BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless,

the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

4.6.84 dsptrs

dsptrs solves a system of linear equations A*X = B with a real symmetric matrix A stored in packed format using the factorization A = U*D*U^T or A = L*D*L^T computed by DSPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsptrs(UPLO, N, NRHS, AP, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dsptrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const double *ap, const armpl_int_t *ipiv, double *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSPTRF, stored as a packed triangular matrix.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSPTRF.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csptrs*, *ssptrs* and *zsptrs*. It also exists with a native C interface as *LAPACKE_dsptrs*.

4.6.85 dsysv

dsysv computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

```
A = U * D * U**T,  if UPLO = 'U', or
A = L * D * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsysv(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsysv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            double *a, const armpl_int_t *lda, armpl_int_t *ipiv, double *b,
            const armpl_int_t *ldb, double *work, const armpl_int_t *lwork,
            armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by DSYTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by DSYTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= 1, and for best performance LWORK >= max(1,N*NB), where NB is the optimal blocksize for DSYTRF. for LWORK < N, TRS will be done with Level BLAS 2 for LWORK >= N, TRS will be done with Level BLAS 3

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *csysv*, *ssysv* and *zsysv*. It also exists with a native C interface as *LAPACKE_dsysv*.

4.6.86 dsysv_aa

DSYSV computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

Aasen's algorithm is used to factor A as

```
A = U * T * U**T,  if UPLO = 'U', or
A = L * T * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is symmetric tridiagonal. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsysv_aa(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsysv_aa_(const char *uplo, const armpl_int_t *n,
               const armpl_int_t *nrhs, double *a, const armpl_int_t *lda,
               armpl_int_t *ipiv, double *b, const armpl_int_t *ldb,
               double *work, const armpl_int_t *lwork, armpl_int_t *info,
               ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the tridiagonal matrix T and the multipliers used to obtain the factor U or L from the factorization A = U*T*U^T or A = L*T*L^T as computed by DSYTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= MAX(1,2*N,3*N-2), and for the best performance, LWORK >= MAX(1,N*NB), where NB is the optimal blocksize for DSYTRF_AA.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *csysv_aa*, *ssysv_aa* and *zsysv_aa*. It also exists with a native C interface as *LAPACKE_dsysv_aa*.

4.6.87 dsysv_rk

DSYSV_RK computes the solution to a real system of linear equations A * X = B, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The bounded Bunch-Kaufman (rook) diagonal pivoting method is used to factor A as

```
A = P*U*D*(U**T)*(P**T),  if UPLO = 'U', or
A = P*L*D*(L**T)*(P**T),  if UPLO = 'L',
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

DSYTRF_RK is called to compute the factorization of a real symmetric matrix. The factored form of A is then used to solve the system of equations A * X = B by calling BLAS3 routine DSYTRS_3.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsysv_rk(UPLO, N, NRHS, A, LDA, E, IPIV, B, LDB, WORK, LWORK,
                    INFO)
```

C specification:

```
#include "armpl.h"

void dsysv_rk_(const char *uplo, const armpl_int_t *n,
               const armpl_int_t *nrhs, double *a, const armpl_int_t *lda,
               double *e, armpl_int_t *ipiv, double *b,
               const armpl_int_t *ldb, double *work, const armpl_int_t *lwork,
               armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, diagonal of the block diagonal matrix D and factors U or L as computed by DSYTRF_RK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

For more info see the description of DSYTRF_RK routine.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). On exit, contains the output computed by the factorization routine DSYTRF_RK, i.e. the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

For more info see the description of DSYTRF_RK routine.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by DSYTRF_RK.

For more info see the description of DSYTRF_RK routine.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)).. Work array used in the factorization stage. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= 1. For best performance of factorization stage LWORK >= max(1,N*NB), where NB is the optimal blocksize for DSYTRF_RK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array for factorization stage, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

Related Information

For this routine in other precisions, please see *csysv_rk*, *ssysv_rk* and *zsysv_rk*. It also exists with a native C interface as *LAPACKE_dsysv_rk*.

4.6.88 dsysv_rook

DSYSV_ROOK computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

```
A = U * D * U**T,  if UPLO = 'U', or
A = L * D * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

DSYTRF_ROOK is called to compute the factorization of a real symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method.

The factored form of A is then used to solve the system of equations A * X = B by calling DSYTRS_ROOK.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsysv_rook(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsysv_rook_(const char *uplo, const armpl_int_t *n,
                 const armpl_int_t *nrhs, double *a, const armpl_int_t *lda,
                 armpl_int_t *ipiv, double *b, const armpl_int_t *ldb,
                 double *work, const armpl_int_t *lwork, armpl_int_t *info,
                 ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by DSYTRF_ROOK.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by DSYTRF_ROOK.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= 1, and for best performance LWORK >= max(1,N*NB), where NB is the optimal blocksize for DSYTRF_ROOK.

TRS will be done with Level 2 BLAS

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *csysv_rook*, *ssysv_rook* and *zsysv_rook*. It also exists with a native C interface as *LAPACKE_dsysv_rook*.

4.6.89 dsysvx

dsysvx uses the diagonal pivoting factorization to compute the solution to a real system of linear equations A * X = B, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the diagonal pivoting method is used to factor A.

```
 The form of the factorization is
   A = U * D * U**T,  if UPLO = 'U', or
   A = L * D * L**T,  if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices, and D is symmetric and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some D(i,i)=0, so that D is exactly singular, then the routine

```
 returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dsysvx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X, LDX,
                  RCOND, FERR, BERR, WORK, LWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsysvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, const double *a, const armpl_int_t *lda,
             double *af, const armpl_int_t *ldaf, armpl_int_t *ipiv,
             const double *b, const armpl_int_t *ldb, double *x,
             const armpl_int_t *ldx, double *rcond, double *ferr,
             double *berr, double *work, const armpl_int_t *lwork,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AF and IPIV contain the factored form of A. AF and IPIV will not be modified. = 'N': The matrix A will be copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by DSYTRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T .

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by DSYTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIV is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by DSYTRF.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= max(1,3*N), and for best performance, when FACT = 'N', LWORK >= max(1,3*N,N*NB), where NB is the optimal blocksize for DSYTRF.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *csysvx*, *ssysvx* and *zsysvx*. It also exists with a native C interface as *LAPACKE_dsysvx*.

4.6.90 dsysvxx

```
DSYSVXX uses the diagonal pivoting factorization to compute the
   solution to a double precision system of linear equations A * X = B, where A
   is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. DSYSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   DSYSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   DSYSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what DSYSVXX would itself produce.

                                                                    The␣
↪following steps are performed:

   1. If FACT = 'E', double precision scaling factors are computed to equilibrate
   the system:

     diag(S)*A*diag(S)      *inv(diag(S))*X = diag(S)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
   the matrix A (after equilibration if FACT = 'E') as

      A = U * D * U**T,  if UPLO = 'U', or
      A = L * D * L**T,  if UPLO = 'L',

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.

   3. If some D(i,i)=0, so that D is exactly singular, then the
   routine returns with INFO = i. Otherwise, the factored form of A
   is used to estimate the condition number of the matrix A (see
   argument RCOND).  If the reciprocal of the condition number is
   less than machine precision, the routine still goes on to solve
   for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form
   of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
   error and error bounds.  Refinement calculates the residual to at
   least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
   diag(R) so that it solves the original system before
   equilibration.                          Some optional parameters are bundled␣
↪in the PARAMS array.  These
```

(continues on next page)

(continued from previous page)

```
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dsysvxx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, EQUED, S, B,
                   LDB, X, LDX, RCOND, RPVGRW, BERR, N_ERR_BNDS,
                   ERR_BNDS_NORM, ERR_BNDS_COMP, NPARAMS, PARAMS, WORK, IWORK,
                   INFO)
```

C specification:

```

              double *err_bnds_norm, double *err_bnds_comp,
              const armpl_int_t *nparams, double *params, double *work,
              armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by S. A, AF, and IPIV are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by DSYTRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T .

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by DSYTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIV is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by DSYTRF.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S)*B;

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

RPVGRW Output parameter.

RPVGRW is DOUBLE PRECISION

Reciprocal pivot growth. On exit, this contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable. If factorization fails with 0<INFO<=N, then this contains the reciprocal pivot growth factor for the leading INFO columns of A.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is DOUBLE PRECISION

PARAMS is an array, dimension (NPARAMS). Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0D+0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the extra-precise refinement algorithm. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

Related Information

For this routine in other precisions, please see *csysvxx*, *ssysvxx* and *zsysvxx*. It also exists with a native C interface as *LAPACKE_dsysvxx*.

4.6.91 dsytrs

dsytrs solves a system of linear equations A*X = B with a real symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by DSYTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytrs(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dsytrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const double *a, const armpl_int_t *lda, const armpl_int_t *ipiv,
             double *b, const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSYTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSYTRF.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csytrs*, *ssytrs* and *zsytrs*. It also exists with a native C interface as *LAPACKE_dsytrs*.

4.6.92 dsytrs2

dsytrs2 solves a system of linear equations A*X = B with a real symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by DSYTRF and converted by DSYCONV.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytrs2(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsytrs2_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
              const double *a, const armpl_int_t *lda,
              const armpl_int_t *ipiv, double *b, const armpl_int_t *ldb,
              double *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSYTRF. Note that A is input / output. This might be counter-intuitive, and one may think that A is input only. A is input / output. This is because, at the start of the subroutine, we permute A in a "better" form and then we permute A back to its original form at the end.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSYTRF.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csytrs2*, *ssytrs2* and *zsytrs2*. It also exists with a native C interface as *LAPACKE_dsytrs2*.

4.6.93 dsytrs_3

DSYTRS_3 solves a system of linear equations A * X = B with a real symmetric matrix A using the factorization computed by DSYTRF_RK or DSYTRF_BK:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This algorithm is using Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytrs_3(UPLO, N, NRHS, A, LDA, E, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dsytrs_3_(const char *uplo, const armpl_int_t *n,
               const armpl_int_t *nrhs, const double *a,
               const armpl_int_t *lda, const double *e,
               const armpl_int_t *ipiv, double *b, const armpl_int_t *ldb,
               armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix: = 'U': Upper triangular, form is A = P*U*D*(U^T)*(P^T); = 'L': Lower triangular, form is A = P*L*D*(L^T)*(P^T).

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). Diagonal of the block diagonal matrix D and factors U or L as computed by DSYTRF_RK and DSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSYTRF_RK or DSYTRF_BK.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

4.6.94 dsytrs_aa

DSYTRS_AA solves a system of linear equations A*X = B with a real symmetric matrix A using the factorization $A = U*T*U^T$ or $A = L*T*L^T$ computed by DSYTRF_AA.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytrs_aa(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsytrs_aa_(const char *uplo, const armpl_int_t *n,
                const armpl_int_t *nrhs, const double *a,
                const armpl_int_t *lda, const armpl_int_t *ipiv, double *b,
                const armpl_int_t *ldb, const double *work,
                const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*T*U^T ; = 'L': Lower triangular, form is A = L*T*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). Details of factors computed by DSYTRF_AA.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges as computed by DSYTRF_AA.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Input parameter.

WORK is DOUBLE array, dimension (MAX(1, LWORK))

LWORK Input parameter.

LWORK is INTEGER, LWORK >= MAX(1,3*N-2).

param[out] INFO verbatim INFO is INTEGER = 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csytrs_aa*, *ssytrs_aa* and *zsytrs_aa*. It also exists with a native C interface as *LAPACKE_dsytrs_aa*.

4.6.95 dsytrs_rook

DSYTRS_ROOK solves a system of linear equations A*X = B with a real symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by DSYTRF_ROOK.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytrs_rook(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dsytrs_rook_(const char *uplo, const armpl_int_t *n,
                  const armpl_int_t *nrhs, const double *a,
                  const armpl_int_t *lda, const armpl_int_t *ipiv, double *b,
                  const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSYTRF_ROOK.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSYTRF_ROOK.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csytrs_rook*, *ssytrs_rook* and *zsytrs_rook*. It also exists with a native C interface as *LAPACKE_dsytrs_rook*.

4.6.96 dtbtrs

dtbtrs solves a triangular system of the form

```
A * X = B  or  A**T * X = B,
```

where A is a triangular band matrix of order N, and B is an N-by NRHS matrix. A check is made to verify that A is nonsingular.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtbtrs(UPLO, TRANS, DIAG, N, KD, NRHS, AB, LDAB, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dtbtrs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_int_t *nrhs, const double *ab,
             const armpl_int_t *ldab, double *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals or subdiagonals of the triangular band matrix A. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first kd+1 rows of AB. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

Related Information

For this routine in other precisions, please see *ctbtrs*, *stbtrs* and *ztbtrs*. It also exists with a native C interface as *LAPACKE_dtbtrs*.

4.6.97 dtptrs

dtptrs solves a triangular system of the form

```
A * X = B  or  A**T * X = B,
```

where A is a triangular matrix of order N stored in packed format, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtptrs(UPLO, TRANS, DIAG, N, NRHS, AP, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dtptrs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *nrhs, const double *ap,
             double *b, const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

Related Information

For this routine in other precisions, please see *ctptrs*, *stptrs* and *ztptrs*. It also exists with a native C interface as *LAPACKE_dtptrs*.

4.6.98 sgbsv

sgbsv computes the solution to a real system of linear equations A * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as A = L * U, where L is a product of permutation and unit lower triangular matrices with KL subdiagonals, and U is upper triangular with KL+KU superdiagonals. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgbsv(N, KL, KU, NRHS, AB, LDAB, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void sgbsv_(const armpl_int_t *n, const armpl_int_t *kl,
            const armpl_int_t *ku, const armpl_int_t *nrhs, float *ab,
            const armpl_int_t *ldab, armpl_int_t *ipiv, float *b,
            const armpl_int_t *ldb, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KL+KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+KL) On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIV(i).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and the solution has not been computed.

Related Information

For this routine in other precisions, please see *cgbsv*, *dgbsv* and *zgbsv*. It also exists with a native C interface as *LAPACKE_sgbsv*.

4.6.99 sgbsvx

sgbsvx uses the LU factorization to compute the solution to a real system of linear equations A * X = B, A^T * X = B, or A^H * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed by this subroutine:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
 the system:
   TRANS = 'N':  diag(R)*A*diag(C)      *inv(diag(C))*X = diag(R)*B
   TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
   TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
or diag(C)*B (if TRANS = 'T' or 'C').
```

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the

```
 matrix A (after equilibration if FACT = 'E') as
   A = L * U,
where L is a product of permutation and unit lower triangular
matrices with KL subdiagonals, and U is upper triangular with
KL+KU superdiagonals.
```

3. If some U(i,i)=0, so that U is exactly singular, then the routine

```
 returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
 diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
that it solves the original system before equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sgbsvx(FACT, TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV,
                  EQUED, R, C, B, LDB, X, LDX, RCOND, FERR, BERR, WORK, IWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sgbsvx_(const char *fact, const char *trans, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku,
             const armpl_int_t *nrhs, float *ab, const armpl_int_t *ldab,
             float *afb, const armpl_int_t *ldafb, armpl_int_t *ipiv,
             char *equed, float *r, float *c, float *b,
             const armpl_int_t *ldb, float *x, const armpl_int_t *ldx,
             float *rcond, float *ferr, float *berr, float *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AFB and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. AB, AFB, and IPIV are not modified. = 'N': The matrix A will be copied to AFB and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AFB and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations. = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. AB is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A EQUED = 'C': A := A * diag(C) EQUED = 'B': A := diag(R) * A * diag(C).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input and output parameter.

AFB is REAL

AFB is an array, dimension (LDAFB, N). If FACT = 'F', then AFB is an input argument and on entry contains details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. If EQUED .ne. 'N', then AFB is the factored form of the equilibrated matrix A.

If FACT = 'N', then AFB is an output argument and on exit returns details of the LU factorization of A.

If FACT = 'E', then AFB is an output argument and on exit returns details of the LU factorization of the equilibrated matrix A (see the description of AB for the form of the equilibrated matrix).

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL+KU+1.

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the factorization A = L*U as computed by SGBTRF; row i of the matrix was interchanged with row IPIV(i).

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = L*U of the original matrix A.

If FACT = 'E', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = L*U of the equilibrated matrix A.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R Input and output parameter.

R is REAL

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C Input and output parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))* X if TRANS = 'N' and EQUED = 'C' or 'B', or inv(diag(R))* X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N). On exit, WORK(1) contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If WORK(1) is much less than 1, then

the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with 0<INFO<=N, then WORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the

Related Information

For this routine in other precisions, please see *cgbsvx*, *dgbsvx* and *zgbsvx*. It also exists with a native C interface as *LAPACKE_sgbsvx*.

4.6.100 sgbsvxx

```
SGBSVXX uses the LU factorization to compute the solution to a
   real system of linear equations  A * X = B,  where A is an
   N-by-N matrix and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. SGBSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   SGBSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   SGBSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what SGBSVXX would itself produce.

                                                                  The␣
↪following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
   the system:

     TRANS = 'N':  diag(R)*A*diag(C)      *inv(diag(C))*X = diag(R)*B
     TRANS = 'T': (diag(R)*A*diag(C))**T  *inv(diag(R))*X = diag(C)*B
     TRANS = 'C': (diag(R)*A*diag(C))**H  *inv(diag(R))*X = diag(C)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
   or diag(C)*B (if TRANS = 'T' or 'C').
```

(continues on next page)

(continued from previous page)

```
   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
   the matrix A (after equilibration if FACT = 'E') as

     A = P * L * U,

   where P is a permutation matrix, L is a unit lower triangular
   matrix, and U is upper triangular.

   3. If some U(i,i)=0, so that U is exactly singular, then the
   routine returns with INFO = i. Otherwise, the factored form of A
   is used to estimate the condition number of the matrix A (see
   argument RCOND). If the reciprocal of the condition number is less
   than machine precision, the routine still goes on to solve for X
   and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form
   of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
   error and error bounds.  Refinement calculates the residual to at
   least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
   diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
   that it solves the original system before equilibration.
↪    Some optional parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sgbsvxx(FACT, TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV,
                   EQUED, R, C, B, LDB, X, LDX, RCOND, RPVGRW, BERR,
                   N_ERR_BNDS, ERR_BNDS_NORM, ERR_BNDS_COMP, NPARAMS, PARAMS,
                   WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgbsvxx_(const char *fact, const char *trans, const armpl_int_t *n,
              const armpl_int_t *kl, const armpl_int_t *ku,
              const armpl_int_t *nrhs, float *ab, const armpl_int_t *ldab,
              float *afb, const armpl_int_t *ldafb, armpl_int_t *ipiv,
              char *equed, float *r, float *c, float *b,
              const armpl_int_t *ldb, float *x, const armpl_int_t *ldx,
              float *rcond, float *rpvgrw, float *berr,
              const armpl_int_t *n_err_bnds, float *err_bnds_norm,
              float *err_bnds_comp, const armpl_int_t *nparams, float *params,
              float *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF, and IPIV are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose = Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

If FACT = 'F' and EQUED is not 'N', then AB must have been equilibrated by the scaling factors in R and/or C. AB is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A EQUED = 'C': A := A * diag(C) EQUED = 'B': A := diag(R) * A * diag(C).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input and output parameter.

AFB is REAL

AFB is an array, dimension (LDAFB, N). If FACT = 'F', then AFB is an input argument and on entry contains details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. If EQUED .ne. 'N', then AFB is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL+KU+1.

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the factorization A = P*L*U as computed by SGETRF; row i of the matrix was interchanged with row IPIV(i).

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the equilibrated matrix A.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R Input and output parameter.

R is REAL

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive. If R is output, each element of R is a power of the radix. If R is input, each element of R should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

C Input and output parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive. If C is output, each element of C is a power of the radix. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))* X if TRANS = 'N' and EQUED = 'C' or 'B', or inv(diag(R))* X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

RPVGRW Output parameter.

RPVGRW is REAL

Reciprocal pivot growth. On exit, this contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable. If factorization fails with 0<INFO<=N, then this contains the reciprocal pivot growth factor for the leading INFO columns of A. In SGESVX, this quantity is returned in WORK(1).

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is REAL

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or

factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

4.6.101 sgbtrs

sgbtrs solves a system of linear equations

```
A * X = B  or  A**T * X = B
```

with a general band matrix A using the LU factorization computed by SGBTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgbtrs(TRANS, N, KL, KU, NRHS, AB, LDAB, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void sgbtrs_(const char *trans, const armpl_int_t *n, const armpl_int_t *kl,
             const armpl_int_t *ku, const armpl_int_t *nrhs, const float *ab,
```

(continues on next page)

(continued from previous page)

```
                const armpl_int_t *ldab, const armpl_int_t *ipiv, float *b,
                const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations. = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^T * X = B (Conjugate transpose = Transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). Details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= N, row i of the matrix was interchanged with row IPIV(i).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgbtrs*, *dgbtrs* and *zgbtrs*. It also exists with a native C interface as *LAPACKE_sgbtrs*.

4.6.102 sgesv

sgesv computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as

```
A = P * L * U,
```

where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgesv(N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void sgesv_(const armpl_int_t *n, const armpl_int_t *nrhs, float *a,
            const armpl_int_t *lda, armpl_int_t *ipiv, float *b,
            const armpl_int_t *ldb, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the N-by-N coefficient matrix A. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIV(i).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS matrix of right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *cgesv*, *dgesv* and *zgesv*. It also exists with a native C interface as *LAPACKE_sgesv*.

4.6.103 sgesvx

sgesvx uses the LU factorization to compute the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
 the system:
   TRANS = 'N':  diag(R)*A*diag(C)      *inv(diag(C))*X = diag(R)*B
   TRANS = 'T': (diag(R)*A*diag(C))**T  *inv(diag(R))*X = diag(C)*B
   TRANS = 'C': (diag(R)*A*diag(C))**H  *inv(diag(R))*X = diag(C)*B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
or diag(C)*B (if TRANS = 'T' or 'C').
```

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the

```
 matrix A (after equilibration if FACT = 'E') as
   A = P * L * U,
where P is a permutation matrix, L is a unit lower triangular
matrix, and U is upper triangular.
```

3. If some U(i,i)=0, so that U is exactly singular, then the routine

```
 returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
 diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
that it solves the original system before equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sgesvx(FACT, TRANS, N, NRHS, A, LDA, AF, LDAF, IPIV, EQUED, R, C,
                  B, LDB, X, LDX, RCOND, FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgesvx_(const char *fact, const char *trans, const armpl_int_t *n,
             const armpl_int_t *nrhs, float *a, const armpl_int_t *lda,
             float *af, const armpl_int_t *ldaf, armpl_int_t *ipiv,
             char *equed, float *r, float *c, float *b,
             const armpl_int_t *ldb, float *x, const armpl_int_t *ldx,
             float *rcond, float *ferr, float *berr, float *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF, and IPIV are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A EQUED = 'C': A := A * diag(C) EQUED = 'B': A := diag(R) * A * diag(C).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is REAL

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the factors L and U from the factorization A = P*L*U as computed by SGETRF. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the factorization A = P*L*U as computed by SGETRF; row i of the matrix was interchanged with row IPIV(i).

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the equilibrated matrix A.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R Input and output parameter.

R is REAL

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C Input and output parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))* X if TRANS = 'N' and EQUED = 'C' or 'B', or inv(diag(R))* X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4*N). On exit, WORK(1) contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If WORK(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with 0<INFO<=N, then WORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *cgesvx*, *dgesvx* and *zgesvx*. It also exists with a native C interface as *LAPACKE_sgesvx*.

4.6.104 sgesvxx

```
SGESVXX uses the LU factorization to compute the solution to a
   real system of linear equations  A * X = B,  where A is an
   N-by-N matrix and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. SGESVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   SGESVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   SGESVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what SGESVXX would itself produce.

                                                                  The␣
↪following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
   the system:

     TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
```

(continues on next page)

(continued from previous page)

```
     TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
     TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
   or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
   the matrix A (after equilibration if FACT = 'E') as

     A = P * L * U,

   where P is a permutation matrix, L is a unit lower triangular
   matrix, and U is upper triangular.

   3. If some U(i,i)=0, so that U is exactly singular, then the
   routine returns with INFO = i. Otherwise, the factored form of A
   is used to estimate the condition number of the matrix A (see
   argument RCOND). If the reciprocal of the condition number is less
   than machine precision, the routine still goes on to solve for X
   and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form
   of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
   error and error bounds.  Refinement calculates the residual to at
   least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
   diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
   that it solves the original system before equilibration.
↪   Some optional parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF, and IPIV are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose = Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A EQUED = 'C': A := A * diag(C) EQUED = 'B': A := diag(R) * A * diag(C).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is REAL

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the factors L and U from the factorization A = P*L*U as computed by SGETRF. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the factorization A = P*L*U as computed by SGETRF; row i of the matrix was interchanged with row IPIV(i).

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the equilibrated matrix A.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R Input and output parameter.

R is REAL

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive. If R is output, each element of R is a power of the radix. If R is input, each element of R should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

C Input and output parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive. If C is output, each element of C is a power of the radix. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))* X if TRANS = 'N' and EQUED = 'C' or 'B', or inv(diag(R))* X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

RPVGRW Output parameter.

RPVGRW is REAL

Reciprocal pivot growth. On exit, this contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable. If factorization fails with 0<INFO<=N, then this contains the reciprocal pivot growth factor for the leading INFO columns of A. In SGESVX, this quantity is returned in WORK(1).

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is REAL

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

4.6.105 sgetrs

sgetrs solves a system of linear equations

```
A * X = B  or  A**T * X = B
```

with a general N-by-N matrix A using the LU factorization computed by SGETRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgetrs(TRANS, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void sgetrs_(const char *trans, const armpl_int_t *n, const armpl_int_t *nrhs,
             const float *a, const armpl_int_t *lda, const armpl_int_t *ipiv,
             float *b, const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^T * X = B (Conjugate transpose = Transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The factors L and U from the factorization A = P*L*U as computed by SGETRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from SGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgetrs*, *dgetrs* and *zgetrs*. It also exists with a native C interface as *LAPACKE_sgetrs*.

4.6.106 sgtsv

sgtsv solves the equation

```
A*X = B,
```

where A is an n by n tridiagonal matrix, by Gaussian elimination with partial pivoting.

Note that the equation A^T *X = B may be solved by interchanging the order of the arguments DU and DL.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgtsv(N, NRHS, DL, D, DU, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void sgtsv_(const armpl_int_t *n, const armpl_int_t *nrhs, float *dl,
            float *d, float *du, float *b, const armpl_int_t *ldb,
            armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input and output parameter.

DL is REAL

DL is an array, dimension (N-1). On entry, DL must contain the (n-1) sub-diagonal elements of A.

On exit, DL is overwritten by the (n-2) elements of the second super-diagonal of the upper triangular matrix U from the LU factorization of A, in DL(1), . . . , DL(n-2).

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, D must contain the diagonal elements of A.

On exit, D is overwritten by the n diagonal elements of U.

DU Input and output parameter.

DU is REAL

DU is an array, dimension (N-1). On entry, DU must contain the (n-1) super-diagonal elements of A.

On exit, DU is overwritten by the (n-1) elements of the first super-diagonal of U.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N by NRHS matrix of right hand side matrix B. On exit, if INFO = 0, the N by NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero, and the solution has not been computed. The factorization has not been completed unless i = N.

Related Information

For this routine in other precisions, please see *cgtsv*, *dgtsv* and *zgtsv*. It also exists with a native C interface as *LAPACKE_sgtsv*.

4.6.107 sgtsvx

sgtsvx uses the LU factorization to compute the solution to a real system of linear equations A * X = B or A^T * X = B, where A is a tridiagonal matrix of order N and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the LU decomposition is used to factor the matrix A

```
 as A = L * U, where L is a product of permutation and unit lower
bidiagonal matrices and U is upper triangular with nonzeros in
only the main diagonal and first two superdiagonals.
```

2. If some U(i,i)=0, so that U is exactly singular, then the routine

```
 returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sgtsvx(FACT, TRANS, N, NRHS, DL, D, DU, DLF, DF, DUF, DU2, IPIV, B,
                  LDB, X, LDX, RCOND, FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgtsvx_(const char *fact, const char *trans, const armpl_int_t *n,
             const armpl_int_t *nrhs, const float *dl, const float *d,
             const float *du, float *dlf, float *df, float *duf, float *du2,
             armpl_int_t *ipiv, const float *b, const armpl_int_t *ldb,
             float *x, const armpl_int_t *ldx, float *rcond, float *ferr,
             float *berr, float *work, armpl_int_t *iwork, armpl_int_t *info,
             ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of A has been supplied on entry. = 'F': DLF, DF, DUF, DU2, and IPIV contain the factored form of A; DL, D, DU, DLF, DF, DUF, DU2 and IPIV will not be modified. = 'N': The matrix will be copied to DLF, DF, and DUF and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input parameter.

DL is REAL

DL is an array, dimension (N-1). The (n-1) subdiagonal elements of A.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of A.

DU Input parameter.

DU is REAL

DU is an array, dimension (N-1). The (n-1) superdiagonal elements of A.

DLF Input and output parameter.

DLF is REAL

DLF is an array, dimension (N-1). If FACT = 'F', then DLF is an input argument and on entry contains the (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

If FACT = 'N', then DLF is an output argument and on exit contains the (n-1) multipliers that define the matrix L from the LU factorization of A.

DF Input and output parameter.

DF is REAL

DF is an array, dimension (N). If FACT = 'F', then DF is an input argument and on entry contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

If FACT = 'N', then DF is an output argument and on exit contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DUF Input and output parameter.

DUF is REAL

DUF is an array, dimension (N-1). If FACT = 'F', then DUF is an input argument and on entry contains the (n-1) elements of the first superdiagonal of U.

If FACT = 'N', then DUF is an output argument and on exit contains the (n-1) elements of the first superdiagonal of U.

DU2 Input and output parameter.

DU2 is REAL

DU2 is an array, dimension (N-2). If FACT = 'F', then DU2 is an input argument and on entry contains the (n-2) elements of the second superdiagonal of U.

If FACT = 'N', then DU2 is an output argument and on exit contains the (n-2) elements of the second superdiagonal of U.

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the LU factorization of A as computed by SGTTRF.

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the LU factorization of A; row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: U(i,i) is exactly zero. The factorization has not been completed unless i = N, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *cgtsvx*, *dgtsvx* and *zgtsvx*. It also exists with a native C interface as *LAPACKE_sgtsvx*.

4.6.108 sgttrs

sgttrs solves one of the systems of equations

```
A*X = B  or  A**T*X = B,
```

with a tridiagonal matrix A using the LU factorization computed by SGTTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgttrs(TRANS, N, NRHS, DL, D, DU, DU2, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void sgttrs_(const char *trans, const armpl_int_t *n, const armpl_int_t *nrhs,
             const float *dl, const float *d, const float *du,
             const float *du2, const armpl_int_t *ipiv, float *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations. = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^T * X = B (Conjugate transpose = Transpose)

N Input parameter.

N is INTEGER

The order of the matrix A.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input parameter.

DL is REAL

DL is an array, dimension (N-1). The (n-1) multipliers that define the matrix L from the LU factorization of A.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DU Input parameter.

DU is REAL

DU is an array, dimension (N-1). The (n-1) elements of the first super-diagonal of U.

DU2 Input parameter.

DU2 is REAL

DU2 is an array, dimension (N-2). The (n-2) elements of the second super-diagonal of U.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the matrix of right hand side vectors B. On exit, B is overwritten by the solution vectors X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgttrs*, *dgttrs* and *zgttrs*. It also exists with a native C interface as *LAPACKE_sgttrs*.

4.6.109 spbsv

spbsv computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric positive definite band matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

```
A = U**T * U,  if UPLO = 'U', or
A = L * L**T,  if UPLO = 'L',
```

where U is an upper triangular band matrix, and L is a lower triangular band matrix, with the same number of superdiagonals or subdiagonals as A. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine spbsv(UPLO, N, KD, NRHS, AB, LDAB, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void spbsv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
            const armpl_int_t *nrhs, float *ab, const armpl_int_t *ldab,
            float *b, const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(KD+1+i-j,j) = A(i,j) for max(1,j-KD)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(N,j+KD). See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the band matrix A, in the same storage format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

Related Information

For this routine in other precisions, please see *cpbsv*, *dpbsv* and *zpbsv*. It also exists with a native C interface as *LAPACKE_spbsv*.

