidiagonal form with

```
Householder transformations, reducing the original problem
into a "bidiagonal least squares problem" (BLS)
```

(2) Solve the BLS using a divide and conquer approach.

(3) Apply back all the Householder transformations to solve

```
the original least squares problem.
```

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgelsd(M, N, NRHS, A, LDA, B, LDB, S, RCOND, RANK, WORK, LWORK,
                  IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgelsd_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *nrhs, const float *a, const armpl_int_t *lda,
             float *b, const armpl_int_t *ldb, float *s, const float *rcond,
             armpl_int_t *rank, float *work, const armpl_int_t *lwork,
             armpl_int_t *iwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A has been destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If m >= n and RANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements n+1:m in that column.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1,max(M, N)).

S Output parameter.

S is REAL

S is an array, dimension (min(M, N)). The singular values of A in decreasing order. The condition number of A in the 2-norm = S(1)/S(min(m,n)).

RCOND Input parameter.

RCOND is REAL

RCOND is used to determine the effective rank of A. Singular values S(i) <= RCOND*S(1) are treated as zero. If RCOND < 0, machine precision is used instead.

RANK Output parameter.

RANK is INTEGER

The effective rank of A, i.e., the number of singular values which are greater than RCOND*S(1).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK must be at least 1. The exact minimum amount of workspace needed depends on M, N and NRHS. As long as LWORK is at least 12* N + 2*N*SMLSIZ + 8*N*NLVL + N* NRHS + (SMLSIZ+1)**2, if M is greater than or equal to N or 12* M + 2*M*SMLSIZ + 8*M*NLVL + M* NRHS + (SMLSIZ+1)**2, if M is less than N, the code will execute correctly. SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25), and NLVL = MAX(0, INT(LOG_2(MIN(M,N)/(SMLSIZ+1))) + 1) For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the array WORK and the minimum size of the array IWORK, and returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1,LIWORK))

LIWORK >= max(1, 3*MINMN*NLVL + 11*MINMN), where MINMN = MIN(M,N). On exit, if INFO = 0, IWORK(1) returns the minimum LIWORK.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *cgelsd*, *dgelsd* and *zgelsd*. It also exists with a native C interface as *LAPACKE_sgelsd*.

4.5.15 sgelss

`sgelss` computes the minimum norm solution to a real linear least squares problem:

Minimize 2-norm(| b - A*x |).

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgelss(M, N, NRHS, A, LDA, B, LDB, S, RCOND, RANK, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sgelss_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *nrhs, float *a, const armpl_int_t *lda,
             float *b, const armpl_int_t *ldb, float *s, const float *rcond,
             armpl_int_t *rank, float *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the first min(m,n) rows of A are overwritten with its right singular vectors, stored rowwise.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If m >= n and RANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements n+1:m in that column.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1,max(M, N)).

S Output parameter.

S is REAL

S is an array, dimension (min(M, N)). The singular values of A in decreasing order. The condition number of A in the 2-norm = S(1)/S(min(m,n)).

RCOND Input parameter.

RCOND is REAL

RCOND is used to determine the effective rank of A. Singular values S(i) <= RCOND*S(1) are treated as zero. If RCOND < 0, machine precision is used instead.

RANK Output parameter.

RANK is INTEGER

The effective rank of A, i.e., the number of singular values which are greater than RCOND*S(1).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 1, and also: LWORK >= 3*min(M, N) + max(2*min(M, N), max(M, N), NRHS) For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *cgelss*, *dgelss* and *zgelss*. It also exists with a native C interface as *LAPACKE_sgelss*.

4.5.16 sgelsy

`sgelsy` computes the minimum-norm solution to a real linear least squares problem:

```
minimize || A * X - B ||
```

using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting:

```
A * P = Q * [ R11 R12 ]
            [  0  R22 ]
```

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by orthogonal transformations from the right, arriving at the complete orthogonal factorization:

```
A * P = Q * [ T11 0 ] * Z
            [  0  0 ]
```

The minimum-norm solution is then

```
X = P * Z**T [ inv(T11)*Q1**T*B ]
             [         0        ]
```

where Q1 consists of the first RANK columns of Q.

This routine is basically identical to the original xGELSX except three differences:

```
o The call to the subroutine xGEQPF has been substituted by the
  the call to the subroutine xGEQP3. This subroutine is a Blas-3
  version of the QR factorization with column pivoting.
o Matrix B (the right hand side) is updated with Blas-3.
o The permutation of matrix B (the right hand side) is faster and
  more simple.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sgelsy(M, N, NRHS, A, LDA, B, LDB, JPVT, RCOND, RANK, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sgelsy_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *nrhs, float *a, const armpl_int_t *lda,
             float *b, const armpl_int_t *ldb, armpl_int_t *jpvt,
             const float *rcond, armpl_int_t *rank, float *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of matrices B and X. NRHS >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M, N).

JPVT Input and output parameter.

JPVT is INTEGER array, dimension (N)

On entry, if JPVT(i) .ne. 0, the i-th column of A is permuted to the front of AP, otherwise column i is a free column. On exit, if JPVT(i) = k, then the i-th column of AP was the k-th column of A.

RCOND Input parameter.

RCOND is REAL

RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number < 1/RCOND.

RANK Output parameter.

RANK is INTEGER

The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. The unblocked strategy requires that: LWORK >= MAX(MN+3*N+1, 2*MN+NRHS), where MN = min(M, N). The block algorithm requires that: LWORK >= MAX(MN+2*N+NB*(N+1), 2*MN+NB* NRHS), where NB is an upper bound on the blocksize returned by ILAENV for the routines SGEQP3, STZRZF, STZRQF, SORMQR, and SORMRZ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: If INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgelsy*, *dgelsy* and *zgelsy*. It also exists with a native C interface as *LAPACKE_sgelsy*.

4.5.17 sggglm

sggglm solves a general Gauss-Markov linear model (GLM) problem:

```
minimize || y ||_2   subject to   d = A*x + B*y
   x
```

where A is an N-by-M matrix, B is an N-by-P matrix, and d is a given N-vector. It is assumed that M <= N <= M+P, and

```
rank(A) = M    and    rank( A B ) = N.
```

Under these assumptions, the constrained equation is always consistent, and there is a unique solution x and a minimal 2-norm solution y, which is obtained using a generalized QR factorization of the matrices (A, B) given by

```
A = Q*(R),   B = Q*T*Z.
      (0)
```

In particular, if matrix B is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

```
minimize || inv(B)*(d-A*x) ||_2
   x
```

where inv(B) denotes the inverse of B.

Syntax

Fortran specification:

```
use armpl_library

subroutine sggglm(N, M, P, A, LDA, B, LDB, D, X, Y, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sggglm_(const armpl_int_t *n, const armpl_int_t *m, const armpl_int_t *p,
             float *a, const armpl_int_t *lda, float *b,
             const armpl_int_t *ldb, float *d, float *x, float *y,
             float *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of rows of the matrices A and B. N >= 0.

M Input parameter.

M is INTEGER

The number of columns of the matrix A. 0 <= M <= N.

P Input parameter.

P is INTEGER

The number of columns of the matrix B. P >= N-M.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, M). On entry, the N-by-M matrix A. On exit, the upper triangular part of the array A contains the M-by-M upper triangular matrix R.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, P). On entry, the N-by-P matrix B. On exit, if N <= P, the upper triangle of the subarray B(1:N,P-N+1:P) contains the N-by-N upper triangular matrix T; if N > P, the elements on and above the (N-P)th subdiagonal contain the N-by-P upper trapezoidal matrix T.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, D is the left hand side of the GLM equation. On exit, D is destroyed.

X Output parameter.

X is REAL

X is an array, dimension (M) .

Y Output parameter.

Y is REAL

Y is an array, dimension (P). On exit, X and Y are the solutions of the GLM problem.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,N+M+P). For optimum performance, LWORK >= M+min(N, P)+max(N, P)*NB, where NB is an upper bound for the optimal blocksizes for SGEQRF, SGERQF, SORMQR and SORMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. = 1: the upper triangular factor R associated with A in the generalized QR factorization of the pair (A, B) is singular, so that rank(A) < M; the least squares solution could not be computed. = 2: the bottom (N-M) by (N-M) part of the upper trapezoidal factor T associated with B in the generalized QR factorization of the pair (A, B) is singular, so that rank(A B) < N; the least squares solution could not be computed.

Related Information

For this routine in other precisions, please see *cggglm*, *dggglm* and *zggglm*. It also exists with a native C interface as *LAPACKE_sggglm*.

4.5.18 sgglse

sgglse solves the linear equality-constrained least squares (LSE) problem:

```
minimize || c - A*x ||_2   subject to   B*x = d
```

where A is an M-by-N matrix, B is a P-by-N matrix, c is a given M-vector, and d is a given P-vector. It is assumed that P <= N <= M+P, and

```
rank(B) = P and  rank( (A) ) = N.
                      ( (B) )
```

These conditions ensure that the LSE problem has a unique solution, which is obtained using a generalized RQ factorization of the matrices (B, A) given by

```
B = (0 R)*Q,    A = Z*T*Q.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sgglse(M, N, P, A, LDA, B, LDB, C, D, X, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgglse_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *p,
             float *a, const armpl_int_t *lda, float *b,
             const armpl_int_t *ldb, float *c, float *d, float *x,
             float *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. 0 <= P <= N <= M+P.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix T.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, the upper triangle of the subarray B(1:P,N-P+1:N) contains the P-by-P upper triangular matrix R.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

C Input and output parameter.

C is REAL

C is an array, dimension (M). On entry, C contains the right hand side vector for the least squares part of the LSE problem. On exit, the residual sum of squares for the solution is given by the sum of squares of elements N-P+1 to M of vector C.

D Input and output parameter.

D is REAL

D is an array, dimension (P). On entry, D contains the right hand side vector for the constrained equation. On exit, D is destroyed.

X Output parameter.

X is REAL

X is an array, dimension (N). On exit, X is the solution of the LSE problem.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,M+N+P). For optimum performance LWORK >= P+min(M, N)+max(M, N)*NB, where NB is an upper bound for the optimal blocksizes for SGEQRF, SGERQF, SORMQR and SORMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. = 1: the upper triangular factor R associated with B in the generalized RQ factorization of the pair (B, A) is singular, so that rank(B) < P; the least squares solution could not be computed. = 2: the (N-P) by (N-P) part of the upper trapezoidal factor T associated with A in the generalized RQ factorization of the pair (B, A) is singular, so that rank((A)) < N; the least squares solution could not ((B)) be computed.

Related Information

For this routine in other precisions, please see *cgglse*, *dgglse* and *zgglse*. It also exists with a native C interface as *LAPACKE_sgglse*.

4.5.19 zgels

zgels solves overdetermined or underdetermined complex linear systems involving an M-by-N matrix A, or its conjugate-transpose, using a QR or LQ factorization of A. It is assumed that A has full rank.

The following options are provided:

1. If TRANS = 'N' and m >= n: find the least squares solution of

```
an overdetermined system, i.e., solve the least squares problem
            minimize || B - A*X ||.
```

2. If TRANS = 'N' and m < n: find the minimum norm solution of

```
an underdetermined system A * X = B.
```

3. If TRANS = 'C' and m >= n: find the minimum norm solution of

```
an underdetermined system A**H * X = B.
```

4. If TRANS = 'C' and m < n: find the least squares solution of

```
an overdetermined system, i.e., solve the least squares problem
            minimize || B - A**H * X ||.
```

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgels(TRANS, M, N, NRHS, A, LDA, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgels_(const char *trans, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_int_t *nrhs, armpl_doublecomplex_t *a,
            const armpl_int_t *lda, armpl_doublecomplex_t *b,
            const armpl_int_t *ldb, armpl_doublecomplex_t *work,
            const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': the linear system involves A; = 'C': the linear system involves A^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. if M >= N, A is overwritten by details of its QR factorization as returned by ZGEQRF; if M < N, A is overwritten by details of its LQ factorization as returned by ZGELQF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the matrix B of right hand side vectors, stored columnwise; B is M-by-NRHS if TRANS = 'N', or N-by-NRHS if TRANS = 'C'. On exit, if INFO = 0, B is overwritten

by the solution vectors, stored columnwise: if TRANS = 'N' and m >= n, rows 1 to n of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of the modulus of elements N+1 to M in that column; if TRANS = 'N' and m < n, rows 1 to N of B contain the minimum norm solution vectors; if TRANS = 'C' and m >= n, rows 1 to M of B contain the minimum norm solution vectors; if TRANS = 'C' and m < n, rows 1 to M of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of the modulus of elements M+1 to N in that column.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= MAX(1, M, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, MN + max(MN, NRHS)). For optimal performance, LWORK >= max(1, MN + max(MN, NRHS)*NB). where MN = min(M, N) and NB is the optimum block size.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of the triangular factor of A is zero, so that A does not have full rank; the least squares solution could not be computed.

Related Information

For this routine in other precisions, please see *cgels*, *dgels* and *sgels*. It also exists with a native C interface as *LAPACKE_zgels*.

4.5.20 zgelsd

zgelsd computes the minimum-norm solution to a real linear least squares problem:

```
minimize 2-norm(| b - A*x |)
```

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The problem is solved in three steps: (1) Reduce the coefficient matrix A to bidiagonal form with

```
Householder transformations, reducing the original problem
into a "bidiagonal least squares problem" (BLS)
```

(2) Solve the BLS using a divide and conquer approach.

(3) Apply back all the Householder transformations to solve

```
the original least squares problem.
```

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgelsd(M, N, NRHS, A, LDA, B, LDB, S, RCOND, RANK, WORK, LWORK,
                  RWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgelsd_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *nrhs, const armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, double *s, const double *rcond,
             armpl_int_t *rank, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, double *rwork, armpl_int_t *iwork,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A has been destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If m >= n and RANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of the modulus of elements n+1:m in that column.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M, N).

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (min(M, N)). The singular values of A in decreasing order. The condition number of A in the 2-norm = S(1)/S(min(m,n)).

RCOND Input parameter.

RCOND is DOUBLE PRECISION

RCOND is used to determine the effective rank of A. Singular values S(i) <= RCOND*S(1) are treated as zero. If RCOND < 0, machine precision is used instead.

RANK Output parameter.

RANK is INTEGER

The effective rank of A, i.e., the number of singular values which are greater than RCOND*S(1).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK must be at least 1. The exact minimum amount of workspace needed depends on M, N and NRHS. As long as LWORK is at least 2* N + N*NRHS if M is greater than or equal to N or 2* M + M*NRHS if M is less than N, the code will execute correctly. For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the array WORK and the minimum sizes of the arrays RWORK and IWORK, and returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (MAX(1,LRWORK)). LRWORK >= 10* N + 2*N*SMLSIZ + 8*N*NLVL + 3*SMLSIZ* NRHS + MAX((SMLSIZ+1)**2, N*(1+NRHS) + 2* NRHS) if M is greater than or equal to N or 10* M + 2*M*SMLSIZ + 8*M*NLVL + 3*SMLSIZ* NRHS + MAX((SMLSIZ+1)**2, N*(1+NRHS) + 2* NRHS) if M is less than N, the code will execute correctly. SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25), and NLVL = MAX(0, INT(LOG_2(MIN(M,N)/(SMLSIZ+1))) + 1) On exit, if INFO = 0, RWORK(1) returns the minimum LRWORK.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1,LIWORK))

LIWORK >= max(1, 3*MINMN*NLVL + 11*MINMN), where MINMN = MIN(M,N). On exit, if INFO = 0, IWORK(1) returns the minimum LIWORK.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *cgelsd*, *dgelsd* and *sgelsd*. It also exists with a native C interface as *LAPACKE_zgelsd*.

4.5.21 zgelss

zgelss computes the minimum norm solution to a complex linear least squares problem:

Minimize 2-norm(| b - A*x |).

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgelss(M, N, NRHS, A, LDA, B, LDB, S, RCOND, RANK, WORK, LWORK,
                  RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgelss_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *nrhs, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, double *s, const double *rcond,
             armpl_int_t *rank, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, double *rwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the first min(m,n) rows of A are overwritten with its right singular vectors, stored rowwise.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If m >= n and RANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of the modulus of elements n+1:m in that column.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M, N).

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (min(M, N)). The singular values of A in decreasing order. The condition number of A in the 2-norm = S(1)/S(min(m,n)).

RCOND Input parameter.

RCOND is DOUBLE PRECISION

RCOND is used to determine the effective rank of A. Singular values S(i) <= RCOND*S(1) are treated as zero. If RCOND < 0, machine precision is used instead.

RANK Output parameter.

RANK is INTEGER

The effective rank of A, i.e., the number of singular values which are greater than RCOND*S(1).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 1, and also: LWORK >= 2*min(M, N) + max(M, N, NRHS) For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (5*min(M, N)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *cgelss*, *dgelss* and *sgelss*. It also exists with a native C interface as *LAPACKE_zgelss*.

4.5.22 zgelsy

zgelsy computes the minimum-norm solution to a complex linear least squares problem:

```
minimize || A * X - B ||
```

using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting:

```
A * P = Q * [ R11 R12 ]
            [  0  R22 ]
```

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by unitary transformations from the right, arriving at the complete orthogonal factorization:

```
A * P = Q * [ T11 0 ] * Z
            [  0  0 ]
```

The minimum-norm solution is then

```
X = P * Z**H [ inv(T11)*Q1**H*B ]
             [         0        ]
```

where Q1 consists of the first RANK columns of Q.

This routine is basically identical to the original xGELSX except three differences:

```
o The permutation of matrix B (the right hand side) is faster and
  more simple.
o The call to the subroutine xGEQPF has been substituted by the
  the call to the subroutine xGEQP3. This subroutine is a Blas-3
  version of the QR factorization with column pivoting.
o Matrix B (the right hand side) is updated with Blas-3.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zgelsy(M, N, NRHS, A, LDA, B, LDB, JPVT, RCOND, RANK, WORK, LWORK,
                  RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgelsy_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *nrhs, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *jpvt, const double *rcond,
             armpl_int_t *rank, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, double *rwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M, N).