4.6.110 spbsvx

spbsvx uses the Cholesky factorization A = U^T *U or A = L*L^T to compute the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric positive definite band matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
 the system:
   diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to

```
 factor the matrix A (after equilibration if FACT = 'E') as
   A = U**T * U,  if UPLO = 'U', or
   A = L * L**T,  if UPLO = 'L',
where U is an upper triangular band matrix, and L is a lower
triangular band matrix.
```

3. If the leading i-by-i principal minor is not positive definite,

```
 then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A.  If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
 diag(S) so that it solves the original system before
equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine spbsvx(FACT, UPLO, N, KD, NRHS, AB, LDAB, AFB, LDAFB, EQUED, S, B,
                  LDB, X, LDX, RCOND, FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"
```

(continues on next page)

(continued from previous page)

```
void spbsvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *kd, const armpl_int_t *nrhs, float *ab,
             const armpl_int_t *ldab, float *afb, const armpl_int_t *ldafb,
             char *equed, float *s, float *b, const armpl_int_t *ldb,
             float *x, const armpl_int_t *ldx, float *rcond, float *ferr,
             float *berr, float *work, armpl_int_t *iwork, armpl_int_t *info,
             ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AFB contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. AB and AFB will not be modified. = 'N': The matrix A will be copied to AFB and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AFB and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix diag(S)*A*diag(S). The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(KD+1+i-j,j) = A(i,j) for max(1,j-KD)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(N,j+KD). See below for further details.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array A. LDAB >= KD+1.

AFB Input and output parameter.

AFB is REAL

AFB is an array, dimension (LDAFB, N). If FACT = 'F', then AFB is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the band matrix A, in the same storage format as A (see AB). If EQUED = 'Y', then AFB is the factored form of the equilibrated matrix A.

If FACT = 'N', then AFB is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T .

If FACT = 'E', then AFB is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= KD+1.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is REAL

S is an array, dimension (N). The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

4.6.111 spbtrs

spbtrs solves a system of linear equations A*X = B with a symmetric positive definite band matrix A using the Cholesky factorization A = U^T *U or A = L*L^T computed by SPBTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine spbtrs(UPLO, N, KD, NRHS, AB, LDAB, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void spbtrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_int_t *nrhs, const float *ab,
             const armpl_int_t *ldab, float *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular factor stored in AB; = 'L': Lower triangular factor stored in AB.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the band matrix A, stored in the first KD+1 rows of the array. The j-th column of U or L is stored in the j-th column of the array AB as follows: if UPLO ='U', AB(kd+1+i-j,j) = U(i,j) for max(1,j-kd)<=i<=j; if UPLO ='L', AB(1+i-j,j) = L(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpbtrs*, *dpbtrs* and *zpbtrs*. It also exists with a native C interface as *LAPACKE_spbtrs*.

4.6.112 spftrs

spftrs solves a system of linear equations A*X = B with a symmetric positive definite matrix A using the Cholesky factorization A = U^T *U or A = L*L^T computed by SPFTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine spftrs(TRANSR, UPLO, N, NRHS, A, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void spftrs_(const char *transr, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, const float *a, float *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal TRANSR of RFP A is stored; = 'T': The Transpose TRANSR of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of RFP A is stored; = 'L': Lower triangle of RFP A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (N*(N+1)/2). The triangular factor U or L from the Cholesky factorization of RFP A = U^H *U or RFP A = L*L^T , as computed by SPFTRF. See note below for more details about RFP A.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpftrs*, *dpftrs* and *zpftrs*. It also exists with a native C interface as *LAPACKE_spftrs*.

4.6.113 sposv

sposv computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric positive definite matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

```
A = U**T* U,  if UPLO = 'U', or
A = L * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine sposv(UPLO, N, NRHS, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void sposv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            float *a, const armpl_int_t *lda, float *b,
            const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular

part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

Related Information

For this routine in other precisions, please see *cposv*, *dposv* and *zposv*. It also exists with a native C interface as *LAPACKE_sposv*.

4.6.114 sposvx

sposvx uses the Cholesky factorization A = U^T *U or A = L*L^T to compute the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric positive definite matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
 the system:
   diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to

```
 factor the matrix A (after equilibration if FACT = 'E') as
   A = U**T* U,  if UPLO = 'U', or
   A = L * L**T,  if UPLO = 'L',
where U is an upper triangular matrix and L is a lower triangular
matrix.
```

3. If the leading i-by-i principal minor is not positive definite,

```
 then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A.  If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
 diag(S) so that it solves the original system before
equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sposvx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, EQUED, S, B, LDB, X,
                  LDX, RCOND, FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sposvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, float *a, const armpl_int_t *lda,
             float *af, const armpl_int_t *ldaf, char *equed, float *s,
             float *b, const armpl_int_t *ldb, float *x,
             const armpl_int_t *ldx, float *rcond, float *ferr, float *berr,
             float *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. A and AF will not be modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix diag(S)*A*diag(S). If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is REAL

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , in the same storage format as A. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix diag(S)*A*diag(S).

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is REAL

S is an array, dimension (N). The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *cposvx*, *dposvx* and *zposvx*. It also exists with a native C interface as *LAPACKE_sposvx*.

4.6.115 sposvxx

```
SPOSVXX uses the Cholesky factorization A = U**T*U or A = L*L**T
   to compute the solution to a real system of linear equations
   A * X = B, where A is an N-by-N symmetric positive definite matrix
   and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. SPOSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   SPOSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   SPOSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what SPOSVXX would itself produce.

                                                                    The␣
↪following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
   the system:

     diag(S)*A*diag(S)      *inv(diag(S))*X = diag(S)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

   2. If FACT = 'N' or 'E', the Cholesky decomposition is used to
   factor the matrix A (after equilibration if FACT = 'E') as
      A = U**T* U,  if UPLO = 'U', or
      A = L * L**T,  if UPLO = 'L',
   where U is an upper triangular matrix and L is a lower triangular
   matrix.

   3. If the leading i-by-i principal minor is not positive definite,
   then the routine returns with INFO = i. Otherwise, the factored
   form of A is used to estimate the condition number of the matrix
   A (see argument RCOND).  If the reciprocal of the condition number
   is less than machine precision, the routine still goes on to solve
   for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form
   of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
   error and error bounds.  Refinement calculates the residual to at
   least twice the working precision.
```

(continues on next page)

(continued from previous page)

```
   6. If equilibration was used, the matrix X is premultiplied by
   diag(S) so that it solves the original system before
   equilibration.                          Some optional parameters are bundled␣
↪in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sposvxx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, EQUED, S, B, LDB, X,
                   LDX, RCOND, RPVGRW, BERR, N_ERR_BNDS, ERR_BNDS_NORM,
                   ERR_BNDS_COMP, NPARAMS, PARAMS, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sposvxx_(const char *fact, const char *uplo, const armpl_int_t *n,
              const armpl_int_t *nrhs, float *a, const armpl_int_t *lda,
              float *af, const armpl_int_t *ldaf, char *equed, float *s,
              float *b, const armpl_int_t *ldb, float *x,
              const armpl_int_t *ldx, float *rcond, float *rpvgrw,
              float *berr, const armpl_int_t *n_err_bnds,
              float *err_bnds_norm, float *err_bnds_comp,
              const armpl_int_t *nparams, float *params, float *work,
              armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by S. A and AF are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix diag(S)*A*diag(S). If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is REAL

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , in the same storage format as A. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix diag(S)*A*diag(S).

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is REAL

S is an array, dimension (N). The row scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S)*B;

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

RPVGRW Output parameter.

RPVGRW is REAL

Reciprocal pivot growth. On exit, this contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable. If factorization fails with 0<INFO<=N, then this contains the reciprocal pivot growth factor for the leading INFO columns of A.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is REAL

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or

factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

4.6.116 spotrs

spotrs solves a system of linear equations A*X = B with a symmetric positive definite matrix A using the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ computed by SPOTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine spotrs(UPLO, N, NRHS, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void spotrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const float *a, const armpl_int_t *lda, float *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by SPOTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpotrs*, *dpotrs* and *zpotrs*. It also exists with a native C interface as *LAPACKE_spotrs*.

4.6.117 sppsv

sppsv computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric positive definite matrix stored in packed format and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

```
A = U**T* U,  if UPLO = 'U', or
A = L * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine sppsv(UPLO, N, NRHS, AP, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void sppsv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            float *ap, float *b, const armpl_int_t *ldb, armpl_int_t *info,
            ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input and output parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , in the same storage format as A.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

Related Information

For this routine in other precisions, please see *cppsv*, *dppsv* and *zppsv*. It also exists with a native C interface as *LAPACKE_sppsv*.

4.6.118 sppsvx

sppsvx uses the Cholesky factorization A = U^T *U or A = L*L^T to compute the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric positive definite matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
 the system:
   diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to

```
 factor the matrix A (after equilibration if FACT = 'E') as
   A = U**T* U,  if UPLO = 'U', or
   A = L * L**T,  if UPLO = 'L',
where U is an upper triangular matrix and L is a lower triangular
matrix.
```

3. If the leading i-by-i principal minor is not positive definite,

```
 then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A.  If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
 diag(S) so that it solves the original system before
equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sppsvx(FACT, UPLO, N, NRHS, AP, AFP, EQUED, S, B, LDB, X, LDX,
                  RCOND, FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sppsvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, float *ap, float *afp, char *equed,
             float *s, float *b, const armpl_int_t *ldb, float *x,
             const armpl_int_t *ldx, float *rcond, float *ferr, float *berr,
             float *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AFP contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. AP and AFP will not be modified. = 'N': The matrix A will be copied to AFP and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AFP and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input and output parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix diag(S)*A*diag(S). The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

AFP Input and output parameter.

AFP is REAL

AFP is an array, dimension (N*(N+1)/2). If FACT = 'F', then AFP is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , in the same storage format as A. If EQUED .ne. 'N', then AFP is the factored form of the equilibrated matrix A.

If FACT = 'N', then AFP is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^T * U or A = L * L^T of the original matrix A.

If FACT = 'E', then AFP is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^T * U or A = L * L^T of the equilibrated matrix A (see the description of AP for the form of the equilibrated matrix).

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is REAL

S is an array, dimension (N). The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an

estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

4.6.119 spptrs

spptrs solves a system of linear equations A*X = B with a symmetric positive definite matrix A in packed storage using the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ computed by SPPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine spptrs(UPLO, N, NRHS, AP, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void spptrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const float *ap, float *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , packed columnwise in a linear array. The j-th column of U or L is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = U(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = L(i,j) for j<=i<=n.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpptrs*, *dpptrs* and *zpptrs*. It also exists with a native C interface as *LAPACKE_spptrs*.

4.6.120 sptsv

sptsv computes the solution to a real system of linear equations A*X = B, where A is an N-by-N symmetric positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

A is factored as A = L*D*L^T , and the factored form of A is then used to solve the system of equations.

Syntax

Fortran specification:

```
use armpl_library

subroutine sptsv(N, NRHS, D, E, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void sptsv_(const armpl_int_t *n, const armpl_int_t *nrhs, float *d, float *e,
            float *b, const armpl_int_t *ldb, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the factorization A = L*D*L^T .

E Input and output parameter.

E is REAL

E is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*D*L^T factorization of A. (E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U^T *D*U factorization of A.)

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the solution has not been computed. The factorization has not been completed unless i = N.

Related Information

For this routine in other precisions, please see *cptsv*, *dptsv* and *zptsv*. It also exists with a native C interface as *LAPACKE_sptsv*.

4.6.121 sptsvx

sptsvx uses the factorization A = L*D*L^T to compute the solution to a real system of linear equations A*X = B, where A is an N-by-N symmetric positive definite tridiagonal matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the matrix A is factored as A = L*D*L^T , where L

```
 is a unit lower bidiagonal matrix and D is diagonal.  The
factorization can also be regarded as having the form
A = U**T*D*U.
```

2. If the leading i-by-i principal minor is not positive definite,

```
 then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A.  If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sptsvx(FACT, N, NRHS, D, E, DF, EF, B, LDB, X, LDX, RCOND, FERR,
                  BERR, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sptsvx_(const char *fact, const armpl_int_t *n, const armpl_int_t *nrhs,
             const float *d, const float *e, float *df, float *ef,
             const float *b, const armpl_int_t *ldb, float *x,
             const armpl_int_t *ldx, float *rcond, float *ferr, float *berr,
             float *work, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, DF and EF contain the factored form of A. D, E, DF, and EF will not be modified. = 'N': The matrix A will be copied to DF and EF and factored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the tridiagonal matrix A.

E Input parameter.

E is REAL

E is an array, dimension (N-1). The (n-1) subdiagonal elements of the tridiagonal matrix A.

DF Input and output parameter.

DF is REAL

DF is an array, dimension (N). If FACT = 'F', then DF is an input argument and on entry contains the n diagonal elements of the diagonal matrix D from the $L*D*L^T$ factorization of A. If FACT = 'N', then DF is an output argument and on exit contains the n diagonal elements of the diagonal matrix D from the $L*D*L^T$ factorization of A.

EF Input and output parameter.

EF is REAL

EF is an array, dimension (N-1). If FACT = 'F', then EF is an input argument and on entry contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L*D*L^T$ factorization of A. If FACT = 'N', then EF is an output argument and on exit contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L*D*L^T$ factorization of A.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). If INFO = 0 of INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j).

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

4.6.122 spttrs

spttrs solves a tridiagonal system of the form

```
A * X = B
```

using the L*D*L^T factorization of A computed by SPTTRF. D is a diagonal matrix specified in the vector D, L is a unit bidiagonal matrix whose subdiagonal is specified in the vector E, and X and B are N by NRHS matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine spttrs(N, NRHS, D, E, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void spttrs_(const armpl_int_t *n, const armpl_int_t *nrhs, const float *d,
             const float *e, float *b, const armpl_int_t *ldb,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the tridiagonal matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the diagonal matrix D from the L*D*L^T factorization of A.

E Input parameter.

E is REAL

E is an array, dimension (N-1). The (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*D*L^T factorization of A. E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the factorization A = U^T *D*U.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpttrs*, *dpttrs* and *zpttrs*. It also exists with a native C interface as *LAPACKE_spttrs*.

4.6.123 sspsv

sspsv computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

```
 A = U * D * U**T,  if UPLO = 'U', or
A = L * D * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine sspsv(UPLO, N, NRHS, AP, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void sspsv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            float *ap, armpl_int_t *ipiv, float *b, const armpl_int_t *ldb,
            armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input and output parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by SSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by SSPTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *cspsv*, *dspsv* and *zspsv*. It also exists with a native C interface as *LAPACKE_sspsv*.

4.6.124 sspsvx

sspsvx uses the diagonal pivoting factorization A = U*D*U^T or A = L*D*L^T to compute the solution to a real system of linear equations A * X = B, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the diagonal pivoting method is used to factor A as

```
   A = U * D * U**T,  if UPLO = 'U', or
   A = L * D * L**T,  if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices and D is symmetric and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some D(i,i)=0, so that D is exactly singular, then the routine

```
 returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sspsvx(FACT, UPLO, N, NRHS, AP, AFP, IPIV, B, LDB, X, LDX, RCOND,
                  FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sspsvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, const float *ap, float *afp,
             armpl_int_t *ipiv, const float *b, const armpl_int_t *ldb,
             float *x, const armpl_int_t *ldx, float *rcond, float *ferr,
             float *berr, float *work, armpl_int_t *iwork, armpl_int_t *info,
             ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AFP and IPIV contain the factored form of A. AP, AFP and IPIV will not be modified. = 'N': The matrix A will be copied to AFP and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

AFP Input and output parameter.

AFP is REAL

AFP is an array, dimension (N*(N+1)/2). If FACT = 'F', then AFP is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by SSPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AFP is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by SSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by SSPTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIV is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by SSPTRF.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

4.6.125 ssptrs

ssptrs solves a system of linear equations A*X = B with a real symmetric matrix A stored in packed format using the factorization A = U*D*U^T or A = L*D*L^T computed by SSPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssptrs(UPLO, N, NRHS, AP, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void ssptrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const float *ap, const armpl_int_t *ipiv, float *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSPTRF, stored as a packed triangular matrix.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSPTRF.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csptrs*, *dsptrs* and *zsptrs*. It also exists with a native C interface as *LAPACKE_ssptrs*.

4.6.126 ssysv

ssysv computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

```
A = U * D * U**T,  if UPLO = 'U', or
A = L * D * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssysv(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssysv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            float *a, const armpl_int_t *lda, armpl_int_t *ipiv, float *b,
            const armpl_int_t *ldb, float *work, const armpl_int_t *lwork,
            armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by SSYTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by SSYTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= 1, and for best performance LWORK >= max(1,N*NB), where NB is the optimal blocksize for SSYTRF. for LWORK < N, TRS will be done with Level BLAS 2 for LWORK >= N, TRS will be done with Level BLAS 3

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *csysv*, *dsysv* and *zsysv*. It also exists with a native C interface as *LAPACKE_ssysv*.

4.6.127 ssysv_aa

SSYSV computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

Aasen's algorithm is used to factor A as

```
A = U * T * U**T,  if UPLO = 'U', or
A = L * T * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is symmetric tridiagonal. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssysv_aa(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssysv_aa_(const char *uplo, const armpl_int_t *n,
               const armpl_int_t *nrhs, float *a, const armpl_int_t *lda,
```

(continues on next page)

(continued from previous page)

```
                armpl_int_t *ipiv, float *b, const armpl_int_t *ldb,
                float *work, const armpl_int_t *lwork, armpl_int_t *info,
                ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the tridiagonal matrix T and the multipliers used to obtain the factor U or L from the factorization A = U*T*U^T or A = L*T*L^T as computed by SSYTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= MAX(1,2*N,3*N-2), and for the best performance, LWORK >= MAX(1,N*NB), where NB is the optimal blocksize for SSYTRF_AA.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *csysv_aa*, *dsysv_aa* and *zsysv_aa*. It also exists with a native C interface as *LAPACKE_ssysv_aa*.

4.6.128 ssysv_rk

SSYSV_RK computes the solution to a real system of linear equations A * X = B, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The bounded Bunch-Kaufman (rook) diagonal pivoting method is used to factor A as

```
A = P*U*D*(U**T)*(P**T),  if UPLO = 'U', or
A = P*L*D*(L**T)*(P**T),  if UPLO = 'L',
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

SSYTRF_RK is called to compute the factorization of a real symmetric matrix. The factored form of A is then used to solve the system of equations A * X = B by calling BLAS3 routine SSYTRS_3.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssysv_rk(UPLO, N, NRHS, A, LDA, E, IPIV, B, LDB, WORK, LWORK,
                    INFO)
```

C specification:

```
#include "armpl.h"

void ssysv_rk_(const char *uplo, const armpl_int_t *n,
               const armpl_int_t *nrhs, float *a, const armpl_int_t *lda,
               float *e, armpl_int_t *ipiv, float *b, const armpl_int_t *ldb,
               float *work, const armpl_int_t *lwork, armpl_int_t *info,
               ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, diagonal of the block diagonal matrix D and factors U or L as computed by SSYTRF_RK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

For more info see the description of DSYTRF_RK routine.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is REAL

E is an array, dimension (N). On exit, contains the output computed by the factorization routine DSYTRF_RK, i.e. the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

For more info see the description of DSYTRF_RK routine.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by SSYTRF_RK.

For more info see the description of DSYTRF_RK routine.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)).. Work array used in the factorization stage. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= 1. For best performance of factorization stage LWORK >= max(1,N*NB), where NB is the optimal blocksize for DSYTRF_RK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array for factorization stage, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

4.6.129 ssysv_rook

SSYSV_ROOK computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

```
A = U * D * U**T,  if UPLO = 'U', or
A = L * D * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

SSYTRF_ROOK is called to compute the factorization of a real symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method.

The factored form of A is then used to solve the system of equations A * X = B by calling SSYTRS_ROOK.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssysv_rook(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssysv_rook_(const char *uplo, const armpl_int_t *n,
                 const armpl_int_t *nrhs, float *a, const armpl_int_t *lda,
                 armpl_int_t *ipiv, float *b, const armpl_int_t *ldb,
                 float *work, const armpl_int_t *lwork, armpl_int_t *info,
                 ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by SSYTRF_ROOK.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by SSYTRF_ROOK.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= 1, and for best performance LWORK >= max(1,N*NB), where NB is the optimal blocksize for SSYTRF_ROOK.

TRS will be done with Level 2 BLAS

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *csysv_rook*, *dsysv_rook* and *zsysv_rook*. It also exists with a native C interface as *LAPACKE_ssysv_rook*.

4.6.130 ssysvx

ssysvx uses the diagonal pivoting factorization to compute the solution to a real system of linear equations A * X = B, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the diagonal pivoting method is used to factor A.

```
 The form of the factorization is
   A = U * D * U**T,  if UPLO = 'U', or
   A = L * D * L**T,  if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices, and D is symmetric and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some D(i,i)=0, so that D is exactly singular, then the routine

```
 returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine ssysvx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X, LDX,
                  RCOND, FERR, BERR, WORK, LWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssysvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, const float *a, const armpl_int_t *lda,
             float *af, const armpl_int_t *ldaf, armpl_int_t *ipiv,
             const float *b, const armpl_int_t *ldb, float *x,
             const armpl_int_t *ldx, float *rcond, float *ferr, float *berr,
             float *work, const armpl_int_t *lwork, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AF and IPIV contain the factored form of A. AF and IPIV will not be modified. = 'N': The matrix A will be copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is REAL

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by SSYTRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T .

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by SSYTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIV is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by SSYTRF.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= max(1,3*N), and for best performance, when FACT = 'N', LWORK >= max(1,3*N,N*NB), where NB is the optimal blocksize for SSYTRF.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *csysvx*, *dsysvx* and *zsysvx*. It also exists with a native C interface as *LAPACKE_ssysvx*.

4.6.131 ssysvxx

```
SSYSVXX uses the diagonal pivoting factorization to compute the
   solution to a real system of linear equations A * X = B, where A
   is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. SSYSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   SSYSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   SSYSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what SSYSVXX would itself produce.

                                                                  The␣
↪following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
   the system:

     diag(S)*A*diag(S)      *inv(diag(S))*X = diag(S)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
   the matrix A (after equilibration if FACT = 'E') as

      A = U * D * U**T,  if UPLO = 'U', or
      A = L * D * L**T,  if UPLO = 'L',

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.

   3. If some D(i,i)=0, so that D is exactly singular, then the
   routine returns with INFO = i. Otherwise, the factored form of A
   is used to estimate the condition number of the matrix A (see
   argument RCOND).  If the reciprocal of the condition number is
   less than machine precision, the routine still goes on to solve
   for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form
   of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
   error and error bounds.  Refinement calculates the residual to at
```

(continues on next page)

(continued from previous page)

```
   least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
   diag(R) so that it solves the original system before
   equilibration.                          Some optional parameters are bundled␣
↪in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine ssysvxx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, EQUED, S, B,
                   LDB, X, LDX, RCOND, RPVGRW, BERR, N_ERR_BNDS,
                   ERR_BNDS_NORM, ERR_BNDS_COMP, NPARAMS, PARAMS, WORK, IWORK,
                   INFO)
```

C specification:

```
#include "armpl.h"

void ssysvxx_(const char *fact, char *uplo, const armpl_int_t *n,
              const armpl_int_t *nrhs, float *a, const armpl_int_t *lda,
              float *af, const armpl_int_t *ldaf, armpl_int_t *ipiv,
              char *equed, float *s, float *b, const armpl_int_t *ldb,
              float *x, const armpl_int_t *ldx, float *rcond, float *rpvgrw,
              float *berr, const armpl_int_t *n_err_bnds,
              float *err_bnds_norm, float *err_bnds_comp,
              const armpl_int_t *nparams, float *params, float *work,
              armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by S. A, AF, and IPIV are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is REAL

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by SSYTRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T .

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by SSYTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIV is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by SSYTRF.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is REAL

S is an array, dimension (N). The scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or

overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S)*B;

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

RPVGRW Output parameter.

RPVGRW is REAL

Reciprocal pivot growth. On exit, this contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable. If factorization fails with 0<INFO<=N, then this contains the reciprocal pivot growth factor for the leading INFO columns of A.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is REAL

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

4.6.132 ssytrs

ssytrs solves a system of linear equations A*X = B with a real symmetric matrix A using the factorization A = $U*D*U^T$ or A = $L*D*L^T$ computed by SSYTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytrs(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void ssytrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const float *a, const armpl_int_t *lda, const armpl_int_t *ipiv,
             float *b, const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSYTRF.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csytrs*, *dsytrs* and *zsytrs*. It also exists with a native C interface as *LAPACKE_ssytrs*.

4.6.133 ssytrs2

`ssytrs2` solves a system of linear equations A*X = B with a real symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by SSYTRF and converted by SSYCONV.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytrs2(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssytrs2_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
              const float *a, const armpl_int_t *lda, const armpl_int_t *ipiv,
              float *b, const armpl_int_t *ldb, float *work,
              armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF. Note that A is input / output. This might be counter-intuitive, and one may think that A is input only. A is input / output. This is because, at the start of the subroutine, we permute A in a "better" form and then we permute A back to its original form at the end.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSYTRF.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csytrs2*, *dsytrs2* and *zsytrs2*. It also exists with a native C interface as *LAPACKE_ssytrs2*.

4.6.134 ssytrs_3

SSYTRS_3 solves a system of linear equations A * X = B with a real symmetric matrix A using the factorization computed by SSYTRF_RK or SSYTRF_BK:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This algorithm is using Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytrs_3(UPLO, N, NRHS, A, LDA, E, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void ssytrs_3_(const char *uplo, const armpl_int_t *n,
               const armpl_int_t *nrhs, const float *a,
               const armpl_int_t *lda, const float *e,
               const armpl_int_t *ipiv, float *b, const armpl_int_t *ldb,
               armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix: = 'U': Upper triangular, form is A = P*U*D*(U^T)*(P^T); = 'L': Lower triangular, form is A = P*L*D*(L^T)*(P^T).

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). Diagonal of the block diagonal matrix D and factors U or L as computed by SSYTRF_RK and SSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is REAL

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSYTRF_RK or SSYTRF_BK.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csytrs_3*, *dsytrs_3* and *zsytrs_3*. It also exists with a native C interface as *LAPACKE_ssytrs_3*.

4.6.135 ssytrs_aa

SSYTRS_AA solves a system of linear equations A*X = B with a real symmetric matrix A using the factorization A = U*T*U^T or A = L*T*L^T computed by SSYTRF_AA.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytrs_aa(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssytrs_aa_(const char *uplo, const armpl_int_t *n,
                const armpl_int_t *nrhs, const float *a,
                const armpl_int_t *lda, const armpl_int_t *ipiv, float *b,
                const armpl_int_t *ldb, const float *work,
                const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*T*U^T ; = 'L': Lower triangular, form is A = L*T*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). Details of factors computed by SSYTRF_AA.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges as computed by SSYTRF_AA.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Input parameter.

WORK is DOUBLE array, dimension (MAX(1, LWORK))

LWORK Input parameter.

LWORK is INTEGER, LWORK >= MAX(1,3*N-2).

param[out] INFO verbatim INFO is INTEGER = 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csytrs_aa*, *dsytrs_aa* and *zsytrs_aa*. It also exists with a native C interface as *LAPACKE_ssytrs_aa*.

4.6.136 ssytrs_rook

SSYTRS_ROOK solves a system of linear equations A*X = B with a real symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by SSYTRF_ROOK.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytrs_rook(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void ssytrs_rook_(const char *uplo, const armpl_int_t *n,
                  const armpl_int_t *nrhs, const float *a,
                  const armpl_int_t *lda, const armpl_int_t *ipiv, float *b,
                  const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF_ROOK.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSYTRF_ROOK.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csytrs_rook*, *dsytrs_rook* and *zsytrs_rook*. It also exists with a native C interface as *LAPACKE_ssytrs_rook*.

4.6.137 stbtrs

stbtrs solves a triangular system of the form

```
A * X = B  or  A**T * X = B,
```

where A is a triangular band matrix of order N, and B is an N-by NRHS matrix. A check is made to verify that A is nonsingular.

Syntax

Fortran specification:

```
use armpl_library

subroutine stbtrs(UPLO, TRANS, DIAG, N, KD, NRHS, AB, LDAB, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void stbtrs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_int_t *nrhs, const float *ab,
             const armpl_int_t *ldab, float *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals or subdiagonals of the triangular band matrix A. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first kd+1 rows of AB. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

Related Information

For this routine in other precisions, please see *ctbtrs*, *dtbtrs* and *ztbtrs*. It also exists with a native C interface as *LAPACKE_stbtrs*.

4.6.138 stptrs

stptrs solves a triangular system of the form

```
A * X = B  or  A**T * X = B,
```

where A is a triangular matrix of order N stored in packed format, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

Syntax

Fortran specification:

```
use armpl_library

subroutine stptrs(UPLO, TRANS, DIAG, N, NRHS, AP, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void stptrs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *nrhs, const float *ap,
             float *b, const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

Related Information

For this routine in other precisions, please see *ctptrs*, *dtptrs* and *ztptrs*. It also exists with a native C interface as *LAPACKE_stptrs*.

4.6.139 zcgesv

zcgesv computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

zcgesv first attempts to factorize the matrix in COMPLEX and use this factorization within an iterative refinement procedure to produce a solution with COMPLEX*16 normwise backward error quality (see below). If the approach fails the method switches to a COMPLEX*16 factorization and solve.

The iterative refinement is not going to be a winning strategy if the ratio COMPLEX performance over COMPLEX*16 performance is too small. A reasonable strategy should take the number of right-hand sides and the size of the matrix into account. This might be done with a call to ILAENV in the future. Up to now, we always try iterative refinement.

The iterative refinement process is stopped if

```
ITER > ITERMAX
```

or for all the RHS we have:

```
RNRM < SQRT(N)*XNRM*ANRM*EPS*BWDMAX
```

where

```
 o ITER is the number of the current iteration in the iterative
  refinement process
o RNRM is the infinity-norm of the residual
o XNRM is the infinity-norm of the solution
o ANRM is the infinity-operator-norm of the matrix A
o EPS is the machine epsilon returned by DLAMCH('Epsilon')
```

The value ITERMAX and BWDMAX are fixed to 30 and 1.0D+00 respectively.

Syntax

Fortran specification:

```
use armpl_library

subroutine zcgesv(N, NRHS, A, LDA, IPIV, B, LDB, X, LDX, WORK, SWORK, RWORK,
                  ITER, INFO)
```

C specification:

```
#include "armpl.h"

void zcgesv_(const armpl_int_t *n, const armpl_int_t *nrhs,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_int_t *ipiv, const armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *x,
             const armpl_int_t *ldx, armpl_doublecomplex_t *work,
             armpl_singlecomplex_t *swork, double *rwork, armpl_int_t *iter,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array,. dimension (LDA, N) On entry, the N-by-N coefficient matrix A. On exit, if iterative refinement has been successfully used (INFO.EQ.0 and ITER.GE.0, see description below), then A is unchanged, if double precision factorization has been used (INFO.EQ.0 and ITER.LT.0, see description below), then the array A contains the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIV(i). Corresponds either to the single precision factorization (if INFO.EQ.0 and ITER.GE.0) or the double precision factorization (if INFO.EQ.0 and ITER.LT.0).

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N, NRHS). This array is used to hold the residual vectors.

SWORK Output parameter.

SWORK is COMPLEX

SWORK is an array, dimension (N*(N+NRHS)). This array is used to use the single precision matrix and the right-hand sides or solutions in single precision.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

ITER Output parameter.

ITER is INTEGER

< 0: iterative refinement has failed, COMPLEX*16 factorization has been performed -1 : the routine fell back to full precision for implementation- or machine-specific reasons -2 : narrowing the precision induced an overflow, the routine fell back to full precision -3 : failure of CGETRF -31: stop the iterative refinement after the 30th iterations > 0: iterative refinement has been successfully used. Returns the number of iterations

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) computed in COMPLEX*16 is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

Related Information

It also exists with a native C interface as *LAPACKE_zcgesv*.

4.6.140 zcposv

zcposv computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian positive definite matrix and X and B are N-by-NRHS matrices.

zcposv first attempts to factorize the matrix in COMPLEX and use this factorization within an iterative refinement procedure to produce a solution with COMPLEX*16 normwise backward error quality (see below). If the approach fails the method switches to a COMPLEX*16 factorization and solve.

The iterative refinement is not going to be a winning strategy if the ratio COMPLEX performance over COMPLEX*16 performance is too small. A reasonable strategy should take the number of right-hand sides and the size of the matrix into account. This might be done with a call to ILAENV in the future. Up to now, we always try iterative refinement.

The iterative refinement process is stopped if

```
ITER > ITERMAX
```

or for all the RHS we have:

```
RNRM < SQRT(N)*XNRM*ANRM*EPS*BWDMAX
```

where

```
 o ITER is the number of the current iteration in the iterative
  refinement process
o RNRM is the infinity-norm of the residual
o XNRM is the infinity-norm of the solution
o ANRM is the infinity-operator-norm of the matrix A
o EPS is the machine epsilon returned by DLAMCH('Epsilon')
```

The value ITERMAX and BWDMAX are fixed to 30 and 1.0D+00 respectively.

Syntax

Fortran specification:

```
use armpl_library

subroutine zcposv(UPLO, N, NRHS, A, LDA, B, LDB, X, LDX, WORK, SWORK, RWORK,
                  ITER, INFO)
```

C specification:

```
#include "armpl.h"

void zcposv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_doublecomplex_t *x, const armpl_int_t *ldx,
             armpl_doublecomplex_t *work, armpl_singlecomplex_t *swork,
             double *rwork, armpl_int_t *iter, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array,. dimension (LDA, N) On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero.

On exit, if iterative refinement has been successfully used (INFO.EQ.0 and ITER.GE.0, see description below), then A is unchanged, if double precision factorization has been used (INFO.EQ.0 and ITER.LT.0, see description below), then the array A contains the factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N, NRHS). This array is used to hold the residual vectors.

SWORK Output parameter.

SWORK is COMPLEX

SWORK is an array, dimension (N*(N+NRHS)). This array is used to use the single precision matrix and the right-hand sides or solutions in single precision.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

ITER Output parameter.

ITER is INTEGER

< 0: iterative refinement has failed, COMPLEX*16 factorization has been performed -1 : the routine fell back to full precision for implementation- or machine-specific reasons -2 : narrowing the precision induced an overflow, the routine fell back to full precision -3 : failure of CPOTRF -31: stop the iterative refinement after the 30th iterations > 0: iterative refinement has been successfully used. Returns the number of iterations

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i of (COMPLEX*16) A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

Related Information

It also exists with a native C interface as *LAPACKE_zcposv*.

4.6.141 zgbsv

zgbsv computes the solution to a complex system of linear equations A * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as A = L * U, where L is a product of permutation and unit lower triangular matrices with KL subdiagonals, and U is upper triangular with KL+KU superdiagonals. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgbsv(N, KL, KU, NRHS, AB, LDAB, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zgbsv_(const armpl_int_t *n, const armpl_int_t *kl,
            const armpl_int_t *ku, const armpl_int_t *nrhs,
            armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
            armpl_int_t *ipiv, armpl_doublecomplex_t *b,
            const armpl_int_t *ldb, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KL+KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+KL) On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIV(i).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and the solution has not been computed.

Related Information

For this routine in other precisions, please see *cgbsv*, *dgbsv* and *sgbsv*. It also exists with a native C interface as *LAPACKE_zgbsv*.

4.6.142 zgbsvx

zgbsvx uses the LU factorization to compute the solution to a complex system of linear equations A * X = B, A^T * X = B, or A^H * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed by this subroutine:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
 the system:
   TRANS = 'N':  diag(R)*A*diag(C)      *inv(diag(C))*X = diag(R)*B
   TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
   TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
or diag(C)*B (if TRANS = 'T' or 'C').
```

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the

```
 matrix A (after equilibration if FACT = 'E') as
   A = L * U,
where L is a product of permutation and unit lower triangular
matrices with KL subdiagonals, and U is upper triangular with
KL+KU superdiagonals.
```

3. If some U(i,i)=0, so that U is exactly singular, then the routine

```
 returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
 diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
that it solves the original system before equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zgbsvx(FACT, TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV,
                  EQUED, R, C, B, LDB, X, LDX, RCOND, FERR, BERR, WORK, RWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zgbsvx_(const char *fact, const char *trans, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku,
             const armpl_int_t *nrhs, armpl_doublecomplex_t *ab,
             const armpl_int_t *ldab, armpl_doublecomplex_t *afb,
             const armpl_int_t *ldafb, armpl_int_t *ipiv, char *equed,
             double *r, double *c, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *x,
             const armpl_int_t *ldx, double *rcond, double *ferr,
             double *berr, armpl_doublecomplex_t *work, double *rwork,
             armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AFB and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. AB, AFB, and IPIV are not modified. = 'N': The matrix A will be copied to AFB and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AFB and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations. = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. AB is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A EQUED = 'C': A := A * diag(C) EQUED = 'B': A := diag(R) * A * diag(C).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input and output parameter.

AFB is COMPLEX*16

AFB is an array, dimension (LDAFB, N). If FACT = 'F', then AFB is an input argument and on entry contains details of the LU factorization of the band matrix A, as computed by ZGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. If EQUED .ne. 'N', then AFB is the factored form of the equilibrated matrix A.

If FACT = 'N', then AFB is an output argument and on exit returns details of the LU factorization of A.

If FACT = 'E', then AFB is an output argument and on exit returns details of the LU factorization of the equilibrated matrix A (see the description of AB for the form of the equilibrated matrix).

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL+KU+1.

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the factorization A = L*U as computed by ZGBTRF; row i of the matrix was interchanged with row IPIV(i).

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = L*U of the original matrix A.

If FACT = 'E', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = L*U of the equilibrated matrix A.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R Input and output parameter.

R is DOUBLE PRECISION

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))* X if TRANS = 'N' and EQUED = 'C' or 'B', or inv(diag(R))* X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N). On exit, RWORK(1) contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If RWORK(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with 0<INFO<=N, then RWORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *cgbsvx*, *dgbsvx* and *sgbsvx*. It also exists with a native C interface as *LAPACKE_zgbsvx*.

4.6.143 zgbsvxx

```
ZGBSVXX uses the LU factorization to compute the solution to a
   complex*16 system of linear equations  A * X = B,  where A is an
   N-by-N matrix and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. ZGBSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   ZGBSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   ZGBSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what ZGBSVXX would itself produce.

                                                                  The␣
↪following steps are performed:

   1. If FACT = 'E', double precision scaling factors are computed to equilibrate
   the system:

     TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
     TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
     TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
```

(continues on next page)

(continued from previous page)

```
   or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
   the matrix A (after equilibration if FACT = 'E') as

     A = P * L * U,

   where P is a permutation matrix, L is a unit lower triangular
   matrix, and U is upper triangular.

   3. If some U(i,i)=0, so that U is exactly singular, then the
   routine returns with INFO = i. Otherwise, the factored form of A
   is used to estimate the condition number of the matrix A (see
   argument RCOND). If the reciprocal of the condition number is less
   than machine precision, the routine still goes on to solve for X
   and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form
   of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
   error and error bounds.  Refinement calculates the residual to at
   least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
   diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
   that it solves the original system before equilibration.
↪    Some optional parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zgbsvxx(FACT, TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV,
                   EQUED, R, C, B, LDB, X, LDX, RCOND, RPVGRW, BERR,
                   N_ERR_BNDS, ERR_BNDS_NORM, ERR_BNDS_COMP, NPARAMS, PARAMS,
                   WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgbsvxx_(const char *fact, const char *trans, const armpl_int_t *n,
              const armpl_int_t *kl, const armpl_int_t *ku,
              const armpl_int_t *nrhs, armpl_doublecomplex_t *ab,
              const armpl_int_t *ldab, armpl_doublecomplex_t *afb,

                armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
                ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF, and IPIV are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose = Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

If FACT = 'F' and EQUED is not 'N', then AB must have been equilibrated by the scaling factors in R and/or C. AB is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A EQUED = 'C': A := A * diag(C) EQUED = 'B': A := diag(R) * A * diag(C).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input and output parameter.

AFB is COMPLEX*16

AFB is an array, dimension (LDAFB, N). If FACT = 'F', then AFB is an input argument and on entry contains details of the LU factorization of the band matrix A, as computed by ZGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. If EQUED .ne. 'N', then AFB is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL+KU+1.

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the factorization A = P*L*U as computed by DGETRF; row i of the matrix was interchanged with row IPIV(i).

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the equilibrated matrix A.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R Input and output parameter.

R is DOUBLE PRECISION

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive. If R is output, each element of R is a power of the radix. If R is input, each element of R should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive. If C is output, each element of C is a power of the radix. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))* X if TRANS = 'N' and EQUED = 'C' or 'B', or inv(diag(R))* X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

RPVGRW Output parameter.

RPVGRW is DOUBLE PRECISION

Reciprocal pivot growth. On exit, this contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable. If factorization fails with 0<INFO<=N, then this contains the reciprocal pivot growth factor for the leading INFO columns of A. In DGESVX, this quantity is returned in WORK(1).

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is DOUBLE PRECISION

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0D+0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the extra-precise refinement algorithm. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

Related Information

For this routine in other precisions, please see *cgbsvxx*, *dgbsvxx* and *sgbsvxx*. It also exists with a native C interface as *LAPACKE_zgbsvxx*.

4.6.144 zgbtrs

zgbtrs solves a system of linear equations

```
A * X = B,  A**T * X = B,  or  A**H * X = B
```

with a general band matrix A using the LU factorization computed by ZGBTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgbtrs(TRANS, N, KL, KU, NRHS, AB, LDAB, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zgbtrs_(const char *trans, const armpl_int_t *n, const armpl_int_t *kl,
             const armpl_int_t *ku, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
             const armpl_int_t *ipiv, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations. = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). Details of the LU factorization of the band matrix A, as computed by ZGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= N, row i of the matrix was interchanged with row IPIV(i).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgbtrs*, *dgbtrs* and *sgbtrs*. It also exists with a native C interface as *LAPACKE_zgbtrs*.

4.6.145 zgesv

zgesv computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as

```
A = P * L * U,
```

where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgesv(N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zgesv_(const armpl_int_t *n, const armpl_int_t *nrhs,
            armpl_doublecomplex_t *a, const armpl_int_t *lda,
            armpl_int_t *ipiv, armpl_doublecomplex_t *b,
            const armpl_int_t *ldb, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N coefficient matrix A. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIV(i).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS matrix of right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *cgesv*, *dgesv* and *sgesv*. It also exists with a native C interface as *LAPACKE_zgesv*.

4.6.146 zgesvx

zgesvx uses the LU factorization to compute the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
 the system:
   TRANS = 'N':  diag(R)*A*diag(C)      *inv(diag(C))*X = diag(R)*B
   TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
   TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
or diag(C)*B (if TRANS = 'T' or 'C').
```

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the

```
 matrix A (after equilibration if FACT = 'E') as
   A = P * L * U,
where P is a permutation matrix, L is a unit lower triangular
matrix, and U is upper triangular.
```

3. If some U(i,i)=0, so that U is exactly singular, then the routine

```
 returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
 diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
that it solves the original system before equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zgesvx(FACT, TRANS, N, NRHS, A, LDA, AF, LDAF, IPIV, EQUED, R, C,
                  B, LDB, X, LDX, RCOND, FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgesvx_(const char *fact, const char *trans, const armpl_int_t *n,
             const armpl_int_t *nrhs, armpl_doublecomplex_t *a,

```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF, and IPIV are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A EQUED = 'C': A := A * diag(C) EQUED = 'B': A := diag(R) * A * diag(C).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the factors L and U from the factorization A = P*L*U as computed by ZGETRF. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the factorization A = P*L*U as computed by ZGETRF; row i of the matrix was interchanged with row IPIV(i).

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the equilibrated matrix A.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R Input and output parameter.

R is DOUBLE PRECISION

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))* X if TRANS = 'N' and EQUED = 'C' or 'B', or inv(diag(R))* X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*N). On exit, RWORK(1) contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If RWORK(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with 0<INFO<=N, then RWORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *cgesvx*, *dgesvx* and *sgesvx*. It also exists with a native C interface as *LAPACKE_zgesvx*.

4.6.147 zgesvxx

```
ZGESVXX uses the LU factorization to compute the solution to a
   complex*16 system of linear equations  A * X = B,  where A is an
   N-by-N matrix and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. ZGESVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.
```

(continues on next page)

(continued from previous page)

```
   ZGESVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   ZGESVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what ZGESVXX would itself produce.

                                                                  The␣
↪following steps are performed:

   1. If FACT = 'E', double precision scaling factors are computed to equilibrate
   the system:

     TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
     TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
     TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
   or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
   the matrix A (after equilibration if FACT = 'E') as

     A = P * L * U,

   where P is a permutation matrix, L is a unit lower triangular
   matrix, and U is upper triangular.

   3. If some U(i,i)=0, so that U is exactly singular, then the
   routine returns with INFO = i. Otherwise, the factored form of A
   is used to estimate the condition number of the matrix A (see
   argument RCOND). If the reciprocal of the condition number is less
   than machine precision, the routine still goes on to solve for X
   and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form
   of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
   error and error bounds.  Refinement calculates the residual to at
   least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
   diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
   that it solves the original system before equilibration.
↪   Some optional parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

              ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF, and IPIV are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A EQUED = 'C': A := A * diag(C) EQUED = 'B': A := diag(R) * A * diag(C).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the factors L and U from the factorization A = P*L*U as computed by ZGETRF. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the factorization A = P*L*U as computed by ZGETRF; row i of the matrix was interchanged with row IPIV(i).

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then IPIV is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the equilibrated matrix A.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R Input and output parameter.

R is DOUBLE PRECISION

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive. If R is output, each element of R is a power of the radix. If R is input, each element of R should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive. If C is output, each element of C is a power of the radix. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause

rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))* X if TRANS = 'N' and EQUED = 'C' or 'B', or inv(diag(R))* X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

RPVGRW Output parameter.

RPVGRW is DOUBLE PRECISION

Reciprocal pivot growth. On exit, this contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable. If factorization fails with 0<INFO<=N, then this contains the reciprocal pivot growth factor for the leading INFO columns of A. In ZGESVX, this quantity is returned in WORK(1).

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is DOUBLE PRECISION

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0D+0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the extra-precise refinement algorithm. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

4.6.148 zgetrs

zgetrs solves a system of linear equations

```
A * X = B,  A**T * X = B,  or  A**H * X = B
```

with a general N-by-N matrix A using the LU factorization computed by ZGETRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgetrs(TRANS, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zgetrs_(const char *trans, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_int_t *ipiv, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The factors L and U from the factorization A = P*L*U as computed by ZGETRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from ZGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgetrs*, *dgetrs* and *sgetrs*. It also exists with a native C interface as *LAPACKE_zgetrs*.

4.6.149 zgtsv

zgtsv solves the equation

```
A*X = B,
```

where A is an N-by-N tridiagonal matrix, by Gaussian elimination with partial pivoting.

Note that the equation A^T *X = B may be solved by interchanging the order of the arguments DU and DL.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgtsv(N, NRHS, DL, D, DU, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zgtsv_(const armpl_int_t *n, const armpl_int_t *nrhs,
            armpl_doublecomplex_t *dl, armpl_doublecomplex_t *d,
            armpl_doublecomplex_t *du, armpl_doublecomplex_t *b,
            const armpl_int_t *ldb, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input and output parameter.

DL is COMPLEX*16

DL is an array, dimension (N-1). On entry, DL must contain the (n-1) subdiagonal elements of A. On exit, DL is overwritten by the (n-2) elements of the second superdiagonal of the upper triangular matrix U from the LU factorization of A, in DL(1), . . . , DL(n-2).

D Input and output parameter.

D is COMPLEX*16

D is an array, dimension (N). On entry, D must contain the diagonal elements of A. On exit, D is overwritten by the n diagonal elements of U.

DU Input and output parameter.

DU is COMPLEX*16

DU is an array, dimension (N-1). On entry, DU must contain the (n-1) superdiagonal elements of A. On exit, DU is overwritten by the (n-1) elements of the first superdiagonal of U.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, U(i,i) is exactly zero, and the solution has not been computed. The factorization has not been completed unless i = N.

Related Information

For this routine in other precisions, please see *cgtsv*, *dgtsv* and *sgtsv*. It also exists with a native C interface as *LAPACKE_zgtsv*.

4.6.150 zgtsvx

zgtsvx uses the LU factorization to compute the solution to a complex system of linear equations A * X = B, A^T * X = B, or A^H * X = B, where A is a tridiagonal matrix of order N and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the LU decomposition is used to factor the matrix A

```
 as A = L * U, where L is a product of permutation and unit lower
bidiagonal matrices and U is upper triangular with nonzeros in
only the main diagonal and first two superdiagonals.
```

2. If some U(i,i)=0, so that U is exactly singular, then the routine

```
 returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zgtsvx(FACT, TRANS, N, NRHS, DL, D, DU, DLF, DF, DUF, DU2, IPIV, B,
                  LDB, X, LDX, RCOND, FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgtsvx_(const char *fact, const char *trans, const armpl_int_t *n,
             const armpl_int_t *nrhs, const armpl_doublecomplex_t *dl,
             const armpl_doublecomplex_t *d, const armpl_doublecomplex_t *du,
             armpl_doublecomplex_t *dlf, armpl_doublecomplex_t *df,
             armpl_doublecomplex_t *duf, armpl_doublecomplex_t *du2,
             armpl_int_t *ipiv, const armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *x,
             const armpl_int_t *ldx, double *rcond, double *ferr,
             double *berr, armpl_doublecomplex_t *work, double *rwork,
             armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of A has been supplied on entry. = 'F': DLF, DF, DUF, DU2, and IPIV contain the factored form of A; DL, D, DU, DLF, DF, DUF, DU2 and IPIV will not be modified. = 'N': The matrix will be copied to DLF, DF, and DUF and factored.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input parameter.

DL is COMPLEX*16

DL is an array, dimension (N-1). The (n-1) subdiagonal elements of A.

D Input parameter.

D is COMPLEX*16

D is an array, dimension (N). The n diagonal elements of A.

DU Input parameter.

DU is COMPLEX*16

DU is an array, dimension (N-1). The (n-1) superdiagonal elements of A.

DLF Input and output parameter.

DLF is COMPLEX*16

DLF is an array, dimension (N-1). If FACT = 'F', then DLF is an input argument and on entry contains the (n-1) multipliers that define the matrix L from the LU factorization of A as computed by ZGTTRF.

If FACT = 'N', then DLF is an output argument and on exit contains the (n-1) multipliers that define the matrix L from the LU factorization of A.

DF Input and output parameter.

DF is COMPLEX*16

DF is an array, dimension (N). If FACT = 'F', then DF is an input argument and on entry contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

If FACT = 'N', then DF is an output argument and on exit contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DUF Input and output parameter.

DUF is COMPLEX*16

DUF is an array, dimension (N-1). If FACT = 'F', then DUF is an input argument and on entry contains the (n-1) elements of the first superdiagonal of U.

If FACT = 'N', then DUF is an output argument and on exit contains the (n-1) elements of the first superdiagonal of U.

DU2 Input and output parameter.

DU2 is COMPLEX*16

DU2 is an array, dimension (N-2). If FACT = 'F', then DU2 is an input argument and on entry contains the (n-2) elements of the second superdiagonal of U.

If FACT = 'N', then DU2 is an output argument and on exit contains the (n-2) elements of the second superdiagonal of U.

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains the pivot indices from the LU factorization of A as computed by ZGTTRF.

If FACT = 'N', then IPIV is an output argument and on exit contains the pivot indices from the LU factorization of A; row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: U(i,i) is exactly zero. The factorization has not been completed unless i = N, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *cgtsvx*, *dgtsvx* and *sgtsvx*. It also exists with a native C interface as *LAPACKE_zgtsvx*.

4.6.151 zgttrs

zgttrs solves one of the systems of equations

```
A * X = B,  A**T * X = B,  or  A**H * X = B,
```

with a tridiagonal matrix A using the LU factorization computed by ZGTTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgttrs(TRANS, N, NRHS, DL, D, DU, DU2, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zgttrs_(const char *trans, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *dl, const armpl_doublecomplex_t *d,
             const armpl_doublecomplex_t *du,
             const armpl_doublecomplex_t *du2, const armpl_int_t *ipiv,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations. = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

N Input parameter.

N is INTEGER

The order of the matrix A.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input parameter.

DL is COMPLEX*16

DL is an array, dimension (N-1). The (n-1) multipliers that define the matrix L from the LU factorization of A.

D Input parameter.

D is COMPLEX*16

D is an array, dimension (N). The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DU Input parameter.

DU is COMPLEX*16

DU is an array, dimension (N-1). The (n-1) elements of the first super-diagonal of U.

DU2 Input parameter.

DU2 is COMPLEX*16

DU2 is an array, dimension (N-2). The (n-2) elements of the second super-diagonal of U.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the matrix of right hand side vectors B. On exit, B is overwritten by the solution vectors X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgttrs*, *dgttrs* and *sgttrs*. It also exists with a native C interface as *LAPACKE_zgttrs*.

4.6.152 zhesv

zhesv computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

```
A = U * D * U**H,  if UPLO = 'U', or
A = L * D * L**H,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhesv(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhesv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            armpl_doublecomplex_t *a, const armpl_int_t *lda,
            armpl_int_t *ipiv, armpl_doublecomplex_t *b,
            const armpl_int_t *ldb, armpl_doublecomplex_t *work,
            const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^H or A = L*D*L^H as computed by ZHETRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by ZHETRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= 1, and for best performance LWORK >= max(1,N*NB), where NB is the optimal blocksize for ZHETRF. for LWORK < N, TRS will be done with Level BLAS 2 for LWORK >= N, TRS will be done with Level BLAS 3

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *chesv*. It also exists with a native C interface as *LAPACKE_zhesv*.

4.6.153 zhesv_aa

ZHESV_AA computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

Aasen's algorithm is used to factor A as

```
A = U * T * U**H,  if UPLO = 'U', or
A = L * T * L**H,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is Hermitian and tridiagonal. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhesv_aa(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhesv_aa_(const char *uplo, const armpl_int_t *n,
               const armpl_int_t *nrhs, armpl_doublecomplex_t *a,
               const armpl_int_t *lda, armpl_int_t *ipiv,
```

(continues on next page)

(continued from previous page)

```
                armpl_doublecomplex_t *b, const armpl_int_t *ldb,
                armpl_doublecomplex_t *work, const armpl_int_t *lwork,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the tridiagonal matrix T and the multipliers used to obtain the factor U or L from the factorization A = U*T*U^H or A = L*T*L^H as computed by ZHETRF_AA.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= MAX(1,2*N,3*N-2), and for best performance LWORK >= max(1,N*NB), where NB is the optimal blocksize for ZHETRF.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *chesv_aa*. It also exists with a native C interface as *LAPACKE_zhesv_aa*.

4.6.154 zhesv_rk

ZHESV_RK computes the solution to a complex system of linear equations A * X = B, where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

The bounded Bunch-Kaufman (rook) diagonal pivoting method is used to factor A as

```
A = P*U*D*(U**H)*(P**T),  if UPLO = 'U', or
A = P*L*D*(L**H)*(P**T),  if UPLO = 'L',
```

where U (or L) is unit upper (or lower) triangular matrix, U^H (or L^H) is the conjugate of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ZHETRF_RK is called to compute the factorization of a complex Hermitian matrix. The factored form of A is then used to solve the system of equations A * X = B by calling BLAS3 routine ZHETRS_3.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhesv_rk(UPLO, N, NRHS, A, LDA, E, IPIV, B, LDB, WORK, LWORK,
                    INFO)
```

C specification:

```
#include "armpl.h"

void zhesv_rk_(const char *uplo, const armpl_int_t *n,
               const armpl_int_t *nrhs, armpl_doublecomplex_t *a,
               const armpl_int_t *lda, armpl_doublecomplex_t *e,
               armpl_int_t *ipiv, armpl_doublecomplex_t *b,
               const armpl_int_t *ldb, armpl_doublecomplex_t *work,
               const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, diagonal of the block diagonal matrix D and factors U or L as computed by ZHETRF_RK: a) ONLY diagonal elements of the Hermitian block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

For more info see the description of ZHETRF_RK routine.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is COMPLEX*16

E is an array, dimension (N). On exit, contains the output computed by the factorization routine ZHETRF_RK, i.e. the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

For more info see the description of ZHETRF_RK routine.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by ZHETRF_RK.

For more info see the description of ZHETRF_RK routine.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)).. Work array used in the factorization stage. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= 1. For best performance of factorization stage LWORK >= max(1,N*NB), where NB is the optimal blocksize for ZHETRF_RK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array for factorization stage, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

Related Information

For this routine in other precisions, please see *chesv_rk*. It also exists with a native C interface as *LAPACKE_zhesv_rk*.

4.6.155 zhesv_rook

ZHESV_ROOK computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

The bounded Bunch-Kaufman ("rook") diagonal pivoting method is used to factor A as

```
 A = U * D * U**T,  if UPLO = 'U', or
A = L * D * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ZHETRF_ROOK is called to compute the factorization of a complex Hermition matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method.

The factored form of A is then used to solve the system of equations A * X = B by calling ZHETRS_ROOK (uses BLAS 2).

Syntax

Fortran specification:

```
use armpl_library

subroutine zhesv_rook(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhesv_rook_(const char *uplo, const armpl_int_t *n,
                 const armpl_int_t *nrhs, armpl_doublecomplex_t *a,
                 const armpl_int_t *lda, armpl_int_t *ipiv,
                 armpl_doublecomplex_t *b, const armpl_int_t *ldb,
                 armpl_doublecomplex_t *work, const armpl_int_t *lwork,
                 armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^H or A = L*D*L^H as computed by ZHETRF_ROOK.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': Only the last KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': Only the first KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= 1, and for best performance LWORK >= max(1,N*NB), where NB is the optimal blocksize for ZHETRF_ROOK. for LWORK < N, TRS will be done with Level BLAS 2 for LWORK >= N, TRS will be done with Level BLAS 3

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *chesv_rook*.

4.6.156 zhesvx

zhesvx uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the diagonal pivoting method is used to factor A.

```
 The form of the factorization is
   A = U * D * U**H,  if UPLO = 'U', or
   A = L * D * L**H,  if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices, and D is Hermitian and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some D(i,i)=0, so that D is exactly singular, then the routine

```
 returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zhesvx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X, LDX,
                  RCOND, FERR, BERR, WORK, LWORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhesvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, const armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *af,
             const armpl_int_t *ldaf, armpl_int_t *ipiv,
             const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_doublecomplex_t *x, const armpl_int_t *ldx, double *rcond,
             double *ferr, double *berr, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, double *rwork, armpl_int_t *info,
             ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AF and IPIV contain the factored form of A. A, AF and IPIV will not be modified. = 'N': The matrix A will be copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^H or A = L*D*L^H as computed by ZHETRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^H or A = L*D*L^H .

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by ZHETRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIV is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by ZHETRF.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= max(1,2*N), and for best performance, when FACT = 'N', LWORK >= max(1,2*N,N*NB), where NB is the optimal blocksize for ZHETRF.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *chesvx*. It also exists with a native C interface as *LAPACKE_zhesvx*.

4.6.157 zhesvxx

```
ZHESVXX uses the diagonal pivoting factorization to compute the
   solution to a complex*16 system of linear equations A * X = B, where
   A is an N-by-N symmetric matrix and X and B are N-by-NRHS
   matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. ZHESVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   ZHESVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   ZHESVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what ZHESVXX would itself produce.

                                                                  The␣
↪following steps are performed:

   1. If FACT = 'E', double precision scaling factors are computed to equilibrate
   the system:

     diag(S)*A*diag(S)     *inv(diag(S))*X = diag(S)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
   the matrix A (after equilibration if FACT = 'E') as

      A = U * D * U**T,  if UPLO = 'U', or
      A = L * D * L**T,  if UPLO = 'L',

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.

   3. If some D(i,i)=0, so that D is exactly singular, then the
   routine returns with INFO = i. Otherwise, the factored form of A
   is used to estimate the condition number of the matrix A (see
   argument RCOND).  If the reciprocal of the condition number is
   less than machine precision, the routine still goes on to solve
   for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form
   of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
   error and error bounds.  Refinement calculates the residual to at
```

(continues on next page)

(continued from previous page)

```
   least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
   diag(R) so that it solves the original system before
   equilibration.                          Some optional parameters are bundled␣
↪in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zhesvxx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, EQUED, S, B,
                   LDB, X, LDX, RCOND, RPVGRW, BERR, N_ERR_BNDS,
                   ERR_BNDS_NORM, ERR_BNDS_COMP, NPARAMS, PARAMS, WORK, RWORK,
                   INFO)
```

C specification:

```

              double *err_bnds_norm, double *err_bnds_comp,
              const armpl_int_t *nparams, double *params,
              armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
              ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by S. A, AF, and IPIV are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by DSYTRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T .

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by ZHETRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIV is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by ZHETRF.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or

overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S)*B;

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

RPVGRW Output parameter.

RPVGRW is DOUBLE PRECISION

Reciprocal pivot growth. On exit, this contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable. If factorization fails with 0<INFO<=N, then this contains the reciprocal pivot growth factor for the leading INFO columns of A.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is DOUBLE PRECISION

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0D+0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the extra-precise refinement algorithm. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (5*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

4.6.158 zhetrs

zhetrs solves a system of linear equations A*X = B with a complex Hermitian matrix A using the factorization A = U*D*U^H or A = L*D*L^H computed by ZHETRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetrs(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zhetrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_int_t *ipiv, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHETRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZHETRF.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *chetrs*. It also exists with a native C interface as *LAPACKE_zhetrs*.

4.6.159 zhetrs2

zhetrs2 solves a system of linear equations A*X = B with a complex Hermitian matrix A using the factorization A = U*D*U^H or A = L*D*L^H computed by ZHETRF and converted by ZSYCONV.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetrs2(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhetrs2_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
              const armpl_doublecomplex_t *a, const armpl_int_t *lda,
              const armpl_int_t *ipiv, armpl_doublecomplex_t *b,
              const armpl_int_t *ldb, armpl_doublecomplex_t *work,
              armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHETRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZHETRF.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *chetrs2*. It also exists with a native C interface as *LAPACKE_zhetrs2*.

4.6.160 zhetrs_3

ZHETRS_3 solves a system of linear equations A * X = B with a complex Hermitian matrix A using the factorization computed by ZHETRF_RK or ZHETRF_BK:

```
A = P*U*D*(U**H)*(P**T) or A = P*L*D*(L**H)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^H (or L^H) is the conjugate of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This algorithm is using Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetrs_3(UPLO, N, NRHS, A, LDA, E, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zhetrs_3_(const char *uplo, const armpl_int_t *n,
               const armpl_int_t *nrhs, const armpl_doublecomplex_t *a,
               const armpl_int_t *lda, const armpl_doublecomplex_t *e,
               const armpl_int_t *ipiv, armpl_doublecomplex_t *b,
               const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix: = 'U': Upper triangular, form is A = P*U*D*(U^H)*(P^T); = 'L': Lower triangular, form is A = P*L*D*(L^H)*(P^T).

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). Diagonal of the block diagonal matrix D and factors U or L as computed by ZHETRF_RK and ZHETRF_BK: a) ONLY diagonal elements of the Hermitian block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is COMPLEX*16

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZHETRF_RK or ZHETRF_BK.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *chetrs_3*. It also exists with a native C interface as *LAPACKE_zhetrs_3*.

4.6.161 zhetrs_aa

ZHETRS_AA solves a system of linear equations A*X = B with a complex hermitian matrix A using the factorization A = U*T*U^H or A = L*T*L^T computed by ZHETRF_AA.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetrs_aa(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhetrs_aa_(const char *uplo, const armpl_int_t *n,
                const armpl_int_t *nrhs, const armpl_doublecomplex_t *a,
                const armpl_int_t *lda, const armpl_int_t *ipiv,
                armpl_doublecomplex_t *b, const armpl_int_t *ldb,
                const armpl_doublecomplex_t *work, const armpl_int_t *lwork,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*T*U^H ; = 'L': Lower triangular, form is A = L*T*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). Details of factors computed by ZHETRF_AA.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges as computed by ZHETRF_AA.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Input parameter.

WORK is DOUBLE array, dimension (MAX(1, LWORK))

LWORK Input parameter.

LWORK is INTEGER, LWORK >= MAX(1,3*N-2).

param[out] INFO verbatim INFO is INTEGER = 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *chetrs_aa*. It also exists with a native C interface as *LAPACKE_zhetrs_aa*.

4.6.162 zhetrs_rook

ZHETRS_ROOK solves a system of linear equations A*X = B with a complex Hermitian matrix A using the factorization A = U*D*U^H or A = L*D*L^H computed by ZHETRF_ROOK.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetrs_rook(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zhetrs_rook_(const char *uplo, const armpl_int_t *n,
                  const armpl_int_t *nrhs, const armpl_doublecomplex_t *a,
                  const armpl_int_t *lda, const armpl_int_t *ipiv,
                  armpl_doublecomplex_t *b, const armpl_int_t *ldb,
                  armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHETRF_ROOK.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZHETRF_ROOK.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *chetrs_rook*. It also exists with a native C interface as *LAPACKE_zhetrs_rook*.

4.6.163 zhpsv

zhpsv computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

```
A = U * D * U**H,  if UPLO = 'U', or
A = L * D * L**H,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhpsv(UPLO, N, NRHS, AP, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zhpsv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            armpl_doublecomplex_t *ap, armpl_int_t *ipiv,
            armpl_doublecomplex_t *b, const armpl_int_t *ldb,
            armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^H or A = L*D*L^H as computed by ZHPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by ZHPTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *chpsv*. It also exists with a native C interface as *LAPACKE_zhpsv*.

4.6.164 zhpsvx

zhpsvx uses the diagonal pivoting factorization A = U*D*U^H or A = L*D*L^H to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N Hermitian matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the diagonal pivoting method is used to factor A as

```
   A = U * D * U**H,  if UPLO = 'U', or
   A = L * D * L**H,  if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices and D is Hermitian and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some D(i,i)=0, so that D is exactly singular, then the routine

```
 returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zhpsvx(FACT, UPLO, N, NRHS, AP, AFP, IPIV, B, LDB, X, LDX, RCOND,
                  FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhpsvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, const armpl_doublecomplex_t *ap,
             armpl_doublecomplex_t *afp, armpl_int_t *ipiv,
             const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_doublecomplex_t *x, const armpl_int_t *ldx, double *rcond,
             double *ferr, double *berr, armpl_doublecomplex_t *work,
             double *rwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AFP and IPIV contain the factored form of A. AFP and IPIV will not be modified. = 'N': The matrix A will be copied to AFP and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

AFP Input and output parameter.

AFP is COMPLEX*16

AFP is an array, dimension (N*(N+1)/2). If FACT = 'F', then AFP is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^H or A = L*D*L^H as computed by ZHPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AFP is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^H or A = L*D*L^H as computed by ZHPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by ZHPTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k)

were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIV is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by ZHPTRF.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *chpsvx*. It also exists with a native C interface as *LAPACKE_zhpsvx*.

4.6.165 zpbsv

zpbsv computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian positive definite band matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

```
A = U**H * U,  if UPLO = 'U', or
A = L * L**H,  if UPLO = 'L',
```

where U is an upper triangular band matrix, and L is a lower triangular band matrix, with the same number of superdiagonals or subdiagonals as A. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpbsv(UPLO, N, KD, NRHS, AB, LDAB, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zpbsv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
            const armpl_int_t *nrhs, armpl_doublecomplex_t *ab,
            const armpl_int_t *ldab, armpl_doublecomplex_t *b,
            const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(KD+1+i-j,j) = A(i,j) for max(1,j-KD)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(N,j+KD). See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the band matrix A, in the same storage format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

Related Information

For this routine in other precisions, please see *cpbsv*, *dpbsv* and *spbsv*. It also exists with a native C interface as *LAPACKE_zpbsv*.

4.6.166 zpbsvx

zpbsvx uses the Cholesky factorization A = U^H *U or A = L*L^H to compute the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian positive definite band matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
 the system:
   diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to

```
 factor the matrix A (after equilibration if FACT = 'E') as
   A = U**H * U,  if UPLO = 'U', or
   A = L * L**H,  if UPLO = 'L',
where U is an upper triangular band matrix, and L is a lower
triangular band matrix.
```

3. If the leading i-by-i principal minor is not positive definite,

```
 then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A.  If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
 diag(S) so that it solves the original system before
equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zpbsvx(FACT, UPLO, N, KD, NRHS, AB, LDAB, AFB, LDAFB, EQUED, S, B,
                  LDB, X, LDX, RCOND, FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zpbsvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *kd, const armpl_int_t *nrhs,
             armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
             armpl_doublecomplex_t *afb, const armpl_int_t *ldafb,
             char *equed, double *s, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *x,
```

(continues on next page)

(continued from previous page)

```
            const armpl_int_t *ldx, double *rcond, double *ferr,
            double *berr, armpl_doublecomplex_t *work, double *rwork,
            armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AFB contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. AB and AFB will not be modified. = 'N': The matrix A will be copied to AFB and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AFB and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix diag(S)*A*diag(S). The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(KD+1+i-j,j) = A(i,j) for max(1,j-KD)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(N,j+KD). See below for further details.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array A. LDAB >= KD+1.