JPVT Input and output parameter.

JPVT is INTEGER array, dimension (N)

On entry, if JPVT(i) .ne. 0, the i-th column of A is permuted to the front of AP, otherwise column i is a free column. On exit, if JPVT(i) = k, then the i-th column of A*P was the k-th column of A.

RCOND Input parameter.

RCOND is DOUBLE PRECISION

RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number < 1/RCOND.

RANK Output parameter.

RANK is INTEGER

The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. The unblocked strategy requires that: LWORK >= MN + MAX(2*MN, N+1, MN+NRHS) where MN = min(M, N). The block algorithm requires that: LWORK >= MN + MAX(2*MN, NB*(N+1), MN+MN*NB, MN+NB* NRHS) where NB is an upper bound on the blocksize returned by ILAENV for the routines ZGEQP3, ZTZRZF, CTZRQF, ZUNMQR, and ZUNMRZ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgelsy*, *dgelsy* and *sgelsy*. It also exists with a native C interface as *LAPACKE_zgelsy*.

4.5.23 zggglm

zggglm solves a general Gauss-Markov linear model (GLM) problem:

```
minimize || y ||_2   subject to   d = A*x + B*y
   x
```

where A is an N-by-M matrix, B is an N-by-P matrix, and d is a given N-vector. It is assumed that M <= N <= M+P, and

```
rank(A) = M    and    rank( A B ) = N.
```

Under these assumptions, the constrained equation is always consistent, and there is a unique solution x and a minimal 2-norm solution y, which is obtained using a generalized QR factorization of the matrices (A, B) given by

```
A = Q*(R),    B = Q*T*Z.
      (0)
```

In particular, if matrix B is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

```
minimize || inv(B)*(d-A*x) ||_2
   x
```

where inv(B) denotes the inverse of B.

Syntax

Fortran specification:

```
use armpl_library

subroutine zggglm(N, M, P, A, LDA, B, LDB, D, X, Y, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zggglm_(const armpl_int_t *n, const armpl_int_t *m, const armpl_int_t *p,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_doublecomplex_t *d, armpl_doublecomplex_t *x,
             armpl_doublecomplex_t *y, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of rows of the matrices A and B. N >= 0.

M Input parameter.

M is INTEGER

The number of columns of the matrix A. 0 <= M <= N.

P Input parameter.

P is INTEGER

The number of columns of the matrix B. P >= N-M.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, M). On entry, the N-by-M matrix A. On exit, the upper triangular part of the array A contains the M-by-M upper triangular matrix R.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, P). On entry, the N-by-P matrix B. On exit, if N <= P, the upper triangle of the subarray B(1:N,P-N+1:P) contains the N-by-N upper triangular matrix T; if N > P, the elements on and above the (N-P)th subdiagonal contain the N-by-P upper trapezoidal matrix T.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

D Input and output parameter.

D is COMPLEX*16

D is an array, dimension (N). On entry, D is the left hand side of the GLM equation. On exit, D is destroyed.

X Output parameter.

X is COMPLEX*16

X is an array, dimension (M) .

Y Output parameter.

Y is COMPLEX*16

Y is an array, dimension (P). On exit, X and Y are the solutions of the GLM problem.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,N+M+P). For optimum performance, LWORK >= M+min(N, P)+max(N, P)*NB, where NB is an upper bound for the optimal blocksizes for ZGEQRF, ZGERQF, ZUNMQR and ZUNMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. = 1: the upper triangular factor R associated with A in the generalized QR factorization of the pair (A, B) is singular, so that rank(A) < M; the least squares solution could not be computed. = 2: the bottom (N-M) by (N-M) part of the upper trapezoidal factor T associated with B in the generalized QR factorization of the pair (A, B) is singular, so that rank(A B) < N; the least squares solution could not be computed.

Related Information

For this routine in other precisions, please see *cggglm*, *dggglm* and *sggglm*. It also exists with a native C interface as *LAPACKE_zggglm*.

4.5.24 zgglse

zgglse solves the linear equality-constrained least squares (LSE) problem:

```
minimize || c - A*x ||_2   subject to   B*x = d
```

where A is an M-by-N matrix, B is a P-by-N matrix, c is a given M-vector, and d is a given P-vector. It is assumed that P <= N <= M+P, and

```
rank(B) = P and  rank( (A) ) = N.
                      ( (B) )
```

These conditions ensure that the LSE problem has a unique solution, which is obtained using a generalized RQ factorization of the matrices (B, A) given by

```
B = (0 R)*Q,    A = Z*T*Q.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zgglse(M, N, P, A, LDA, B, LDB, C, D, X, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgglse_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *p,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_doublecomplex_t *c, armpl_doublecomplex_t *d,
             armpl_doublecomplex_t *x, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. 0 <= P <= N <= M+P.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M, N)-by-N upper trapezoidal matrix T.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, the upper triangle of the subarray B(1:P,N-P+1:N) contains the P-by-P upper triangular matrix R.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (M). On entry, C contains the right hand side vector for the least squares part of the LSE problem. On exit, the residual sum of squares for the solution is given by the sum of squares of elements N-P+1 to M of vector C.

D Input and output parameter.

D is COMPLEX*16

D is an array, dimension (P). On entry, D contains the right hand side vector for the constrained equation. On exit, D is destroyed.

X Output parameter.

X is COMPLEX*16

X is an array, dimension (N). On exit, X is the solution of the LSE problem.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,M+N+P). For optimum performance LWORK >= P+min(M, N)+max(M, N)*NB, where NB is an upper bound for the optimal blocksizes for ZGEQRF, CGERQF, ZUNMQR and CUNMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. = 1: the upper triangular factor R associated with B in the generalized RQ factorization of the pair (B, A) is singular, so that rank(B) < P; the least squares solution could not be computed. = 2: the (N-P) by (N-P) part of the upper trapezoidal factor T associated with A in the generalized RQ factorization of the pair (B, A) is singular, so that rank((A)) < N; the least squares solution could not ((B)) be computed.

4.6 LAPACK linear equation solving routines

4.6.1 cgbsv

`cgbsv` computes the solution to a complex system of linear equations A * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as A = L * U, where L is a product of permutation and unit lower triangular matrices with KL subdiagonals, and U is upper triangular with KL+KU superdiagonals. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgbsv(N, KL, KU, NRHS, AB, LDAB, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void cgbsv_(const armpl_int_t *n, const armpl_int_t *kl,
            const armpl_int_t *ku, const armpl_int_t *nrhs,
            armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
            armpl_int_t *ipiv, armpl_singlecomplex_t *b,
            const armpl_int_t *ldb, armpl_int_t *info);
```

Parameters

N Input parameter.

`N` is `INTEGER`

The number of linear equations, i.e., the order of the matrix A. `N` >= 0.

KL Input parameter.

`KL` is `INTEGER`

The number of subdiagonals within the band of A. `KL` >= 0.

KU Input parameter.

`KU` is `INTEGER`

The number of superdiagonals within the band of A. `KU` >= 0.

NRHS Input parameter.

`NRHS` is `INTEGER`

The number of right hand sides, i.e., the number of columns of the matrix `B`. `NRHS` >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KL+KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+KL) On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIV(i).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and the solution has not been computed.

Related Information

For this routine in other precisions, please see *dgbsv*, *sgbsv* and *zgbsv*. It also exists with a native C interface as *LAPACKE_cgbsv*.

4.6.2 cgbsvx

cgbsvx uses the LU factorization to compute the solution to a complex system of linear equations A * X = B, A^T * X = B, or A^H * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed by this subroutine:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
the system:
   TRANS = 'N':  diag(R)*A*diag(C)      *inv(diag(C))*X = diag(R)*B
   TRANS = 'T': (diag(R)*A*diag(C))**T  *inv(diag(R))*X = diag(C)*B
   TRANS = 'C': (diag(R)*A*diag(C))**H  *inv(diag(R))*X = diag(C)*B
```

(continues on next page)

(continued from previous page)

```
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
or diag(C)*B (if TRANS = 'T' or 'C').
```

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the

```
matrix A (after equilibration if FACT = 'E') as
   A = L * U,
where L is a product of permutation and unit lower triangular
matrices with KL subdiagonals, and U is upper triangular with
KL+KU superdiagonals.
```

3. If some U(i,i)=0, so that U is exactly singular, then the routine

```
returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
that it solves the original system before equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cgbsvx(FACT, TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV,
                  EQUED, R, C, B, LDB, X, LDX, RCOND, FERR, BERR, WORK, RWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void cgbsvx_(const char *fact, const char *trans, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku,
             const armpl_int_t *nrhs, armpl_singlecomplex_t *ab,
             const armpl_int_t *ldab, armpl_singlecomplex_t *afb,
             const armpl_int_t *ldafb, armpl_int_t *ipiv, char *equed,
             float *r, float *c, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *x,
             const armpl_int_t *ldx, float *rcond, float *ferr, float *berr,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AFB and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. AB, AFB, and IPIV are not modified. = 'N': The matrix A will be copied to AFB and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AFB and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations. = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. AB is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A EQUED = 'C': A := A * diag(C) EQUED = 'B': A := diag(R) * A * diag(C).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input and output parameter.

AFB is COMPLEX

AFB is an array, dimension (LDAFB, N). If FACT = 'F', then AFB is an input argument and on entry contains details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. If EQUED .ne. 'N', then AFB is the factored form of the equilibrated matrix A.

If FACT = 'N', then AFB is an output argument and on exit returns details of the LU factorization of A.

If FACT = 'E', then AFB is an output argument and on exit returns details of the LU factorization of the equilibrated matrix A (see the description of AB for the form of the equilibrated matrix).

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL+KU+1.

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the factorization A = L*U as computed by CGBTRF; row i of the matrix was interchanged with row IPIV(i).

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = L*U of the original matrix A.

If FACT = 'E', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = L*U of the equilibrated matrix A.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R Input and output parameter.

R is REAL

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C Input and output parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))* X if TRANS = 'N' and EQUED = 'C' or 'B', or inv(diag(R))* X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N). On exit, RWORK(1) contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If RWORK(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with 0<INFO<=N, then RWORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *dgbsvx*, *sgbsvx* and *zgbsvx*. It also exists with a native C interface as *LAPACKE_cgbsvx*.

4.6.3 cgbsvxx

```
CGBSVXX uses the LU factorization to compute the solution to a
   complex system of linear equations  A * X = B,  where A is an
   N-by-N matrix and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. CGBSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   CGBSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   CGBSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what CGBSVXX would itself produce.

                                                                  The␣
↪following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
   the system:

     TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
     TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
     TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
   or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
   the matrix A (after equilibration if FACT = 'E') as

     A = P * L * U,

   where P is a permutation matrix, L is a unit lower triangular
   matrix, and U is upper triangular.

   3. If some U(i,i)=0, so that U is exactly singular, then the
   routine returns with INFO = i. Otherwise, the factored form of A
   is used to estimate the condition number of the matrix A (see
   argument RCOND). If the reciprocal of the condition number is less
   than machine precision, the routine still goes on to solve for X
   and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form
   of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
   error and error bounds.  Refinement calculates the residual to at
   least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
   diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
   that it solves the original system before equilibration.
↪    Some optional parameters are bundled in the PARAMS array.  These␣
```

(continues on next page)

(continued from previous page)

```
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cgbsvxx(FACT, TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV,
                   EQUED, R, C, B, LDB, X, LDX, RCOND, RPVGRW, BERR,
                   N_ERR_BNDS, ERR_BNDS_NORM, ERR_BNDS_COMP, NPARAMS, PARAMS,
                   WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgbsvxx_(const char *fact, const char *trans, const armpl_int_t *n,
              const armpl_int_t *kl, const armpl_int_t *ku,
              const armpl_int_t *nrhs, armpl_singlecomplex_t *ab,
              const armpl_int_t *ldab, armpl_singlecomplex_t *afb,

              float *berr, const armpl_int_t *n_err_bnds,
              float *err_bnds_norm, float *err_bnds_comp,
              const armpl_int_t *nparams, float *params,
              armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
              ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF, and IPIV are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose = Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

If FACT = 'F' and EQUED is not 'N', then AB must have been equilibrated by the scaling factors in R and/or C. AB is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A EQUED = 'C': A := A * diag(C) EQUED = 'B': A := diag(R) * A * diag(C).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input and output parameter.

AFB is COMPLEX

AFB is an array, dimension (LDAFB, N). If FACT = 'F', then AFB is an input argument and on entry contains details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. If EQUED .ne. 'N', then AFB is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL+KU+1.

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the factorization A = P*L*U as computed by SGETRF; row i of the matrix was interchanged with row IPIV(i).

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the equilibrated matrix A.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R Input and output parameter.

R is REAL

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive. If R is output, each element of R is a power of the radix. If R is input, each element of R should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

C Input and output parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive. If C is output, each element of C is a power of the radix. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))* X if TRANS = 'N' and EQUED = 'C' or 'B', or inv(diag(R))* X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

RPVGRW Output parameter.

RPVGRW is REAL

Reciprocal pivot growth. On exit, this contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable. If factorization fails with 0<INFO<=N, then this contains the reciprocal pivot growth factor for the leading INFO columns of A. In SGESVX, this quantity is returned in WORK(1).

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is REAL

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3)

= 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check `ERR_BNDS_NORM` or `ERR_BNDS_COMP`.

Related Information

4.6.4 cgbtrs

`cgbtrs` solves a system of linear equations

```
A * X = B,  A**T * X = B,  or  A**H * X = B
```

with a general band matrix A using the LU factorization computed by CGBTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgbtrs(TRANS, N, KL, KU, NRHS, AB, LDAB, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void cgbtrs_(const char *trans, const armpl_int_t *n, const armpl_int_t *kl,
             const armpl_int_t *ku, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
             const armpl_int_t *ipiv, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

`TRANS` is `CHARACTER*1`

Specifies the form of the system of equations. = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0.

KL Input parameter.

`KL` is `INTEGER`

The number of subdiagonals within the band of A. `KL` >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= N, row i of the matrix was interchanged with row IPIV(i).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgbtrs*, *sgbtrs* and *zgbtrs*. It also exists with a native C interface as *LAPACKE_cgbtrs*.

4.6.5 cgesv

cgesv computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as

```
A = P * L * U,
```

where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgesv(N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void cgesv_(const armpl_int_t *n, const armpl_int_t *nrhs,
            armpl_singlecomplex_t *a, const armpl_int_t *lda,
            armpl_int_t *ipiv, armpl_singlecomplex_t *b,
            const armpl_int_t *ldb, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N coefficient matrix A. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIV(i).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS matrix of right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *dgesv*, *sgesv* and *zgesv*. It also exists with a native C interface as *LAPACKE_cgesv*.

4.6.6 cgesvx

`cgesvx` uses the LU factorization to compute the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
 the system:
   TRANS = 'N':  diag(R)*A*diag(C)      *inv(diag(C))*X = diag(R)*B
   TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
   TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
or diag(C)*B (if TRANS = 'T' or 'C').
```

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the

```
 matrix A (after equilibration if FACT = 'E') as
   A = P * L * U,
where P is a permutation matrix, L is a unit lower triangular
matrix, and U is upper triangular.
```

3. If some U(i,i)=0, so that U is exactly singular, then the routine

```
 returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
 diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
that it solves the original system before equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cgesvx(FACT, TRANS, N, NRHS, A, LDA, AF, LDAF, IPIV, EQUED, R, C,
                  B, LDB, X, LDX, RCOND, FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgesvx_(const char *fact, const char *trans, const armpl_int_t *n,
             const armpl_int_t *nrhs, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *af,
             const armpl_int_t *ldaf, armpl_int_t *ipiv, char *equed,
             float *r, float *c, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *x,
             const armpl_int_t *ldx, float *rcond, float *ferr, float *berr,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF, and IPIV are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A EQUED = 'C': A := A * diag(C) EQUED = 'B': A := diag(R) * A * diag(C).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the factors L and U from the factorization A = P*L*U as computed by CGETRF. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the factorization A = P*L*U as computed by CGETRF; row i of the matrix was interchanged with row IPIV(i).