AFB Input and output parameter.

AFB is COMPLEX*16

AFB is an array, dimension (LDAFB, N). If FACT = 'F', then AFB is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the band matrix A, in the same storage format as A (see AB). If EQUED = 'Y', then AFB is the factored form of the equilibrated matrix A.

If FACT = 'N', then AFB is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H .

If FACT = 'E', then AFB is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= KD+1.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude

of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *cpbsvx*, *dpbsvx* and *spbsvx*. It also exists with a native C interface as *LAPACKE_zpbsvx*.

4.6.167 zpbtrs

zpbtrs solves a system of linear equations A*X = B with a Hermitian positive definite band matrix A using the Cholesky factorization A = U^H *U or A = L*L^H computed by ZPBTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpbtrs(UPLO, N, KD, NRHS, AB, LDAB, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zpbtrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_int_t *nrhs, const armpl_doublecomplex_t *ab,
             const armpl_int_t *ldab, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular factor stored in AB; = 'L': Lower triangular factor stored in AB.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the band matrix A, stored in the first KD+1 rows of the array. The j-th column of U or L is stored in the j-th column of the array AB as follows: if UPLO ='U', AB(kd+1+i-j,j) = U(i,j) for max(1,j-kd)<=i<=j; if UPLO ='L', AB(1+i-j,j) = L(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpbtrs*, *dpbtrs* and *spbtrs*. It also exists with a native C interface as *LAPACKE_zpbtrs*.

4.6.168 zpftrs

zpftrs solves a system of linear equations A*X = B with a Hermitian positive definite matrix A using the Cholesky factorization A = U^H *U or A = L*L^H computed by ZPFTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpftrs(TRANSR, UPLO, N, NRHS, A, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zpftrs_(const char *transr, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, const armpl_doublecomplex_t *a,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal TRANSR of RFP A is stored; = 'C': The Conjugate-transpose TRANSR of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of RFP A is stored; = 'L': Lower triangle of RFP A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (N*(N+1)/2);. The triangular factor U or L from the Cholesky factorization of RFP A = U^H *U or RFP A = L*L^H , as computed by ZPFTRF. See note below for more details about RFP A.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpftrs*, *dpftrs* and *spftrs*. It also exists with a native C interface as *LAPACKE_zpftrs*.

4.6.169 zposv

zposv computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian positive definite matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

```
A = U**H* U,  if UPLO = 'U', or
A = L * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine zposv(UPLO, N, NRHS, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zposv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            armpl_doublecomplex_t *a, const armpl_int_t *lda,
            armpl_doublecomplex_t *b, const armpl_int_t *ldb,
            armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

Related Information

For this routine in other precisions, please see *cposv*, *dposv* and *sposv*. It also exists with a native C interface as *LAPACKE_zposv*.

4.6.170 zposvx

zposvx uses the Cholesky factorization A = U^H *U or A = L*L^H to compute the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian positive definite matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
 the system:
   diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to

```
 factor the matrix A (after equilibration if FACT = 'E') as
   A = U**H* U,  if UPLO = 'U', or
   A = L * L**H,  if UPLO = 'L',
where U is an upper triangular matrix and L is a lower triangular
matrix.
```

3. If the leading i-by-i principal minor is not positive definite,

```
 then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A.  If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
 diag(S) so that it solves the original system before
equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zposvx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, EQUED, S, B, LDB, X,
                  LDX, RCOND, FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zposvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *af,
             const armpl_int_t *ldaf, char *equed, double *s,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_doublecomplex_t *x, const armpl_int_t *ldx, double *rcond,
             double *ferr, double *berr, armpl_doublecomplex_t *work,
             double *rwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. A and AF will not be modified. =

'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix diag(S)*A*diag(S). If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , in the same storage format as A. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix diag(S)*A*diag(S).

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS righthand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *cposvx*, *dposvx* and *sposvx*. It also exists with a native C interface as *LAPACKE_zposvx*.

4.6.171 zposvxx

```
ZPOSVXX uses the Cholesky factorization A = U**T*U or A = L*L**T
   to compute the solution to a complex*16 system of linear equations
   A * X = B, where A is an N-by-N symmetric positive definite matrix
   and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. ZPOSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   ZPOSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   ZPOSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what ZPOSVXX would itself produce.

                                                                  The␣
↪following steps are performed:

   1. If FACT = 'E', double precision scaling factors are computed to equilibrate
   the system:

     diag(S)*A*diag(S)      *inv(diag(S))*X = diag(S)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

   2. If FACT = 'N' or 'E', the Cholesky decomposition is used to
   factor the matrix A (after equilibration if FACT = 'E') as
      A = U**T* U,  if UPLO = 'U', or
      A = L * L**T,  if UPLO = 'L',
   where U is an upper triangular matrix and L is a lower triangular
   matrix.

   3. If the leading i-by-i principal minor is not positive definite,
   then the routine returns with INFO = i. Otherwise, the factored
   form of A is used to estimate the condition number of the matrix
   A (see argument RCOND).  If the reciprocal of the condition number
   is less than machine precision, the routine still goes on to solve
   for X and compute error bounds as described below.
```

(continues on next page)

(continued from previous page)

```
   4. The system of equations is solved for X using the factored form
   of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
   error and error bounds.  Refinement calculates the residual to at
   least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
   diag(S) so that it solves the original system before
   equilibration.                          Some optional parameters are bundled␣
↪in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zposvxx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, EQUED, S, B, LDB, X,
                   LDX, RCOND, RPVGRW, BERR, N_ERR_BNDS, ERR_BNDS_NORM,
                   ERR_BNDS_COMP, NPARAMS, PARAMS, WORK, RWORK, INFO)
```

C specification:

              armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
              ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by S. A and AF are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix diag(S)*A*diag(S). If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , in the same storage format as A. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix diag(S)*A*diag(S).

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The row scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or

overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S)*B;

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

RPVGRW Output parameter.

RPVGRW is DOUBLE PRECISION

Reciprocal pivot growth. On exit, this contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable. If factorization fails with 0<INFO<=N, then this contains the reciprocal pivot growth factor for the leading INFO columns of A.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is DOUBLE PRECISION

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0D+0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the extra-precise refinement algorithm. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

Related Information

For this routine in other precisions, please see *cposvxx*, *dposvxx* and *sposvxx*. It also exists with a native C interface as *LAPACKE_zposvxx*.

4.6.172 zpotrs

zpotrs solves a system of linear equations A*X = B with a Hermitian positive definite matrix A using the Cholesky factorization $A = U^H * U$ or $A = L * L^H$ computed by ZPOTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpotrs(UPLO, N, NRHS, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zpotrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The triangular factor U or L from the Cholesky factorization A = U^H * U or A = L * L^H , as computed by ZPOTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpotrs*, *dpotrs* and *spotrs*. It also exists with a native C interface as *LAPACKE_zpotrs*.

4.6.173 zppsv

zppsv computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian positive definite matrix stored in packed format and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

```
A = U**H * U,  if UPLO = 'U', or
A = L * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine zppsv(UPLO, N, NRHS, AP, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zppsv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            armpl_doublecomplex_t *ap, armpl_doublecomplex_t *b,
            const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , in the same storage format as A.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

Related Information

For this routine in other precisions, please see *cppsv*, *dppsv* and *sppsv*. It also exists with a native C interface as *LAPACKE_zppsv*.

4.6.174 zppsvx

zppsvx uses the Cholesky factorization A = U^H * U or A = L * L^H to compute the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian positive definite matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
 the system:
   diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to

```
 factor the matrix A (after equilibration if FACT = 'E') as
   A = U**H * U ,  if UPLO = 'U', or
   A = L * L**H,  if UPLO = 'L',
where U is an upper triangular matrix, L is a lower triangular
matrix, and **H indicates conjugate transpose.
```

3. If the leading i-by-i principal minor is not positive definite,

```
 then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A.  If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
```

(continues on next page)

(continued from previous page)

```
still goes on to solve for X and compute error bounds as
described below.
```

4. The system of equations is solved for X using the factored form

```
of A.
```

5. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

6. If equilibration was used, the matrix X is premultiplied by

```
 diag(S) so that it solves the original system before
equilibration.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zppsvx(FACT, UPLO, N, NRHS, AP, AFP, EQUED, S, B, LDB, X, LDX,
                  RCOND, FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zppsvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, armpl_doublecomplex_t *ap,
             armpl_doublecomplex_t *afp, char *equed, double *s,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_doublecomplex_t *x, const armpl_int_t *ldx, double *rcond,
             double *ferr, double *berr, armpl_doublecomplex_t *work,
             double *rwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AFP contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. AP and AFP will not be modified. = 'N': The matrix A will be copied to AFP and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AFP and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix diag(S)*A*diag(S). The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

AFP Input and output parameter.

AFP is COMPLEX*16

AFP is an array, dimension (N*(N+1)/2). If FACT = 'F', then AFP is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , in the same storage format as A. If EQUED .ne. 'N', then AFP is the factored form of the equilibrated matrix A.

If FACT = 'N', then AFP is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^H * U or A = L * L^H of the original matrix A.

If FACT = 'E', then AFP is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U^H * U or A = L * L^H of the equilibrated matrix A (see the description of AP for the form of the equilibrated matrix).

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

4.6.175 zpptrs

zpptrs solves a system of linear equations A*X = B with a Hermitian positive definite matrix A in packed storage using the Cholesky factorization $A = U^H * U$ or $A = L * L^H$ computed by ZPPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpptrs(UPLO, N, NRHS, AP, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zpptrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *ap, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The triangular factor U or L from the Cholesky factorization A = U^H * U or A = L * L^H , packed columnwise in a linear array. The j-th column of U or L is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = U(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = L(i,j) for j<=i<=n.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpptrs*, *dpptrs* and *spptrs*. It also exists with a native C interface as *LAPACKE_zpptrs*.

4.6.176 zptsv

`zptsv` computes the solution to a complex system of linear equations A*X = B, where A is an N-by-N Hermitian positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

A is factored as A = L*D*L^H , and the factored form of A is then used to solve the system of equations.

Syntax

Fortran specification:

```
use armpl_library

subroutine zptsv(N, NRHS, D, E, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zptsv_(const armpl_int_t *n, const armpl_int_t *nrhs, double *d,
            armpl_doublecomplex_t *e, armpl_doublecomplex_t *b,
            const armpl_int_t *ldb, armpl_int_t *info);
```

Parameters

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0.

NRHS Input parameter.

`NRHS` is `INTEGER`

The number of right hand sides, i.e., the number of columns of the matrix `B`. `NRHS` >= 0.

D Input and output parameter.

`D` is `DOUBLE PRECISION`

`D` is an array, dimension (`N`). On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix `D` from the factorization A = L*D*L^H .

E Input and output parameter.

`E` is `COMPLEX*16`

`E` is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*D*L^H factorization of A. `E` can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U^H *D*U factorization of A.

B Input and output parameter.

`B` is `COMPLEX*16`

`B` is an array, dimension (`LDB`, `NRHS`). On entry, the N-by-NRHS right hand side matrix `B`. On exit, if `INFO` = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

`LDB` is `INTEGER`

The leading dimension of the array `B`. `LDB` >= max(1, `N`).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the leading minor of order i is not positive definite, and the solution has not been computed. The factorization has not been completed unless i = N.

Related Information

For this routine in other precisions, please see *cptsv*, *dptsv* and *sptsv*. It also exists with a native C interface as *LAPACKE_zptsv*.

4.6.177 zptsvx

zptsvx uses the factorization A = L*D*L^H to compute the solution to a complex system of linear equations A*X = B, where A is an N-by-N Hermitian positive definite tridiagonal matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the matrix A is factored as A = L*D*L^H , where L

```
 is a unit lower bidiagonal matrix and D is diagonal.  The
factorization can also be regarded as having the form
A = U**H*D*U.
```

2. If the leading i-by-i principal minor is not positive definite,

```
 then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A.  If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zptsvx(FACT, N, NRHS, D, E, DF, EF, B, LDB, X, LDX, RCOND, FERR,
                  BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zptsvx_(const char *fact, const armpl_int_t *n, const armpl_int_t *nrhs,
             const double *d, const armpl_doublecomplex_t *e, double *df,
             armpl_doublecomplex_t *ef, const armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *x,
             const armpl_int_t *ldx, double *rcond, double *ferr,
             double *berr, armpl_doublecomplex_t *work, double *rwork,
             armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry. = 'F': On entry, DF and EF contain the factored form of A. D, E, DF, and EF will not be modified. = 'N': The matrix A will be copied to DF and EF and factored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n diagonal elements of the tridiagonal matrix A.

E Input parameter.

E is COMPLEX*16

E is an array, dimension (N-1). The (n-1) subdiagonal elements of the tridiagonal matrix A.

DF Input and output parameter.

DF is DOUBLE PRECISION

DF is an array, dimension (N). If FACT = 'F', then DF is an input argument and on entry contains the n diagonal elements of the diagonal matrix D from the L*D*L^H factorization of A. If FACT = 'N', then DF is an output argument and on exit contains the n diagonal elements of the diagonal matrix D from the L*D*L^H factorization of A.

EF Input and output parameter.

EF is COMPLEX*16

EF is an array, dimension (N-1). If FACT = 'F', then EF is an input argument and on entry contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*D*L^H factorization of A. If FACT = 'N', then EF is an output argument and on exit contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*D*L^H factorization of A.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j).

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *cptsvx*, *dptsvx* and *sptsvx*. It also exists with a native C interface as *LAPACKE_zptsvx*.

4.6.178 zpttrs

zpttrs solves a tridiagonal system of the form

```
A * X = B
```

using the factorization A = U^H *D* U or A = L*D*L^H computed by ZPTTRF. D is a diagonal matrix specified in the vector D, U (or L) is a unit bidiagonal matrix whose superdiagonal (subdiagonal) is specified in the vector E, and X and B are N by NRHS matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpttrs(UPLO, N, NRHS, D, E, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zpttrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const double *d, const armpl_doublecomplex_t *e,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies the form of the factorization and whether the vector E is the superdiagonal of the upper bidiagonal factor U or the subdiagonal of the lower bidiagonal factor L. = 'U': A = U^H *D*U, E is the superdiagonal of U = 'L': A = L*D*L^H , E is the subdiagonal of L

N Input parameter.

N is INTEGER

The order of the tridiagonal matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n diagonal elements of the diagonal matrix D from the factorization A = U^H *D*U or A = L*D*L^H .

E Input parameter.

E is COMPLEX*16

E is an array, dimension (N-1). If UPLO = 'U', the (n-1) superdiagonal elements of the unit bidiagonal factor U from the factorization A = U^H *D*U. If UPLO = 'L', the (n-1) subdiagonal elements of the unit bidiagonal factor L from the factorization A = L*D*L^H .

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpttrs*, *dpttrs* and *spttrs*. It also exists with a native C interface as *LAPACKE_zpttrs*.

4.6.179 zspsv

zspsv computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

```
A = U * D * U**T,  if UPLO = 'U', or
A = L * D * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine zspsv(UPLO, N, NRHS, AP, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zspsv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            armpl_doublecomplex_t *ap, armpl_int_t *ipiv,
            armpl_doublecomplex_t *b, const armpl_int_t *ldb,
            armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by ZSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by ZSPTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *cspsv*, *dspsv* and *sspsv*. It also exists with a native C interface as *LAPACKE_zspsv*.

4.6.180 zspsvx

zspsvx uses the diagonal pivoting factorization A = U*D*U^T or A = L*D*L^T to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the diagonal pivoting method is used to factor A as

```
   A = U * D * U**T,  if UPLO = 'U', or
   A = L * D * L**T,  if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices and D is symmetric and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some D(i,i)=0, so that D is exactly singular, then the routine

```
 returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zspsvx(FACT, UPLO, N, NRHS, AP, AFP, IPIV, B, LDB, X, LDX, RCOND,
                  FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zspsvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, const armpl_doublecomplex_t *ap,
             armpl_doublecomplex_t *afp, armpl_int_t *ipiv,
             const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_doublecomplex_t *x, const armpl_int_t *ldx, double *rcond,
             double *ferr, double *berr, armpl_doublecomplex_t *work,
             double *rwork, armpl_int_t *info, ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AFP and IPIV contain the factored form of A. AP, AFP and IPIV will not be modified. = 'N': The matrix A will be copied to AFP and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

AFP Input and output parameter.

AFP is COMPLEX*16

AFP is an array, dimension (N*(N+1)/2). If FACT = 'F', then AFP is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by ZSPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AFP is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by ZSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by ZSPTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIV is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by ZSPTRF.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *cspsvx*, *dspsvx* and *sspsvx*. It also exists with a native C interface as *LAPACKE_zspsvx*.

4.6.181 zsptrs

zsptrs solves a system of linear equations A*X = B with a complex symmetric matrix A stored in packed format using the factorization A = U*D*U^T or A = L*D*L^T computed by ZSPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsptrs(UPLO, N, NRHS, AP, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zsptrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *ap, const armpl_int_t *ipiv,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSPTRF, stored as a packed triangular matrix.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSPTRF.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csptrs*, *dsptrs* and *ssptrs*. It also exists with a native C interface as *LAPACKE_zsptrs*.

4.6.182 zsysv

zsysv computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

```
A = U * D * U**T,  if UPLO = 'U', or
A = L * D * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsysv(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsysv_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
            armpl_doublecomplex_t *a, const armpl_int_t *lda,
            armpl_int_t *ipiv, armpl_doublecomplex_t *b,
            const armpl_int_t *ldb, armpl_doublecomplex_t *work,
            const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by ZSYTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by ZSYTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= 1, and for best performance LWORK >= max(1,N*NB), where NB is the optimal blocksize for ZSYTRF. for LWORK < N, TRS will be done with Level BLAS 2 for LWORK >= N, TRS will be done with Level BLAS 3

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *csysv*, *dsysv* and *ssysv*. It also exists with a native C interface as *LAPACKE_zsysv*.

4.6.183 zsysv_aa

ZSYSV computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

Aasen's algorithm is used to factor A as

```
A = U * T * U**T,  if UPLO = 'U', or
A = L * T * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is symmetric tridiagonal. The factored form of A is then used to solve the system of equations A * X = B.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsysv_aa(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsysv_aa_(const char *uplo, const armpl_int_t *n,
               const armpl_int_t *nrhs, armpl_doublecomplex_t *a,
               const armpl_int_t *lda, armpl_int_t *ipiv,
               armpl_doublecomplex_t *b, const armpl_int_t *ldb,
               armpl_doublecomplex_t *work, const armpl_int_t *lwork,
               armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the tridiagonal matrix T and the multipliers used to obtain the factor U or L from the factorization A = U*T*U^T or A = L*T*L^T as computed by ZSYTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= MAX(1,2*N,3*N-2), and for the best performance, LWORK >= MAX(1,N*NB), where NB is the optimal blocksize for ZSYTRF_AA.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *csysv_aa*, *dsysv_aa* and *ssysv_aa*. It also exists with a native C interface as *LAPACKE_zsysv_aa*.

4.6.184 zsysv_rk

ZSYSV_RK computes the solution to a complex system of linear equations A * X = B, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The bounded Bunch-Kaufman (rook) diagonal pivoting method is used to factor A as

```
A = P*U*D*(U**T)*(P**T),  if UPLO = 'U', or
A = P*L*D*(L**T)*(P**T),  if UPLO = 'L',
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ZSYTRF_RK is called to compute the factorization of a complex symmetric matrix. The factored form of A is then used to solve the system of equations A * X = B by calling BLAS3 routine ZSYTRS_3.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsysv_rk(UPLO, N, NRHS, A, LDA, E, IPIV, B, LDB, WORK, LWORK,
                    INFO)
```

C specification:

```
#include "armpl.h"

void zsysv_rk_(const char *uplo, const armpl_int_t *n,
               const armpl_int_t *nrhs, armpl_doublecomplex_t *a,
               const armpl_int_t *lda, armpl_doublecomplex_t *e,
               armpl_int_t *ipiv, armpl_doublecomplex_t *b,
               const armpl_int_t *ldb, armpl_doublecomplex_t *work,
               const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, diagonal of the block diagonal matrix D and factors U or L as computed by ZSYTRF_RK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

For more info see the description of ZSYTRF_RK routine.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is COMPLEX*16

E is an array, dimension (N). On exit, contains the output computed by the factorization routine ZSYTRF_RK, i.e. the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

For more info see the description of ZSYTRF_RK routine.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by ZSYTRF_RK.

For more info see the description of ZSYTRF_RK routine.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)).. Work array used in the factorization stage. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= 1. For best performance of factorization stage LWORK >= max(1,N*NB), where NB is the optimal blocksize for ZSYTRF_RK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array for factorization stage, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

Related Information

For this routine in other precisions, please see *csysv_rk*, *dsysv_rk* and *ssysv_rk*. It also exists with a native C interface as *LAPACKE_zsysv_rk*.

4.6.185 zsysv_rook

ZSYSV_ROOK computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

```
A = U * D * U**T,  if UPLO = 'U', or
A = L * D * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ZSYTRF_ROOK is called to compute the factorization of a complex symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method.

The factored form of A is then used to solve the system of equations A * X = B by calling ZSYTRS_ROOK.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsysv_rook(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsysv_rook_(const char *uplo, const armpl_int_t *n,
                 const armpl_int_t *nrhs, armpl_doublecomplex_t *a,
```

                armpl_doublecomplex_t *work, const armpl_int_t *lwork,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by ZSYTRF_ROOK.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D, as determined by ZSYTRF_ROOK.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= 1, and for best performance LWORK >= max(1,N*NB), where NB is the optimal blocksize for ZSYTRF_ROOK.

TRS will be done with Level 2 BLAS

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Related Information

For this routine in other precisions, please see *csysv_rook*, *dsysv_rook* and *ssysv_rook*. It also exists with a native C interface as *LAPACKE_zsysv_rook*.

4.6.186 zsysvx

zsysvx uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

```
The following steps are performed:
```

1. If FACT = 'N', the diagonal pivoting method is used to factor A.

```
 The form of the factorization is
   A = U * D * U**T,  if UPLO = 'U', or
   A = L * D * L**T,  if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices, and D is symmetric and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some D(i,i)=0, so that D is exactly singular, then the routine

```
 returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A.  If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
```

3. The system of equations is solved for X using the factored form

```
of A.
```

4. Iterative refinement is applied to improve the computed solution

```
 matrix and calculate error bounds and backward error estimates
for it.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zsysvx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X, LDX,
                  RCOND, FERR, BERR, WORK, LWORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsysvx_(const char *fact, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, const armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *af,
             const armpl_int_t *ldaf, armpl_int_t *ipiv,
             const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_doublecomplex_t *x, const armpl_int_t *ldx, double *rcond,
             double *ferr, double *berr, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, double *rwork, armpl_int_t *info,
             ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AF and IPIV contain the factored form of A. A, AF and IPIV will not be modified. = 'N': The matrix A will be copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by ZSYTRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T .

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by ZSYTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIV is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by ZSYTRF.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The N-by-NRHS right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of WORK. LWORK >= max(1,2*N), and for best performance, when FACT = 'N', LWORK >= max(1,2*N,N*NB), where NB is the optimal blocksize for ZSYTRF.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Related Information

For this routine in other precisions, please see *csysvx*, *dsysvx* and *ssysvx*. It also exists with a native C interface as *LAPACKE_zsysvx*.

4.6.187 zsysvxx

```
ZSYSVXX uses the diagonal pivoting factorization to compute the
   solution to a complex*16 system of linear equations A * X = B, where
   A is an N-by-N symmetric matrix and X and B are N-by-NRHS
   matrices.

   If requested, both normwise and maximum componentwise error bounds
```

(continues on next page)

(continued from previous page)

```
   are returned. ZSYSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   ZSYSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   ZSYSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what ZSYSVXX would itself produce.

                                                                  The␣
↪following steps are performed:

   1. If FACT = 'E', double precision scaling factors are computed to equilibrate
   the system:

     diag(S)*A*diag(S)      *inv(diag(S))*X = diag(S)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
   the matrix A (after equilibration if FACT = 'E') as

      A = U * D * U**T,  if UPLO = 'U', or
      A = L * D * L**T,  if UPLO = 'L',

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.

   3. If some D(i,i)=0, so that D is exactly singular, then the
   routine returns with INFO = i. Otherwise, the factored form of A
   is used to estimate the condition number of the matrix A (see
   argument RCOND).  If the reciprocal of the condition number is
   less than machine precision, the routine still goes on to solve
   for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form
   of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
   error and error bounds.  Refinement calculates the residual to at
   least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
   diag(R) so that it solves the original system before
   equilibration.                          Some optional parameters are bundled␣
↪in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zsysvxx(FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, EQUED, S, B,

              armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
              ... );
```

Parameters

FACT Input parameter.

FACT is CHARACTER*1

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIV contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by S. A, AF, and IPIV are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input and output parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by DSYTRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T .

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

If FACT = 'F', then IPIV is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by DSYTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIV is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by DSYTRF.

EQUED Input and output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N'). = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S Input and output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S)*B;

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). If INFO = 0, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(S))*X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

RPVGRW Output parameter.

RPVGRW is DOUBLE PRECISION

Reciprocal pivot growth. On exit, this contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable. If factorization fails with 0<INFO<=N, then this contains the reciprocal pivot growth factor for the leading INFO columns of A.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is DOUBLE PRECISION

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0D+0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the extra-precise refinement algorithm. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

4.6.188 zsytrs

zsytrs solves a system of linear equations A*X = B with a complex symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by ZSYTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytrs(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zsytrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_int_t *ipiv, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSYTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSYTRF.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csytrs*, *dsytrs* and *ssytrs*. It also exists with a native C interface as *LAPACKE_zsytrs*.

4.6.189 zsytrs2

zsytrs2 solves a system of linear equations A*X = B with a real symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by ZSYTRF and converted by ZSYCONV.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytrs2(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsytrs2_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
              const armpl_doublecomplex_t *a, const armpl_int_t *lda,
              const armpl_int_t *ipiv, armpl_doublecomplex_t *b,
              const armpl_int_t *ldb, armpl_doublecomplex_t *work,
              armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSYTRF. Note that A is input / output. This might be counter-intuitive, and one may think that A is input only. A is input / output. This is because, at the start of the subroutine, we permute A in a "better" form and then we permute A back to its original form at the end.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSYTRF.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csytrs2*, *dsytrs2* and *ssytrs2*. It also exists with a native C interface as *LAPACKE_zsytrs2*.

4.6.190 zsytrs_3

ZSYTRS_3 solves a system of linear equations A * X = B with a complex symmetric matrix A using the factorization computed by ZSYTRF_RK or ZSYTRF_BK:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This algorithm is using Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytrs_3(UPLO, N, NRHS, A, LDA, E, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zsytrs_3_(const char *uplo, const armpl_int_t *n,
               const armpl_int_t *nrhs, const armpl_doublecomplex_t *a,
               const armpl_int_t *lda, const armpl_doublecomplex_t *e,
               const armpl_int_t *ipiv, armpl_doublecomplex_t *b,
               const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix: = 'U': Upper triangular, form is A = P*U*D*(U^T)*(P^T); = 'L': Lower triangular, form is A = P*L*D*(L^T)*(P^T).

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). Diagonal of the block diagonal matrix D and factors U or L as computed by ZSYTRF_RK and ZSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is COMPLEX*16

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSYTRF_RK or ZSYTRF_BK.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csytrs_3*, *dsytrs_3* and *ssytrs_3*. It also exists with a native C interface as *LAPACKE_zsytrs_3*.

4.6.191 zsytrs_aa

ZSYTRS_AA solves a system of linear equations A*X = B with a complex symmetric matrix A using the factorization A = U*T*U^T or A = L*T*L^T computed by ZSYTRF_AA.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytrs_aa(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsytrs_aa_(const char *uplo, const armpl_int_t *n,
                const armpl_int_t *nrhs, const armpl_doublecomplex_t *a,
                const armpl_int_t *lda, const armpl_int_t *ipiv,
                armpl_doublecomplex_t *b, const armpl_int_t *ldb,
                const armpl_doublecomplex_t *work, const armpl_int_t *lwork,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*T*U^T ; = 'L': Lower triangular, form is A = L*T*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). Details of factors computed by ZSYTRF_AA.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges as computed by ZSYTRF_AA.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Input parameter.

WORK is DOUBLE array, dimension (MAX(1, LWORK))

LWORK Input parameter.

LWORK is INTEGER, LWORK >= MAX(1,3*N-2).

param[out] INFO verbatim INFO is INTEGER = 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csytrs_aa*, *dsytrs_aa* and *ssytrs_aa*. It also exists with a native C interface as *LAPACKE_zsytrs_aa*.

4.6.192 zsytrs_rook

ZSYTRS_ROOK solves a system of linear equations A*X = B with a complex symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by ZSYTRF_ROOK.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytrs_rook(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zsytrs_rook_(const char *uplo, const armpl_int_t *n,
                  const armpl_int_t *nrhs, const armpl_doublecomplex_t *a,
                  const armpl_int_t *lda, const armpl_int_t *ipiv,
                  armpl_doublecomplex_t *b, const armpl_int_t *ldb,
                  armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSYTRF_ROOK.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSYTRF_ROOK.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csytrs_rook*, *dsytrs_rook* and *ssytrs_rook*. It also exists with a native C interface as *LAPACKE_zsytrs_rook*.

4.6.193 ztbtrs

ztbtrs solves a triangular system of the form

```
A * X = B,  A**T * X = B,  or  A**H * X = B,
```

where A is a triangular band matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztbtrs(UPLO, TRANS, DIAG, N, KD, NRHS, AB, LDAB, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void ztbtrs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_int_t *nrhs, const armpl_doublecomplex_t *ab,
             const armpl_int_t *ldab, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals or subdiagonals of the triangular band matrix A. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first kd+1 rows of AB. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

Related Information

For this routine in other precisions, please see *ctbtrs*, *dtbtrs* and *stbtrs*. It also exists with a native C interface as *LAPACKE_ztbtrs*.

4.6.194 ztptrs

ztptrs solves a triangular system of the form

```
A * X = B,  A**T * X = B,  or  A**H * X = B,
```

where A is a triangular matrix of order N stored in packed format, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztptrs(UPLO, TRANS, DIAG, N, NRHS, AP, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void ztptrs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *ap, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

Related Information

For this routine in other precisions, please see *ctptrs*, *dtptrs* and *stptrs*. It also exists with a native C interface as *LAPACKE_ztptrs*.

4.7 LAPACK matrix equilibration routines

4.7.1 cgbequ

cgbequ computes row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgbequ(M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void cgbequ_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku,
             const armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
             float *r, float *c, float *rowcnd, float *colcnd, float *amax,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). The band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

R Output parameter.

R is REAL

R is an array, dimension (M). If INFO = 0, or INFO > M, R contains the row scale factors for A.

C Output parameter.

C is REAL

C is an array, dimension (N). If INFO = 0, C contains the column scale factors for A.

ROWCND Output parameter.

ROWCND is REAL

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND Output parameter.

COLCND is REAL

If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX Output parameter.

AMAX is REAL

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= M: the i-th row of A is exactly zero > M: the (i-M)-th column of A is exactly zero

Related Information

For this routine in other precisions, please see *dgbequ*, *sgbequ* and *zgbequ*. It also exists with a native C interface as *LAPACKE_cgbequ*.

4.7.2 cgbequb

cgbequb computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have an absolute value of at most the radix.

R(i) and C(j) are restricted to be a power of the radix between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

This routine differs from CGEEQU by restricting the scaling factors to a power of the radix. Barring over- and underflow, scaling by these factors introduces no additional rounding errors. However, the scaled entries' magnitudes are no longer approximately 1 but lie between sqrt(radix) and 1/sqrt(radix).

Syntax

Fortran specification:

```
use armpl_library

subroutine cgbequb(M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void cgbequb_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *kl, const armpl_int_t *ku,
              const armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
```

(continues on next page)

(continued from previous page)

```
                float *r, float *c, float *rowcnd, float *colcnd, float *amax,
                armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array A. LDAB >= max(1, M).

R Output parameter.

R is REAL

R is an array, dimension (M). If INFO = 0 or INFO > M, R contains the row scale factors for A.

C Output parameter.

C is REAL

C is an array, dimension (N). If INFO = 0, C contains the column scale factors for A.

ROWCND Output parameter.

ROWCND is REAL

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND Output parameter.

COLCND is REAL

If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX Output parameter.

AMAX is REAL

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= M: the i-th row of A is exactly zero > M: the (i-M)-th column of A is exactly zero

Related Information

4.7.3 cgeequ

cgeequ computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgeequ(M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void cgeequ_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda, float *r,
             float *c, float *rowcnd, float *colcnd, float *amax,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The M-by-N matrix whose equilibration factors are to be computed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

R Output parameter.

R is REAL

R is an array, dimension (M). If INFO = 0 or INFO > M, R contains the row scale factors for A.

C Output parameter.

C is REAL

C is an array, dimension (N). If INFO = 0, C contains the column scale factors for A.

ROWCND Output parameter.

ROWCND is REAL

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND Output parameter.

COLCND is REAL

If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX Output parameter.

AMAX is REAL

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= M: the i-th row of A is exactly zero > M: the (i-M)-th column of A is exactly zero

Related Information

For this routine in other precisions, please see *dgeequ*, *sgeequ* and *zgeequ*. It also exists with a native C interface as *LAPACKE_cgeequ*.

4.7.4 cgeequb

cgeequb computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have an absolute value of at most the radix.

R(i) and C(j) are restricted to be a power of the radix between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

This routine differs from CGEEQU by restricting the scaling factors to a power of the radix. Barring over- and underflow, scaling by these factors introduces no additional rounding errors. However, the scaled entries' magnitudes are no longer approximately 1 but lie between sqrt(radix) and 1/sqrt(radix).

Syntax

Fortran specification:

```
use armpl_library

subroutine cgeequb(M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void cgeequb_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_singlecomplex_t *a, const armpl_int_t *lda,
              float *r, float *c, float *rowcnd, float *colcnd, float *amax,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The M-by-N matrix whose equilibration factors are to be computed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

R Output parameter.

R is REAL

R is an array, dimension (M). If INFO = 0 or INFO > M, R contains the row scale factors for A.

C Output parameter.

C is REAL

C is an array, dimension (N). If INFO = 0, C contains the column scale factors for A.

ROWCND Output parameter.

ROWCND is REAL

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND Output parameter.

COLCND is REAL

If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX Output parameter.

AMAX is REAL

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= M: the i-th row of A is exactly zero > M: the (i-M)-th column of A is exactly zero

Related Information

For this routine in other precisions, please see *dgeequb*, *sgeequb* and *zgeequb*. It also exists with a native C interface as *LAPACKE_cgeequb*.

4.7.5 cheequb

cheequb computes row and column scalings intended to equilibrate a Hermitian matrix A (with respect to the Euclidean norm) and reduce its condition number. The scale factors S are computed by the BIN algorithm (see references) so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has a condition number within a factor N of the smallest possible condition number over all possible diagonal scalings.

Syntax

Fortran specification:

```
use armpl_library

subroutine cheequb(UPLO, N, A, LDA, S, SCOND, AMAX, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cheequb_(char *uplo, const armpl_int_t *n,
              const armpl_singlecomplex_t *a, const armpl_int_t *lda,
              float *s, float *scond, float *amax,
              armpl_singlecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The N-by-N Hermitian matrix whose scaling factors are to be computed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

S Output parameter.

S is REAL

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is REAL

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is REAL

Largest absolute value of any matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *zheequb*. It also exists with a native C interface as *LAPACKE_cheequb*.

4.7.6 cpbequ

cpbequ computes row and column scalings intended to equilibrate a Hermitian positive definite band matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpbequ(UPLO, N, KD, AB, LDAB, S, SCOND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void cpbequ_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
             float *s, float *scond, float *amax, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular of A is stored; = 'L': Lower triangular of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). The upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array A. LDAB >= KD+1.

S Output parameter.

S is REAL

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is REAL

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is REAL

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *dpbequ*, *spbequ* and *zpbequ*. It also exists with a native C interface as *LAPACKE_cpbequ*.

4.7.7 cpoequ

`cpoequ` computes row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpoequ(N, A, LDA, S, SCOND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void cpoequ_(const armpl_int_t *n, const armpl_singlecomplex_t *a,
             const armpl_int_t *lda, float *s, float *scond, float *amax,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The N-by-N Hermitian positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

S Output parameter.

S is REAL

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is REAL

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is REAL

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *dpoequ*, *spoequ* and *zpoequ*. It also exists with a native C interface as *LAPACKE_cpoequ*.

4.7.8 cpoequb

cpoequb computes row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

This routine differs from CPOEQU by restricting the scaling factors to a power of the radix. Barring over- and underflow, scaling by these factors introduces no additional rounding errors. However, the scaled diagonal entries are no longer approximately 1 but lie between sqrt(radix) and 1/sqrt(radix).

Syntax

Fortran specification:

```
use armpl_library

subroutine cpoequb(N, A, LDA, S, SCOND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void cpoequb_(const armpl_int_t *n, const armpl_singlecomplex_t *a,
              const armpl_int_t *lda, float *s, float *scond, float *amax,
              armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The N-by-N Hermitian positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

S Output parameter.

S is REAL

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is REAL

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is REAL

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *dpoequb*, *spoequb* and *zpoequb*. It also exists with a native C interface as *LAPACKE_cpoequb*.

4.7.9 cppequ

cppequ computes row and column scalings intended to equilibrate a Hermitian positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i)=1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j)=S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

Syntax

Fortran specification:

```
use armpl_library

subroutine cppequ(UPLO, N, AP, S, SCOND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void cppequ_(const char *uplo, const armpl_int_t *n,
             const armpl_singlecomplex_t *ap, float *s, float *scond,
             float *amax, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

S Output parameter.

S is REAL

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is REAL

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is REAL

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *dppequ*, *sppequ* and *zppequ*. It also exists with a native C interface as *LAPACKE_cppequ*.

4.7.10 csyequb

csyequb computes row and column scalings intended to equilibrate a symmetric matrix A (with respect to the Euclidean norm) and reduce its condition number. The scale factors S are computed by the BIN algorithm (see references) so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has a condition number within a factor N of the smallest possible condition number over all possible diagonal scalings.

Syntax

Fortran specification:

```
use armpl_library

subroutine csyequb(UPLO, N, A, LDA, S, SCOND, AMAX, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void csyequb_(char *uplo, const armpl_int_t *n,
              const armpl_singlecomplex_t *a, const armpl_int_t *lda,
              float *s, float *scond, float *amax,
              armpl_singlecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The N-by-N symmetric matrix whose scaling factors are to be computed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

S Output parameter.

S is REAL

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is REAL

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is REAL

Largest absolute value of any matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *dsyequb*, *ssyequb* and *zsyequb*. It also exists with a native C interface as *LAPACKE_csyequb*.

4.7.11 dgbequ

dgbequ computes row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgbequ(M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void dgbequ_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku, const double *ab,
             const armpl_int_t *ldab, double *r, double *c, double *rowcnd,
             double *colcnd, double *amax, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). The band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

R Output parameter.

R is DOUBLE PRECISION

R is an array, dimension (M). If INFO = 0, or INFO > M, R contains the row scale factors for A.

C Output parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). If INFO = 0, C contains the column scale factors for A.

ROWCND Output parameter.

ROWCND is DOUBLE PRECISION

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND Output parameter.

COLCND is DOUBLE PRECISION

If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX Output parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= M: the i-th row of A is exactly zero > M: the (i-M)-th column of A is exactly zero

4.7.12 dgbequb

dgbequb computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have an absolute value of at most the radix.

R(i) and C(j) are restricted to be a power of the radix between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

This routine differs from DGEEQU by restricting the scaling factors to a power of the radix. Barring over- and underflow, scaling by these factors introduces no additional rounding errors. However, the scaled entries' magnitudes are no longer approximately 1 but lie between sqrt(radix) and 1/sqrt(radix).

Syntax

Fortran specification:

```
use armpl_library

subroutine dgbequb(M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void dgbequb_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *kl, const armpl_int_t *ku, const double *ab,
              const armpl_int_t *ldab, double *r, double *c, double *rowcnd,
              double *colcnd, double *amax, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array A. LDAB >= max(1, M).

R Output parameter.

R is DOUBLE PRECISION

R is an array, dimension (M). If INFO = 0 or INFO > M, R contains the row scale factors for A.

C Output parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). If INFO = 0, C contains the column scale factors for A.

ROWCND Output parameter.

ROWCND is DOUBLE PRECISION

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND Output parameter.

COLCND is DOUBLE PRECISION

If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX Output parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= M: the i-th row of A is exactly zero > M: the (i-M)-th column of A is exactly zero

4.7.13 dgeequ

dgeequ computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgeequ(M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void dgeequ_(const armpl_int_t *m, const armpl_int_t *n, const double *a,
             const armpl_int_t *lda, double *r, double *c, double *rowcnd,
             double *colcnd, double *amax, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The M-by-N matrix whose equilibration factors are to be computed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

R Output parameter.

R is DOUBLE PRECISION

R is an array, dimension (M). If INFO = 0 or INFO > M, R contains the row scale factors for A.

C Output parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). If INFO = 0, C contains the column scale factors for A.

ROWCND Output parameter.

ROWCND is DOUBLE PRECISION

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND Output parameter.

COLCND is DOUBLE PRECISION

If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX Output parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= M: the i-th row of A is exactly zero > M: the (i-M)-th column of A is exactly zero

Related Information

For this routine in other precisions, please see *cgeequ*, *sgeequ* and *zgeequ*. It also exists with a native C interface as *LAPACKE_dgeequ*.

4.7.14 dgeequb

`dgeequb` computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have an absolute value of at most the radix.

R(i) and C(j) are restricted to be a power of the radix between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

This routine differs from DGEEQU by restricting the scaling factors to a power of the radix. Barring over- and underflow, scaling by these factors introduces no additional rounding errors. However, the scaled entries' magnitudes are no longer approximately 1 but lie between sqrt(radix) and 1/sqrt(radix).

Syntax

Fortran specification:

```
use armpl_library

subroutine dgeequb(M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void dgeequb_(const armpl_int_t *m, const armpl_int_t *n, const double *a,
              const armpl_int_t *lda, double *r, double *c, double *rowcnd,
              double *colcnd, double *amax, armpl_int_t *info);
```

Parameters

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix `A`. `M` >= 0.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix `A`. `N` >= 0.

A Input parameter.

`A` is `DOUBLE PRECISION`

`A` is an array, dimension (`LDA`, `N`). The M-by-N matrix whose equilibration factors are to be computed.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `M`).

R Output parameter.

`R` is `DOUBLE PRECISION`

`R` is an array, dimension (`M`). If `INFO` = 0 or `INFO` > `M`, `R` contains the row scale factors for `A`.

C Output parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). If INFO = 0, C contains the column scale factors for A.

ROWCND Output parameter.

ROWCND is DOUBLE PRECISION

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND Output parameter.

COLCND is DOUBLE PRECISION

If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX Output parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= M: the i-th row of A is exactly zero > M: the (i-M)-th column of A is exactly zero

Related Information

For this routine in other precisions, please see *cgeequb*, *sgeequb* and *zgeequb*. It also exists with a native C interface as *LAPACKE_dgeequb*.

4.7.15 dpbequ

dpbequ computes row and column scalings intended to equilibrate a symmetric positive definite band matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpbequ(UPLO, N, KD, AB, LDAB, S, SCOND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void dpbequ_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             const double *ab, const armpl_int_t *ldab, double *s,
             double *scond, double *amax, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular of A is stored; = 'L': Lower triangular of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). The upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array A. LDAB >= KD+1.

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is DOUBLE PRECISION

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *cpbequ*, *spbequ* and *zpbequ*. It also exists with a native C interface as *LAPACKE_dpbequ*.

4.7.16 dpoequ

dpoequ computes row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpoequ(N, A, LDA, S, SCOND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void dpoequ_(const armpl_int_t *n, const double *a, const armpl_int_t *lda,
             double *s, double *scond, double *amax, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The N-by-N symmetric positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is DOUBLE PRECISION

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *cpoequ*, *spoequ* and *zpoequ*. It also exists with a native C interface as *LAPACKE_dpoequ*.

4.7.17 dpoequb

dpoequb computes row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

This routine differs from DPOEQU by restricting the scaling factors to a power of the radix. Barring over- and underflow, scaling by these factors introduces no additional rounding errors. However, the scaled diagonal entries are no longer approximately 1 but lie between sqrt(radix) and 1/sqrt(radix).

Syntax

Fortran specification:

```
use armpl_library

subroutine dpoequb(N, A, LDA, S, SCOND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void dpoequb_(const armpl_int_t *n, const double *a, const armpl_int_t *lda,
              double *s, double *scond, double *amax, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The N-by-N symmetric positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is DOUBLE PRECISION

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *cpoequb*, *spoequb* and *zpoequb*. It also exists with a native C interface as *LAPACKE_dpoequb*.

4.7.18 dppequ

dppequ computes row and column scalings intended to equilibrate a symmetric positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i)=1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j)=S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

Syntax

Fortran specification:

```
use armpl_library

subroutine dppequ(UPLO, N, AP, S, SCOND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void dppequ_(const char *uplo, const armpl_int_t *n, const double *ap,
             double *s, double *scond, double *amax, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is DOUBLE PRECISION

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *cppequ*, *sppequ* and *zppequ*. It also exists with a native C interface as *LAPACKE_dppequ*.

4.7.19 dsyequb

dsyequb computes row and column scalings intended to equilibrate a symmetric matrix A (with respect to the Euclidean norm) and reduce its condition number. The scale factors S are computed by the BIN algorithm (see references) so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has a condition number within a factor N of the smallest possible condition number over all possible diagonal scalings.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsyequb(UPLO, N, A, LDA, S, SCOND, AMAX, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsyequb_(char *uplo, const armpl_int_t *n, const double *a,
              const armpl_int_t *lda, double *s, double *scond, double *amax,
              double *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The N-by-N symmetric matrix whose scaling factors are to be computed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is DOUBLE PRECISION

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is DOUBLE PRECISION

Largest absolute value of any matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *csyequb*, *ssyequb* and *zsyequb*. It also exists with a native C interface as *LAPACKE_dsyequb*.

4.7.20 sgbequ

sgbequ computes row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgbequ(M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void sgbequ_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku, const float *ab,
             const armpl_int_t *ldab, float *r, float *c, float *rowcnd,
             float *colcnd, float *amax, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). The band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

R Output parameter.

R is REAL

R is an array, dimension (M). If INFO = 0, or INFO > M, R contains the row scale factors for A.

C Output parameter.

C is REAL

C is an array, dimension (N). If INFO = 0, C contains the column scale factors for A.

ROWCND Output parameter.

ROWCND is REAL

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND Output parameter.

COLCND is REAL

If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX Output parameter.

AMAX is REAL

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= M: the i-th row of A is exactly zero > M: the (i-M)-th column of A is exactly zero

Related Information

4.7.21 sgbequb

sgbequb computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have an absolute value of at most the radix.

R(i) and C(j) are restricted to be a power of the radix between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

This routine differs from SGEEQU by restricting the scaling factors to a power of the radix. Barring over- and underflow, scaling by these factors introduces no additional rounding errors. However, the scaled entries' magnitudes are no longer approximately 1 but lie between sqrt(radix) and 1/sqrt(radix).

Syntax

Fortran specification:

```
use armpl_library

subroutine sgbequb(M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void sgbequb_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *kl, const armpl_int_t *ku, const float *ab,
              const armpl_int_t *ldab, float *r, float *c, float *rowcnd,
              float *colcnd, float *amax, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array A. LDAB >= max(1, M).

R Output parameter.

R is REAL

R is an array, dimension (M). If INFO = 0 or INFO > M, R contains the row scale factors for A.

C Output parameter.

C is REAL

C is an array, dimension (N). If INFO = 0, C contains the column scale factors for A.

ROWCND Output parameter.

ROWCND is REAL

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND Output parameter.

COLCND is REAL

If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX Output parameter.

AMAX is REAL

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= M: the i-th row of A is exactly zero > M: the (i-M)-th column of A is exactly zero

4.7.22 sgeequ

sgeequ computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgeequ(M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void sgeequ_(const armpl_int_t *m, const armpl_int_t *n, const float *a,
             const armpl_int_t *lda, float *r, float *c, float *rowcnd,
             float *colcnd, float *amax, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The M-by-N matrix whose equilibration factors are to be computed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

R Output parameter.

R is REAL

R is an array, dimension (M). If INFO = 0 or INFO > M, R contains the row scale factors for A.

C Output parameter.

C is REAL

C is an array, dimension (N). If INFO = 0, C contains the column scale factors for A.

ROWCND Output parameter.

ROWCND is REAL

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND Output parameter.

COLCND is REAL

If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX Output parameter.

AMAX is REAL

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= M: the i-th row of A is exactly zero > M: the (i-M)-th column of A is exactly zero

Related Information

For this routine in other precisions, please see *cgeequ*, *dgeequ* and *zgeequ*. It also exists with a native C interface as *LAPACKE_sgeequ*.

4.7.23 sgeequb

sgeequb computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have an absolute value of at most the radix.

R(i) and C(j) are restricted to be a power of the radix between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

This routine differs from SGEEQU by restricting the scaling factors to a power of the radix. Barring over- and underflow, scaling by these factors introduces no additional rounding errors. However, the scaled entries' magnitudes are no longer approximately 1 but lie between sqrt(radix) and 1/sqrt(radix).

Syntax

Fortran specification:

```
use armpl_library

subroutine sgeequb(M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void sgeequb_(const armpl_int_t *m, const armpl_int_t *n, const float *a,
              const armpl_int_t *lda, float *r, float *c, float *rowcnd,
              float *colcnd, float *amax, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The M-by-N matrix whose equilibration factors are to be computed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

R Output parameter.

R is REAL

R is an array, dimension (M). If INFO = 0 or INFO > M, R contains the row scale factors for A.

C Output parameter.

C is REAL

C is an array, dimension (N). If INFO = 0, C contains the column scale factors for A.

ROWCND Output parameter.

ROWCND is REAL

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND Output parameter.

COLCND is REAL

If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX Output parameter.

AMAX is REAL

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= M: the i-th row of A is exactly zero > M: the (i-M)-th column of A is exactly zero

Related Information

For this routine in other precisions, please see *cgeequb*, *dgeequb* and *zgeequb*. It also exists with a native C interface as *LAPACKE_sgeequb*.

4.7.24 spbequ

spbequ computes row and column scalings intended to equilibrate a symmetric positive definite band matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

Syntax

Fortran specification:

```
use armpl_library

subroutine spbequ(UPLO, N, KD, AB, LDAB, S, SCOND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void spbequ_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             const float *ab, const armpl_int_t *ldab, float *s, float *scond,
             float *amax, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular of A is stored; = 'L': Lower triangular of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). The upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array A. LDAB >= KD+1.

S Output parameter.

S is REAL

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is REAL

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is REAL

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *cpbequ*, *dpbequ* and *zpbequ*. It also exists with a native C interface as *LAPACKE_spbequ*.

4.7.25 spoequ

spoequ computes row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

Syntax

Fortran specification:

```
use armpl_library

subroutine spoequ(N, A, LDA, S, SCOND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void spoequ_(const armpl_int_t *n, const float *a, const armpl_int_t *lda,
             float *s, float *scond, float *amax, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The N-by-N symmetric positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

S Output parameter.

S is REAL

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is REAL

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is REAL

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *cpoequ*, *dpoequ* and *zpoequ*. It also exists with a native C interface as *LAPACKE_spoequ*.

4.7.26 spoequb

spoequb computes row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

This routine differs from SPOEQU by restricting the scaling factors to a power of the radix. Barring over- and underflow, scaling by these factors introduces no additional rounding errors. However, the scaled diagonal entries are no longer approximately 1 but lie between sqrt(radix) and 1/sqrt(radix).

Syntax

Fortran specification:

```
use armpl_library

subroutine spoequb(N, A, LDA, S, SCOND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void spoequb_(const armpl_int_t *n, const float *a, const armpl_int_t *lda,
              float *s, float *scond, float *amax, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The N-by-N symmetric positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

S Output parameter.

S is REAL

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is REAL

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is REAL

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *cpoequb*, *dpoequb* and *zpoequb*. It also exists with a native C interface as *LAPACKE_spoequb*.

4.7.27 sppequ

sppequ computes row and column scalings intended to equilibrate a symmetric positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i)=1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j)=S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

Syntax

Fortran specification:

```
use armpl_library

subroutine sppequ(UPLO, N, AP, S, SCOND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void sppequ_(const char *uplo, const armpl_int_t *n, const float *ap,
             float *s, float *scond, float *amax, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

S Output parameter.

S is REAL

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is REAL

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is REAL

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *cppequ*, *dppequ* and *zppequ*. It also exists with a native C interface as *LAPACKE_sppequ*.

4.7.28 ssyequb

ssyequb computes row and column scalings intended to equilibrate a symmetric matrix A (with respect to the Euclidean norm) and reduce its condition number. The scale factors S are computed by the BIN algorithm (see references) so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has a condition number within a factor N of the smallest possible condition number over all possible diagonal scalings.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssyequb(UPLO, N, A, LDA, S, SCOND, AMAX, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssyequb_(char *uplo, const armpl_int_t *n, const float *a,
              const armpl_int_t *lda, float *s, float *scond, float *amax,
              float *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The N-by-N symmetric matrix whose scaling factors are to be computed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

S Output parameter.

S is REAL

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is REAL

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is REAL

Largest absolute value of any matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *csyequb*, *dsyequb* and *zsyequb*. It also exists with a native C interface as *LAPACKE_ssyequb*.

4.7.29 zgbequ

zgbequ computes row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgbequ(M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void zgbequ_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku,
             const armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
             double *r, double *c, double *rowcnd, double *colcnd,
             double *amax, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). The band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

R Output parameter.

R is DOUBLE PRECISION

R is an array, dimension (M). If INFO = 0, or INFO > M, R contains the row scale factors for A.

C Output parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). If INFO = 0, C contains the column scale factors for A.

ROWCND Output parameter.

ROWCND is DOUBLE PRECISION

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND Output parameter.

COLCND is DOUBLE PRECISION

If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX Output parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= M: the i-th row of A is exactly zero > M: the (i-M)-th column of A is exactly zero

Related Information

For this routine in other precisions, please see *cgbequ*, *dgbequ* and *sgbequ*. It also exists with a native C interface as *LAPACKE_zgbequ*.

4.7.30 zgbequb

zgbequb computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have an absolute value of at most the radix.

R(i) and C(j) are restricted to be a power of the radix between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

This routine differs from ZGEEQU by restricting the scaling factors to a power of the radix. Barring over- and underflow, scaling by these factors introduces no additional rounding errors. However, the scaled entries' magnitudes are no longer approximately 1 but lie between sqrt(radix) and 1/sqrt(radix).

Syntax

Fortran specification:

```
use armpl_library

subroutine zgbequb(M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void zgbequb_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *kl, const armpl_int_t *ku,
              const armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
```

(continues on next page)

(continued from previous page)

```
                double *r, double *c, double *rowcnd, double *colcnd,
                double *amax, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array A. LDAB >= max(1, M).

R Output parameter.

R is DOUBLE PRECISION

R is an array, dimension (M). If INFO = 0 or INFO > M, R contains the row scale factors for A.

C Output parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). If INFO = 0, C contains the column scale factors for A.

ROWCND Output parameter.

ROWCND is DOUBLE PRECISION

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND Output parameter.

COLCND is DOUBLE PRECISION

If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX Output parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= M: the i-th row of A is exactly zero > M: the (i-M)-th column of A is exactly zero

Related Information

For this routine in other precisions, please see *cgbequb*, *dgbequb* and *sgbequb*. It also exists with a native C interface as *LAPACKE_zgbequb*.

4.7.31 zgeequ

zgeequ computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgeequ(M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void zgeequ_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             double *r, double *c, double *rowcnd, double *colcnd,
             double *amax, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The M-by-N matrix whose equilibration factors are to be computed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

R Output parameter.

R is DOUBLE PRECISION

R is an array, dimension (M). If INFO = 0 or INFO > M, R contains the row scale factors for A.

C Output parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). If INFO = 0, C contains the column scale factors for A.

ROWCND Output parameter.

ROWCND is DOUBLE PRECISION

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND Output parameter.

COLCND is DOUBLE PRECISION

If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX Output parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= M: the i-th row of A is exactly zero > M: the (i-M)-th column of A is exactly zero

Related Information

For this routine in other precisions, please see *cgeequ*, *dgeequ* and *sgeequ*. It also exists with a native C interface as *LAPACKE_zgeequ*.

4.7.32 zgeequb

zgeequb computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have an absolute value of at most the radix.

R(i) and C(j) are restricted to be a power of the radix between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

This routine differs from ZGEEQU by restricting the scaling factors to a power of the radix. Barring over- and underflow, scaling by these factors introduces no additional rounding errors. However, the scaled entries' magnitudes are no longer approximately 1 but lie between sqrt(radix) and 1/sqrt(radix).

Syntax

Fortran specification:

```
use armpl_library

subroutine zgeequb(M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void zgeequb_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_doublecomplex_t *a, const armpl_int_t *lda,
              double *r, double *c, double *rowcnd, double *colcnd,
              double *amax, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The M-by-N matrix whose equilibration factors are to be computed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

R Output parameter.

R is DOUBLE PRECISION

R is an array, dimension (M). If INFO = 0 or INFO > M, R contains the row scale factors for A.

C Output parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). If INFO = 0, C contains the column scale factors for A.

ROWCND Output parameter.

ROWCND is DOUBLE PRECISION

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND Output parameter.

COLCND is DOUBLE PRECISION

If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX Output parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is <= M: the i-th row of A is exactly zero > M: the (i-M)-th column of A is exactly zero

Related Information

For this routine in other precisions, please see *cgeequb*, *dgeequb* and *sgeequb*. It also exists with a native C interface as *LAPACKE_zgeequb*.

4.7.33 zheequb

zheequb computes row and column scalings intended to equilibrate a Hermitian matrix A (with respect to the Euclidean norm) and reduce its condition number. The scale factors S are computed by the BIN algorithm (see references) so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has a condition number within a factor N of the smallest possible condition number over all possible diagonal scalings.

Syntax

Fortran specification:

```
use armpl_library

subroutine zheequb(UPLO, N, A, LDA, S, SCOND, AMAX, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zheequb_(char *uplo, const armpl_int_t *n,
              const armpl_doublecomplex_t *a, const armpl_int_t *lda,
              double *s, double *scond, double *amax,
              armpl_doublecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The N-by-N Hermitian matrix whose scaling factors are to be computed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is DOUBLE PRECISION

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is DOUBLE PRECISION

Largest absolute value of any matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *cheequb*. It also exists with a native C interface as *LAPACKE_zheequb*.

4.7.34 zpbequ

zpbequ computes row and column scalings intended to equilibrate a Hermitian positive definite band matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpbequ(UPLO, N, KD, AB, LDAB, S, SCOND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void zpbequ_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
             double *s, double *scond, double *amax, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular of A is stored; = 'L': Lower triangular of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). The upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array A. LDAB >= KD+1.

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is DOUBLE PRECISION

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *cpbequ*, *dpbequ* and *spbequ*. It also exists with a native C interface as *LAPACKE_zpbequ*.

4.7.35 zpoequ

zpoequ computes row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpoequ(N, A, LDA, S, SCOND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void zpoequ_(const armpl_int_t *n, const armpl_doublecomplex_t *a,
             const armpl_int_t *lda, double *s, double *scond, double *amax,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The N-by-N Hermitian positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is DOUBLE PRECISION

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *cpoequ*, *dpoequ* and *spoequ*. It also exists with a native C interface as *LAPACKE_zpoequ*.

4.7.36 zpoequb

zpoequb computes row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

This routine differs from ZPOEQU by restricting the scaling factors to a power of the radix. Barring over- and underflow, scaling by these factors introduces no additional rounding errors. However, the scaled diagonal entries are no longer approximately 1 but lie between sqrt(radix) and 1/sqrt(radix).

Syntax

Fortran specification:

```
use armpl_library

subroutine zpoequb(N, A, LDA, S, SCOND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void zpoequb_(const armpl_int_t *n, const armpl_doublecomplex_t *a,
              const armpl_int_t *lda, double *s, double *scond, double *amax,
              armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The N-by-N Hermitian positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is DOUBLE PRECISION

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *cpoequb*, *dpoequb* and *spoequb*. It also exists with a native C interface as *LAPACKE_zpoequb*.

4.7.37 zppequ

zppequ computes row and column scalings intended to equilibrate a Hermitian positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i)=1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j)=S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

Syntax

Fortran specification:

```
use armpl_library

subroutine zppequ(UPLO, N, AP, S, SCOND, AMAX, INFO)
```

C specification:

```
#include "armpl.h"

void zppequ_(const char *uplo, const armpl_int_t *n,
             const armpl_doublecomplex_t *ap, double *s, double *scond,
             double *amax, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is DOUBLE PRECISION

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *cppequ*, *dppequ* and *sppequ*. It also exists with a native C interface as *LAPACKE_zppequ*.

4.7.38 zsyequb

zsyequb computes row and column scalings intended to equilibrate a symmetric matrix A (with respect to the Euclidean norm) and reduce its condition number. The scale factors S are computed by the BIN algorithm (see references) so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has a condition number within a factor N of the smallest possible condition number over all possible diagonal scalings.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsyequb(UPLO, N, A, LDA, S, SCOND, AMAX, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsyequb_(char *uplo, const armpl_int_t *n,
              const armpl_doublecomplex_t *a, const armpl_int_t *lda,
              double *s, double *scond, double *amax,
              armpl_doublecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The N-by-N symmetric matrix whose scaling factors are to be computed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). If INFO = 0, S contains the scale factors for A.

SCOND Output parameter.

SCOND is DOUBLE PRECISION

If INFO = 0, S contains the ratio of the smallest S(i) to the largest S(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by S.

AMAX Output parameter.

AMAX is DOUBLE PRECISION

Largest absolute value of any matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element is nonpositive.

Related Information

For this routine in other precisions, please see *csyequb*, *dsyequb* and *ssyequb*. It also exists with a native C interface as *LAPACKE_zsyequb*.

4.8 LAPACK cosine sine routines

4.8.1 cbbcsd

cbbcsd computes the CS decomposition of a unitary matrix in bidiagonal-block form,

```
[ B11 | B12 0  0 ]
[  0  |  0 -I  0 ]
```

X = [————————-]

```
[ B21 | B22 0  0 ]
[  0  |  0  0  I ]

                           [  C | -S  0  0 ]
             [ U1 |    ] [  0 |  0 -I  0 ] [ V1 |    ]**H
           = [---------] [----------------] [---------]   .
             [    | U2 ] [  S |  C  0  0 ] [    | V2 ]
                           [  0 |  0  0  I ]
```

X is M-by-M, its top-left block is P-by-Q, and Q must be no larger than P, M-P, or M-Q. (If Q is not the smallest index, then X must be transposed and/or permuted. This can be done in constant time using the TRANS and SIGNS options. See CUNCSD for details.)

The bidiagonal matrices B11, B12, B21, and B22 are represented implicitly by angles THETA(1:Q) and PHI(1:Q-1).

The unitary matrices U1, U2, V1T, and V2T are input/output. The input matrices are pre- or post-multiplied by the appropriate singular vector matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine cbbcsd(JOBU1, JOBU2, JOBV1T, JOBV2T, TRANS, M, P, Q, THETA, PHI,
                  U1, LDU1, U2, LDU2, V1T, LDV1T, V2T, LDV2T, B11D, B11E,
                  B12D, B12E, B21D, B21E, B22D, B22E, RWORK, LRWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cbbcsd_(const char *jobu1, const char *jobu2, const char *jobv1t,
             const char *jobv2t, const char *trans, const armpl_int_t *m,
             const armpl_int_t *p, const armpl_int_t *q, float *theta,
```

(continues on next page)

(continued from previous page)

```
                float *phi, armpl_singlecomplex_t *u1, const armpl_int_t *ldu1,
                armpl_singlecomplex_t *u2, const armpl_int_t *ldu2,
                armpl_singlecomplex_t *v1t, const armpl_int_t *ldv1t,
                armpl_singlecomplex_t *v2t, const armpl_int_t *ldv2t,
                float *b11d, float *b11e, float *b12d, float *b12e, float *b21d,
                float *b21e, float *b22d, float *b22e, float *rwork,
                const armpl_int_t *lrwork, armpl_int_t *info, ... );
```

Parameters

JOBU1 Input parameter.

JOBU1 is CHARACTER

= 'Y': U1 is updated; otherwise: U1 is not updated.

JOBU2 Input parameter.

JOBU2 is CHARACTER

= 'Y': U2 is updated; otherwise: U2 is not updated.

JOBV1T Input parameter.

JOBV1T is CHARACTER

= 'Y': V1T is updated; otherwise: V1T is not updated.

JOBV2T Input parameter.

JOBV2T is CHARACTER

= 'Y': V2T is updated; otherwise: V2T is not updated.

TRANS Input parameter.

TRANS is CHARACTER

= 'T': X, U1, U2, V1T, and V2T are stored in row-major order; otherwise: X, U1, U2, V1T, and V2T are stored in column- major order.

M Input parameter.

M is INTEGER

The number of rows and columns in X, the unitary matrix in bidiagonal-block form.

P Input parameter.

P is INTEGER

The number of rows in the top-left block of X. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in the top-left block of X. 0 <= Q <= MIN(P,M-P,M-Q).

THETA Input and output parameter.

THETA is REAL

THETA is an array, dimension (Q). On entry, the angles THETA(1),...,THETA(Q) that, along with PHI(1), ...,PHI(Q-1), define the matrix in bidiagonal-block form. On exit, the angles whose cosines and sines define the diagonal blocks in the CS decomposition.