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the equilibrated matrix A.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R Input and output parameter.

R is REAL

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C Input and output parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))* X if TRANS = 'N' and EQUED = 'C' or 'B', or inv(diag(R))* X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*N). On exit, RWORK(1) contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If RWORK(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with 0<INFO<=N, then RWORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *dgesvx*, *sgesvx* and *zgesvx*. It also exists with a native C interface as *LAPACKE_cgesvx*.

4.6.7 cgesvxx

```
CGESVXX uses the LU factorization to compute the solution to a
   complex system of linear equations  A * X = B,  where A is an
   N-by-N matrix and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. CGESVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   CGESVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   CGESVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what CGESVXX would itself produce.

                                                                  The␣
↪following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
   the system:

     TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
     TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
     TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
   or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
   the matrix A (after equilibration if FACT = 'E') as

     A = P * L * U,

   where P is a permutation matrix, L is a unit lower triangular
   matrix, and U is upper triangular.

   3. If some U(i,i)=0, so that U is exactly singular, then the
   routine returns with INFO = i. Otherwise, the factored form of A
   is used to estimate the condition number of the matrix A (see
   argument RCOND). If the reciprocal of the condition number is less
   than machine precision, the routine still goes on to solve for X
   and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form
   of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
```

(continues on next page)

(continued from previous page)

```
   error and error bounds.  Refinement calculates the residual to at
   least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
   diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
   that it solves the original system before equilibration.
↪    Some optional parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cgesvxx(FACT, TRANS, N, NRHS, A, LDA, AF, LDAF, IPIV, EQUED, R, C,
                   B, LDB, X, LDX, RCOND, RPVGRW, BERR, N_ERR_BNDS,
                   ERR_BNDS_NORM, ERR_BNDS_COMP, NPARAMS, PARAMS, WORK, RWORK,
                   INFO)
```

C specification:

```
#include "armpl.h"

void cgesvxx_(const char *fact, const char *trans, const armpl_int_t *n,
              const armpl_int_t *nrhs, armpl_singlecomplex_t *a,
              const armpl_int_t *lda, armpl_singlecomplex_t *af,
              const armpl_int_t *ldaf, armpl_int_t *ipiv, char *equed,
              float *r, float *c, armpl_singlecomplex_t *b,
              const armpl_int_t *ldb, armpl_singlecomplex_t *x,
              const armpl_int_t *ldx, float *rcond, float *rpvgrw,
              float *berr, const armpl_int_t *n_err_bnds,
              float *err_bnds_norm, float *err_bnds_comp,
              const armpl_int_t *nparams, float *params,
              armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
              ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF, and IPIV are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A EQUED = 'C': A := A * diag(C) EQUED = 'B': A := diag(R) * A * diag(C).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the factors L and U from the factorization A = P*L*U as computed by CGETRF. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the factorization A = P*L*U as computed by CGETRF; row i of the matrix was interchanged with row IPIV(i).

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the equilibrated matrix A.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R Input and output parameter.

R is REAL

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive. If R is output, each element of R is a power of the radix. If R is input, each element of R should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

C Input and output parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive. If C is output, each element of C is a power of the radix. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))* X if TRANS = 'N' and EQUED = 'C' or 'B', or inv(diag(R))* X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

RPVGRW Output parameter.

RPVGRW is REAL

Reciprocal pivot growth. On exit, this contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable. If factorization fails with 0<INFO<=N, then this contains the reciprocal pivot growth factor for the leading INFO columns of A. In CGESVX, this quantity is returned in WORK(1).

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is REAL

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of

ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

Related Information

For this routine in other precisions, please see *dgesvxx*, *sgesvxx* and *zgesvxx*. It also exists with a native C interface as *LAPACKE_cgesvxx*.

4.6.8 cgetrs

cgetrs solves a system of linear equations

```
A * X = B,  A**T * X = B,  or  A**H * X = B
```

with a general N-by-N matrix A using the LU factorization computed by CGETRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgetrs(TRANS, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void cgetrs_(const char *trans, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_int_t *ipiv, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The factors L and U from the factorization A = P*L*U as computed by CGETRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from CGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgetrs*, *sgetrs* and *zgetrs*. It also exists with a native C interface as *LAPACKE_cgetrs*.

4.6.9 cgtsv

cgtsv solves the equation

```
A*X = B,
```

where A is an N-by-N tridiagonal matrix, by Gaussian elimination with partial pivoting.

Note that the equation A^T *X = B may be solved by interchanging the order of the arguments DU and DL.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgtsv(N, NRHS, DL, D, DU, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void cgtsv_(const armpl_int_t *n, const armpl_int_t *nrhs,
            armpl_singlecomplex_t *dl, armpl_singlecomplex_t *d,
            armpl_singlecomplex_t *du, armpl_singlecomplex_t *b,
            const armpl_int_t *ldb, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input and output parameter.

DL is COMPLEX

DL is an array, dimension (N-1). On entry, DL must contain the (n-1) subdiagonal elements of A. On exit, DL is overwritten by the (n-2) elements of the second superdiagonal of the upper triangular matrix U from the LU factorization of A, in DL(1), . . . , DL(n-2).

D Input and output parameter.

D is COMPLEX

D is an array, dimension (N). On entry, D must contain the diagonal elements of A. On exit, D is overwritten by the n diagonal elements of U.

DU Input and output parameter.

DU is COMPLEX

DU is an array, dimension (N-1). On entry, DU must contain the (n-1) superdiagonal elements of A. On exit, DU is overwritten by the (n-1) elements of the first superdiagonal of U.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero, and the solution has not been computed. The factorization has not been completed unless i = N.

Related Information

For this routine in other precisions, please see *dgtsv*, *sgtsv* and *zgtsv*. It also exists with a native C interface as *LAPACKE_cgtsv*.

4.6.10 cgtsvx

cgtsvx uses the LU factorization to compute the solution to a complex system of linear equations A * X = B, A^T * X = B, or A^H * X = B, where A is a tridiagonal matrix of order N and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the LU decomposition is used to factor the matrix A

```
as A = L * U, where L is a product of permutation and unit lower
bidiagonal matrices and U is upper triangular with nonzeros in
only the main diagonal and first two superdiagonals.
```

2. If some U(i,i)=0, so that U is exactly singular, then the routine

```
returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cgtsvx(FACT, TRANS, N, NRHS, DL, D, DU, DLF, DF, DUF, DU2, IPIV, B,
                  LDB, X, LDX, RCOND, FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgtsvx_(const char *fact, const char *trans, const armpl_int_t *n,
             const armpl_int_t *nrhs, const armpl_singlecomplex_t *dl,
             const armpl_singlecomplex_t *d, const armpl_singlecomplex_t *du,
             armpl_singlecomplex_t *dlf, armpl_singlecomplex_t *df,
             armpl_singlecomplex_t *duf, armpl_singlecomplex_t *du2,
             armpl_int_t *ipiv, const armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *x,
             const armpl_int_t *ldx, float *rcond, float *ferr, float *berr,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of A has been supplied on entry. = 'F': DLF, DF, DUF, DU2, and IPIV contain the factored form of A; DL, D, DU, DLF, DF, DUF, DU2 and IPIV will not be modified. = 'N': The matrix will be copied to DLF, DF, and DUF and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input parameter.

DL is COMPLEX

DL is an array, dimension (N-1). The (n-1) subdiagonal elements of A.

D Input parameter.

D is COMPLEX

D is an array, dimension (N). The n diagonal elements of A.

DU Input parameter.

DU is COMPLEX

DU is an array, dimension (N-1). The (n-1) superdiagonal elements of A.

DLF Input and output parameter.

DLF is COMPLEX

DLF is an array, dimension (N-1). If FACT = 'F', then DLF is an input argument and on entry contains the (n-1) multipliers that define the matrix L from the LU factorization of A as computed by CGTTRF.

If FACT = 'N', then DLF is an output argument and on exit contains the (n-1) multipliers that define the matrix L from the LU factorization of A.

DF Input and output parameter.

DF is COMPLEX

DF is an array, dimension (N). If FACT = 'F', then DF is an input argument and on entry contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

If FACT = 'N', then DF is an output argument and on exit contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DUF Input and output parameter.

DUF is COMPLEX

DUF is an array, dimension (N-1). If FACT = 'F', then DUF is an input argument and on entry contains the (n-1) elements of the first superdiagonal of U.

If FACT = 'N', then DUF is an output argument and on exit contains the (n-1) elements of the first superdiagonal of U.

DU2 Input and output parameter.

DU2 is COMPLEX

DU2 is an array, dimension (N-2). If FACT = 'F', then DU2 is an input argument and on entry contains the (n-2) elements of the second superdiagonal of U.

If FACT = 'N', then DU2 is an output argument and on exit contains the (n-2) elements of the second superdiagonal of U.

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the LU factorization of A as computed by CGTTRF.

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the LU factorization of A; row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: U(i,i) is exactly zero. The factorization has not been completed unless i = N, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

4.6.11 cgttrs

cgttrs solves one of the systems of equations

```
A * X = B,  A**T * X = B,  or  A**H * X = B,
```

with a tridiagonal matrix A using the LU factorization computed by CGTTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgttrs(TRANS, N, NRHS, DL, D, DU, DU2, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void cgttrs_(const char *trans, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *dl, const armpl_singlecomplex_t *d,
             const armpl_singlecomplex_t *du,
             const armpl_singlecomplex_t *du2, const armpl_int_t *ipiv,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations. = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

N Input parameter.

N is INTEGER

The order of the matrix A.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input parameter.

DL is COMPLEX

DL is an array, dimension (N-1). The (n-1) multipliers that define the matrix L from the LU factorization of A.

D Input parameter.

D is COMPLEX

D is an array, dimension (N). The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DU Input parameter.

DU is COMPLEX

DU is an array, dimension (N-1). The (n-1) elements of the first super-diagonal of U.

DU2 Input parameter.

DU2 is COMPLEX

DU2 is an array, dimension (N-2). The (n-2) elements of the second super-diagonal of U.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the matrix of right hand side vectors B. On exit, B is overwritten by the solution vectors X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgttrs*, *sgttrs* and *zgttrs*. It also exists with a native C interface as *LAPACKE_cgttrs*.

4.6.12 chesv

chesv computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

```
A = U * D * U**H,  if UPLO = 'U', or
A = L * D * L**H,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine chesv(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chesv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            armpl_singlecomplex_t *a, const armpl_int_t *lda,
            armpl_int_t *ipiv, armpl_singlecomplex_t *b,
            const armpl_int_t *ldb, armpl_singlecomplex_t *work,
            const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^H or A = L*D*L^H as computed by CHETRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by CHETRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= 1, and for best performance LWORK >= max(1,N*NB), where NB is the optimal blocksize for CHETRF. for LWORK < N, TRS will be done with Level BLAS 2 for LWORK >= N, TRS will be done with Level BLAS 3

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *zhesv*. It also exists with a native C interface as *LAPACKE_chesv*.

4.6.13 chesv_aa

CHESV_AA computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

Aasen's algorithm is used to factor A as

```
 A = U * T * U**H,  if UPLO = 'U', or
A = L * T * L**H,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is Hermitian and tridiagonal. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine chesv_aa(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chesv_aa_(const char *uplo, const armpl_int_t *n,
               const armpl_int_t *nrhs, armpl_singlecomplex_t *a,
               const armpl_int_t *lda, armpl_int_t *ipiv,
               armpl_singlecomplex_t *b, const armpl_int_t *ldb,
               armpl_singlecomplex_t *work, const armpl_int_t *lwork,
               armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the tridiagonal matrix T and the multipliers used to obtain the factor U or L from the factorization A = U*T*U^H or A = L*T*L^H as computed by CHETRF_AA.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= MAX(1,2*N,3*N-2), and for best performance LWORK >= MAX(1,N*NB), where NB is the optimal blocksize for CHETRF.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *zhesv_aa*. It also exists with a native C interface as *LAPACKE_chesv_aa*.

4.6.14 chesv_rk

CHESV_RK computes the solution to a complex system of linear equations A * X = B, where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

The bounded Bunch-Kaufman (rook) diagonal pivoting method is used to factor A as

```
A = P*U*D*(U**H)*(P**T),  if UPLO = 'U', or
A = P*L*D*(L**H)*(P**T),  if UPLO = 'L',
```

where U (or L) is unit upper (or lower) triangular matrix, U^H (or L^H) is the conjugate of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

CHETRF_RK is called to compute the factorization of a complex Hermitian matrix. The factored form of A is then used to solve the system of equations A * X = B by calling BLAS3 routine CHETRS_3.

Syntax

Fortran specification:

```
use armpl_library

subroutine chesv_rk(UPLO, N, NRHS, A, LDA, E, IPIV, B, LDB, WORK, LWORK,
                    INFO)
```

C specification:

```
#include "armpl.h"

void chesv_rk_(const char *uplo, const armpl_int_t *n,
               const armpl_int_t *nrhs, armpl_singlecomplex_t *a,
               const armpl_int_t *lda, armpl_singlecomplex_t *e,
               armpl_int_t *ipiv, armpl_singlecomplex_t *b,
               const armpl_int_t *ldb, armpl_singlecomplex_t *work,
               const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, diagonal of the block diagonal matrix D and factors U or L as computed by CHETRF_RK: a) ONLY diagonal elements of the Hermitian block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

For more info see the description of CHETRF_RK routine.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is COMPLEX

E is an array, dimension (N). On exit, contains the output computed by the factorization routine CHETRF_RK, i.e. the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix D with 1-by-1 or

2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

For more info see the description of CHETRF_RK routine.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by CHETRF_RK.

For more info see the description of CHETRF_RK routine.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)).. Work array used in the factorization stage. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= 1. For best performance of factorization stage LWORK >= max(1,N*NB), where NB is the optimal blocksize for CHETRF_RK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array for factorization stage, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

Related Information

For this routine in other precisions, please see *zhesv_rk*. It also exists with a native C interface as *LAPACKE_chesv_rk*.

4.6.15 chesv_rook

CHESV_ROOK computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

The bounded Bunch-Kaufman ("rook") diagonal pivoting method is used to factor A as

```
A = U * D * U**T,  if UPLO = 'U', or
A = L * D * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

CHETRF_ROOK is called to compute the factorization of a complex Hermition matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method.

The factored form of A is then used to solve the system of equations A * X = B by calling CHETRS_ROOK (uses BLAS 2).

Syntax

Fortran specification:

```
use armpl_library

subroutine chesv_rook(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chesv_rook_(const char *uplo, const armpl_int_t *n,
                 const armpl_int_t *nrhs, armpl_singlecomplex_t *a,
                 const armpl_int_t *lda, armpl_int_t *ipiv,
                 armpl_singlecomplex_t *b, const armpl_int_t *ldb,
                 armpl_singlecomplex_t *work, const armpl_int_t *lwork,
                 armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^H or A = L*D*L^H as computed by CHETRF_ROOK.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': Only the last KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': Only the first KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= 1, and for best performance LWORK >= max(1,N*NB), where NB is the optimal blocksize for CHETRF_ROOK. for LWORK < N, TRS will be done with Level BLAS 2 for LWORK >= N, TRS will be done with Level BLAS 3

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *zhesv_rook*.

4.6.16 chesvx

chesvx uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the diagonal pivoting method is used to factor A.

```
 The form of the factorization is
   A = U * D * U**H,  if UPLO = 'U', or
   A = L * D * L**H,  if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices, and D is Hermitian and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some D(i,i)=0, so that D is exactly singular, then the routine

```
 returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine chesvx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X, LDX,
                  RCOND, FERR, BERR, WORK, LWORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

                ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AF and IPIV contain the factored form of A. A, AF and IPIV will not be modified. = 'N': The matrix A will be copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^H or A = L*D*L^H as computed by CHETRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^H or A = L*D*L^H .

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CHETRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIV is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by CHETRF.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= max(1,2*N), and for best performance, when FACT = 'N', LWORK >= max(1,2*N,N*NB), where NB is the optimal blocksize for CHETRF.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *zhesvx*. It also exists with a native C interface as *LAPACKE_chesvx*.

4.6.17 chesvxx

```
CHESVXX uses the diagonal pivoting factorization to compute the
   solution to a complex system of linear equations A * X = B, where
   A is an N-by-N symmetric matrix and X and B are N-by-NRHS
   matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. CHESVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   CHESVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   CHESVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what CHESVXX would itself produce.

                                                                  The␣
↪following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
   the system:

     diag(S)*A*diag(S)      *inv(diag(S))*X = diag(S)*B
```

(continues on next page)

(continued from previous page)

```
   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
   the matrix A (after equilibration if FACT = 'E') as

      A = U * D * U**T,  if UPLO = 'U', or
      A = L * D * L**T,  if UPLO = 'L',

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.

   3. If some D(i,i)=0, so that D is exactly singular, then the
   routine returns with INFO = i. Otherwise, the factored form of A
   is used to estimate the condition number of the matrix A (see
   argument RCOND).  If the reciprocal of the condition number is
   less than machine precision, the routine still goes on to solve
   for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form
   of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
   error and error bounds.  Refinement calculates the residual to at
   least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
   diag(R) so that it solves the original system before
   equilibration.                          Some optional parameters are bundled␣
↪in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine chesvxx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, EQUED, S, B,
                   LDB, X, LDX, RCOND, RPVGRW, BERR, N_ERR_BNDS,
                   ERR_BNDS_NORM, ERR_BNDS_COMP, NPARAMS, PARAMS, WORK, RWORK,
                   INFO)
```

                armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
                ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by S. A, AF, and IPIV are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by SSYTRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T .

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CHETRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIV is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by CHETRF.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is REAL

S is an array, dimension (N). The scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S)*B;

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

RPVGRW Output parameter.

RPVGRW is REAL

Reciprocal pivot growth. On exit, this contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable. If factorization fails with 0<INFO<=N, then this contains the reciprocal pivot growth factor for the leading INFO columns of A.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then

ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is REAL

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (5*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The

solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check `ERR_BNDS_NORM` or `ERR_BNDS_COMP`.

Related Information

For this routine in other precisions, please see *zhesvxx*. It also exists with a native C interface as *LAPACKE_chesvxx*.

4.6.18 chetrs

`chetrs` solves a system of linear equations A*X = B with a complex Hermitian matrix A using the factorization A = U*D*U^H or A = L*D*L^H computed by CHETRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetrs(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void chetrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_int_t *ipiv, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = '`U`': Upper triangular, form is `A` = U*D*U^H ; = '`L`': Lower triangular, form is `A` = L*D*L^H .

N Input parameter.

`N` is `INTEGER`

The order of the matrix `A`. `N` >= 0.

NRHS Input parameter.

`NRHS` is `INTEGER`

The number of right hand sides, i.e., the number of columns of the matrix `B`. `NRHS` >= 0.

A Input parameter.

`A` is `COMPLEX`

`A` is an array, dimension (`LDA`, `N`). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHETRF.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zhetrs*. It also exists with a native C interface as *LAPACKE_chetrs*.

4.6.19 chetrs2

chetrs2 solves a system of linear equations A*X = B with a complex Hermitian matrix A using the factorization A = U*D*U^H or A = L*D*L^H computed by CHETRF and converted by CSYCONV.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetrs2(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void chetrs2_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
              const armpl_singlecomplex_t *a, const armpl_int_t *lda,
              const armpl_int_t *ipiv, armpl_singlecomplex_t *b,
              const armpl_int_t *ldb, armpl_singlecomplex_t *work,
              armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHETRF.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zhetrs2*. It also exists with a native C interface as *LAPACKE_chetrs2*.

4.6.20 chetrs_3

CHETRS_3 solves a system of linear equations A * X = B with a complex Hermitian matrix A using the factorization computed by CHETRF_RK or CHETRF_BK:

```
A = P*U*D*(U**H)*(P**T) or A = P*L*D*(L**H)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^H (or L^H) is the conjugate of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This algorithm is using Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetrs_3(UPLO, N, NRHS, A, LDA, E, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void chetrs_3_(const char *uplo, const armpl_int_t *n,
               const armpl_int_t *nrhs, const armpl_singlecomplex_t *a,
               const armpl_int_t *lda, const armpl_singlecomplex_t *e,
               const armpl_int_t *ipiv, armpl_singlecomplex_t *b,
               const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix: = 'U': Upper triangular, form is A = P*U*D*(U^H)*(P^T); = 'L': Lower triangular, form is A = P*L*D*(L^H)*(P^T).

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). Diagonal of the block diagonal matrix D and factors U or L as computed by CHETRF_RK and CHETRF_BK: a) ONLY diagonal elements of the Hermitian block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is COMPLEX

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHETRF_RK or CHETRF_BK.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zhetrs_3*. It also exists with a native C interface as *LAPACKE_chetrs_3*.

4.6.21 chetrs_aa

CHETRS_AA solves a system of linear equations A*X = B with a complex hermitian matrix A using the factorization A = U*T*U^H or A = L*T*L^H computed by CHETRF_AA.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetrs_aa(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chetrs_aa_(const char *uplo, const armpl_int_t *n,
                const armpl_int_t *nrhs, const armpl_singlecomplex_t *a,
                const armpl_int_t *lda, const armpl_int_t *ipiv,
                armpl_singlecomplex_t *b, const armpl_int_t *ldb,
                const armpl_singlecomplex_t *work, const armpl_int_t *lwork,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*T*U^H ; = 'L': Lower triangular, form is A = L*T*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). Details of factors computed by CHETRF_AA.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges as computed by CHETRF_AA.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Input parameter.

WORK is DOUBLE array, dimension (MAX(1, LWORK))

LWORK Input parameter.

LWORK is INTEGER, LWORK >= MAX(1,3*N-2).

param[out] INFO verbatim INFO is INTEGER = 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zhetrs_aa*. It also exists with a native C interface as *LAPACKE_chetrs_aa*.

4.6.22 chetrs_rook

CHETRS_ROOK solves a system of linear equations A*X = B with a complex Hermitian matrix A using the factorization A = U*D*U^H or A = L*D*L^H computed by CHETRF_ROOK.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetrs_rook(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void chetrs_rook_(const char *uplo, const armpl_int_t *n,
                  const armpl_int_t *nrhs, const armpl_singlecomplex_t *a,
                  const armpl_int_t *lda, const armpl_int_t *ipiv,
                  armpl_singlecomplex_t *b, const armpl_int_t *ldb,
                  armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF_ROOK.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHETRF_ROOK.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zhetrs_rook*. It also exists with a native C interface as *LAPACKE_chetrs_rook*.

4.6.23 chpsv

chpsv computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

```
 A = U * D * U**H,  if UPLO = 'U', or
A = L * D * L**H,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine chpsv(UPLO, N, NRHS, AP, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void chpsv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            armpl_singlecomplex_t *ap, armpl_int_t *ipiv,
            armpl_singlecomplex_t *b, const armpl_int_t *ldb,
            armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^H or A = L*D*L^H as computed by CHPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by CHPTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *zhpsv*. It also exists with a native C interface as *LAPACKE_chpsv*.

4.6.24 chpsvx

chpsvx uses the diagonal pivoting factorization A = U*D*U^H or A = L*D*L^H to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N Hermitian matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the diagonal pivoting method is used to factor A as

```
    A = U * D * U**H,  if UPLO = 'U', or
   A = L * D * L**H,  if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices and D is Hermitian and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some D(i,i)=0, so that D is exactly singular, then the routine

```
 returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine chpsvx(FACT, UPLO, N, NRHS, AP, AFP, IPIV, B, LDB, X, LDX, RCOND,
                  FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chpsvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, const armpl_singlecomplex_t *ap,
             armpl_singlecomplex_t *afp, armpl_int_t *ipiv,
             const armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_singlecomplex_t *x, const armpl_int_t *ldx, float *rcond,
             float *ferr, float *berr, armpl_singlecomplex_t *work,
             float *rwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AFP and IPIV contain the factored form of A. AFP and IPIV will not be modified. = 'N': The matrix A will be copied to AFP and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

AFP Input and output parameter.

AFP is COMPLEX

AFP is an array, dimension (N*(N+1)/2). If FACT = 'F', then AFP is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^H or A = L*D*L^H as computed by CHPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AFP is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^H or A = L*D*L^H as computed by CHPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CHPTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIV is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by CHPTRF.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *zhpsvx*. It also exists with a native C interface as *LAPACKE_chpsvx*.

4.6.25 cpbsv

cpbsv computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian positive definite band matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

```
A = U**H * U,  if UPLO = 'U', or
A = L * L**H,  if UPLO = 'L',
```

where U is an upper triangular band matrix, and L is a lower triangular band matrix, with the same number of superdiagonals or subdiagonals as A. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpbsv(UPLO, N, KD, NRHS, AB, LDAB, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void cpbsv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
            const armpl_int_t *nrhs, armpl_singlecomplex_t *ab,
            const armpl_int_t *ldab, armpl_singlecomplex_t *b,
            const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(KD+1+i-j,j) = A(i,j) for max(1,j-KD)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(N,j+KD). See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the band matrix A, in the same storage format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

Related Information

For this routine in other precisions, please see *dpbsv*, *spbsv* and *zpbsv*. It also exists with a native C interface as *LAPACKE_cpbsv*.

4.6.26 cpbsvx

cpbsvx uses the Cholesky factorization A = U^H *U or A = L*L^H to compute the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian positive definite band matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
 the system:
   diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to

```
 factor the matrix A (after equilibration if FACT = 'E') as
   A = U**H * U,  if UPLO = 'U', or
   A = L * L**H,  if UPLO = 'L',
where U is an upper triangular band matrix, and L is a lower
triangular band matrix.
```

3. If the leading i-by-i principal minor is not positive definite,

```
 then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A.  If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
 diag(S) so that it solves the original system before
equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cpbsvx(FACT, UPLO, N, KD, NRHS, AB, LDAB, AFB, LDAFB, EQUED, S, B,
                  LDB, X, LDX, RCOND, FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cpbsvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *kd, const armpl_int_t *nrhs,
             armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
             armpl_singlecomplex_t *afb, const armpl_int_t *ldafb,
             char *equed, float *s, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *x,
             const armpl_int_t *ldx, float *rcond, float *ferr, float *berr,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AFB contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. AB and AFB will not be modified. = 'N': The matrix A will be copied to AFB and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AFB and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix diag(S)*A*diag(S). The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(KD+1+i-j,j) = A(i,j) for max(1,j-KD)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(N,j+KD). See below for further details.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array A. LDAB >= KD+1.

AFB Input and output parameter.

AFB is COMPLEX

AFB is an array, dimension (LDAFB, N). If FACT = 'F', then AFB is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the band matrix A, in the same storage format as A (see AB). If EQUED = 'Y', then AFB is the factored form of the equilibrated matrix A.

If FACT = 'N', then AFB is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H .

If FACT = 'E', then AFB is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= KD+1.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is REAL

S is an array, dimension (N). The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *dpbsvx*, *spbsvx* and *zpbsvx*. It also exists with a native C interface as *LAPACKE_cpbsvx*.

4.6.27 cpbtrs

`cpbtrs` solves a system of linear equations A*X = B with a Hermitian positive definite band matrix A using the Cholesky factorization A = U^H *U or A = L*L^H computed by CPBTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpbtrs(UPLO, N, KD, NRHS, AB, LDAB, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void cpbtrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_int_t *nrhs, const armpl_singlecomplex_t *ab,
             const armpl_int_t *ldab, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

= '`U`': Upper triangular factor stored in AB; = '`L`': Lower triangular factor stored in `AB`.

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0.

KD Input parameter.

`KD` is `INTEGER`

The number of superdiagonals of the matrix A if `UPLO` = '`U`', or the number of subdiagonals if `UPLO` = '`L`'. `KD` >= 0.

NRHS Input parameter.

`NRHS` is `INTEGER`

The number of right hand sides, i.e., the number of columns of the matrix `B`. `NRHS` >= 0.

AB Input parameter.

`AB` is `COMPLEX`

`AB` is an array, dimension (`LDAB`, `N`). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the band matrix A, stored in the first KD+1 rows of the array. The j-th column of U or L is stored in the j-th column of the array `AB` as follows: if `UPLO` ='`U`', AB(kd+1+i-j,j) = U(i,j) for max(1,j-kd)<=i<=j; if `UPLO` ='`L`', AB(1+i-j,j) = L(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dpbtrs*, *spbtrs* and *zpbtrs*. It also exists with a native C interface as *LAPACKE_cpbtrs*.

4.6.28 cpftrs

cpftrs solves a system of linear equations A*X = B with a Hermitian positive definite matrix A using the Cholesky factorization A = U^H *U or A = L*L^H computed by CPFTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpftrs(TRANSR, UPLO, N, NRHS, A, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void cpftrs_(const char *transr, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, const armpl_singlecomplex_t *a,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal TRANSR of RFP A is stored; = 'C': The Conjugate-transpose TRANSR of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of RFP A is stored; = 'L': Lower triangle of RFP A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (N*(N+1)/2);. The triangular factor U or L from the Cholesky factorization of RFP A = U^H *U or RFP A = L*L^H , as computed by CPFTRF. See note below for more details about RFP A.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dpftrs*, *spftrs* and *zpftrs*. It also exists with a native C interface as *LAPACKE_cpftrs*.

4.6.29 cposv

cposv computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian positive definite matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

```
A = U**H* U,  if UPLO = 'U', or
A = L * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine cposv(UPLO, N, NRHS, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void cposv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            armpl_singlecomplex_t *a, const armpl_int_t *lda,
            armpl_singlecomplex_t *b, const armpl_int_t *ldb,
            armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

Related Information

For this routine in other precisions, please see *dposv*, *sposv* and *zposv*. It also exists with a native C interface as *LAPACKE_cposv*.

4.6.30 cposvx

cposvx uses the Cholesky factorization A = U^H *U or A = L*L^H to compute the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian positive definite matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
 the system:
   diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to

```
 factor the matrix A (after equilibration if FACT = 'E') as
   A = U**H* U,  if UPLO = 'U', or
   A = L * L**H,  if UPLO = 'L',
where U is an upper triangular matrix and L is a lower triangular
matrix.
```

3. If the leading i-by-i principal minor is not positive definite,

```
 then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A.  If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
 diag(S) so that it solves the original system before
equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cposvx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, EQUED, S, B, LDB, X,
                  LDX, RCOND, FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cposvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *af,
             const armpl_int_t *ldaf, char *equed, float *s,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_singlecomplex_t *x, const armpl_int_t *ldx, float *rcond,
             float *ferr, float *berr, armpl_singlecomplex_t *work,
             float *rwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. A and AF will not be modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix diag(S)*A*diag(S). If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , in the same storage format as A. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix diag(S)*A*diag(S).

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is REAL

S is an array, dimension (N). The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS righthand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *dposvx*, *sposvx* and *zposvx*. It also exists with a native C interface as *LAPACKE_cposvx*.

4.6.31 cposvxx

```
CPOSVXX uses the Cholesky factorization A = U**T*U or A = L*L**T
   to compute the solution to a complex system of linear equations
   A * X = B, where A is an N-by-N symmetric positive definite matrix
   and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. CPOSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   CPOSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   CPOSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
```

(continues on next page)

(continued from previous page)

```
   user-provided factorizations and equilibration factors if they
   differ from what CPOSVXX would itself produce.

                                                                    The␣
↪following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
   the system:

     diag(S)*A*diag(S)      *inv(diag(S))*X = diag(S)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

   2. If FACT = 'N' or 'E', the Cholesky decomposition is used to
   factor the matrix A (after equilibration if FACT = 'E') as
      A = U**T* U,  if UPLO = 'U', or
      A = L * L**T,  if UPLO = 'L',
   where U is an upper triangular matrix and L is a lower triangular
   matrix.

   3. If the leading i-by-i principal minor is not positive definite,
   then the routine returns with INFO = i. Otherwise, the factored
   form of A is used to estimate the condition number of the matrix
   A (see argument RCOND).  If the reciprocal of the condition number
   is less than machine precision, the routine still goes on to solve
   for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form
   of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
   error and error bounds.  Refinement calculates the residual to at
   least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
   diag(S) so that it solves the original system before
   equilibration.                          Some optional parameters are bundled␣
↪in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cposvxx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, EQUED, S, B, LDB, X,
                   LDX, RCOND, RPVGRW, BERR, N_ERR_BNDS, ERR_BNDS_NORM,

              ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by S. A and AF are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the symmetric matrix A, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix diag(S)*A*diag(S). If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , in the same storage format as A. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix diag(S)*A*diag(S).

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is REAL

S is an array, dimension (N). The row scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S)*B;

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the

matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

RPVGRW Output parameter.

RPVGRW is REAL

Reciprocal pivot growth. On exit, this contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable. If factorization fails with 0<INFO<=N, then this contains the reciprocal pivot growth factor for the leading INFO columns of A.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is REAL

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

4.6.32 cpotrs

cpotrs solves a system of linear equations A*X = B with a Hermitian positive definite matrix A using the Cholesky factorization $A = U^H * U$ or $A = L * L^H$ computed by CPOTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpotrs(UPLO, N, NRHS, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void cpotrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , as computed by CPOTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dpotrs*, *spotrs* and *zpotrs*. It also exists with a native C interface as *LAPACKE_cpotrs*.

4.6.33 cppsv

cppsv computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian positive definite matrix stored in packed format and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

```
A = U**H * U,  if UPLO = 'U', or
A = L * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine cppsv(UPLO, N, NRHS, AP, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void cppsv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            armpl_singlecomplex_t *ap, armpl_singlecomplex_t *b,
            const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , in the same storage format as A.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

Related Information

For this routine in other precisions, please see *dppsv*, *sppsv* and *zppsv*. It also exists with a native C interface as *LAPACKE_cppsv*.