PHI Input and output parameter.

PHI is REAL

PHI is an array, dimension (Q-1). The angles PHI(1),...,PHI(Q-1) that, along with THETA(1),..., THETA(Q), define the matrix in bidiagonal-block form.

U1 Input and output parameter.

U1 is COMPLEX

U1 is an array, dimension (LDU1, P). On entry, a P-by-P matrix. On exit, U1 is postmultiplied by the left singular vector matrix common to [B11 ; 0] and [B12 0 0 ; 0 -I 0 0].

LDU1 Input parameter.

LDU1 is INTEGER

The leading dimension of the array U1, LDU1 >= MAX(1, P).

U2 Input and output parameter.

U2 is COMPLEX

U2 is an array, dimension (LDU2,M-P). On entry, an (M-P)-by-(M-P) matrix. On exit, U2 is postmultiplied by the left singular vector matrix common to [B21 ; 0] and [B22 0 0 ; 0 0 I].

LDU2 Input parameter.

LDU2 is INTEGER

The leading dimension of the array U2, LDU2 >= MAX(1,M-P).

V1T Input and output parameter.

V1T is COMPLEX

V1T is an array, dimension (LDV1T, Q). On entry, a Q-by-Q matrix. On exit, V1T is premultiplied by the conjugate transpose of the right singular vector matrix common to [B11 ; 0] and [B21 ; 0].

LDV1T Input parameter.

LDV1T is INTEGER

The leading dimension of the array V1T, LDV1T >= MAX(1, Q).

V2T Input and output parameter.

V2T is COMPLEX

V2T is an array, dimension (LDV2T,M-Q). On entry, an (M-Q)-by-(M-Q) matrix. On exit, V2T is premultiplied by the conjugate transpose of the right singular vector matrix common to [B12 0 0 ; 0 -I 0] and [B22 0 0 ; 0 0 I].

LDV2T Input parameter.

LDV2T is INTEGER

The leading dimension of the array V2T, LDV2T >= MAX(1,M-Q).

B11D Output parameter.

B11D is REAL

B11D is an array, dimension (Q). When CBBCSD converges, B11D contains the cosines of THETA(1), ..., THETA(Q). If CBBCSD fails to converge, then B11D contains the diagonal of the partially reduced top-left block.

B11E Output parameter.

B11E is REAL

B11E is an array, dimension (Q-1). When CBBCSD converges, B11E contains zeros. If CBBCSD fails to converge, then B11E contains the superdiagonal of the partially reduced top-left block.

B12D Output parameter.

B12D is REAL

B12D is an array, dimension (Q). When CBBCSD converges, B12D contains the negative sines of THETA(1), ..., THETA(Q). If CBBCSD fails to converge, then B12D contains the diagonal of the partially reduced top-right block.

B12E Output parameter.

B12E is REAL

B12E is an array, dimension (Q-1). When CBBCSD converges, B12E contains zeros. If CBBCSD fails to converge, then B12E contains the subdiagonal of the partially reduced top-right block.

B21D Output parameter.

B21D is REAL

B21D is an array, dimension (Q). When CBBCSD converges, B21D contains the negative sines of THETA(1), ..., THETA(Q). If CBBCSD fails to converge, then B21D contains the diagonal of the partially reduced bottom-left block.

B21E Output parameter.

B21E is REAL

B21E is an array, dimension (Q-1). When CBBCSD converges, B21E contains zeros. If CBBCSD fails to converge, then B21E contains the subdiagonal of the partially reduced bottom-left block.

B22D Output parameter.

B22D is REAL

B22D is an array, dimension (Q). When CBBCSD converges, B22D contains the negative sines of THETA(1), ..., THETA(Q). If CBBCSD fails to converge, then B22D contains the diagonal of the partially reduced bottom-right block.

B22E Output parameter.

B22E is REAL

B22E is an array, dimension (Q-1). When CBBCSD converges, B22E contains zeros. If CBBCSD fails to converge, then B22E contains the subdiagonal of the partially reduced bottom-right block.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (MAX(1, LRWORK)). On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of the array RWORK. LRWORK >= MAX(1,8*Q).

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the work array, and no error message related to LRWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if CBBCSD did not converge, INFO specifies the number of nonzero entries in PHI, and B11D, B11E, etc., contain the partially reduced matrix.

Related Information

For this routine in other precisions, please see *dbbcsd*, *sbbcsd* and *zbbcsd*. It also exists with a native C interface as *LAPACKE_cbbcsd*.

4.8.2 cunbdb

cunbdb simultaneously bidiagonalizes the blocks of an M-by-M partitioned unitary matrix X:

```
                                [ B11 | B12 0  0 ]
[ X11 | X12 ]   [ P1 |    ] [  0  |  0 -I  0 ] [ Q1 |    ]**H
```

X = [————] = [————] [————————-] [————] .

```
[ X21 | X22 ]   [    | P2 ] [ B21 | B22 0  0 ] [    | Q2 ]
                                [  0  |  0  0  I ]
```

X11 is P-by-Q. Q must be no larger than P, M-P, or M-Q. (If this is not the case, then X must be transposed and/or permuted. This can be done in constant time using the TRANS and SIGNS options. See CUNCSD for details.)

The unitary matrices P1, P2, Q1, and Q2 are P-by-P, (M-P)-by- (M-P), Q-by-Q, and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11, B12, B21, and B22 are Q-by-Q bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine cunbdb(TRANS, SIGNS, M, P, Q, X11, LDX11, X12, LDX12, X21, LDX21,
                  X22, LDX22, THETA, PHI, TAUP1, TAUP2, TAUQ1, TAUQ2, WORK,
                  LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cunbdb_(const char *trans, const char *signs, const armpl_int_t *m,
             const armpl_int_t *p, const armpl_int_t *q,
             armpl_singlecomplex_t *x11, const armpl_int_t *ldx11,
             armpl_singlecomplex_t *x12, const armpl_int_t *ldx12,
             armpl_singlecomplex_t *x21, const armpl_int_t *ldx21,
             armpl_singlecomplex_t *x22, const armpl_int_t *ldx22,
             float *theta, float *phi, armpl_singlecomplex_t *taup1,
             armpl_singlecomplex_t *taup2, armpl_singlecomplex_t *tauq1,
             armpl_singlecomplex_t *tauq2, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER

= ‘T’: X, U1, U2, V1T, and V2T are stored in row-major order; otherwise: X, U1, U2, V1T, and V2T are stored in column- major order.

SIGNS Input parameter.

SIGNS is CHARACTER

= 'O': The lower-left block is made nonpositive (the "other" convention); otherwise: The upper-right block is made nonpositive (the "default" convention).

M Input parameter.

M is INTEGER

The number of rows and columns in X.

P Input parameter.

P is INTEGER

The number of rows in X11 and X12. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= MIN(P,M-P,M-Q).

X11 Input and output parameter.

X11 is COMPLEX

X11 is an array, dimension (LDX11, Q). On entry, the top-left block of the unitary matrix to be reduced. On exit, the form depends on TRANS: If TRANS = 'N', then the columns of tril(X11) specify reflectors for P1, the rows of triu(X11,1) specify reflectors for Q1; else TRANS = 'T', and the rows of triu(X11) specify reflectors for P1, the columns of tril(X11,-1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. If TRANS = 'N', then LDX11 >= P; else LDX11 >= Q.

X12 Input and output parameter.

X12 is COMPLEX

X12 is an array, dimension (LDX12,M-Q). On entry, the top-right block of the unitary matrix to be reduced. On exit, the form depends on TRANS: If TRANS = 'N', then the rows of triu(X12) specify the first P reflectors for Q2; else TRANS = 'T', and the columns of tril(X12) specify the first P reflectors for Q2.

LDX12 Input parameter.

LDX12 is INTEGER

The leading dimension of X12. If TRANS = 'N', then LDX12 >= P; else LDX11 >= M-Q.

X21 Input and output parameter.

X21 is COMPLEX

X21 is an array, dimension (LDX21, Q). On entry, the bottom-left block of the unitary matrix to be reduced. On exit, the form depends on TRANS: If TRANS = 'N', then the columns of tril(X21) specify reflectors for P2; else TRANS = 'T', and the rows of triu(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. If TRANS = 'N', then LDX21 >= M-P; else LDX21 >= Q.

X22 Input and output parameter.

X22 is COMPLEX

X22 is an array, dimension (LDX22,M-Q). On entry, the bottom-right block of the unitary matrix to be reduced. On exit, the form depends on TRANS: If TRANS = 'N', then the rows of triu(X22(Q+1:M-P,P+1:M-Q)) specify the last M-P-Q reflectors for Q2, else TRANS = 'T', and the columns of tril(X22(P+1:M-Q,Q+1:M-P)) specify the last M-P-Q reflectors for P2.

LDX22 Input parameter.

LDX22 is INTEGER

The leading dimension of X22. If TRANS = 'N', then LDX22 >= M-P; else LDX22 >= M-Q.

THETA Output parameter.

THETA is REAL

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B12, B21, B22 can be computed from the angles THETA and PHI. See Further Details.

PHI Output parameter.

PHI is REAL

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B12, B21, B22 can be computed from the angles THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is COMPLEX

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is COMPLEX

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is COMPLEX

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

TAUQ2 Output parameter.

TAUQ2 is COMPLEX

TAUQ2 is an array, dimension (M-Q). The scalar factors of the elementary reflectors that define Q2.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *zunbdb*. It also exists with a native C interface as *LAPACKE_cunbdb*.

4.8.3 cuncsd

`cuncsd` computes the CS decomposition of an M-by-M partitioned unitary matrix X:

```
                                [  I  0  0 |  0  0  0 ]
                                [  0  C  0 |  0 -S  0 ]
[ X11 | X12 ]   [ U1 |    ] [  0  0  0 |  0  0 -I ] [ V1 |    ]**H
```

X = [————] = [———] [————————] [———] .

```
[ X21 | X22 ]   [    | U2 ] [  0  0  0 |  I  0  0 ] [    | V2 ]
                                [  0  S  0 |  0  C  0 ]
                                [  0  0  I |  0  0  0 ]
```

X11 is P-by-Q. The unitary matrices U1, U2, V1, and V2 are P-by-P, (M-P)-by-(M-P), Q-by-Q, and (M-Q)-by-(M-Q), respectively. C and S are R-by-R nonnegative diagonal matrices satisfying C^2 + S^2 = I, in which R = MIN(P,M-P,Q,M-Q).

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine cuncsd(JOBU1, JOBU2, JOBV1T, JOBV2T, TRANS, SIGNS, M, P,
                            Q, X11, LDX11, X12, LDX12, X21, LDX21, X22, LDX22,
                            THETA, U1, LDU1, U2, LDU2, V1T, LDV1T, V2T, LDV2T,
                            WORK, LWORK, RWORK, LRWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

```

Parameters

JOBU1 Input parameter.

`JOBU1` is CHARACTER

= 'Y': `U1` is computed; otherwise: `U1` is not computed.

JOBU2 Input parameter.

JOBU2 is CHARACTER

= 'Y': U2 is computed; otherwise: U2 is not computed.

JOBV1T Input parameter.

JOBV1T is CHARACTER

= 'Y': V1T is computed; otherwise: V1T is not computed.

JOBV2T Input parameter.

JOBV2T is CHARACTER

= 'Y': V2T is computed; otherwise: V2T is not computed.

TRANS Input parameter.

TRANS is CHARACTER

= 'T': X, U1, U2, V1T, and V2T are stored in row-major order; otherwise: X, U1, U2, V1T, and V2T are stored in column- major order.

SIGNS Input parameter.

SIGNS is CHARACTER

= 'O': The lower-left block is made nonpositive (the "other" convention); otherwise: The upper-right block is made nonpositive (the "default" convention).

M Input parameter.

M is INTEGER

The number of rows and columns in X.

P Input parameter.

P is INTEGER

The number of rows in X11 and X12. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M.

X11 Input and output parameter.

X11 is COMPLEX

X11 is an array, dimension (LDX11, Q). On entry, part of the unitary matrix whose CSD is desired.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= MAX(1, P).

X12 Input and output parameter.

X12 is COMPLEX

X12 is an array, dimension (LDX12,M-Q). On entry, part of the unitary matrix whose CSD is desired.

LDX12 Input parameter.

LDX12 is INTEGER

The leading dimension of X12. LDX12 >= MAX(1, P).

X21 Input and output parameter.

X21 is COMPLEX

X21 is an array, dimension (LDX21, Q). On entry, part of the unitary matrix whose CSD is desired.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X11. LDX21 >= MAX(1,M-P).

X22 Input and output parameter.

X22 is COMPLEX

X22 is an array, dimension (LDX22,M-Q). On entry, part of the unitary matrix whose CSD is desired.

LDX22 Input parameter.

LDX22 is INTEGER

The leading dimension of X11. LDX22 >= MAX(1,M-P).

THETA Output parameter.

THETA is REAL

THETA is an array, dimension (R), in which R =. MIN(P,M-P, Q,M-Q). C = DIAG(COS(THETA(1)), ... , COS(THETA(R))) and S = DIAG(SIN(THETA(1)), ... , SIN(THETA(R))).

U1 Output parameter.

U1 is COMPLEX

U1 is an array, dimension (LDU1, P). If JOBU1 = 'Y', U1 contains the P-by-P unitary matrix U1.

LDU1 Input parameter.

LDU1 is INTEGER

The leading dimension of U1. If JOBU1 = 'Y', LDU1 >= MAX(1, P).

U2 Output parameter.

U2 is COMPLEX

U2 is an array, dimension (LDU2,M-P). If JOBU2 = 'Y', U2 contains the (M-P)-by-(M-P) unitary matrix U2.

LDU2 Input parameter.

LDU2 is INTEGER

The leading dimension of U2. If JOBU2 = 'Y', LDU2 >= MAX(1,M-P).

V1T Output parameter.

V1T is COMPLEX

V1T is an array, dimension (LDV1T, Q). If JOBV1T = 'Y', V1T contains the Q-by-Q matrix unitary matrix $V1^H$.

LDV1T Input parameter.

LDV1T is INTEGER

The leading dimension of V1T. If JOBV1T = 'Y', LDV1T >= MAX(1, Q).

V2T Output parameter.

V2T is COMPLEX

V2T is an array, dimension (LDV2T,M-Q). If JOBV2T = 'Y', V2T contains the (M-Q)-by-(M-Q) unitary matrix $V2^H$.

LDV2T Input parameter.

LDV2T is INTEGER

The leading dimension of V2T. If JOBV2T = 'Y', LDV2T >= MAX(1,M-Q).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the work array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension MAX(1, LRWORK). On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK. If INFO > 0 on exit, RWORK(2:R) contains the values PHI(1), ..., PHI(R-1) that, together with THETA(1), ..., THETA(R), define the matrix in intermediate bidiagonal-block form remaining after nonconvergence. INFO specifies the number of nonzero PHI's.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of the array RWORK.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the work array, and no error message related to LRWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (M-MIN(P,M-P, Q,M-Q))

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: CBBCSD did not converge. See the description of RWORK above for details.

Related Information

For this routine in other precisions, please see *zuncsd*. It also exists with a native C interface as *LAPACKE_cuncsd*.

4.8.4 cuncsd2by1

CUNCSD2BY1 computes the CS decomposition of an M-by-Q matrix X with orthonormal columns that has been partitioned into a 2-by-1 block structure:

```
                           [  I1 0  0 ]
                           [  0  C  0 ]
    [ X11 ]   [ U1 |    ] [  0  0  0 ]
X = [-----] = [---------] [----------] V1**T .
    [ X21 ]   [    | U2 ] [  0  0  0 ]
```

(continues on next page)

(continued from previous page)

```
                          [  0   S   0 ]
                          [  0   0   I2]
```

X11 is P-by-Q. The unitary matrices U1, U2, and V1 are P-by-P, (M-P)-by-(M-P), and Q-by-Q, respectively. C and S are R-by-R nonnegative diagonal matrices satisfying C^2 + S^2 = I, in which R = MIN(P,M-P,Q,M-Q). I1 is a K1-by-K1 identity matrix and I2 is a K2-by-K2 identity matrix, where K1 = MAX(Q+P-M,0), K2 = MAX(Q-P,0).

Syntax

Fortran specification:

```
use armpl_library

subroutine cuncsd2by1(JOBU1, JOBU2, JOBV1T, M, P, Q, X11, LDX11, X21, LDX21,
                      THETA, U1, LDU1, U2, LDU2, V1T, LDV1T, WORK, LWORK,
                      RWORK, LRWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cuncsd2by1_(const char *jobu1, const char *jobu2, const char *jobv1t,
                 const armpl_int_t *m, const armpl_int_t *p,
                 const armpl_int_t *q, armpl_singlecomplex_t *x11,
                 const armpl_int_t *ldx11, armpl_singlecomplex_t *x21,
                 const armpl_int_t *ldx21, float *theta,
                 armpl_singlecomplex_t *u1, const armpl_int_t *ldu1,
                 armpl_singlecomplex_t *u2, const armpl_int_t *ldu2,
                 armpl_singlecomplex_t *v1t, const armpl_int_t *ldv1t,
                 armpl_singlecomplex_t *work, const armpl_int_t *lwork,
                 float *rwork, const armpl_int_t *lrwork, armpl_int_t *iwork,
                 armpl_int_t *info, ... );
```

Parameters

JOBU1 Input parameter.

JOBU1 is CHARACTER

= 'Y': U1 is computed; otherwise: U1 is not computed.

JOBU2 Input parameter.

JOBU2 is CHARACTER

= 'Y': U2 is computed; otherwise: U2 is not computed.

JOBV1T Input parameter.

JOBV1T is CHARACTER

= 'Y': V1T is computed; otherwise: V1T is not computed.

M Input parameter.

M is INTEGER

The number of rows in X.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M.

X11 Input and output parameter.

X11 is COMPLEX

X11 is an array, dimension (LDX11, Q). On entry, part of the unitary matrix whose CSD is desired.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= MAX(1, P).

X21 Input and output parameter.

X21 is COMPLEX

X21 is an array, dimension (LDX21, Q). On entry, part of the unitary matrix whose CSD is desired.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= MAX(1,M-P).

THETA Output parameter.

THETA is REAL

THETA is an array, dimension (R), in which R =. MIN(P,M-P, Q,M-Q). C = DIAG(COS(THETA(1)), ... , COS(THETA(R))) and S = DIAG(SIN(THETA(1)), ... , SIN(THETA(R))).

U1 Output parameter.

U1 is COMPLEX

U1 is an array, dimension (P). If JOBU1 = 'Y', U1 contains the P-by-P unitary matrix U1.

LDU1 Input parameter.

LDU1 is INTEGER

The leading dimension of U1. If JOBU1 = 'Y', LDU1 >= MAX(1, P).

U2 Output parameter.

U2 is COMPLEX

U2 is an array, dimension (M-P). If JOBU2 = 'Y', U2 contains the (M-P)-by-(M-P) unitary matrix U2.

LDU2 Input parameter.

LDU2 is INTEGER

The leading dimension of U2. If JOBU2 = 'Y', LDU2 >= MAX(1,M-P).

V1T Output parameter.

V1T is COMPLEX

V1T is an array, dimension (Q). If JOBV1T = 'Y', V1T contains the Q-by-Q matrix unitary matrix $V1^T$.

LDV1T Input parameter.

LDV1T is INTEGER

The leading dimension of V1T. If JOBV1T = 'Y', LDV1T >= MAX(1, Q).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the work array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (MAX(1, LRWORK)). On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK. If INFO > 0 on exit, RWORK(2:R) contains the values PHI(1), ..., PHI(R-1) that, together with THETA(1), ..., THETA(R), define the matrix in intermediate bidiagonal-block form remaining after nonconvergence. INFO specifies the number of nonzero PHI's.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of the array RWORK.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the work array, and no error message related to LRWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (M-MIN(P,M-P, Q,M-Q))

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: CBBCSD did not converge. See the description of WORK above for details.

4.8.5 dbbcsd

dbbcsd computes the CS decomposition of an orthogonal matrix in bidiagonal-block form,

```
[ B11 | B12 0  0 ]
[  0  |  0 -I  0 ]
```

X = [————————-]

```
[ B21 | B22 0  0 ]
[  0  |  0  0  I ]

                          [  C | -S  0  0 ]
              [ U1 |    ] [  0 |  0 -I  0 ] [ V1 |    ]**T
```

(continues on next page)

(continued from previous page)

```
             = [---------] [---------------] [---------]    .
               [     | U2 ] [  S |  C   0   0 ] [     | V2 ]
                            [  0 |  0   0   I ]
```

X is M-by-M, its top-left block is P-by-Q, and Q must be no larger than P, M-P, or M-Q. (If Q is not the smallest index, then X must be transposed and/or permuted. This can be done in constant time using the TRANS and SIGNS options. See DORCSD for details.)

The bidiagonal matrices B11, B12, B21, and B22 are represented implicitly by angles THETA(1:Q) and PHI(1:Q-1).

The orthogonal matrices U1, U2, V1T, and V2T are input/output. The input matrices are pre- or post-multiplied by the appropriate singular vector matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine dbbcsd(JOBU1, JOBU2, JOBV1T, JOBV2T, TRANS, M, P, Q, THETA, PHI,

             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOBU1 Input parameter.

JOBU1 is CHARACTER

= 'Y': U1 is updated; otherwise: U1 is not updated.

JOBU2 Input parameter.

JOBU2 is CHARACTER

= 'Y': U2 is updated; otherwise: U2 is not updated.

JOBV1T Input parameter.

JOBV1T is CHARACTER

= 'Y': V1T is updated; otherwise: V1T is not updated.

JOBV2T Input parameter.

JOBV2T is CHARACTER

= 'Y': V2T is updated; otherwise: V2T is not updated.

TRANS Input parameter.

TRANS is CHARACTER

= 'T': X, U1, U2, V1T, and V2T are stored in row-major order; otherwise: X, U1, U2, V1T, and V2T are stored in column- major order.

M Input parameter.

M is INTEGER

The number of rows and columns in X, the orthogonal matrix in bidiagonal-block form.

P Input parameter.

P is INTEGER

The number of rows in the top-left block of X. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in the top-left block of X. 0 <= Q <= MIN(P,M-P,M-Q).

THETA Input and output parameter.

THETA is DOUBLE PRECISION

THETA is an array, dimension (Q). On entry, the angles THETA(1),...,THETA(Q) that, along with PHI(1), ...,PHI(Q-1), define the matrix in bidiagonal-block form. On exit, the angles whose cosines and sines define the diagonal blocks in the CS decomposition.

PHI Input and output parameter.

PHI is DOUBLE PRECISION

PHI is an array, dimension (Q-1). The angles PHI(1),...,PHI(Q-1) that, along with THETA(1),..., THETA(Q), define the matrix in bidiagonal-block form.

U1 Input and output parameter.

U1 is DOUBLE PRECISION

U1 is an array, dimension (LDU1, P). On entry, a P-by-P matrix. On exit, U1 is postmultiplied by the left singular vector matrix common to [B11 ; 0] and [B12 0 0 ; 0 -I 0 0].

LDU1 Input parameter.

LDU1 is INTEGER

The leading dimension of the array U1, LDU1 >= MAX(1, P).

U2 Input and output parameter.

U2 is DOUBLE PRECISION

U2 is an array, dimension (LDU2,M-P). On entry, an (M-P)-by-(M-P) matrix. On exit, U2 is postmultiplied by the left singular vector matrix common to [B21 ; 0] and [B22 0 0 ; 0 0 I].

LDU2 Input parameter.

LDU2 is INTEGER

The leading dimension of the array U2, LDU2 >= MAX(1,M-P).

V1T Input and output parameter.

V1T is DOUBLE PRECISION

V1T is an array, dimension (LDV1T, Q). On entry, a Q-by-Q matrix. On exit, V1T is premultiplied by the transpose of the right singular vector matrix common to [B11 ; 0] and [B21 ; 0].

LDV1T Input parameter.

LDV1T is INTEGER

The leading dimension of the array V1T, LDV1T >= MAX(1, Q).

V2T Input and output parameter.

V2T is DOUBLE PRECISION

V2T is an array, dimension (LDV2T,M-Q). On entry, an (M-Q)-by-(M-Q) matrix. On exit, V2T is premultiplied by the transpose of the right singular vector matrix common to [B12 0 0 ; 0 -I 0] and [B22 0 0 ; 0 0 I].

LDV2T Input parameter.

LDV2T is INTEGER

The leading dimension of the array V2T, LDV2T >= MAX(1,M-Q).

B11D Output parameter.

B11D is DOUBLE PRECISION

B11D is an array, dimension (Q). When DBBCSD converges, B11D contains the cosines of THETA(1), ..., THETA(Q). If DBBCSD fails to converge, then B11D contains the diagonal of the partially reduced top-left block.

B11E Output parameter.

B11E is DOUBLE PRECISION

B11E is an array, dimension (Q-1). When DBBCSD converges, B11E contains zeros. If DBBCSD fails to converge, then B11E contains the superdiagonal of the partially reduced top-left block.

B12D Output parameter.

B12D is DOUBLE PRECISION

B12D is an array, dimension (Q). When DBBCSD converges, B12D contains the negative sines of THETA(1), ..., THETA(Q). If DBBCSD fails to converge, then B12D contains the diagonal of the partially reduced top-right block.

B12E Output parameter.

B12E is DOUBLE PRECISION

B12E is an array, dimension (Q-1). When DBBCSD converges, B12E contains zeros. If DBBCSD fails to converge, then B12E contains the subdiagonal of the partially reduced top-right block.

B21D Output parameter.

B21D is DOUBLE PRECISION array, dimension (Q)

When DBBCSD converges, B21D contains the negative sines of THETA(1), ..., THETA(Q). If DBBCSD fails to converge, then B21D contains the diagonal of the partially reduced bottom-left block.

B21E Output parameter.

B21E is DOUBLE PRECISION array, dimension (Q-1)

When DBBCSD converges, B21E contains zeros. If DBBCSD fails to converge, then B21E contains the subdiagonal of the partially reduced bottom-left block.

B22D Output parameter.

B22D is DOUBLE PRECISION array, dimension (Q)

When DBBCSD converges, B22D contains the negative sines of THETA(1), ..., THETA(Q). If DBBCSD fails to converge, then B22D contains the diagonal of the partially reduced bottom-right block.

B22E Output parameter.

B22E is DOUBLE PRECISION array, dimension (Q-1)

When DBBCSD converges, B22E contains zeros. If DBBCSD fails to converge, then B22E contains the subdiagonal of the partially reduced bottom-right block.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= MAX(1,8*Q).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the work array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if DBBCSD did not converge, INFO specifies the number of nonzero entries in PHI, and B11D, B11E, etc., contain the partially reduced matrix.

Related Information

For this routine in other precisions, please see *cbbcsd*, *sbbcsd* and *zbbcsd*. It also exists with a native C interface as *LAPACKE_dbbcsd*.

4.8.6 dorbdb

dorbdb simultaneously bidiagonalizes the blocks of an M-by-M partitioned orthogonal matrix X:

```
                                [ B11 | B12 0  0 ]
[ X11 | X12 ]   [ P1 |    ] [  0  |  0 -I  0 ] [ Q1 |    ]**T
```

X = [————] = [————] [————————-] [————] .

```
[ X21 | X22 ]   [    | P2 ] [ B21 | B22 0  0 ] [    | Q2 ]
                            [  0  |  0  0  I ]
```

X11 is P-by-Q. Q must be no larger than P, M-P, or M-Q. (If this is not the case, then X must be transposed and/or permuted. This can be done in constant time using the TRANS and SIGNS options. See DORCSD for details.)

The orthogonal matrices P1, P2, Q1, and Q2 are P-by-P, (M-P)-by- (M-P), Q-by-Q, and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11, B12, B21, and B22 are Q-by-Q bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine dorbdb(TRANS, SIGNS, M, P, Q, X11, LDX11, X12, LDX12, X21, LDX21,
                  X22, LDX22, THETA, PHI, TAUP1, TAUP2, TAUQ1, TAUQ2, WORK,
                  LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorbdb_(const char *trans, const char *signs, const armpl_int_t *m,
             const armpl_int_t *p, const armpl_int_t *q, double *x11,
             const armpl_int_t *ldx11, double *x12, const armpl_int_t *ldx12,
             double *x21, const armpl_int_t *ldx21, double *x22,
             const armpl_int_t *ldx22, double *theta, double *phi,
             double *taup1, double *taup2, double *tauq1, double *tauq2,
             double *work, const armpl_int_t *lwork, armpl_int_t *info,
             ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER

= 'T': X, U1, U2, V1T, and V2T are stored in row-major order; otherwise: X, U1, U2, V1T, and V2T are stored in column- major order.

SIGNS Input parameter.

SIGNS is CHARACTER

= 'O': The lower-left block is made nonpositive (the "other" convention); otherwise: The upper-right block is made nonpositive (the "default" convention).

M Input parameter.

M is INTEGER

The number of rows and columns in X.

P Input parameter.

P is INTEGER

The number of rows in X11 and X12. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= MIN(P,M-P,M-Q).

X11 Input and output parameter.

X11 is DOUBLE PRECISION

X11 is an array, dimension (LDX11, Q). On entry, the top-left block of the orthogonal matrix to be reduced. On exit, the form depends on TRANS: If TRANS = 'N', then the columns of tril(X11) specify reflectors for P1, the rows of triu(X11,1) specify reflectors for Q1; else TRANS = 'T', and the rows of triu(X11) specify reflectors for P1, the columns of tril(X11,-1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. If TRANS = 'N', then LDX11 >= P; else LDX11 >= Q.

X12 Input and output parameter.

X12 is DOUBLE PRECISION

X12 is an array, dimension (LDX12,M-Q). On entry, the top-right block of the orthogonal matrix to be reduced. On exit, the form depends on TRANS: If TRANS = 'N', then the rows of triu(X12) specify the first P reflectors for Q2; else TRANS = 'T', and the columns of tril(X12) specify the first P reflectors for Q2.

LDX12 Input parameter.

LDX12 is INTEGER

The leading dimension of X12. If TRANS = 'N', then LDX12 >= P; else LDX11 >= M-Q.

X21 Input and output parameter.

X21 is DOUBLE PRECISION

X21 is an array, dimension (LDX21, Q). On entry, the bottom-left block of the orthogonal matrix to be reduced. On exit, the form depends on TRANS: If TRANS = 'N', then the columns of tril(X21) specify reflectors for P2; else TRANS = 'T', and the rows of triu(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. If TRANS = 'N', then LDX21 >= M-P; else LDX21 >= Q.

X22 Input and output parameter.

X22 is DOUBLE PRECISION

X22 is an array, dimension (LDX22,M-Q). On entry, the bottom-right block of the orthogonal matrix to be reduced. On exit, the form depends on TRANS: If TRANS = 'N', then the rows of triu(X22(Q+1:M-P,P+1:M-Q)) specify the last M-P-Q reflectors for Q2, else TRANS = 'T', and the columns of tril(X22(P+1:M-Q,Q+1:M-P)) specify the last M-P-Q reflectors for P2.

LDX22 Input parameter.

LDX22 is INTEGER

The leading dimension of X22. If TRANS = 'N', then LDX22 >= M-P; else LDX22 >= M-Q.

THETA Output parameter.

THETA is DOUBLE PRECISION

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B12, B21, B22 can be computed from the angles THETA and PHI. See Further Details.

PHI Output parameter.

PHI is DOUBLE PRECISION

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B12, B21, B22 can be computed from the angles THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is DOUBLE PRECISION

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is DOUBLE PRECISION

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is DOUBLE PRECISION

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

TAUQ2 Output parameter.

TAUQ2 is DOUBLE PRECISION

TAUQ2 is an array, dimension (M-Q). The scalar factors of the elementary reflectors that define Q2.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *sorbdb*. It also exists with a native C interface as *LAPACKE_dorbdb*.

4.8.7 dorcsd

dorcsd computes the CS decomposition of an M-by-M partitioned orthogonal matrix X:

```
                              [  I  0  0 |  0  0  0 ]
                              [  0  C  0 |  0 -S  0 ]
[ X11 | X12 ]   [ U1 |    ] [  0  0  0 |  0  0 -I ] [ V1 |    ]**T
```

X = [————] = [———] [—————————] [———] .

```
[ X21 | X22 ]   [    | U2 ] [  0  0  0 |  I  0  0 ] [    | V2 ]
                              [  0  S  0 |  0  C  0 ]
                              [  0  0  I |  0  0  0 ]
```

X11 is P-by-Q. The orthogonal matrices U1, U2, V1, and V2 are P-by-P, (M-P)-by-(M-P), Q-by-Q, and (M-Q)-by-(M-Q), respectively. C and S are R-by-R nonnegative diagonal matrices satisfying C^2 + S^2 = I, in which R = MIN(P,M-P,Q,M-Q).

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine dorcsd(JOBU1, JOBU2, JOBV1T, JOBV2T, TRANS, SIGNS, M, P,
                            Q, X11, LDX11, X12, LDX12, X21, LDX21, X22, LDX22,
                            THETA, U1, LDU1, U2, LDU2, V1T, LDV1T, V2T, LDV2T,
                            WORK, LWORK, IWORK, INFO)
```

C specification:

```

             const armpl_int_t *ldv2t, double *work, const armpl_int_t *lwork,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

JOBU1 Input parameter.

JOBU1 is CHARACTER

= 'Y': U1 is computed; otherwise: U1 is not computed.

JOBU2 Input parameter.

JOBU2 is CHARACTER

= 'Y': U2 is computed; otherwise: U2 is not computed.

JOBV1T Input parameter.

JOBV1T is CHARACTER

= 'Y': V1T is computed; otherwise: V1T is not computed.

JOBV2T Input parameter.

JOBV2T is CHARACTER

= 'Y': V2T is computed; otherwise: V2T is not computed.

TRANS Input parameter.

TRANS is CHARACTER

= 'T': X, U1, U2, V1T, and V2T are stored in row-major order; otherwise: X, U1, U2, V1T, and V2T are stored in column- major order.

SIGNS Input parameter.

SIGNS is CHARACTER

= 'O': The lower-left block is made nonpositive (the "other" convention); otherwise: The upper-right block is made nonpositive (the "default" convention).

M Input parameter.

M is INTEGER

The number of rows and columns in X.

P Input parameter.

P is INTEGER

The number of rows in X11 and X12. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M.

X11 Input and output parameter.

X11 is DOUBLE PRECISION

X11 is an array, dimension (LDX11, Q). On entry, part of the orthogonal matrix whose CSD is desired.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= MAX(1, P).

X12 Input and output parameter.

X12 is DOUBLE PRECISION

X12 is an array, dimension (LDX12,M-Q). On entry, part of the orthogonal matrix whose CSD is desired.

LDX12 Input parameter.

LDX12 is INTEGER

The leading dimension of X12. LDX12 >= MAX(1, P).

X21 Input and output parameter.

X21 is DOUBLE PRECISION

X21 is an array, dimension (LDX21, Q). On entry, part of the orthogonal matrix whose CSD is desired.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X11. LDX21 >= MAX(1,M-P).

X22 Input and output parameter.

X22 is DOUBLE PRECISION

X22 is an array, dimension (LDX22,M-Q). On entry, part of the orthogonal matrix whose CSD is desired.

LDX22 Input parameter.

LDX22 is INTEGER

The leading dimension of X11. LDX22 >= MAX(1,M-P).

THETA Output parameter.

THETA is DOUBLE PRECISION

THETA is an array, dimension (R), in which R =. MIN(P,M-P, Q,M-Q). C = DIAG(COS(THETA(1)), ... , COS(THETA(R))) and S = DIAG(SIN(THETA(1)), ... , SIN(THETA(R))).

U1 Output parameter.

U1 is DOUBLE PRECISION

U1 is an array, dimension (LDU1, P). If JOBU1 = 'Y', U1 contains the P-by-P orthogonal matrix U1.

LDU1 Input parameter.

LDU1 is INTEGER

The leading dimension of U1. If JOBU1 = 'Y', LDU1 >= MAX(1, P).

U2 Output parameter.

U2 is DOUBLE PRECISION

U2 is an array, dimension (LDU2,M-P). If JOBU2 = 'Y', U2 contains the (M-P)-by-(M-P) orthogonal matrix U2.

LDU2 Input parameter.

LDU2 is INTEGER

The leading dimension of U2. If JOBU2 = 'Y', LDU2 >= MAX(1,M-P).

V1T Output parameter.

V1T is DOUBLE PRECISION

V1T is an array, dimension (LDV1T, Q). If JOBV1T = 'Y', V1T contains the Q-by-Q matrix orthogonal matrix $V1^T$.

LDV1T Input parameter.

LDV1T is INTEGER

The leading dimension of V1T. If JOBV1T = 'Y', LDV1T >= MAX(1, Q).

V2T Output parameter.

V2T is DOUBLE PRECISION

V2T is an array, dimension (LDV2T,M-Q). If JOBV2T = 'Y', V2T contains the (M-Q)-by-(M-Q) orthogonal matrix $V2^T$.

LDV2T Input parameter.

LDV2T is INTEGER

The leading dimension of V2T. If JOBV2T = 'Y', LDV2T >= MAX(1,M-Q).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK. If INFO > 0 on exit, WORK(2:R) contains the values PHI(1), ..., PHI(R-1) that, together with THETA(1), ..., THETA(R), define the matrix in intermediate bidiagonal-block form remaining after nonconvergence. INFO specifies the number of nonzero PHI's.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the work array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (M-MIN(P, M-P, Q, M-Q))

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: DBBCSD did not converge. See the description of WORK above for details.

Related Information

For this routine in other precisions, please see *sorcsd*. It also exists with a native C interface as *LAPACKE_dorcsd*.

4.8.8 dorcsd2by1

DORCSD2BY1 computes the CS decomposition of an M-by-Q matrix X with orthonormal columns that has been partitioned into a 2-by-1 block structure:

```
                            [  I1 0  0 ]
                            [  0  C  0 ]
    [ X11 ]   [ U1 |    ] [  0  0  0 ]
X = [-----] = [---------] [----------] V1**T .
    [ X21 ]   [    | U2 ] [  0  0  0 ]
                            [  0  S  0 ]
                            [  0  0  I2]
```

X11 is P-by-Q. The orthogonal matrices U1, U2, and V1 are P-by-P, (M-P)-by-(M-P), and Q-by-Q, respectively. C and S are R-by-R nonnegative diagonal matrices satisfying C^2 + S^2 = I, in which R = MIN(P,M-P,Q,M-Q). I1 is a K1-by-K1 identity matrix and I2 is a K2-by-K2 identity matrix, where K1 = MAX(Q+P-M,0), K2 = MAX(Q-P,0).

Syntax

Fortran specification:

```
use armpl_library

subroutine dorcsd2by1(JOBU1, JOBU2, JOBV1T, M, P, Q, X11, LDX11, X21, LDX21,
                      THETA, U1, LDU1, U2, LDU2, V1T, LDV1T, WORK, LWORK,
                      IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorcsd2by1_(const char *jobu1, const char *jobu2, const char *jobv1t,
                 const armpl_int_t *m, const armpl_int_t *p,
                 const armpl_int_t *q, double *x11, const armpl_int_t *ldx11,
                 double *x21, const armpl_int_t *ldx21, double *theta,
                 double *u1, const armpl_int_t *ldu1, double *u2,
                 const armpl_int_t *ldu2, double *v1t,
                 const armpl_int_t *ldv1t, double *work,
                 const armpl_int_t *lwork, armpl_int_t *iwork,
                 armpl_int_t *info, ... );
```

Parameters

JOBU1 Input parameter.

JOBU1 is CHARACTER

= 'Y': U1 is computed; otherwise: U1 is not computed.

JOBU2 Input parameter.

JOBU2 is CHARACTER

= 'Y': U2 is computed; otherwise: U2 is not computed.

JOBV1T Input parameter.

JOBV1T is CHARACTER

= 'Y': V1T is computed; otherwise: V1T is not computed.

M Input parameter.

M is INTEGER

The number of rows in X.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M.

X11 Input and output parameter.

X11 is DOUBLE PRECISION

X11 is an array, dimension (LDX11, Q). On entry, part of the orthogonal matrix whose CSD is desired.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= MAX(1, P).

X21 Input and output parameter.

X21 is DOUBLE PRECISION

X21 is an array, dimension (LDX21, Q). On entry, part of the orthogonal matrix whose CSD is desired.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= MAX(1,M-P).

THETA Output parameter.

THETA is DOUBLE PRECISION

THETA is an array, dimension (R), in which R =. MIN(P,M-P, Q,M-Q). C = DIAG(COS(THETA(1)), ... , COS(THETA(R))) and S = DIAG(SIN(THETA(1)), ... , SIN(THETA(R))).

U1 Output parameter.

U1 is DOUBLE PRECISION

U1 is an array, dimension (P). If JOBU1 = 'Y', U1 contains the P-by-P orthogonal matrix U1.

LDU1 Input parameter.

LDU1 is INTEGER

The leading dimension of U1. If JOBU1 = 'Y', LDU1 >= MAX(1, P).

U2 Output parameter.

U2 is DOUBLE PRECISION

U2 is an array, dimension (M-P). If JOBU2 = 'Y', U2 contains the (M-P)-by-(M-P) orthogonal matrix U2.

LDU2 Input parameter.

LDU2 is INTEGER

The leading dimension of U2. If JOBU2 = 'Y', LDU2 >= MAX(1,M-P).

V1T Output parameter.

V1T is DOUBLE PRECISION

V1T is an array, dimension (Q). If JOBV1T = 'Y', V1T contains the Q-by-Q matrix orthogonal matrix $V1^T$.

LDV1T Input parameter.

LDV1T is INTEGER

The leading dimension of V1T. If JOBV1T = 'Y', LDV1T >= MAX(1, Q).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK. If INFO > 0 on exit, WORK(2:R) contains the values PHI(1), . . . , PHI(R-1) that, together with THETA(1), . . . , THETA(R), define the matrix in intermediate bidiagonal-block form remaining after nonconvergence. INFO specifies the number of nonzero PHI's.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the work array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (M-MIN(P,M-P, Q,M-Q))

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: DBBCSD did not converge. See the description of WORK above for details.

Related Information

For this routine in other precisions, please see *sorcsd2by1*. It also exists with a native C interface as *LAPACKE_dorcsd2by1*.

4.8.9 sbbcsd

sbbcsd computes the CS decomposition of an orthogonal matrix in bidiagonal-block form,

```
[ B11 | B12 0  0 ]
[  0  |  0 -I  0 ]
```

X = [————————-]

```
[ B21 | B22 0  0 ]
[  0  |  0  0  I ]

                          [  C | -S  0  0 ]
            [ U1 |    ] [  0 |  0 -I  0 ] [ V1 |    ]**T
          = [---------] [---------------] [---------]   .
            [    | U2 ] [  S |  C  0  0 ] [    | V2 ]
                          [  0 |  0  0  I ]
```

X is M-by-M, its top-left block is P-by-Q, and Q must be no larger than P, M-P, or M-Q. (If Q is not the smallest index, then X must be transposed and/or permuted. This can be done in constant time using the TRANS and SIGNS options. See SORCSD for details.)

The bidiagonal matrices B11, B12, B21, and B22 are represented implicitly by angles THETA(1:Q) and PHI(1:Q-1).

The orthogonal matrices U1, U2, V1T, and V2T are input/output. The input matrices are pre- or post-multiplied by the appropriate singular vector matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine sbbcsd(JOBU1, JOBU2, JOBV1T, JOBV2T, TRANS, M, P, Q, THETA, PHI,
                  U1, LDU1, U2, LDU2, V1T, LDV1T, V2T, LDV2T, B11D, B11E,
                  B12D, B12E, B21D, B21E, B22D, B22E, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sbbcsd_(const char *jobu1, const char *jobu2, const char *jobv1t,
             const char *jobv2t, const char *trans, const armpl_int_t *m,
             const armpl_int_t *p, const armpl_int_t *q, float *theta,
             float *phi, float *u1, const armpl_int_t *ldu1, float *u2,
             const armpl_int_t *ldu2, float *v1t, const armpl_int_t *ldv1t,
             float *v2t, const armpl_int_t *ldv2t, float *b11d, float *b11e,
             float *b12d, float *b12e, float *b21d, float *b21e, float *b22d,
             float *b22e, float *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

JOBU1 Input parameter.

JOBU1 is CHARACTER

= 'Y': U1 is updated; otherwise: U1 is not updated.

JOBU2 Input parameter.

JOBU2 is CHARACTER

= 'Y': U2 is updated; otherwise: U2 is not updated.

JOBV1T Input parameter.

JOBV1T is CHARACTER

= 'Y': V1T is updated; otherwise: V1T is not updated.

JOBV2T Input parameter.

JOBV2T is CHARACTER

= 'Y': V2T is updated; otherwise: V2T is not updated.

TRANS Input parameter.

TRANS is CHARACTER

= 'T': X, U1, U2, V1T, and V2T are stored in row-major order; otherwise: X, U1, U2, V1T, and V2T are stored in column- major order.

M Input parameter.

M is INTEGER

The number of rows and columns in X, the orthogonal matrix in bidiagonal-block form.

P Input parameter.

P is INTEGER

The number of rows in the top-left block of X. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in the top-left block of X. 0 <= Q <= MIN(P,M-P,M-Q).

THETA Input and output parameter.

THETA is REAL

THETA is an array, dimension (Q). On entry, the angles THETA(1),...,THETA(Q) that, along with PHI(1), ...,PHI(Q-1), define the matrix in bidiagonal-block form. On exit, the angles whose cosines and sines define the diagonal blocks in the CS decomposition.

PHI Input and output parameter.

PHI is REAL

PHI is an array, dimension (Q-1). The angles PHI(1),...,PHI(Q-1) that, along with THETA(1),..., THETA(Q), define the matrix in bidiagonal-block form.

U1 Input and output parameter.

U1 is REAL

U1 is an array, dimension (LDU1, P). On entry, a P-by-P matrix. On exit, U1 is postmultiplied by the left singular vector matrix common to [B11 ; 0] and [B12 0 0 ; 0 -I 0 0].

LDU1 Input parameter.

LDU1 is INTEGER

The leading dimension of the array U1, LDU1 >= MAX(1, P).

U2 Input and output parameter.

U2 is REAL

U2 is an array, dimension (LDU2,M-P). On entry, an (M-P)-by-(M-P) matrix. On exit, U2 is postmultiplied by the left singular vector matrix common to [B21 ; 0] and [B22 0 0 ; 0 0 I].

LDU2 Input parameter.

LDU2 is INTEGER

The leading dimension of the array U2, LDU2 >= MAX(1,M-P).

V1T Input and output parameter.

V1T is REAL

V1T is an array, dimension (LDV1T, Q). On entry, a Q-by-Q matrix. On exit, V1T is premultiplied by the transpose of the right singular vector matrix common to [B11 ; 0] and [B21 ; 0].

LDV1T Input parameter.

LDV1T is INTEGER

The leading dimension of the array V1T, LDV1T >= MAX(1, Q).

V2T Input and output parameter.

V2T is REAL

V2T is an array, dimension (LDV2T,M-Q). On entry, an (M-Q)-by-(M-Q) matrix. On exit, V2T is premultiplied by the transpose of the right singular vector matrix common to [B12 0 0 ; 0 -I 0] and [B22 0 0 ; 0 0 I].

LDV2T Input parameter.

LDV2T is INTEGER

The leading dimension of the array V2T, LDV2T >= MAX(1,M-Q).

B11D Output parameter.

B11D is REAL

B11D is an array, dimension (Q). When SBBCSD converges, B11D contains the cosines of THETA(1), ..., THETA(Q). If SBBCSD fails to converge, then B11D contains the diagonal of the partially reduced top-left block.

B11E Output parameter.

B11E is REAL

B11E is an array, dimension (Q-1). When SBBCSD converges, B11E contains zeros. If SBBCSD fails to converge, then B11E contains the superdiagonal of the partially reduced top-left block.

B12D Output parameter.

B12D is REAL

B12D is an array, dimension (Q). When SBBCSD converges, B12D contains the negative sines of THETA(1), ..., THETA(Q). If SBBCSD fails to converge, then B12D contains the diagonal of the partially reduced top-right block.

B12E Output parameter.

B12E is REAL

B12E is an array, dimension (Q-1). When SBBCSD converges, B12E contains zeros. If SBBCSD fails to converge, then B12E contains the subdiagonal of the partially reduced top-right block.

B21D Output parameter.

B21D is REAL

B21D is an array, dimension (Q). When SBBCSD converges, B21D contains the negative sines of THETA(1), ..., THETA(Q). If SBBCSD fails to converge, then B21D contains the diagonal of the partially reduced bottom-left block.

B21E Output parameter.

B21E is REAL

B21E is an array, dimension (Q-1). When SBBCSD converges, B21E contains zeros. If SBBCSD fails to converge, then B21E contains the subdiagonal of the partially reduced bottom-left block.

B22D Output parameter.

B22D is REAL

B22D is an array, dimension (Q). When SBBCSD converges, B22D contains the negative sines of THETA(1), ..., THETA(Q). If SBBCSD fails to converge, then B22D contains the diagonal of the partially reduced bottom-right block.

B22E Output parameter.

B22E is REAL

B22E is an array, dimension (Q-1). When SBBCSD converges, B22E contains zeros. If SBBCSD fails to converge, then B22E contains the subdiagonal of the partially reduced bottom-right block.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= MAX(1,8*Q).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the work array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if SBBCSD did not converge, INFO specifies the number of nonzero entries in PHI, and B11D, B11E, etc., contain the partially reduced matrix.

For this routine in other precisions, please see *cbbcsd*, *dbbcsd* and *zbbcsd*. It also exists with a native C interface as *LAPACKE_sbbcsd*.

4.8.10 sorbdb

sorbdb simultaneously bidiagonalizes the blocks of an M-by-M partitioned orthogonal matrix X:

```
                                [ B11 | B12 0  0 ]
[ X11 | X12 ]   [ P1 |    ] [  0  |  0 -I  0 ] [ Q1 |    ]**T
```

X = [————] = [———] [————————-] [———] .

```
[ X21 | X22 ]   [    | P2 ] [ B21 | B22 0  0 ] [    | Q2 ]
                           [  0  |  0  0  I ]
```

X11 is P-by-Q. Q must be no larger than P, M-P, or M-Q. (If this is not the case, then X must be transposed and/or permuted. This can be done in constant time using the TRANS and SIGNS options. See SORCSD for details.)

The orthogonal matrices P1, P2, Q1, and Q2 are P-by-P, (M-P)-by- (M-P), Q-by-Q, and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11, B12, B21, and B22 are Q-by-Q bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine sorbdb(TRANS, SIGNS, M, P, Q, X11, LDX11, X12, LDX12, X21, LDX21,
                  X22, LDX22, THETA, PHI, TAUP1, TAUP2, TAUQ1, TAUQ2, WORK,
                  LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorbdb_(const char *trans, const char *signs, const armpl_int_t *m,
             const armpl_int_t *p, const armpl_int_t *q, float *x11,
             const armpl_int_t *ldx11, float *x12, const armpl_int_t *ldx12,
             float *x21, const armpl_int_t *ldx21, float *x22,
```

(continues on next page)

(continued from previous page)

```
            const armpl_int_t *ldx22, float *theta, float *phi, float *taup1,
            float *taup2, float *tauq1, float *tauq2, float *work,
            const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER

= 'T': X, U1, U2, V1T, and V2T are stored in row-major order; otherwise: X, U1, U2, V1T, and V2T are stored in column- major order.

SIGNS Input parameter.

SIGNS is CHARACTER

= 'O': The lower-left block is made nonpositive (the "other" convention); otherwise: The upper-right block is made nonpositive (the "default" convention).

M Input parameter.

M is INTEGER

The number of rows and columns in X.

P Input parameter.

P is INTEGER

The number of rows in X11 and X12. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= MIN(P,M-P,M-Q).

X11 Input and output parameter.

X11 is REAL

X11 is an array, dimension (LDX11, Q). On entry, the top-left block of the orthogonal matrix to be reduced. On exit, the form depends on TRANS: If TRANS = 'N', then the columns of tril(X11) specify reflectors for P1, the rows of triu(X11,1) specify reflectors for Q1; else TRANS = 'T', and the rows of triu(X11) specify reflectors for P1, the columns of tril(X11,-1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. If TRANS = 'N', then LDX11 >= P; else LDX11 >= Q.

X12 Input and output parameter.

X12 is REAL

X12 is an array, dimension (LDX12,M-Q). On entry, the top-right block of the orthogonal matrix to be reduced. On exit, the form depends on TRANS: If TRANS = 'N', then the rows of triu(X12) specify the first P reflectors for Q2; else TRANS = 'T', and the columns of tril(X12) specify the first P reflectors for Q2.

LDX12 Input parameter.

LDX12 is INTEGER

The leading dimension of X12. If TRANS = 'N', then LDX12 >= P; else LDX11 >= M-Q.

X21 Input and output parameter.

X21 is REAL

X21 is an array, dimension (LDX21, Q). On entry, the bottom-left block of the orthogonal matrix to be reduced. On exit, the form depends on TRANS: If TRANS = 'N', then the columns of tril(X21) specify reflectors for P2; else TRANS = 'T', and the rows of triu(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. If TRANS = 'N', then LDX21 >= M-P; else LDX21 >= Q.

X22 Input and output parameter.

X22 is REAL

X22 is an array, dimension (LDX22,M-Q). On entry, the bottom-right block of the orthogonal matrix to be reduced. On exit, the form depends on TRANS: If TRANS = 'N', then the rows of triu(X22(Q+1:M-P,P+1:M-Q)) specify the last M-P-Q reflectors for Q2, else TRANS = 'T', and the columns of tril(X22(P+1:M-Q,Q+1:M-P)) specify the last M-P-Q reflectors for P2.

LDX22 Input parameter.

LDX22 is INTEGER

The leading dimension of X22. If TRANS = 'N', then LDX22 >= M-P; else LDX22 >= M-Q.

THETA Output parameter.

THETA is REAL

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B12, B21, B22 can be computed from the angles THETA and PHI. See Further Details.

PHI Output parameter.

PHI is REAL

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B12, B21, B22 can be computed from the angles THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is REAL

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is REAL

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is REAL

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

TAUQ2 Output parameter.

TAUQ2 is REAL

TAUQ2 is an array, dimension (M-Q). The scalar factors of the elementary reflectors that define Q2.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dorbdb*. It also exists with a native C interface as *LAPACKE_sorbdb*.

4.8.11 sorcsd

sorcsd computes the CS decomposition of an M-by-M partitioned orthogonal matrix X:

```
                               [  I  0  0 |  0  0  0 ]
                               [  0  C  0 |  0 -S  0 ]
[ X11 | X12 ]   [ U1 |    ] [  0  0  0 |  0  0 -I ] [ V1 |    ]**T
```

X = [————] = [———] [————————] [———] .

```
[ X21 | X22 ]   [    | U2 ] [  0  0  0 |  I  0  0 ] [    | V2 ]
                           [  0  S  0 |  0  C  0 ]
                           [  0  0  I |  0  0  0 ]
```

X11 is P-by-Q. The orthogonal matrices U1, U2, V1, and V2 are P-by-P, (M-P)-by-(M-P), Q-by-Q, and (M-Q)-by-(M-Q), respectively. C and S are R-by-R nonnegative diagonal matrices satisfying C^2 + S^2 = I, in which R = MIN(P,M-P,Q,M-Q).

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine sorcsd(JOBU1, JOBU2, JOBV1T, JOBV2T, TRANS, SIGNS, M, P,
                            Q, X11, LDX11, X12, LDX12, X21, LDX21, X22, LDX22,

```

Parameters

JOBU1 Input parameter.

JOBU1 is CHARACTER

= 'Y': U1 is computed; otherwise: U1 is not computed.

JOBU2 Input parameter.

JOBU2 is CHARACTER

= 'Y': U2 is computed; otherwise: U2 is not computed.

JOBV1T Input parameter.

JOBV1T is CHARACTER

= 'Y': V1T is computed; otherwise: V1T is not computed.

JOBV2T Input parameter.

JOBV2T is CHARACTER

= 'Y': V2T is computed; otherwise: V2T is not computed.

TRANS Input parameter.

TRANS is CHARACTER

= 'T': X, U1, U2, V1T, and V2T are stored in row-major order; otherwise: X, U1, U2, V1T, and V2T are stored in column- major order.

SIGNS Input parameter.

SIGNS is CHARACTER

= 'O': The lower-left block is made nonpositive (the "other" convention); otherwise: The upper-right block is made nonpositive (the "default" convention).

M Input parameter.

M is INTEGER

The number of rows and columns in X.

P Input parameter.

P is INTEGER

The number of rows in X11 and X12. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M.

X11 Input and output parameter.

X11 is REAL

X11 is an array, dimension (LDX11, Q). On entry, part of the orthogonal matrix whose CSD is desired.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= MAX(1, P).

X12 Input and output parameter.

X12 is REAL

X12 is an array, dimension (LDX12,M-Q). On entry, part of the orthogonal matrix whose CSD is desired.

LDX12 Input parameter.

LDX12 is INTEGER

The leading dimension of X12. LDX12 >= MAX(1, P).

X21 Input and output parameter.

X21 is REAL

X21 is an array, dimension (LDX21, Q). On entry, part of the orthogonal matrix whose CSD is desired.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X11. LDX21 >= MAX(1,M-P).

X22 Input and output parameter.

X22 is REAL

X22 is an array, dimension (LDX22,M-Q). On entry, part of the orthogonal matrix whose CSD is desired.

LDX22 Input parameter.

LDX22 is INTEGER

The leading dimension of X11. LDX22 >= MAX(1,M-P).

THETA Output parameter.

THETA is REAL

THETA is an array, dimension (R), in which R =. MIN(P,M-P, Q,M-Q). C = DIAG(COS(THETA(1)), ... , COS(THETA(R))) and S = DIAG(SIN(THETA(1)), ... , SIN(THETA(R))).

U1 Output parameter.

U1 is REAL

U1 is an array, dimension (LDU1, P). If JOBU1 = 'Y', U1 contains the P-by-P orthogonal matrix U1.

LDU1 Input parameter.

LDU1 is INTEGER

The leading dimension of U1. If JOBU1 = 'Y', LDU1 >= MAX(1, P).

U2 Output parameter.

U2 is REAL

U2 is an array, dimension (LDU2,M-P). If JOBU2 = 'Y', U2 contains the (M-P)-by-(M-P) orthogonal matrix U2.

LDU2 Input parameter.

LDU2 is INTEGER

The leading dimension of U2. If JOBU2 = 'Y', LDU2 >= MAX(1,M-P).

V1T Output parameter.

V1T is REAL

V1T is an array, dimension (LDV1T, Q). If JOBV1T = 'Y', V1T contains the Q-by-Q matrix orthogonal matrix $V1^T$.

LDV1T Input parameter.

LDV1T is INTEGER

The leading dimension of V1T. If JOBV1T = 'Y', LDV1T >= MAX(1, Q).

V2T Output parameter.

V2T is REAL

V2T is an array, dimension (LDV2T,M-Q). If JOBV2T = 'Y', V2T contains the (M-Q)-by-(M-Q) orthogonal matrix $V2^T$.

LDV2T Input parameter.

LDV2T is INTEGER

The leading dimension of V2T. If JOBV2T = 'Y', LDV2T >= MAX(1,M-Q).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK. If INFO > 0 on exit, WORK(2:R) contains the values PHI(1), ..., PHI(R-1) that, together with THETA(1), ..., THETA(R), define the matrix in intermediate bidiagonal-block form remaining after nonconvergence. INFO specifies the number of nonzero PHI's.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the work array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (M-MIN(P, M-P, Q, M-Q))

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: SBBCSD did not converge. See the description of WORK above for details.

Related Information

For this routine in other precisions, please see *dorcsd*. It also exists with a native C interface as *LAPACKE_sorcsd*.

4.8.12 sorcsd2by1

SORCSD2BY1 computes the CS decomposition of an M-by-Q matrix X with orthonormal columns that has been partitioned into a 2-by-1 block structure:

```
                            [  I1 0  0 ]
                            [  0  C  0 ]
    [ X11 ]   [ U1 |    ] [  0  0  0 ]
X = [-----] = [---------] [----------] V1**T .
    [ X21 ]   [    | U2 ] [  0  0  0 ]
                            [  0  S  0 ]
                            [  0  0  I2]
```

X11 is P-by-Q. The orthogonal matrices U1, U2, and V1 are P-by-P, (M-P)-by-(M-P), and Q-by-Q, respectively. C and S are R-by-R nonnegative diagonal matrices satisfying C^2 + S^2 = I, in which R = MIN(P,M-P,Q,M-Q). I1 is a K1-by-K1 identity matrix and I2 is a K2-by-K2 identity matrix, where K1 = MAX(Q+P-M,0), K2 = MAX(Q-P,0).

Syntax

Fortran specification:

```
use armpl_library

subroutine sorcsd2by1(JOBU1, JOBU2, JOBV1T, M, P, Q, X11, LDX11, X21, LDX21,
                      THETA, U1, LDU1, U2, LDU2, V1T, LDV1T, WORK, LWORK,
                      IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorcsd2by1_(const char *jobu1, const char *jobu2, const char *jobv1t,
                 const armpl_int_t *m, const armpl_int_t *p,
                 const armpl_int_t *q, float *x11, const armpl_int_t *ldx11,
                 float *x21, const armpl_int_t *ldx21, float *theta,
                 float *u1, const armpl_int_t *ldu1, float *u2,
                 const armpl_int_t *ldu2, float *v1t,
                 const armpl_int_t *ldv1t, float *work,
                 const armpl_int_t *lwork, armpl_int_t *iwork,
                 armpl_int_t *info, ... );
```

Parameters

JOBU1 Input parameter.

JOBU1 is CHARACTER

= 'Y': U1 is computed; otherwise: U1 is not computed.

JOBU2 Input parameter.

JOBU2 is CHARACTER

= 'Y': U2 is computed; otherwise: U2 is not computed.

JOBV1T Input parameter.

JOBV1T is CHARACTER

= 'Y': V1T is computed; otherwise: V1T is not computed.

M Input parameter.

M is INTEGER

The number of rows in X.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M.

X11 Input and output parameter.

X11 is REAL

X11 is an array, dimension (LDX11, Q). On entry, part of the orthogonal matrix whose CSD is desired.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= MAX(1, P).

X21 Input and output parameter.

X21 is REAL

X21 is an array, dimension (LDX21, Q). On entry, part of the orthogonal matrix whose CSD is desired.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= MAX(1,M-P).

THETA Output parameter.

THETA is REAL

THETA is an array, dimension (R), in which R =. MIN(P,M-P, Q,M-Q). C = DIAG(COS(THETA(1)), ... , COS(THETA(R))) and S = DIAG(SIN(THETA(1)), ... , SIN(THETA(R))).

U1 Output parameter.

U1 is REAL

U1 is an array, dimension (P). If JOBU1 = 'Y', U1 contains the P-by-P orthogonal matrix U1.

LDU1 Input parameter.

LDU1 is INTEGER

The leading dimension of U1. If JOBU1 = 'Y', LDU1 >= MAX(1, P).

U2 Output parameter.

U2 is REAL

U2 is an array, dimension (M-P). If JOBU2 = 'Y', U2 contains the (M-P)-by-(M-P) orthogonal matrix U2.

LDU2 Input parameter.

LDU2 is INTEGER

The leading dimension of U2. If JOBU2 = 'Y', LDU2 >= MAX(1,M-P).

V1T Output parameter.

V1T is REAL

V1T is an array, dimension (Q). If JOBV1T = 'Y', V1T contains the Q-by-Q matrix orthogonal matrix $V1^T$.

LDV1T Input parameter.

LDV1T is INTEGER

The leading dimension of V1T. If JOBV1T = 'Y', LDV1T >= MAX(1, Q).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK. If INFO > 0 on exit, WORK(2:R) contains the values PHI(1), ..., PHI(R-1) that, together with THETA(1), ..., THETA(R), define the matrix in intermediate bidiagonal-block form remaining after nonconvergence. INFO specifies the number of nonzero PHI's.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the work array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (M-MIN(P,M-P, Q,M-Q))

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: SBBCSD did not converge. See the description of WORK above for details.

Related Information

For this routine in other precisions, please see *dorcsd2by1*. It also exists with a native C interface as *LAPACKE_sorcsd2by1*.

4.8.13 zbbcsd

zbbcsd computes the CS decomposition of a unitary matrix in bidiagonal-block form,

```
[ B11 | B12 0  0 ]
[  0  |  0 -I  0 ]
```

X = [————————-]

```
[ B21 | B22 0  0 ]
[  0  |  0  0  I ]

                           [  C | -S  0  0 ]
             [ U1 |    ] [  0 |  0 -I  0 ] [ V1 |    ]**H
           = [---------] [---------------] [---------]   .
             [    | U2 ] [  S |  C  0  0 ] [    | V2 ]
                           [  0 |  0  0  I ]
```

X is M-by-M, its top-left block is P-by-Q, and Q must be no larger than P, M-P, or M-Q. (If Q is not the smallest index, then X must be transposed and/or permuted. This can be done in constant time using the TRANS and SIGNS options. See ZUNCSD for details.)

The bidiagonal matrices B11, B12, B21, and B22 are represented implicitly by angles THETA(1:Q) and PHI(1:Q-1).