4.6.34 cppsvx

cppsvx uses the Cholesky factorization A = U^H *U or A = L*L^H to compute the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian positive definite matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
 the system:
   diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to

```
 factor the matrix A (after equilibration if FACT = 'E') as
   A = U**H * U ,  if UPLO = 'U', or
   A = L * L**H,  if UPLO = 'L',
where U is an upper triangular matrix, L is a lower triangular
matrix, and **H indicates conjugate transpose.
```

3. If the leading i-by-i principal minor is not positive definite,

```
 then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A.  If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
 diag(S) so that it solves the original system before
equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cppsvx(FACT, UPLO, N, NRHS, AP, AFP, EQUED, S, B, LDB, X, LDX,
                  RCOND, FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cppsvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, armpl_singlecomplex_t *ap,
             armpl_singlecomplex_t *afp, char *equed, float *s,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_singlecomplex_t *x, const armpl_int_t *ldx, float *rcond,
             float *ferr, float *berr, armpl_singlecomplex_t *work,
             float *rwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AFP contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. AP and AFP will not be modified. = 'N': The matrix A will be copied to AFP and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AFP and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix diag(S)*A*diag(S). The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

AFP Input and output parameter.

AFP is COMPLEX

AFP is an array, dimension (N*(N+1)/2). If FACT = 'F', then AFP is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , in the same storage format as A. If EQUED .ne. 'N', then AFP is the factored form of the equilibrated matrix A.

If FACT = 'N', then AFP is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^H * U or A = L * L^H of the original matrix A.

If FACT = 'E', then AFP is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the equilibrated matrix A (see the description of AP for the form of the equilibrated matrix).

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is REAL

S is an array, dimension (N). The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *dppsvx*, *sppsvx* and *zppsvx*. It also exists with a native C interface as *LAPACKE_cppsvx*.

4.6.35 cpptrs

cpptrs solves a system of linear equations A*X = B with a Hermitian positive definite matrix A in packed storage using the Cholesky factorization A = U^H *U or A = L*L^H computed by CPPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpptrs(UPLO, N, NRHS, AP, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void cpptrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *ap, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , packed columnwise in a linear array. The j-th column of U or L is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = U(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = L(i,j) for j<=i<=n.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dpptrs*, *spptrs* and *zpptrs*. It also exists with a native C interface as *LAPACKE_cpptrs*.

4.6.36 cptsv

cptsv computes the solution to a complex system of linear equations A*X = B, where A is an N-by-N Hermitian positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

A is factored as A = L*D*L^H , and the factored form of A is then used to solve the system of equations.

Syntax

Fortran specification:

```
use armpl_library

subroutine cptsv(N, NRHS, D, E, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void cptsv_(const armpl_int_t *n, const armpl_int_t *nrhs, float *d,
            armpl_singlecomplex_t *e, armpl_singlecomplex_t *b,
            const armpl_int_t *ldb, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the factorization A = L*D*L^H .

E Input and output parameter.

E is COMPLEX

E is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*D*L^H factorization of A. E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U^H *D*U factorization of A.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the solution has not been computed. The factorization has not been completed unless i = N.

Related Information

For this routine in other precisions, please see *dptsv*, *sptsv* and *zptsv*. It also exists with a native C interface as *LAPACKE_cptsv*.

4.6.37 cptsvx

cptsvx uses the factorization A = L*D*L^H to compute the solution to a complex system of linear equations A*X = B, where A is an N-by-N Hermitian positive definite tridiagonal matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the matrix A is factored as A = L*D*L^H , where L

```
is a unit lower bidiagonal matrix and D is diagonal.  The
factorization can also be regarded as having the form
A = U**H*D*U.
```

2. If the leading i-by-i principal minor is not positive definite,

```
then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A.  If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cptsvx(FACT, N, NRHS, D, E, DF, EF, B, LDB, X, LDX, RCOND, FERR,
                  BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cptsvx_(const char *fact, const armpl_int_t *n, const armpl_int_t *nrhs,
             const float *d, const armpl_singlecomplex_t *e, float *df,
             armpl_singlecomplex_t *ef, const armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *x,
             const armpl_int_t *ldx, float *rcond, float *ferr, float *berr,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry. = 'F': On entry, DF and EF contain the factored form of A. D, E, DF, and EF will not be modified. = 'N': The matrix A will be copied to DF and EF and factored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the tridiagonal matrix A.

E Input parameter.

E is COMPLEX

E is an array, dimension (N-1). The (n-1) subdiagonal elements of the tridiagonal matrix A.

DF Input and output parameter.

DF is REAL

DF is an array, dimension (N). If FACT = 'F', then DF is an input argument and on entry contains the n diagonal elements of the diagonal matrix D from the $L*D*L^H$ factorization of A. If FACT = 'N', then DF is an output argument and on exit contains the n diagonal elements of the diagonal matrix D from the $L*D*L^H$ factorization of A.

EF Input and output parameter.

EF is COMPLEX

EF is an array, dimension (N-1). If FACT = 'F', then EF is an input argument and on entry contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L*D*L^H$ factorization of A. If FACT = 'N', then EF is an output argument and on exit contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L*D*L^H$ factorization of A.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j).

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *dptsvx*, *sptsvx* and *zptsvx*. It also exists with a native C interface as *LAPACKE_cptsvx*.

4.6.38 cpttrs

cpttrs solves a tridiagonal system of the form

```
A * X = B
```

using the factorization A = U^H *D*U or A = L*D*L^H computed by CPTTRF. D is a diagonal matrix specified in the vector D, U (or L) is a unit bidiagonal matrix whose superdiagonal (subdiagonal) is specified in the vector E, and X and B are N by NRHS matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpttrs(UPLO, N, NRHS, D, E, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void cpttrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const float *d, const armpl_singlecomplex_t *e,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies the form of the factorization and whether the vector E is the superdiagonal of the upper bidiagonal factor U or the subdiagonal of the lower bidiagonal factor L. = 'U': A = U^H *D*U, E is the superdiagonal of U = 'L': A = L*D*L^H , E is the subdiagonal of L

N Input parameter.

N is INTEGER

The order of the tridiagonal matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the diagonal matrix D from the factorization A = U^H *D*U or A = L*D*L^H .

E Input parameter.

E is COMPLEX

E is an array, dimension (N-1). If UPLO = 'U', the (n-1) superdiagonal elements of the unit bidiagonal factor U from the factorization A = U^H *D*U. If UPLO = 'L', the (n-1) subdiagonal elements of the unit bidiagonal factor L from the factorization A = L*D*L^H .

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dpttrs*, *spttrs* and *zpttrs*. It also exists with a native C interface as *LAPACKE_cpttrs*.

4.6.39 cspsv

cspsv computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

```
A = U * D * U**T,  if UPLO = 'U', or
A = L * D * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine cspsv(UPLO, N, NRHS, AP, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void cspsv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            armpl_singlecomplex_t *ap, armpl_int_t *ipiv,
            armpl_singlecomplex_t *b, const armpl_int_t *ldb,
            armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by CSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by CSPTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *dspsv*, *sspsv* and *zspsv*. It also exists with a native C interface as *LAPACKE_cspsv*.

4.6.40 cspsvx

cspsvx uses the diagonal pivoting factorization A = U*D*U^T or A = L*D*L^T to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the diagonal pivoting method is used to factor A as

```
   A = U * D * U**T,  if UPLO = 'U', or
   A = L * D * L**T,  if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices and D is symmetric and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some D(i,i)=0, so that D is exactly singular, then the routine

```
returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cspsvx(FACT, UPLO, N, NRHS, AP, AFP, IPIV, B, LDB, X, LDX, RCOND,
                  FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cspsvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, const armpl_singlecomplex_t *ap,
             armpl_singlecomplex_t *afp, armpl_int_t *ipiv,
             const armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_singlecomplex_t *x, const armpl_int_t *ldx, float *rcond,
             float *ferr, float *berr, armpl_singlecomplex_t *work,
             float *rwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AFP and IPIV contain the factored form of A. AP, AFP and IPIV will not be modified. = 'N': The matrix A will be copied to AFP and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

AFP Input and output parameter.

AFP is COMPLEX

AFP is an array, dimension (N*(N+1)/2). If FACT = 'F', then AFP is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by CSPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AFP is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by CSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CSPTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIV is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by CSPTRF.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

4.6.41 csptrs

csptrs solves a system of linear equations A*X = B with a complex symmetric matrix A stored in packed format using the factorization A = U*D*U^T or A = L*D*L^T computed by CSPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine csptrs(UPLO, N, NRHS, AP, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void csptrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *ap, const armpl_int_t *ipiv,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSPTRF, stored as a packed triangular matrix.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSPTRF.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsptrs*, *ssptrs* and *zsptrs*. It also exists with a native C interface as *LAPACKE_csptrs*.

4.6.42 csysv

csysv computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

```
A = U * D * U**T,  if UPLO = 'U', or
A = L * D * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine csysv(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void csysv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            armpl_singlecomplex_t *a, const armpl_int_t *lda,
            armpl_int_t *ipiv, armpl_singlecomplex_t *b,
            const armpl_int_t *ldb, armpl_singlecomplex_t *work,
            const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by CSYTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by CSYTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= 1, and for best performance LWORK >= max(1,N*NB), where NB is the optimal blocksize for CSYTRF. for LWORK < N, TRS will be done with Level BLAS 2 for LWORK >= N, TRS will be done with Level BLAS 3

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *dsysv*, *ssysv* and *zsysv*. It also exists with a native C interface as *LAPACKE_csysv*.

4.6.43 csysv_aa

CSYSV computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

Aasen's algorithm is used to factor A as

```
A = U * T * U**T,  if UPLO = 'U', or
A = L * T * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is symmetric tridiagonal. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine csysv_aa(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void csysv_aa_(const char *uplo, const armpl_int_t *n,
               const armpl_int_t *nrhs, armpl_singlecomplex_t *a,
```

(continues on next page)

(continued from previous page)

```
                const armpl_int_t *lda, armpl_int_t *ipiv,
                armpl_singlecomplex_t *b, const armpl_int_t *ldb,
                armpl_singlecomplex_t *work, const armpl_int_t *lwork,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the tridiagonal matrix T and the multipliers used to obtain the factor U or L from the factorization A = U*T*U^T or A = L*T*L^T as computed by CSYTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= MAX(2*N, 3*N-2), and for the best performance, LWORK >= max(1,N*NB), where NB is the optimal blocksize for CSYTRF_AA.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

4.6.44 csysv_rk

CSYSV_RK computes the solution to a complex system of linear equations A * X = B, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The bounded Bunch-Kaufman (rook) diagonal pivoting method is used to factor A as

```
A = P*U*D*(U**T)*(P**T),  if UPLO = 'U', or
A = P*L*D*(L**T)*(P**T),  if UPLO = 'L',
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

CSYTRF_RK is called to compute the factorization of a complex symmetric matrix. The factored form of A is then used to solve the system of equations A * X = B by calling BLAS3 routine CSYTRS_3.

Syntax

Fortran specification:

```
use armpl_library

subroutine csysv_rk(UPLO, N, NRHS, A, LDA, E, IPIV, B, LDB, WORK, LWORK,
                    INFO)
```

C specification:

```
#include "armpl.h"

void csysv_rk_(const char *uplo, const armpl_int_t *n,
               const armpl_int_t *nrhs, armpl_singlecomplex_t *a,
               const armpl_int_t *lda, armpl_singlecomplex_t *e,
               armpl_int_t *ipiv, armpl_singlecomplex_t *b,
               const armpl_int_t *ldb, armpl_singlecomplex_t *work,
               const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, diagonal of the block diagonal matrix D and factors U or L as computed by CSYTRF_RK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

For more info see the description of CSYTRF_RK routine.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is COMPLEX

E is an array, dimension (N). On exit, contains the output computed by the factorization routine CSYTRF_RK, i.e. the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

For more info see the description of CSYTRF_RK routine.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by CSYTRF_RK.

For more info see the description of CSYTRF_RK routine.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)).. Work array used in the factorization stage. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= 1. For best performance of factorization stage LWORK >= max(1,N*NB), where NB is the optimal blocksize for CSYTRF_RK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array for factorization stage, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

Related Information

For this routine in other precisions, please see *dsysv_rk*, *ssysv_rk* and *zsysv_rk*. It also exists with a native C interface as *LAPACKE_csysv_rk*.

4.6.45 csysv_rook

CSYSV_ROOK computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

```
A = U * D * U**T,  if UPLO = 'U', or
A = L * D * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

CSYTRF_ROOK is called to compute the factorization of a complex symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method.

The factored form of A is then used to solve the system of equations A * X = B by calling CSYTRS_ROOK.

Syntax

Fortran specification:

```
use armpl_library

subroutine csysv_rook(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void csysv_rook_(const char *uplo, const armpl_int_t *n,
                 const armpl_int_t *nrhs, armpl_singlecomplex_t *a,
                 const armpl_int_t *lda, armpl_int_t *ipiv,
                 armpl_singlecomplex_t *b, const armpl_int_t *ldb,
                 armpl_singlecomplex_t *work, const armpl_int_t *lwork,
                 armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by CSYTRF_ROOK.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by CSYTRF_ROOK.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= 1, and for best performance LWORK >= max(1,N*NB), where NB is the optimal blocksize for CSYTRF_ROOK.

TRS will be done with Level 2 BLAS

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *dsysv_rook*, *ssysv_rook* and *zsysv_rook*. It also exists with a native C interface as *LAPACKE_csysv_rook*.

4.6.46 csysvx

csysvx uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the diagonal pivoting method is used to factor A.

```
 The form of the factorization is
   A = U * D * U**T,  if UPLO = 'U', or
   A = L * D * L**T,  if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices, and D is symmetric and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some D(i,i)=0, so that D is exactly singular, then the routine

```
returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine csysvx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X, LDX,
                  RCOND, FERR, BERR, WORK, LWORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void csysvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, const armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *af,
             const armpl_int_t *ldaf, armpl_int_t *ipiv,
             const armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_singlecomplex_t *x, const armpl_int_t *ldx, float *rcond,
             float *ferr, float *berr, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AF and IPIV contain the factored form of A. A, AF and IPIV will not be modified. = 'N': The matrix A will be copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by CSYTRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T .

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CSYTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIV is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by CSYTRF.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= max(1,2*N), and for best performance, when FACT = 'N', LWORK >= max(1,2*N,N*NB), where NB is the optimal blocksize for CSYTRF.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *dsysvx*, *ssysvx* and *zsysvx*. It also exists with a native C interface as *LAPACKE_csysvx*.

4.6.47 csysvxx

```
CSYSVXX uses the diagonal pivoting factorization to compute the
   solution to a complex system of linear equations A * X = B, where
   A is an N-by-N symmetric matrix and X and B are N-by-NRHS
   matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. CSYSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   CSYSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   CSYSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what CSYSVXX would itself produce.

                                                                  The␣
↪following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
   the system:

     diag(S)*A*diag(S)     *inv(diag(S))*X = diag(S)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
   the matrix A (after equilibration if FACT = 'E') as

      A = U * D * U**T,  if UPLO = 'U', or
      A = L * D * L**T,  if UPLO = 'L',

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.

   3. If some D(i,i)=0, so that D is exactly singular, then the
   routine returns with INFO = i. Otherwise, the factored form of A
   is used to estimate the condition number of the matrix A (see
   argument RCOND).  If the reciprocal of the condition number is
   less than machine precision, the routine still goes on to solve
   for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form
   of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
```

(continues on next page)

(continued from previous page)

```
   error and error bounds.  Refinement calculates the residual to at
   least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
   diag(R) so that it solves the original system before
   equilibration.                          Some optional parameters are bundled␣
↪in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine csysvxx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, EQUED, S, B,
                   LDB, X, LDX, RCOND, RPVGRW, BERR, N_ERR_BNDS,
                   ERR_BNDS_NORM, ERR_BNDS_COMP, NPARAMS, PARAMS, WORK, RWORK,
                   INFO)
```

C specification:

```
#include "armpl.h"

void csysvxx_(const char *fact, char *uplo, const armpl_int_t *n,
              const armpl_int_t *nrhs, armpl_singlecomplex_t *a,
              const armpl_int_t *lda, armpl_singlecomplex_t *af,
              const armpl_int_t *ldaf, armpl_int_t *ipiv, char *equed,

              float *rpvgrw, float *berr, const armpl_int_t *n_err_bnds,
              float *err_bnds_norm, float *err_bnds_comp,
              const armpl_int_t *nparams, float *params,
              armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
              ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by S. A, AF, and IPIV are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by SSYTRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T .

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by SSYTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIV is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by SSYTRF.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is REAL

S is an array, dimension (N). The scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or

overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S)*B;

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

RPVGRW Output parameter.

RPVGRW is REAL

Reciprocal pivot growth. On exit, this contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable. If factorization fails with 0<INFO<=N, then this contains the reciprocal pivot growth factor for the leading INFO columns of A.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is REAL

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

Related Information

For this routine in other precisions, please see *dsysvxx*, *ssysvxx* and *zsysvxx*. It also exists with a native C interface as *LAPACKE_csysvxx*.

4.6.48 csytrs

csytrs solves a system of linear equations A*X = B with a complex symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by CSYTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytrs(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void csytrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_int_t *ipiv, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSYTRF.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsytrs*, *ssytrs* and *zsytrs*. It also exists with a native C interface as *LAPACKE_csytrs*.

4.6.49 csytrs2

`csytrs2` solves a system of linear equations A*X = B with a COMPLEX symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by CSYTRF and converted by CSYCONV.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytrs2(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void csytrs2_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
              const armpl_singlecomplex_t *a, const armpl_int_t *lda,
              const armpl_int_t *ipiv, armpl_singlecomplex_t *b,
              const armpl_int_t *ldb, armpl_singlecomplex_t *work,
              armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is `A` = U*D*U^T ; = 'L': Lower triangular, form is `A` = L*D*L^T .

N Input parameter.

`N` is `INTEGER`

The order of the matrix `A`. `N` >= 0.

NRHS Input parameter.

`NRHS` is `INTEGER`

The number of right hand sides, i.e., the number of columns of the matrix `B`. `NRHS` >= 0.

A Input and output parameter.

`A` is `COMPLEX`

`A` is an array, dimension (`LDA`, `N`). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF. Note that `A` is input / output. This might be counter-intuitive, and one may think that `A` is input only. `A` is input / output. This is because, at the start of the subroutine, we permute `A` in a "better" form and then we permute `A` back to its original form at the end.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `N`).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSYTRF.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsytrs2*, *ssytrs2* and *zsytrs2*. It also exists with a native C interface as *LAPACKE_csytrs2*.

4.6.50 csytrs_3

CSYTRS_3 solves a system of linear equations A * X = B with a complex symmetric matrix A using the factorization computed by CSYTRF_RK or CSYTRF_BK:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This algorithm is using Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytrs_3(UPLO, N, NRHS, A, LDA, E, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void csytrs_3_(const char *uplo, const armpl_int_t *n,
               const armpl_int_t *nrhs, const armpl_singlecomplex_t *a,
               const armpl_int_t *lda, const armpl_singlecomplex_t *e,
               const armpl_int_t *ipiv, armpl_singlecomplex_t *b,
               const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix: = 'U': Upper triangular, form is A = P*U*D*(U^T)*(P^T); = 'L': Lower triangular, form is A = P*L*D*(L^T)*(P^T).

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). Diagonal of the block diagonal matrix D and factors U or L as computed by CSYTRF_RK and CSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is COMPLEX

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSYTRF_RK or CSYTRF_BK.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsytrs_3*, *ssytrs_3* and *zsytrs_3*. It also exists with a native C interface as *LAPACKE_csytrs_3*.

4.6.51 csytrs_aa

CSYTRS_AA solves a system of linear equations A*X = B with a complex symmetric matrix A using the factorization A = U*T*U^T or A = L*T*L^T computed by CSYTRF_AA.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytrs_aa(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void csytrs_aa_(const char *uplo, const armpl_int_t *n,
                const armpl_int_t *nrhs, const armpl_singlecomplex_t *a,
                const armpl_int_t *lda, const armpl_int_t *ipiv,
                armpl_singlecomplex_t *b, const armpl_int_t *ldb,
                const armpl_singlecomplex_t *work, const armpl_int_t *lwork,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*T*U^T ; = 'L': Lower triangular, form is A = L*T*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). Details of factors computed by CSYTRF_AA.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges as computed by CSYTRF_AA.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Input parameter.

WORK is DOUBLE array, dimension (MAX(1, LWORK))

LWORK Input parameter.

LWORK is INTEGER, LWORK >= MAX(1,3*N-2).

param[out] INFO verbatim INFO is INTEGER = 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

4.6.52 csytrs_rook

CSYTRS_ROOK solves a system of linear equations A*X = B with a complex symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by CSYTRF_ROOK.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytrs_rook(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void csytrs_rook_(const char *uplo, const armpl_int_t *n,
                  const armpl_int_t *nrhs, const armpl_singlecomplex_t *a,
                  const armpl_int_t *lda, const armpl_int_t *ipiv,
                  armpl_singlecomplex_t *b, const armpl_int_t *ldb,
                  armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF_ROOK.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSYTRF_ROOK.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsytrs_rook*, *ssytrs_rook* and *zsytrs_rook*. It also exists with a native C interface as *LAPACKE_csytrs_rook*.

4.6.53 ctbtrs

ctbtrs solves a triangular system of the form

```
A * X = B,  A**T * X = B,  or  A**H * X = B,
```

where A is a triangular band matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctbtrs(UPLO, TRANS, DIAG, N, KD, NRHS, AB, LDAB, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void ctbtrs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_int_t *nrhs, const armpl_singlecomplex_t *ab,
             const armpl_int_t *ldab, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals or subdiagonals of the triangular band matrix A. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first kd+1 rows of AB. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

Related Information

For this routine in other precisions, please see *dtbtrs*, *stbtrs* and *ztbtrs*. It also exists with a native C interface as *LAPACKE_ctbtrs*.

4.6.54 ctptrs

ctptrs solves a triangular system of the form

```
A * X = B,  A**T * X = B,  or  A**H * X = B,
```

where A is a triangular matrix of order N stored in packed format, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctptrs(UPLO, TRANS, DIAG, N, NRHS, AP, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void ctptrs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *ap, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

Related Information

For this routine in other precisions, please see *dtptrs*, *stptrs* and *ztptrs*. It also exists with a native C interface as *LAPACKE_ctptrs*.

4.6.55 dgbsv

dgbsv computes the solution to a real system of linear equations A * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as A = L * U, where L is a product of permutation and unit lower triangular matrices with KL subdiagonals, and U is upper triangular with KL+KU superdiagonals. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgbsv(N, KL, KU, NRHS, AB, LDAB, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dgbsv_(const armpl_int_t *n, const armpl_int_t *kl,
            const armpl_int_t *ku, const armpl_int_t *nrhs, double *ab,
            const armpl_int_t *ldab, armpl_int_t *ipiv, double *b,
            const armpl_int_t *ldb, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KL+KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+KL) On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIV(i).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and the solution has not been computed.

Related Information

For this routine in other precisions, please see *cgbsv*, *sgbsv* and *zgbsv*. It also exists with a native C interface as *LAPACKE_dgbsv*.

4.6.56 dgbsvx

dgbsvx uses the LU factorization to compute the solution to a real system of linear equations A * X = B, A^T * X = B, or A^H * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed by this subroutine:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
 the system:
   TRANS = 'N':  diag(R)*A*diag(C)      *inv(diag(C))*X = diag(R)*B
   TRANS = 'T': (diag(R)*A*diag(C))**T  *inv(diag(R))*X = diag(C)*B
   TRANS = 'C': (diag(R)*A*diag(C))**H  *inv(diag(R))*X = diag(C)*B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
or diag(C)*B (if TRANS = 'T' or 'C').
```

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the

```
matrix A (after equilibration if FACT = 'E') as
   A = L * U,
where L is a product of permutation and unit lower triangular
```

(continues on next page)

(continued from previous page)

```
matrices with KL subdiagonals, and U is upper triangular with
KL+KU superdiagonals.
```

3. If some U(i,i)=0, so that U is exactly singular, then the routine

```
returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
 diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
that it solves the original system before equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dgbsvx(FACT, TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV,
                  EQUED, R, C, B, LDB, X, LDX, RCOND, FERR, BERR, WORK, IWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dgbsvx_(const char *fact, const char *trans, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku,
             const armpl_int_t *nrhs, double *ab, const armpl_int_t *ldab,
             double *afb, const armpl_int_t *ldafb, armpl_int_t *ipiv,
             char *equed, double *r, double *c, double *b,
             const armpl_int_t *ldb, double *x, const armpl_int_t *ldx,
             double *rcond, double *ferr, double *berr, double *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AFB and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. AB, AFB, and IPIV are not modified. = 'N': The matrix A will be copied to AFB and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AFB and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations. = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. AB is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A EQUED = 'C': A := A * diag(C) EQUED = 'B': A := diag(R) * A * diag(C).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input and output parameter.

AFB is DOUBLE PRECISION

AFB is an array, dimension (LDAFB, N). If FACT = 'F', then AFB is an input argument and on entry contains details of the LU factorization of the band matrix A, as computed by DGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. If EQUED .ne. 'N', then AFB is the factored form of the equilibrated matrix A.

If FACT = 'N', then AFB is an output argument and on exit returns details of the LU factorization of A.

If FACT = 'E', then AFB is an output argument and on exit returns details of the LU factorization of the equilibrated matrix A (see the description of AB for the form of the equilibrated matrix).

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL+KU+1.

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the factorization A = L*U as computed by DGBTRF; row i of the matrix was interchanged with row IPIV(i).

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = L*U of the original matrix A.

If FACT = 'E', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = L*U of the equilibrated matrix A.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R Input and output parameter.

R is DOUBLE PRECISION

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))* X if TRANS = 'N' and EQUED = 'C' or 'B', or inv(diag(R))* X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N). On exit, WORK(1) contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If WORK(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with 0<INFO<=N, then WORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

For this routine in other precisions, please see *cgbsvx*, *sgbsvx* and *zgbsvx*. It also exists with a native C interface as *LAPACKE_dgbsvx*.

4.6.57 dgbsvxx

```
DGBSVXX uses the LU factorization to compute the solution to a
   double precision system of linear equations  A * X = B,  where A is an
   N-by-N matrix and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. DGBSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
```

(continues on next page)

(continued from previous page)

```
   calculated and returned.

   DGBSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   DGBSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what DGBSVXX would itself produce.

                                                                  The␣
↪following steps are performed:

   1. If FACT = 'E', double precision scaling factors are computed to equilibrate
   the system:

     TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
     TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
     TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
   or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
   the matrix A (after equilibration if FACT = 'E') as

     A = P * L * U,

   where P is a permutation matrix, L is a unit lower triangular
   matrix, and U is upper triangular.

   3. If some U(i,i)=0, so that U is exactly singular, then the
   routine returns with INFO = i. Otherwise, the factored form of A
   is used to estimate the condition number of the matrix A (see
   argument RCOND). If the reciprocal of the condition number is less
   than machine precision, the routine still goes on to solve for X
   and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form
   of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
   error and error bounds.  Refinement calculates the residual to at
   least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
   diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
   that it solves the original system before equilibration.
↪   Some optional parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dgbsvxx(FACT, TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV,
                   EQUED, R, C, B, LDB, X, LDX, RCOND, RPVGRW, BERR,
                   N_ERR_BNDS, ERR_BNDS_NORM, ERR_BNDS_COMP, NPARAMS, PARAMS,
                   WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgbsvxx_(const char *fact, const char *trans, const armpl_int_t *n,
              const armpl_int_t *kl, const armpl_int_t *ku,
              const armpl_int_t *nrhs, double *ab, const armpl_int_t *ldab,
              double *afb, const armpl_int_t *ldafb, armpl_int_t *ipiv,
              char *equed, double *r, double *c, double *b,
              const armpl_int_t *ldb, double *x, const armpl_int_t *ldx,
              double *rcond, double *rpvgrw, double *berr,
              const armpl_int_t *n_err_bnds, double *err_bnds_norm,
              double *err_bnds_comp, const armpl_int_t *nparams,
              double *params, double *work, armpl_int_t *iwork,
              armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF, and IPIV are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose = Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

If FACT = 'F' and EQUED is not 'N', then AB must have been equilibrated by the scaling factors in R and/or C. AB is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A EQUED = 'C': A := A * diag(C) EQUED = 'B': A := diag(R) * A * diag(C).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input and output parameter.

AFB is DOUBLE PRECISION

AFB is an array, dimension (LDAFB, N). If FACT = 'F', then AFB is an input argument and on entry contains details of the LU factorization of the band matrix A, as computed by DGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. If EQUED .ne. 'N', then AFB is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL+KU+1.

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the factorization A = P*L*U as computed by DGETRF; row i of the matrix was interchanged with row IPIV(i).

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the equilibrated matrix A.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R Input and output parameter.

R is DOUBLE PRECISION

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive. If R

is output, each element of R is a power of the radix. If R is input, each element of R should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive. If C is output, each element of C is a power of the radix. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))* X if TRANS = 'N' and EQUED = 'C' or 'B', or inv(diag(R))* X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

RPVGRW Output parameter.

RPVGRW is DOUBLE PRECISION

Reciprocal pivot growth. On exit, this contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable. If factorization fails with 0<INFO<=N, then this contains the reciprocal pivot growth factor for the leading INFO columns of A. In DGESVX, this quantity is returned in WORK(1).

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is DOUBLE PRECISION

PARAMS is an array, dimension (NPARAMS). Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0D+0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the extra-precise refinement algorithm. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

Related Information

For this routine in other precisions, please see *cgbsvxx*, *sgbsvxx* and *zgbsvxx*. It also exists with a native C interface as *LAPACKE_dgbsvxx*.

4.6.58 dgbtrs

`dgbtrs` solves a system of linear equations

```
A * X = B  or  A**T * X = B
```

with a general band matrix A using the LU factorization computed by DGBTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgbtrs(TRANS, N, KL, KU, NRHS, AB, LDAB, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dgbtrs_(const char *trans, const armpl_int_t *n, const armpl_int_t *kl,
             const armpl_int_t *ku, const armpl_int_t *nrhs, const double *ab,
             const armpl_int_t *ldab, const armpl_int_t *ipiv, double *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

`TRANS` is `CHARACTER*1`

Specifies the form of the system of equations. = 'N': A * X = `B` (No transpose) = 'T': A^T * X = `B` (Transpose) = 'C': A^T * X = `B` (Conjugate transpose = Transpose)

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0.

KL Input parameter.

`KL` is `INTEGER`

The number of subdiagonals within the band of A. `KL` >= 0.

KU Input parameter.

`KU` is `INTEGER`

The number of superdiagonals within the band of A. `KU` >= 0.

NRHS Input parameter.

`NRHS` is `INTEGER`

The number of right hand sides, i.e., the number of columns of the matrix `B`. `NRHS` >= 0.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). Details of the LU factorization of the band matrix A, as computed by DGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= N, row i of the matrix was interchanged with row IPIV(i).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgbtrs*, *sgbtrs* and *zgbtrs*. It also exists with a native C interface as *LAPACKE_dgbtrs*.

4.6.59 dgesv

dgesv computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as

```
A = P * L * U,
```

where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgesv(N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dgesv_(const armpl_int_t *n, const armpl_int_t *nrhs, double *a,
            const armpl_int_t *lda, armpl_int_t *ipiv, double *b,
            const armpl_int_t *ldb, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the N-by-N coefficient matrix A. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIV(i).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS matrix of right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *cgesv*, *sgesv* and *zgesv*. It also exists with a native C interface as *LAPACKE_dgesv*.