The unitary matrices U1, U2, V1T, and V2T are input/output. The input matrices are pre- or post-multiplied by the appropriate singular vector matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine zbbcsd(JOBU1, JOBU2, JOBV1T, JOBV2T, TRANS, M, P, Q, THETA, PHI,
                  U1, LDU1, U2, LDU2, V1T, LDV1T, V2T, LDV2T, B11D, B11E,
                  B12D, B12E, B21D, B21E, B22D, B22E, RWORK, LRWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zbbcsd_(const char *jobu1, const char *jobu2, const char *jobv1t,
             const char *jobv2t, const char *trans, const armpl_int_t *m,
             const armpl_int_t *p, const armpl_int_t *q, double *theta,
             double *phi, armpl_doublecomplex_t *u1, const armpl_int_t *ldu1,
             armpl_doublecomplex_t *u2, const armpl_int_t *ldu2,
             armpl_doublecomplex_t *v1t, const armpl_int_t *ldv1t,
             armpl_doublecomplex_t *v2t, const armpl_int_t *ldv2t,
             double *b11d, double *b11e, double *b12d, double *b12e,
             double *b21d, double *b21e, double *b22d, double *b22e,
             double *rwork, const armpl_int_t *lrwork, armpl_int_t *info,
             ... );
```

Parameters

JOBU1 Input parameter.

JOBU1 is CHARACTER

= 'Y': U1 is updated; otherwise: U1 is not updated.

JOBU2 Input parameter.

JOBU2 is CHARACTER

= 'Y': U2 is updated; otherwise: U2 is not updated.

JOBV1T Input parameter.

JOBV1T is CHARACTER

= 'Y': V1T is updated; otherwise: V1T is not updated.

JOBV2T Input parameter.

JOBV2T is CHARACTER

= 'Y': V2T is updated; otherwise: V2T is not updated.

TRANS Input parameter.

TRANS is CHARACTER

= 'T': X, U1, U2, V1T, and V2T are stored in row-major order; otherwise: X, U1, U2, V1T, and V2T are stored in column- major order.

M Input parameter.

M is INTEGER

The number of rows and columns in X, the unitary matrix in bidiagonal-block form.

P Input parameter.

P is INTEGER

The number of rows in the top-left block of X. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in the top-left block of X. 0 <= Q <= MIN(P,M-P,M-Q).

THETA Input and output parameter.

THETA is DOUBLE PRECISION

THETA is an array, dimension (Q). On entry, the angles THETA(1),...,THETA(Q) that, along with PHI(1), ...,PHI(Q-1), define the matrix in bidiagonal-block form. On exit, the angles whose cosines and sines define the diagonal blocks in the CS decomposition.

PHI Input and output parameter.

PHI is DOUBLE PRECISION

PHI is an array, dimension (Q-1). The angles PHI(1),...,PHI(Q-1) that, along with THETA(1),..., THETA(Q), define the matrix in bidiagonal-block form.

U1 Input and output parameter.

U1 is COMPLEX*16

U1 is an array, dimension (LDU1, P). On entry, a P-by-P matrix. On exit, U1 is postmultiplied by the left singular vector matrix common to [B11 ; 0] and [B12 0 0 ; 0 -I 0 0].

LDU1 Input parameter.

LDU1 is INTEGER

The leading dimension of the array U1, LDU1 >= MAX(1, P).

U2 Input and output parameter.

U2 is COMPLEX*16

U2 is an array, dimension (LDU2,M-P). On entry, an (M-P)-by-(M-P) matrix. On exit, U2 is postmultiplied by the left singular vector matrix common to [B21 ; 0] and [B22 0 0 ; 0 0 I].

LDU2 Input parameter.

LDU2 is INTEGER

The leading dimension of the array U2, LDU2 >= MAX(1,M-P).

V1T Input and output parameter.

V1T is COMPLEX*16

V1T is an array, dimension (LDV1T, Q). On entry, a Q-by-Q matrix. On exit, V1T is premultiplied by the conjugate transpose of the right singular vector matrix common to [B11 ; 0] and [B21 ; 0].

LDV1T Input parameter.

LDV1T is INTEGER

The leading dimension of the array V1T, LDV1T >= MAX(1, Q).

V2T Input and output parameter.

V2T is COMPLEX*16

V2T is an array, dimension (LDV2T,M-Q). On entry, an (M-Q)-by-(M-Q) matrix. On exit, V2T is premultiplied by the conjugate transpose of the right singular vector matrix common to [B12 0 0 ; 0 -I 0] and [B22 0 0 ; 0 0 I].

LDV2T Input parameter.

LDV2T is INTEGER

The leading dimension of the array V2T, LDV2T >= MAX(1,M-Q).

B11D Output parameter.

B11D is DOUBLE PRECISION

B11D is an array, dimension (Q). When ZBBCSD converges, B11D contains the cosines of THETA(1), ..., THETA(Q). If ZBBCSD fails to converge, then B11D contains the diagonal of the partially reduced top-left block.

B11E Output parameter.

B11E is DOUBLE PRECISION

B11E is an array, dimension (Q-1). When ZBBCSD converges, B11E contains zeros. If ZBBCSD fails to converge, then B11E contains the superdiagonal of the partially reduced top-left block.

B12D Output parameter.

B12D is DOUBLE PRECISION

B12D is an array, dimension (Q). When ZBBCSD converges, B12D contains the negative sines of THETA(1), ..., THETA(Q). If ZBBCSD fails to converge, then B12D contains the diagonal of the partially reduced top-right block.

B12E Output parameter.

B12E is DOUBLE PRECISION

B12E is an array, dimension (Q-1). When ZBBCSD converges, B12E contains zeros. If ZBBCSD fails to converge, then B12E contains the subdiagonal of the partially reduced top-right block.

B21D Output parameter.

B21D is DOUBLE PRECISION

B21D is an array, dimension (Q). When ZBBCSD converges, B21D contains the negative sines of THETA(1), ..., THETA(Q). If ZBBCSD fails to converge, then B21D contains the diagonal of the partially reduced bottom-left block.

B21E Output parameter.

B21E is DOUBLE PRECISION

B21E is an array, dimension (Q-1). When ZBBCSD converges, B21E contains zeros. If ZBBCSD fails to converge, then B21E contains the subdiagonal of the partially reduced bottom-left block.

B22D Output parameter.

B22D is DOUBLE PRECISION

B22D is an array, dimension (Q). When ZBBCSD converges, B22D contains the negative sines of THETA(1), ..., THETA(Q). If ZBBCSD fails to converge, then B22D contains the diagonal of the partially reduced bottom-right block.

B22E Output parameter.

B22E is DOUBLE PRECISION

B22E is an array, dimension (Q-1). When ZBBCSD converges, B22E contains zeros. If ZBBCSD fails to converge, then B22E contains the subdiagonal of the partially reduced bottom-right block.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (MAX(1, LRWORK)). On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of the array RWORK. LRWORK >= MAX(1,8*Q).

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the work array, and no error message related to LRWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if ZBBCSD did not converge, INFO specifies the number of nonzero entries in PHI, and B11D, B11E, etc., contain the partially reduced matrix.

4.8.14 zunbdb

zunbdb simultaneously bidiagonalizes the blocks of an M-by-M partitioned unitary matrix X:

```
                                [ B11 | B12 0  0 ]
[ X11 | X12 ]   [ P1 |    ] [  0  |  0 -I  0 ] [ Q1 |    ]**H
```

X = [————] = [————] [————————-] [————] .

```
[ X21 | X22 ]   [    | P2 ] [ B21 | B22 0  0 ] [    | Q2 ]
                                [  0  |  0  0  I ]
```

X11 is P-by-Q. Q must be no larger than P, M-P, or M-Q. (If this is not the case, then X must be transposed and/or permuted. This can be done in constant time using the TRANS and SIGNS options. See ZUNCSD for details.)

The unitary matrices P1, P2, Q1, and Q2 are P-by-P, (M-P)-by- (M-P), Q-by-Q, and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11, B12, B21, and B22 are Q-by-Q bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine zunbdb(TRANS, SIGNS, M, P, Q, X11, LDX11, X12, LDX12, X21, LDX21,
                  X22, LDX22, THETA, PHI, TAUP1, TAUP2, TAUQ1, TAUQ2, WORK,
                  LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zunbdb_(const char *trans, const char *signs, const armpl_int_t *m,
             const armpl_int_t *p, const armpl_int_t *q,
             armpl_doublecomplex_t *x11, const armpl_int_t *ldx11,
             armpl_doublecomplex_t *x12, const armpl_int_t *ldx12,
             armpl_doublecomplex_t *x21, const armpl_int_t *ldx21,
             armpl_doublecomplex_t *x22, const armpl_int_t *ldx22,
             double *theta, double *phi, armpl_doublecomplex_t *taup1,
             armpl_doublecomplex_t *taup2, armpl_doublecomplex_t *tauq1,
             armpl_doublecomplex_t *tauq2, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER

= 'T': X, U1, U2, V1T, and V2T are stored in row-major order; otherwise: X, U1, U2, V1T, and V2T are stored in column- major order.

SIGNS Input parameter.

SIGNS is CHARACTER

= 'O': The lower-left block is made nonpositive (the "other" convention); otherwise: The upper-right block is made nonpositive (the "default" convention).

M Input parameter.

M is INTEGER

The number of rows and columns in X.

P Input parameter.

P is INTEGER

The number of rows in X11 and X12. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= MIN(P,M-P,M-Q).

X11 Input and output parameter.

X11 is COMPLEX*16

X11 is an array, dimension (LDX11, Q). On entry, the top-left block of the unitary matrix to be reduced. On exit, the form depends on TRANS: If TRANS = 'N', then the columns of tril(X11) specify reflectors for P1, the rows of triu(X11,1) specify reflectors for Q1; else TRANS = 'T', and the rows of triu(X11) specify reflectors for P1, the columns of tril(X11,-1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. If TRANS = 'N', then LDX11 >= P; else LDX11 >= Q.

X12 Input and output parameter.

X12 is COMPLEX*16

X12 is an array, dimension (LDX12,M-Q). On entry, the top-right block of the unitary matrix to be reduced. On exit, the form depends on TRANS: If TRANS = 'N', then the rows of triu(X12) specify the first P reflectors for Q2; else TRANS = 'T', and the columns of tril(X12) specify the first P reflectors for Q2.

LDX12 Input parameter.

LDX12 is INTEGER

The leading dimension of X12. If TRANS = 'N', then LDX12 >= P; else LDX11 >= M-Q.

X21 Input and output parameter.

X21 is COMPLEX*16

X21 is an array, dimension (LDX21, Q). On entry, the bottom-left block of the unitary matrix to be reduced. On exit, the form depends on TRANS: If TRANS = 'N', then the columns of tril(X21) specify reflectors for P2; else TRANS = 'T', and the rows of triu(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. If TRANS = 'N', then LDX21 >= M-P; else LDX21 >= Q.

X22 Input and output parameter.

X22 is COMPLEX*16

X22 is an array, dimension (LDX22,M-Q). On entry, the bottom-right block of the unitary matrix to be reduced. On exit, the form depends on TRANS: If TRANS = 'N', then the rows of triu(X22(Q+1:M-P,P+1:M-Q)) specify the last M-P-Q reflectors for Q2, else TRANS = 'T', and the columns of tril(X22(P+1:M-Q,Q+1:M-P)) specify the last M-P-Q reflectors for P2.

LDX22 Input parameter.

LDX22 is INTEGER

The leading dimension of X22. If TRANS = 'N', then LDX22 >= M-P; else LDX22 >= M-Q.

THETA Output parameter.

THETA is DOUBLE PRECISION

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B12, B21, B22 can be computed from the angles THETA and PHI. See Further Details.

PHI Output parameter.

PHI is DOUBLE PRECISION

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B12, B21, B22 can be computed from the angles THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is COMPLEX*16

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is COMPLEX*16

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is COMPLEX*16

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

TAUQ2 Output parameter.

TAUQ2 is COMPLEX*16

TAUQ2 is an array, dimension (M-Q). The scalar factors of the elementary reflectors that define Q2.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cunbdb*. It also exists with a native C interface as *LAPACKE_zunbdb*.

4.8.15 zuncsd

`zuncsd` computes the CS decomposition of an M-by-M partitioned unitary matrix X:

```
                                [  I  0  0 |  0  0  0 ]
                                [  0  C  0 |  0 -S  0 ]
[ X11 | X12 ]   [ U1 |    ] [  0  0  0 |  0  0 -I ] [ V1 |    ]**H
```

X = [————] = [———] [—————————] [———] .

```
[ X21 | X22 ]   [    | U2 ] [  0  0  0 |  I  0  0 ] [    | V2 ]
                                [  0  S  0 |  0  C  0 ]
                                [  0  0  I |  0  0  0 ]
```

X11 is P-by-Q. The unitary matrices U1, U2, V1, and V2 are P-by-P, (M-P)-by-(M-P), Q-by-Q, and (M-Q)-by-(M-Q), respectively. C and S are R-by-R nonnegative diagonal matrices satisfying C^2 + S^2 = I, in which R = MIN(P,M-P,Q,M-Q).

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine zuncsd(JOBU1, JOBU2, JOBV1T, JOBV2T, TRANS, SIGNS, M, P,

Parameters

JOBU1 Input parameter.

`JOBU1` is CHARACTER

= 'Y': `U1` is computed; otherwise: `U1` is not computed.

JOBU2 Input parameter.

JOBU2 is CHARACTER

= 'Y': U2 is computed; otherwise: U2 is not computed.

JOBV1T Input parameter.

JOBV1T is CHARACTER

= 'Y': V1T is computed; otherwise: V1T is not computed.

JOBV2T Input parameter.

JOBV2T is CHARACTER

= 'Y': V2T is computed; otherwise: V2T is not computed.

TRANS Input parameter.

TRANS is CHARACTER

= 'T': X, U1, U2, V1T, and V2T are stored in row-major order; otherwise: X, U1, U2, V1T, and V2T are stored in column- major order.

SIGNS Input parameter.

SIGNS is CHARACTER

= 'O': The lower-left block is made nonpositive (the "other" convention); otherwise: The upper-right block is made nonpositive (the "default" convention).

M Input parameter.

M is INTEGER

The number of rows and columns in X.

P Input parameter.

P is INTEGER

The number of rows in X11 and X12. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M.

X11 Input and output parameter.

X11 is COMPLEX*16

X11 is an array, dimension (LDX11, Q). On entry, part of the unitary matrix whose CSD is desired.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= MAX(1, P).

X12 Input and output parameter.

X12 is COMPLEX*16

X12 is an array, dimension (LDX12,M-Q). On entry, part of the unitary matrix whose CSD is desired.

LDX12 Input parameter.

LDX12 is INTEGER

The leading dimension of X12. LDX12 >= MAX(1, P).

X21 Input and output parameter.

X21 is COMPLEX*16

X21 is an array, dimension (LDX21, Q). On entry, part of the unitary matrix whose CSD is desired.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X11. LDX21 >= MAX(1,M-P).

X22 Input and output parameter.

X22 is COMPLEX*16

X22 is an array, dimension (LDX22,M-Q). On entry, part of the unitary matrix whose CSD is desired.

LDX22 Input parameter.

LDX22 is INTEGER

The leading dimension of X11. LDX22 >= MAX(1,M-P).

THETA Output parameter.

THETA is DOUBLE PRECISION

THETA is an array, dimension (R), in which R =. MIN(P,M-P, Q,M-Q). C = DIAG(COS(THETA(1)), ... , COS(THETA(R))) and S = DIAG(SIN(THETA(1)), ... , SIN(THETA(R))).

U1 Output parameter.

U1 is COMPLEX*16

U1 is an array, dimension (LDU1, P). If JOBU1 = 'Y', U1 contains the P-by-P unitary matrix U1.

LDU1 Input parameter.

LDU1 is INTEGER

The leading dimension of U1. If JOBU1 = 'Y', LDU1 >= MAX(1, P).

U2 Output parameter.

U2 is COMPLEX*16

U2 is an array, dimension (LDU2,M-P). If JOBU2 = 'Y', U2 contains the (M-P)-by-(M-P) unitary matrix U2.

LDU2 Input parameter.

LDU2 is INTEGER

The leading dimension of U2. If JOBU2 = 'Y', LDU2 >= MAX(1,M-P).

V1T Output parameter.

V1T is COMPLEX*16

V1T is an array, dimension (LDV1T, Q). If JOBV1T = 'Y', V1T contains the Q-by-Q matrix unitary matrix $V1^H$.

LDV1T Input parameter.

LDV1T is INTEGER

The leading dimension of V1T. If JOBV1T = 'Y', LDV1T >= MAX(1, Q).

V2T Output parameter.

V2T is COMPLEX*16

V2T is an array, dimension (LDV2T,M-Q). If JOBV2T = 'Y', V2T contains the (M-Q)-by-(M-Q) unitary matrix $V2^H$.

LDV2T Input parameter.

LDV2T is INTEGER

The leading dimension of V2T. If JOBV2T = 'Y', LDV2T >= MAX(1,M-Q).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the work array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension MAX(1, LRWORK). On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK. If INFO > 0 on exit, RWORK(2:R) contains the values PHI(1), ..., PHI(R-1) that, together with THETA(1), ..., THETA(R), define the matrix in intermediate bidiagonal-block form remaining after nonconvergence. INFO specifies the number of nonzero PHI's.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of the array RWORK.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the work array, and no error message related to LRWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (M-MIN(P,M-P, Q,M-Q))

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: ZBBCSD did not converge. See the description of RWORK above for details.

Related Information

For this routine in other precisions, please see *cuncsd*. It also exists with a native C interface as *LAPACKE_zuncsd*.

4.8.16 zuncsd2by1

ZUNCSD2BY1 computes the CS decomposition of an M-by-Q matrix X with orthonormal columns that has been partitioned into a 2-by-1 block structure:

```
                           [  I1 0  0 ]
                           [  0  C  0 ]
    [ X11 ]   [ U1 |    ] [  0  0  0 ]
X = [-----] = [---------] [----------] V1**T .
    [ X21 ]   [    | U2 ] [  0  0  0 ]
```

(continues on next page)

(continued from previous page)

```
                          [  0  S  0 ]
                          [  0  0  I2]
```

X11 is P-by-Q. The unitary matrices U1, U2, and V1 are P-by-P, (M-P)-by-(M-P), and Q-by-Q, respectively. C and S are R-by-R nonnegative diagonal matrices satisfying C^2 + S^2 = I, in which R = MIN(P,M-P,Q,M-Q). I1 is a K1-by-K1 identity matrix and I2 is a K2-by-K2 identity matrix, where K1 = MAX(Q+P-M,0), K2 = MAX(Q-P,0).

Syntax

Fortran specification:

```
use armpl_library

subroutine zuncsd2by1(JOBU1, JOBU2, JOBV1T, M, P, Q, X11, LDX11, X21, LDX21,
                      THETA, U1, LDU1, U2, LDU2, V1T, LDV1T, WORK, LWORK,
                      RWORK, LRWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zuncsd2by1_(const char *jobu1, const char *jobu2, const char *jobv1t,
                 const armpl_int_t *m, const armpl_int_t *p,
                 const armpl_int_t *q, armpl_doublecomplex_t *x11,
                 const armpl_int_t *ldx11, armpl_doublecomplex_t *x21,
                 const armpl_int_t *ldx21, double *theta,
                 armpl_doublecomplex_t *u1, const armpl_int_t *ldu1,
                 armpl_doublecomplex_t *u2, const armpl_int_t *ldu2,
                 armpl_doublecomplex_t *v1t, const armpl_int_t *ldv1t,
                 armpl_doublecomplex_t *work, const armpl_int_t *lwork,
                 double *rwork, const armpl_int_t *lrwork, armpl_int_t *iwork,
                 armpl_int_t *info, ... );
```

Parameters

JOBU1 Input parameter.

JOBU1 is CHARACTER

= 'Y': U1 is computed; otherwise: U1 is not computed.

JOBU2 Input parameter.

JOBU2 is CHARACTER

= 'Y': U2 is computed; otherwise: U2 is not computed.

JOBV1T Input parameter.

JOBV1T is CHARACTER

= 'Y': V1T is computed; otherwise: V1T is not computed.

M Input parameter.

M is INTEGER

The number of rows in X.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M.

X11 Input and output parameter.

X11 is COMPLEX*16

X11 is an array, dimension (LDX11, Q). On entry, part of the unitary matrix whose CSD is desired.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= MAX(1, P).

X21 Input and output parameter.

X21 is COMPLEX*16

X21 is an array, dimension (LDX21, Q). On entry, part of the unitary matrix whose CSD is desired.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= MAX(1,M-P).

THETA Output parameter.

THETA is DOUBLE PRECISION

THETA is an array, dimension (R), in which R =. MIN(P,M-P, Q,M-Q). C = DIAG(COS(THETA(1)), ... , COS(THETA(R))) and S = DIAG(SIN(THETA(1)), ... , SIN(THETA(R))).

U1 Output parameter.

U1 is COMPLEX*16

U1 is an array, dimension (P). If JOBU1 = 'Y', U1 contains the P-by-P unitary matrix U1.

LDU1 Input parameter.

LDU1 is INTEGER

The leading dimension of U1. If JOBU1 = 'Y', LDU1 >= MAX(1, P).

U2 Output parameter.

U2 is COMPLEX*16

U2 is an array, dimension (M-P). If JOBU2 = 'Y', U2 contains the (M-P)-by-(M-P) unitary matrix U2.

LDU2 Input parameter.

LDU2 is INTEGER

The leading dimension of U2. If JOBU2 = 'Y', LDU2 >= MAX(1,M-P).

V1T Output parameter.

V1T is COMPLEX*16

V1T is an array, dimension (Q). If JOBV1T = 'Y', V1T contains the Q-by-Q matrix unitary matrix $V1^T$.

LDV1T Input parameter.

LDV1T is INTEGER

The leading dimension of V1T. If JOBV1T = 'Y', LDV1T >= MAX(1, Q).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the work array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (MAX(1, LRWORK)). On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK. If INFO > 0 on exit, RWORK(2:R) contains the values PHI(1), ..., PHI(R-1) that, together with THETA(1), ..., THETA(R), define the matrix in intermediate bidiagonal-block form remaining after nonconvergence. INFO specifies the number of nonzero PHI's.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of the array RWORK.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the work array, and no error message related to LRWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (M-MIN(P,M-P, Q,M-Q))

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: ZBBCSD did not converge. See the description of WORK above for details.

4.9 LAPACK solution refinement routines

4.9.1 cgbrfs

cgbrfs improves the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgbrfs(TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV, B, LDB,
                  X, LDX, FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgbrfs_(const char *trans, const armpl_int_t *n, const armpl_int_t *kl,
             const armpl_int_t *ku, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
             const armpl_singlecomplex_t *afb, const armpl_int_t *ldafb,
             const armpl_int_t *ipiv, const armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *x,
             const armpl_int_t *ldx, float *ferr, float *berr,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). The original band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input parameter.

AFB is COMPLEX

AFB is an array, dimension (LDAFB, N). Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL*KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from CGBTRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by CGBTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

4.9.2 cgbrfsx

```
CGBRFSX improves the computed solution to a system of linear
   equations and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED, R
   and C below. In this case, the solution and error bounds returned
   are for the original unequilibrated system.                    Some␣
↪optional parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cgbrfsx(TRANS, EQUED, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV,
                   R, C, B, LDB, X, LDX, RCOND, BERR, N_ERR_BNDS,
                   ERR_BNDS_NORM, ERR_BNDS_COMP, NPARAMS, PARAMS, WORK, RWORK,
                   INFO)
```

C specification:

```
#include "armpl.h"

void cgbrfsx_(const char *trans, const char *equed, const armpl_int_t *n,
              const armpl_int_t *kl, const armpl_int_t *ku,
              const armpl_int_t *nrhs, const armpl_singlecomplex_t *ab,
              const armpl_int_t *ldab, const armpl_singlecomplex_t *afb,
              const armpl_int_t *ldafb, const armpl_int_t *ipiv,
              const float *r, const float *c, const armpl_singlecomplex_t *b,
              const armpl_int_t *ldb, armpl_singlecomplex_t *x,
              const armpl_int_t *ldx, float *rcond, float *berr,
              const armpl_int_t *n_err_bnds, float *err_bnds_norm,
              float *err_bnds_comp, const armpl_int_t *nparams, float *params,
              armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
              ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

EQUED Input parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done to A before calling this routine. This is needed to compute the solution and error bounds correctly. = 'N': No equilibration = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). The right hand side B has been changed accordingly.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). The original band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input parameter.

AFB is COMPLEX

AFB is an array, dimension (LDAFB, N). Details of the LU factorization of the band matrix A, as computed by DGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL*KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from SGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

R Input and output parameter.

R is REAL

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive. If R is output, each element of R is a power of the radix. If R is input, each element of R should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

C Input and output parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive. If C is output, each element of C is a power of the radix. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by SGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix

Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is REAL

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

Related Information

For this routine in other precisions, please see *dgbrfsx*, *sgbrfsx* and *zgbrfsx*. It also exists with a native C interface as *LAPACKE_cgbrfsx*.

4.9.3 cgerfs

`cgerfs` improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgerfs(TRANS, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X, LDX,
                  FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgerfs_(const char *trans, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *af, const armpl_int_t *ldaf,
             const armpl_int_t *ipiv, const armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *x,
             const armpl_int_t *ldx, float *ferr, float *berr,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

TRANS Input parameter.

`TRANS` is `CHARACTER*1`

Specifies the form of the system of equations: = 'N': `A` * `X` = `B` (No transpose) = 'T': A^T * `X` = `B` (Transpose) = 'C': A^H * `X` = `B` (Conjugate transpose)

N Input parameter.

`N` is `INTEGER`

The order of the matrix `A`. `N` >= 0.

NRHS Input parameter.

`NRHS` is `INTEGER`

The number of right hand sides, i.e., the number of columns of the matrices `B` and `X`. `NRHS` >= 0.

A Input parameter.

`A` is `COMPLEX`

`A` is an array, dimension (`LDA`, `N`). The original N-by-N matrix `A`.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `N`).

AF Input parameter.

`AF` is `COMPLEX`

`AF` is an array, dimension (`LDAF`, `N`). The factors L and U from the factorization `A` = P*L*U as computed by CGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from CGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by CGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgerfs*, *sgerfs* and *zgerfs*. It also exists with a native C interface as *LAPACKE_cgerfs*.

4.9.4 cgerfsx

```
CGERFSX improves the computed solution to a system of linear
   equations and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED, R
   and C below. In this case, the solution and error bounds returned
   are for the original unequilibrated system.                    Some␣
↪optional parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the

              armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
              ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

EQUED Input parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done to A before calling this routine. This is needed to compute the solution and error bounds correctly. = 'N': No equilibration = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). The right hand side B has been changed accordingly.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The original N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by CGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from CGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

R Input parameter.

R is REAL

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. If R is accessed, each element of R should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

C Input parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. If C is accessed, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by CGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is REAL

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

(continued from previous page)

```
                const armpl_singlecomplex_t *duf,
                const armpl_singlecomplex_t *du2, const armpl_int_t *ipiv,
                const armpl_singlecomplex_t *b, const armpl_int_t *ldb,
                armpl_singlecomplex_t *x, const armpl_int_t *ldx, float *ferr,
                float *berr, armpl_singlecomplex_t *work, float *rwork,
                armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input parameter.

DL is COMPLEX

DL is an array, dimension (N-1). The (n-1) subdiagonal elements of A.

D Input parameter.

D is COMPLEX

D is an array, dimension (N). The diagonal elements of A.

DU Input parameter.

DU is COMPLEX

DU is an array, dimension (N-1). The (n-1) superdiagonal elements of A.

DLF Input parameter.

DLF is COMPLEX

DLF is an array, dimension (N-1). The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by CGTTRF.

DF Input parameter.

DF is COMPLEX

DF is an array, dimension (N). The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DUF Input parameter.

DUF is COMPLEX

DUF is an array, dimension (N-1). The (n-1) elements of the first superdiagonal of U.

DU2 Input parameter.

DU2 is COMPLEX

DU2 is an array, dimension (N-2). The (n-2) elements of the second superdiagonal of U.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by CGTTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgtrfs*, *sgtrfs* and *zgtrfs*. It also exists with a native C interface as *LAPACKE_cgtrfs*.

4.9.6 cherfs

`cherfs` improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine cherfs(UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X, LDX, FERR,
                  BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cherfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *af, const armpl_int_t *ldaf,
             const armpl_int_t *ipiv, const armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *x,
             const armpl_int_t *ldx, float *ferr, float *berr,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^H or A = L*D*L^H as computed by CHETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHETRF.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by CHETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zherfs*. It also exists with a native C interface as *LAPACKE_cherfs*.

4.9.7 cherfsx

```
CHERFSX improves the computed solution to a system of linear
   equations when the coefficient matrix is Hermitian indefinite, and
   provides error bounds and backward error estimates for the
   solution.  In addition to normwise error bound, the code provides
   maximum componentwise error bound if possible.  See comments for
   ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED and S
   below. In this case, the solution and error bounds returned are
   for the original unequilibrated system.                          Some optional␣
↪parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cherfsx(UPLO, EQUED, N, NRHS, A, LDA, AF, LDAF, IPIV, S, B, LDB, X,
                   LDX, RCOND, BERR, N_ERR_BNDS, ERR_BNDS_NORM, ERR_BNDS_COMP,
                   NPARAMS, PARAMS, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cherfsx_(const char *uplo, const char *equed, const armpl_int_t *n,
              const armpl_int_t *nrhs, const armpl_singlecomplex_t *a,
              const armpl_int_t *lda, const armpl_singlecomplex_t *af,
              const armpl_int_t *ldaf, const armpl_int_t *ipiv,
              const float *s, const armpl_singlecomplex_t *b,
              const armpl_int_t *ldb, armpl_singlecomplex_t *x,
              const armpl_int_t *ldx, float *rcond, float *berr,
              const armpl_int_t *n_err_bnds, float *err_bnds_norm,
              float *err_bnds_comp, const armpl_int_t *nparams, float *params,
              armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
              ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

EQUED Input parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done to A before calling this routine. This is needed to compute the solution and error bounds correctly. = 'N': No equilibration = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). The right hand side B has been changed accordingly.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by SSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSYTRF.

S Input and output parameter.

S is REAL

S is an array, dimension (N). The scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by SGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is REAL

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

Related Information

For this routine in other precisions, please see *zherfsx*. It also exists with a native C interface as *LAPACKE_cherfsx*.

4.9.8 chprfs

chprfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite and packed, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine chprfs(UPLO, N, NRHS, AP, AFP, IPIV, B, LDB, X, LDX, FERR, BERR,
                  WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chprfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *ap,
             const armpl_singlecomplex_t *afp, const armpl_int_t *ipiv,
             const armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_singlecomplex_t *x, const armpl_int_t *ldx, float *ferr,
             float *berr, armpl_singlecomplex_t *work, float *rwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

AFP Input parameter.

AFP is COMPLEX

AFP is an array, dimension (N*(N+1)/2). The factored form of the matrix A. AFP contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^H or A = L*D*L^H as computed by CHPTRF, stored as a packed triangular matrix.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHPTRF.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by CHPTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

4.9.9 cpbrfs

cpbrfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and banded, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpbrfs(UPLO, N, KD, NRHS, AB, LDAB, AFB, LDAFB, B, LDB, X, LDX,
                  FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cpbrfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_int_t *nrhs, const armpl_singlecomplex_t *ab,
             const armpl_int_t *ldab, const armpl_singlecomplex_t *afb,
             const armpl_int_t *ldafb, const armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *x,
             const armpl_int_t *ldx, float *ferr, float *berr,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). The upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

AFB Input parameter.

AFB is COMPLEX

AFB is an array, dimension (LDAFB, N). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the band matrix A as computed by CPBTRF, in the same storage format as A (see AB).

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= KD+1.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by CPBTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

4.9.10 cporfs

cporfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine cporfs(UPLO, N, NRHS, A, LDA, AF, LDAF, B, LDB, X, LDX, FERR, BERR,
                  WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cporfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *af, const armpl_int_t *ldaf,
             const armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_singlecomplex_t *x, const armpl_int_t *ldx, float *ferr,
```

(continues on next page)

(continued from previous page)

```
            float *berr, armpl_singlecomplex_t *work, float *rwork,
            armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , as computed by CPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by CPOTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dporfs*, *sporfs* and *zporfs*. It also exists with a native C interface as *LAPACKE_cporfs*.

4.9.11 cporfsx

```
CPORFSX improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric positive
   definite, and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED and S
   below. In this case, the solution and error bounds returned are
   for the original unequilibrated system.                          Some optional␣
↪parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cporfsx(UPLO, EQUED, N, NRHS, A, LDA, AF, LDAF, S, B, LDB, X, LDX,
                   RCOND, BERR, N_ERR_BNDS, ERR_BNDS_NORM, ERR_BNDS_COMP,
                   NPARAMS, PARAMS, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cporfsx_(const char *uplo, const char *equed, const armpl_int_t *n,
              const armpl_int_t *nrhs, const armpl_singlecomplex_t *a,
              const armpl_int_t *lda, const armpl_singlecomplex_t *af,
              const armpl_int_t *ldaf, const float *s,
              const armpl_singlecomplex_t *b, const armpl_int_t *ldb,
              armpl_singlecomplex_t *x, const armpl_int_t *ldx, float *rcond,
              float *berr, const armpl_int_t *n_err_bnds,
              float *err_bnds_norm, float *err_bnds_comp,
              const armpl_int_t *nparams, float *params,
              armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
              ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

EQUED Input parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done to A before calling this routine. This is needed to compute the solution and error bounds correctly. = 'N': No equilibration = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). The right hand side B has been changed accordingly.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by SPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

S Input and output parameter.

S is REAL

S is an array, dimension (N). The row scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by SGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is REAL

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

Related Information

4.9.12 cpprfs

cpprfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and packed, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpprfs(UPLO, N, NRHS, AP, AFP, B, LDB, X, LDX, FERR, BERR, WORK,
                  RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cpprfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *ap,
             const armpl_singlecomplex_t *afp, const armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *x,
             const armpl_int_t *ldx, float *ferr, float *berr,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

AFP Input parameter.

AFP is COMPLEX

AFP is an array, dimension (N*(N+1)/2). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , as computed by SPPTRF/CPPTRF, packed columnwise in a linear array in the same format as A (see AP).

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by CPPTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

4.9.13 cptrfs

cptrfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine cptrfs(UPLO, N, NRHS, D, E, DF, EF, B, LDB, X, LDX, FERR, BERR,
                  WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cptrfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const float *d, const armpl_singlecomplex_t *e, const float *df,
             const armpl_singlecomplex_t *ef, const armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *x,
             const armpl_int_t *ldx, float *ferr, float *berr,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and the form of the factorization: = 'U': E is the superdiagonal of A, and A = U^H *D*U; = 'L': E is the subdiagonal of A, and A = L*D*L^H . (The two forms are equivalent if A is real.)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

D Input parameter.

D is REAL

D is an array, dimension (N). The n real diagonal elements of the tridiagonal matrix A.

E Input parameter.

E is COMPLEX

E is an array, dimension (N-1). The (n-1) off-diagonal elements of the tridiagonal matrix A (see UPLO).

DF Input parameter.

DF is REAL

DF is an array, dimension (N). The n diagonal elements of the diagonal matrix D from the factorization computed by CPTTRF.

EF Input parameter.

EF is COMPLEX

EF is an array, dimension (N-1). The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by CPTTRF (see UPLO).

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by CPTTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j).