4.6.60 dgesvx

dgesvx uses the LU factorization to compute the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
 the system:
   TRANS = 'N':  diag(R)*A*diag(C)      *inv(diag(C))*X = diag(R)*B
   TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
   TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
or diag(C)*B (if TRANS = 'T' or 'C').
```

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the

```
 matrix A (after equilibration if FACT = 'E') as
   A = P * L * U,
where P is a permutation matrix, L is a unit lower triangular
matrix, and U is upper triangular.
```

3. If some U(i,i)=0, so that U is exactly singular, then the routine

```
 returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
 diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
that it solves the original system before equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dgesvx(FACT, TRANS, N, NRHS, A, LDA, AF, LDAF, IPIV, EQUED, R, C,
                  B, LDB, X, LDX, RCOND, FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgesvx_(const char *fact, const char *trans, const armpl_int_t *n,
             const armpl_int_t *nrhs, double *a, const armpl_int_t *lda,
             double *af, const armpl_int_t *ldaf, armpl_int_t *ipiv,
             char *equed, double *r, double *c, double *b,
             const armpl_int_t *ldb, double *x, const armpl_int_t *ldx,
             double *rcond, double *ferr, double *berr, double *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF, and IPIV are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A EQUED = 'C': A := A * diag(C) EQUED = 'B': A := diag(R) * A * diag(C).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the factors L and U from the factorization A = P*L*U as computed by DGETRF. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the factorization A = P*L*U as computed by DGETRF; row i of the matrix was interchanged with row IPIV(i).

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the equilibrated matrix A.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R Input and output parameter.

R is DOUBLE PRECISION

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))* X if TRANS = 'N' and EQUED = 'C' or 'B', or inv(diag(R))* X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4*N). On exit, WORK(1) contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If WORK(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with 0<INFO<=N, then WORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *cgesvx*, *sgesvx* and *zgesvx*. It also exists with a native C interface as *LAPACKE_dgesvx*.

4.6.61 dgesvxx

```
DGESVXX uses the LU factorization to compute the solution to a
   double precision system of linear equations  A * X = B,  where A is an
   N-by-N matrix and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. DGESVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   DGESVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   DGESVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what DGESVXX would itself produce.

                                                                    The␣
↪following steps are performed:

   1. If FACT = 'E', double precision scaling factors are computed to equilibrate
   the system:

     TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
     TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
     TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
   or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
   the matrix A (after equilibration if FACT = 'E') as

     A = P * L * U,

   where P is a permutation matrix, L is a unit lower triangular
   matrix, and U is upper triangular.

   3. If some U(i,i)=0, so that U is exactly singular, then the
   routine returns with INFO = i. Otherwise, the factored form of A
   is used to estimate the condition number of the matrix A (see
   argument RCOND). If the reciprocal of the condition number is less
   than machine precision, the routine still goes on to solve for X
   and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form
   of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
   error and error bounds.  Refinement calculates the residual to at
   least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
   diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
   that it solves the original system before equilibration.
↪   Some optional parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
```

(continues on next page)

(continued from previous page)

```
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dgesvxx(FACT, TRANS, N, NRHS, A, LDA, AF, LDAF, IPIV, EQUED, R, C,
                   B, LDB, X, LDX, RCOND, RPVGRW, BERR, N_ERR_BNDS,

              armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF, and IPIV are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose = Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A EQUED = 'C': A := A * diag(C) EQUED = 'B': A := diag(R) * A * diag(C).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the factors L and U from the factorization A = P*L*U as computed by DGETRF. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the factorization A = P*L*U as computed by DGETRF; row i of the matrix was interchanged with row IPIV(i).

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the equilibrated matrix A.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R Input and output parameter.

R is DOUBLE PRECISION

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive. If R is output, each element of R is a power of the radix. If R is input, each element of R should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive. If C is output, each element of C is a power of the radix. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))* X if TRANS = 'N' and EQUED = 'C' or 'B', or inv(diag(R))* X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

RPVGRW Output parameter.

RPVGRW is DOUBLE PRECISION

Reciprocal pivot growth. On exit, this contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable. If factorization fails with 0<INFO<=N, then this contains the reciprocal pivot growth factor for the leading INFO columns of A. In DGESVX, this quantity is returned in WORK(1).

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix

Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is DOUBLE PRECISION

PARAMS is an array, dimension (NPARAMS). Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0D+0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the extra-precise refinement algorithm. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

Related Information

For this routine in other precisions, please see *cgesvxx*, *sgesvxx* and *zgesvxx*. It also exists with a native C interface as *LAPACKE_dgesvxx*.

4.6.62 dgetrs

dgetrs solves a system of linear equations

```
A * X = B  or  A**T * X = B
```

with a general N-by-N matrix A using the LU factorization computed by DGETRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgetrs(TRANS, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dgetrs_(const char *trans, const armpl_int_t *n, const armpl_int_t *nrhs,
             const double *a, const armpl_int_t *lda, const armpl_int_t *ipiv,
             double *b, const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^T * X = B (Conjugate transpose = Transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The factors L and U from the factorization A = P*L*U as computed by DGETRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from DGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgetrs*, *sgetrs* and *zgetrs*. It also exists with a native C interface as *LAPACKE_dgetrs*.

4.6.63 dgtsv

dgtsv solves the equation

```
A*X = B,
```

where A is an n by n tridiagonal matrix, by Gaussian elimination with partial pivoting.

Note that the equation A^T *X = B may be solved by interchanging the order of the arguments DU and DL.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgtsv(N, NRHS, DL, D, DU, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dgtsv_(const armpl_int_t *n, const armpl_int_t *nrhs, double *dl,
            double *d, double *du, double *b, const armpl_int_t *ldb,
            armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input and output parameter.

DL is DOUBLE PRECISION

DL is an array, dimension (N-1). On entry, DL must contain the (n-1) sub-diagonal elements of A.

On exit, DL is overwritten by the (n-2) elements of the second super-diagonal of the upper triangular matrix U from the LU factorization of A, in DL(1), . . . , DL(n-2).

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, D must contain the diagonal elements of A.

On exit, D is overwritten by the n diagonal elements of U.

DU Input and output parameter.

DU is DOUBLE PRECISION

DU is an array, dimension (N-1). On entry, DU must contain the (n-1) super-diagonal elements of A.

On exit, DU is overwritten by the (n-1) elements of the first super-diagonal of U.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N by NRHS matrix of right hand side matrix B. On exit, if INFO = 0, the N by NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero, and the solution has not been computed. The factorization has not been completed unless i = N.

Related Information

For this routine in other precisions, please see *cgtsv*, *sgtsv* and *zgtsv*. It also exists with a native C interface as *LAPACKE_dgtsv*.

4.6.64 dgtsvx

dgtsvx uses the LU factorization to compute the solution to a real system of linear equations A * X = B or A^T * X = B, where A is a tridiagonal matrix of order N and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the LU decomposition is used to factor the matrix A

```
 as A = L * U, where L is a product of permutation and unit lower
bidiagonal matrices and U is upper triangular with nonzeros in
only the main diagonal and first two superdiagonals.
```

2. If some U(i,i)=0, so that U is exactly singular, then the routine

```
 returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dgtsvx(FACT, TRANS, N, NRHS, DL, D, DU, DLF, DF, DUF, DU2, IPIV, B,
                  LDB, X, LDX, RCOND, FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgtsvx_(const char *fact, const char *trans, const armpl_int_t *n,
             const armpl_int_t *nrhs, const double *dl, const double *d,
             const double *du, double *dlf, double *df, double *duf,
             double *du2, armpl_int_t *ipiv, const double *b,
             const armpl_int_t *ldb, double *x, const armpl_int_t *ldx,
             double *rcond, double *ferr, double *berr, double *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of A has been supplied on entry. = 'F': DLF, DF, DUF, DU2, and IPIV contain the factored form of A; DL, D, DU, DLF, DF, DUF, DU2 and IPIV will not be modified. = 'N': The matrix will be copied to DLF, DF, and DUF and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input parameter.

DL is DOUBLE PRECISION

DL is an array, dimension (N-1). The (n-1) subdiagonal elements of A.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n diagonal elements of A.

DU Input parameter.

DU is DOUBLE PRECISION

DU is an array, dimension (N-1). The (n-1) superdiagonal elements of A.

DLF Input and output parameter.

DLF is DOUBLE PRECISION

DLF is an array, dimension (N-1). If FACT = 'F', then DLF is an input argument and on entry contains the (n-1) multipliers that define the matrix L from the LU factorization of A as computed by DGTTRF.

If FACT = 'N', then DLF is an output argument and on exit contains the (n-1) multipliers that define the matrix L from the LU factorization of A.

DF Input and output parameter.

DF is DOUBLE PRECISION

DF is an array, dimension (N). If FACT = 'F', then DF is an input argument and on entry contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

If FACT = 'N', then DF is an output argument and on exit contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DUF Input and output parameter.

DUF is DOUBLE PRECISION

DUF is an array, dimension (N-1). If FACT = 'F', then DUF is an input argument and on entry contains the (n-1) elements of the first superdiagonal of U.

If FACT = 'N', then DUF is an output argument and on exit contains the (n-1) elements of the first superdiagonal of U.

DU2 Input and output parameter.

DU2 is DOUBLE PRECISION

DU2 is an array, dimension (N-2). If FACT = 'F', then DU2 is an input argument and on entry contains the (n-2) elements of the second superdiagonal of U.

If FACT = 'N', then DU2 is an output argument and on exit contains the (n-2) elements of the second superdiagonal of U.

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the LU factorization of A as computed by DGTTRF.

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the LU factorization of A; row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: U(i,i) is exactly zero. The factorization has not been completed unless i = N, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *cgtsvx*, *sgtsvx* and *zgtsvx*. It also exists with a native C interface as *LAPACKE_dgtsvx*.

4.6.65 dgttrs

dgttrs solves one of the systems of equations

```
A*X = B  or  A**T*X = B,
```

with a tridiagonal matrix A using the LU factorization computed by DGTTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgttrs(TRANS, N, NRHS, DL, D, DU, DU2, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dgttrs_(const char *trans, const armpl_int_t *n, const armpl_int_t *nrhs,
             const double *dl, const double *d, const double *du,
             const double *du2, const armpl_int_t *ipiv, double *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations. = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^T * X = B (Conjugate transpose = Transpose)

N Input parameter.

N is INTEGER

The order of the matrix A.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input parameter.

DL is DOUBLE PRECISION

DL is an array, dimension (N-1). The (n-1) multipliers that define the matrix L from the LU factorization of A.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DU Input parameter.

DU is DOUBLE PRECISION

DU is an array, dimension (N-1). The (n-1) elements of the first super-diagonal of U.

DU2 Input parameter.

DU2 is DOUBLE PRECISION

DU2 is an array, dimension (N-2). The (n-2) elements of the second super-diagonal of U.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the matrix of right hand side vectors B. On exit, B is overwritten by the solution vectors X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgttrs*, *sgttrs* and *zgttrs*. It also exists with a native C interface as *LAPACKE_dgttrs*.

4.6.66 dpbsv

dpbsv computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric positive definite band matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

```
A = U**T * U,  if UPLO = 'U', or
A = L * L**T,  if UPLO = 'L',
```

where U is an upper triangular band matrix, and L is a lower triangular band matrix, with the same number of superdiagonals or subdiagonals as A. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpbsv(UPLO, N, KD, NRHS, AB, LDAB, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dpbsv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
            const armpl_int_t *nrhs, double *ab, const armpl_int_t *ldab,
            double *b, const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(KD+1+i-j,j) = A(i,j) for max(1,j-KD)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(N,j+KD). See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the band matrix A, in the same storage format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

Related Information

For this routine in other precisions, please see *cpbsv*, *spbsv* and *zpbsv*. It also exists with a native C interface as *LAPACKE_dpbsv*.

4.6.67 dpbsvx

dpbsvx uses the Cholesky factorization A = U^T *U or A = L*L^T to compute the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric positive definite band matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
 the system:
   diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to

```
 factor the matrix A (after equilibration if FACT = 'E') as
   A = U**T * U,  if UPLO = 'U', or
   A = L * L**T,  if UPLO = 'L',
where U is an upper triangular band matrix, and L is a lower
triangular band matrix.
```

3. If the leading i-by-i principal minor is not positive definite,

```
 then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A.  If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
 diag(S) so that it solves the original system before
equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dpbsvx(FACT, UPLO, N, KD, NRHS, AB, LDAB, AFB, LDAFB, EQUED, S, B,
                  LDB, X, LDX, RCOND, FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dpbsvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *kd, const armpl_int_t *nrhs, double *ab,
             const armpl_int_t *ldab, double *afb, const armpl_int_t *ldafb,
             char *equed, double *s, double *b, const armpl_int_t *ldb,
             double *x, const armpl_int_t *ldx, double *rcond, double *ferr,
             double *berr, double *work, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AFB contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. AB and AFB will not be modified. = 'N': The matrix A will be copied to AFB and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AFB and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix diag(S)*A*diag(S). The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(KD+1+i-j,j) = A(i,j) for max(1,j-KD)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(N,j+KD). See below for further details.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array A. LDAB >= KD+1.

AFB Input and output parameter.

AFB is DOUBLE PRECISION

AFB is an array, dimension (LDAFB, N). If FACT = 'F', then AFB is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the band matrix A, in the same storage format as A (see AB). If EQUED = 'Y', then AFB is the factored form of the equilibrated matrix A.

If FACT = 'N', then AFB is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T .

If FACT = 'E', then AFB is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= KD+1.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *cpbsvx*, *spbsvx* and *zpbsvx*. It also exists with a native C interface as *LAPACKE_dpbsvx*.

4.6.68 dpbtrs

dpbtrs solves a system of linear equations A*X = B with a symmetric positive definite band matrix A using the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ computed by DPBTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpbtrs(UPLO, N, KD, NRHS, AB, LDAB, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dpbtrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_int_t *nrhs, const double *ab,
             const armpl_int_t *ldab, double *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular factor stored in AB; = 'L': Lower triangular factor stored in AB.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the band matrix A, stored in the first KD+1 rows of the array. The j-th column of U or L is stored in the j-th column of the array AB as follows: if UPLO ='U', AB(kd+1+i-j,j) = U(i,j) for max(1,j-kd)<=i<=j; if UPLO ='L', AB(1+i-j,j) = L(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpbtrs*, *spbtrs* and *zpbtrs*. It also exists with a native C interface as *LAPACKE_dpbtrs*.

4.6.69 dpftrs

dpftrs solves a system of linear equations A*X = B with a symmetric positive definite matrix A using the Cholesky factorization A = U^T *U or A = L*L^T computed by DPFTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpftrs(TRANSR, UPLO, N, NRHS, A, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dpftrs_(const char *transr, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, const double *a, double *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal TRANSR of RFP A is stored; = 'T': The Transpose TRANSR of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of RFP A is stored; = 'L': Lower triangle of RFP A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (N*(N+1)/2).. The triangular factor U or L from the Cholesky factorization of RFP A = U^T *U or RFP A = L*L^T , as computed by DPFTRF. See note below for more details about RFP A.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpftrs*, *spftrs* and *zpftrs*. It also exists with a native C interface as *LAPACKE_dpftrs*.

4.6.70 dposv

dposv computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric positive definite matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

```
A = U**T* U,  if UPLO = 'U', or
A = L * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine dposv(UPLO, N, NRHS, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dposv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            double *a, const armpl_int_t *lda, double *b,
            const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

Related Information

For this routine in other precisions, please see *cposv*, *sposv* and *zposv*. It also exists with a native C interface as *LAPACKE_dposv*.

4.6.71 dposvx

dposvx uses the Cholesky factorization A = U^T *U or A = L*L^T to compute the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric positive definite matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
 the system:
   diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to

```
 factor the matrix A (after equilibration if FACT = 'E') as
   A = U**T* U,  if UPLO = 'U', or
   A = L * L**T,  if UPLO = 'L',
where U is an upper triangular matrix and L is a lower triangular
matrix.
```

3. If the leading i-by-i principal minor is not positive definite,

```
 then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A.  If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
 diag(S) so that it solves the original system before
equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dposvx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, EQUED, S, B, LDB, X,
                  LDX, RCOND, FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dposvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, double *a, const armpl_int_t *lda,
             double *af, const armpl_int_t *ldaf, char *equed, double *s,
             double *b, const armpl_int_t *ldb, double *x,
             const armpl_int_t *ldx, double *rcond, double *ferr,
             double *berr, double *work, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. A and AF will not be modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix diag(S)*A*diag(S). If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , in the same storage format as A. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix diag(S)*A*diag(S).

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *cposvx*, *sposvx* and *zposvx*. It also exists with a native C interface as *LAPACKE_dposvx*.

4.6.72 dposvxx

```
DPOSVXX uses the Cholesky factorization A = U**T*U or A = L*L**T
   to compute the solution to a double precision system of linear equations
   A * X = B, where A is an N-by-N symmetric positive definite matrix
   and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. DPOSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   DPOSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   DPOSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what DPOSVXX would itself produce.

                                                                  The␣
↪following steps are performed:

   1. If FACT = 'E', double precision scaling factors are computed to equilibrate
   the system:

     diag(S)*A*diag(S)      *inv(diag(S))*X = diag(S)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

   2. If FACT = 'N' or 'E', the Cholesky decomposition is used to
   factor the matrix A (after equilibration if FACT = 'E') as
      A = U**T* U,  if UPLO = 'U', or
      A = L * L**T,  if UPLO = 'L',
   where U is an upper triangular matrix and L is a lower triangular
   matrix.
```

(continues on next page)

(continued from previous page)

```
   3. If the leading i-by-i principal minor is not positive definite,
   then the routine returns with INFO = i. Otherwise, the factored
   form of A is used to estimate the condition number of the matrix
   A (see argument RCOND).  If the reciprocal of the condition number
   is less than machine precision, the routine still goes on to solve
   for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form
   of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
   error and error bounds.  Refinement calculates the residual to at
   least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
   diag(S) so that it solves the original system before
   equilibration.                          Some optional parameters are bundled␣
↪in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dposvxx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, EQUED, S, B, LDB, X,
                   LDX, RCOND, RPVGRW, BERR, N_ERR_BNDS, ERR_BNDS_NORM,
                   ERR_BNDS_COMP, NPARAMS, PARAMS, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dposvxx_(const char *fact, const char *uplo, const armpl_int_t *n,
              const armpl_int_t *nrhs, double *a, const armpl_int_t *lda,
              double *af, const armpl_int_t *ldaf, char *equed, double *s,
              double *b, const armpl_int_t *ldb, double *x,
              const armpl_int_t *ldx, double *rcond, double *rpvgrw,
              double *berr, const armpl_int_t *n_err_bnds,
              double *err_bnds_norm, double *err_bnds_comp,
              const armpl_int_t *nparams, double *params, double *work,
              armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by S. A and AF are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix diag(S)*A*diag(S). If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , in the same storage format as A. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix diag(S)*A*diag(S).

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The row scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the

radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S)*B;

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

RPVGRW Output parameter.

RPVGRW is DOUBLE PRECISION

Reciprocal pivot growth. On exit, this contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable. If factorization fails with 0<INFO<=N, then this contains the reciprocal pivot growth factor for the leading INFO columns of A.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is DOUBLE PRECISION

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0D+0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the extra-precise refinement algorithm. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

4.6.73 dpotrs

dpotrs solves a system of linear equations A*X = B with a symmetric positive definite matrix A using the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ computed by DPOTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpotrs(UPLO, N, NRHS, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dpotrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const double *a, const armpl_int_t *lda, double *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by DPOTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpotrs*, *spotrs* and *zpotrs*. It also exists with a native C interface as *LAPACKE_dpotrs*.

4.6.74 dppsv

dppsv computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric positive definite matrix stored in packed format and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

```
A = U**T* U,  if UPLO = 'U', or
A = L * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine dppsv(UPLO, N, NRHS, AP, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dppsv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            double *ap, double *b, const armpl_int_t *ldb, armpl_int_t *info,
            ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input and output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , in the same storage format as A.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

Related Information

For this routine in other precisions, please see *cppsv*, *sppsv* and *zppsv*. It also exists with a native C interface as *LAPACKE_dppsv*.

4.6.75 dppsvx

dppsvx uses the Cholesky factorization A = U^T *U or A = L*L^T to compute the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric positive definite matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
 the system:
   diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to

```
 factor the matrix A (after equilibration if FACT = 'E') as
   A = U**T* U,  if UPLO = 'U', or
   A = L * L**T,  if UPLO = 'L',
where U is an upper triangular matrix and L is a lower triangular
matrix.
```

3. If the leading i-by-i principal minor is not positive definite,

```
 then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A.  If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
```

(continues on next page)

(continued from previous page)

```
still goes on to solve for X and compute error bounds as
described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
 diag(S) so that it solves the original system before
equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dppsvx(FACT, UPLO, N, NRHS, AP, AFP, EQUED, S, B, LDB, X, LDX,
                  RCOND, FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dppsvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, double *ap, double *afp, char *equed,
             double *s, double *b, const armpl_int_t *ldb, double *x,
             const armpl_int_t *ldx, double *rcond, double *ferr,
             double *berr, double *work, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AFP contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. AP and AFP will not be modified. = 'N': The matrix A will be copied to AFP and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AFP and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input and output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix diag(S)*A*diag(S). The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

AFP Input and output parameter.

AFP is DOUBLE PRECISION

AFP is an array, dimension (N*(N+1)/2). If FACT = 'F', then AFP is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$, in the same storage format as A. If EQUED .ne. 'N', then AFP is the factored form of the equilibrated matrix A.

If FACT = 'N', then AFP is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ of the original matrix A.

If FACT = 'E', then AFP is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ of the equilibrated matrix A (see the description of AP for the form of the equilibrated matrix).

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *cppsvx*, *sppsvx* and *zppsvx*. It also exists with a native C interface as *LAPACKE_dppsvx*.

4.6.76 dpptrs

dpptrs solves a system of linear equations A*X = B with a symmetric positive definite matrix A in packed storage using the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ computed by DPPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpptrs(UPLO, N, NRHS, AP, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dpptrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const double *ap, double *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , packed columnwise in a linear array. The j-th column of U or L is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = U(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = L(i,j) for j<=i<=n.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpptrs*, *spptrs* and *zpptrs*. It also exists with a native C interface as *LAPACKE_dpptrs*.

4.6.77 dptsv

`dptsv` computes the solution to a real system of linear equations A*X = B, where A is an N-by-N symmetric positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

A is factored as A = L*D*L^T , and the factored form of A is then used to solve the system of equations.

Syntax

Fortran specification:

```
use armpl_library

subroutine dptsv(N, NRHS, D, E, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dptsv_(const armpl_int_t *n, const armpl_int_t *nrhs, double *d,
            double *e, double *b, const armpl_int_t *ldb, armpl_int_t *info);
```

Parameters

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0.

NRHS Input parameter.

`NRHS` is `INTEGER`

The number of right hand sides, i.e., the number of columns of the matrix `B`. `NRHS` >= 0.

D Input and output parameter.

`D` is `DOUBLE PRECISION`

`D` is an array, dimension (`N`). On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix `D` from the factorization A = L*D*L^T .

E Input and output parameter.

`E` is `DOUBLE PRECISION`

`E` is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*D*L^T factorization of A. (E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U^T *D*U factorization of A.)

B Input and output parameter.

`B` is `DOUBLE PRECISION`

`B` is an array, dimension (`LDB`, `NRHS`). On entry, the N-by-NRHS right hand side matrix `B`. On exit, if `INFO` = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

`LDB` is `INTEGER`

The leading dimension of the array `B`. `LDB` >= max(1, `N`).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the solution has not been computed. The factorization has not been completed unless i = N.

Related Information

For this routine in other precisions, please see *cptsv*, *sptsv* and *zptsv*. It also exists with a native C interface as *LAPACKE_dptsv*.

4.6.78 dptsvx

dptsvx uses the factorization A = L*D*L^T to compute the solution to a real system of linear equations A*X = B, where A is an N-by-N symmetric positive definite tridiagonal matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the matrix A is factored as A = L*D*L^T , where L

```
 is a unit lower bidiagonal matrix and D is diagonal.  The
factorization can also be regarded as having the form
A = U**T*D*U.
```

2. If the leading i-by-i principal minor is not positive definite,

```
 then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A.  If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dptsvx(FACT, N, NRHS, D, E, DF, EF, B, LDB, X, LDX, RCOND, FERR,
                  BERR, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dptsvx_(const char *fact, const armpl_int_t *n, const armpl_int_t *nrhs,
             const double *d, const double *e, double *df, double *ef,
             const double *b, const armpl_int_t *ldb, double *x,
             const armpl_int_t *ldx, double *rcond, double *ferr,
             double *berr, double *work, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, DF and EF contain the factored form of A. D, E, DF, and EF will not be modified. = 'N': The matrix A will be copied to DF and EF and factored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n diagonal elements of the tridiagonal matrix A.

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The (n-1) subdiagonal elements of the tridiagonal matrix A.

DF Input and output parameter.

DF is DOUBLE PRECISION

DF is an array, dimension (N). If FACT = 'F', then DF is an input argument and on entry contains the n diagonal elements of the diagonal matrix D from the L*D*L^T factorization of A. If FACT = 'N', then DF is an output argument and on exit contains the n diagonal elements of the diagonal matrix D from the L*D*L^T factorization of A.

EF Input and output parameter.

EF is DOUBLE PRECISION

EF is an array, dimension (N-1). If FACT = 'F', then EF is an input argument and on entry contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*D*L^T factorization of A. If FACT = 'N', then EF is an output argument and on exit contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*D*L^T factorization of A.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). If INFO = 0 of INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j).

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

4.6.79 dpttrs

dpttrs solves a tridiagonal system of the form

```
A * X = B
```

using the L*D*L^T factorization of A computed by DPTTRF. D is a diagonal matrix specified in the vector D, L is a unit bidiagonal matrix whose subdiagonal is specified in the vector E, and X and B are N by NRHS matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpttrs(N, NRHS, D, E, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dpttrs_(const armpl_int_t *n, const armpl_int_t *nrhs, const double *d,
             const double *e, double *b, const armpl_int_t *ldb,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the tridiagonal matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n diagonal elements of the diagonal matrix D from the L*D*L^T factorization of A.

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*D*L^T factorization of A. E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the factorization A = U^T *D*U.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpttrs*, *spttrs* and *zpttrs*. It also exists with a native C interface as *LAPACKE_dpttrs*.

4.6.80 dsgesv

dsgesv computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

dsgesv first attempts to factorize the matrix in SINGLE PRECISION and use this factorization within an iterative refinement procedure to produce a solution with DOUBLE PRECISION normwise backward error quality (see below). If the approach fails the method switches to a DOUBLE PRECISION factorization and solve.

The iterative refinement is not going to be a winning strategy if the ratio SINGLE PRECISION performance over DOUBLE PRECISION performance is too small. A reasonable strategy should take the number of right-hand sides and the size of the matrix into account. This might be done with a call to ILAENV in the future. Up to now, we always try iterative refinement.

The iterative refinement process is stopped if

```
ITER > ITERMAX
```

or for all the RHS we have:

```
RNRM < SQRT(N)*XNRM*ANRM*EPS*BWDMAX
```

where

```
o ITER is the number of the current iteration in the iterative
  refinement process
o RNRM is the infinity-norm of the residual
o XNRM is the infinity-norm of the solution
o ANRM is the infinity-operator-norm of the matrix A
o EPS is the machine epsilon returned by DLAMCH('Epsilon')
```

The value ITERMAX and BWDMAX are fixed to 30 and 1.0D+00 respectively.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsgesv(N, NRHS, A, LDA, IPIV, B, LDB, X, LDX, WORK, SWORK, ITER,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dsgesv_(const armpl_int_t *n, const armpl_int_t *nrhs, double *a,
             const armpl_int_t *lda, armpl_int_t *ipiv, const double *b,
             const armpl_int_t *ldb, double *x, const armpl_int_t *ldx,
             double *work, float *swork, armpl_int_t *iter,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array,. dimension (LDA, N) On entry, the N-by-N coefficient matrix A. On exit, if iterative refinement has been successfully used (INFO.EQ.0 and ITER.GE.0, see description below), then A is unchanged, if double precision factorization has been used (INFO.EQ.0 and ITER.LT.0, see description below), then the array A contains the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIV(i). Corresponds either to the single precision factorization (if INFO.EQ.0 and ITER.GE.0) or the double precision factorization (if INFO.EQ.0 and ITER.LT.0).

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N, NRHS). This array is used to hold the residual vectors.

SWORK Output parameter.

SWORK is REAL

SWORK is an array, dimension (N*(N+NRHS)). This array is used to use the single precision matrix and the right-hand sides or solutions in single precision.

ITER Output parameter.

ITER is INTEGER

< 0: iterative refinement has failed, double precision factorization has been performed -1 : the routine fell back to full precision for implementation- or machine-specific reasons -2 : narrowing the precision induced an overflow, the routine fell back to full precision -3 : failure of SGETRF -31: stop the iterative refinement after the 30th iterations > 0: iterative refinement has been successfully used. Returns the number of iterations

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) computed in DOUBLE PRECISION is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

Related Information

It also exists with a native C interface as *LAPACKE_dsgesv*.

4.6.81 dsposv

dsposv computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric positive definite matrix and X and B are N-by-NRHS matrices.

dsposv first attempts to factorize the matrix in SINGLE PRECISION and use this factorization within an iterative refinement procedure to produce a solution with DOUBLE PRECISION normwise backward error quality (see below). If the approach fails the method switches to a DOUBLE PRECISION factorization and solve.

The iterative refinement is not going to be a winning strategy if the ratio SINGLE PRECISION performance over DOUBLE PRECISION performance is too small. A reasonable strategy should take the number of right-hand sides and the size of the matrix into account. This might be done with a call to ILAENV in the future. Up to now, we always try iterative refinement.

The iterative refinement process is stopped if

```
ITER > ITERMAX
```

or for all the RHS we have:

```
RNRM < SQRT(N)*XNRM*ANRM*EPS*BWDMAX
```

where

```
o ITER is the number of the current iteration in the iterative
  refinement process
o RNRM is the infinity-norm of the residual
o XNRM is the infinity-norm of the solution
o ANRM is the infinity-operator-norm of the matrix A
o EPS is the machine epsilon returned by DLAMCH('Epsilon')
```

The value ITERMAX and BWDMAX are fixed to 30 and 1.0D+00 respectively.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsposv(UPLO, N, NRHS, A, LDA, B, LDB, X, LDX, WORK, SWORK, ITER,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dsposv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             double *a, const armpl_int_t *lda, const double *b,
             const armpl_int_t *ldb, double *x, const armpl_int_t *ldx,
             double *work, float *swork, armpl_int_t *iter, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array,. dimension (LDA, N) On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if iterative refinement has been successfully used (INFO.EQ.0 and ITER.GE.0, see description below), then A is unchanged, if double precision factorization has been used (INFO.EQ.0 and ITER.LT.0, see description below), then the array A contains the factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N, NRHS). This array is used to hold the residual vectors.

SWORK Output parameter.

SWORK is REAL

SWORK is an array, dimension (N*(N+NRHS)). This array is used to use the single precision matrix and the right-hand sides or solutions in single precision.

ITER Output parameter.

ITER is INTEGER

< 0: iterative refinement has failed, double precision factorization has been performed -1 : the routine fell back to full precision for implementation- or machine-specific reasons -2 : narrowing the precision induced an overflow, the routine fell back to full precision -3 : failure of SPOTRF -31: stop the iterative refinement after the 30th iterations > 0: iterative refinement has been successfully used. Returns the number of iterations

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i of (DOUBLE PRECISION) A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

Related Information

It also exists with a native C interface as *LAPACKE_dsposv*.

4.6.82 dspsv

dspsv computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

```
sA = U * D * U**T,  if UPLO = 'U', or
A = L * D * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine dspsv(UPLO, N, NRHS, AP, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dspsv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            double *ap, armpl_int_t *ipiv, double *b, const armpl_int_t *ldb,
            armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input and output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by DSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by DSPTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *cspsv*, *sspsv* and *zspsv*. It also exists with a native C interface as *LAPACKE_dspsv*.

4.6.83 dspsvx

dspsvx uses the diagonal pivoting factorization A = U*D*U^T or A = L*D*L^T to compute the solution to a real system of linear equations A * X = B, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the diagonal pivoting method is used to factor A as

```
   A = U * D * U**T,  if UPLO = 'U', or
   A = L * D * L**T,  if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices and D is symmetric and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some D(i,i)=0, so that D is exactly singular, then the routine

```
returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dspsvx(FACT, UPLO, N, NRHS, AP, AFP, IPIV, B, LDB, X, LDX, RCOND,
                  FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dspsvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, const double *ap, double *afp,
             armpl_int_t *ipiv, const double *b, const armpl_int_t *ldb,
             double *x, const armpl_int_t *ldx, double *rcond, double *ferr,
             double *berr, double *work, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AFP and IPIV contain the factored form of A. AP, AFP and IPIV will not be modified. = 'N': The matrix A will be copied to AFP and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

AFP Input and output parameter.

AFP is DOUBLE PRECISION

AFP is an array, dimension (N*(N+1)/2). If FACT = 'F', then AFP is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by DSPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AFP is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by DSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by DSPTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If

UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIV is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by DSPTRF.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION
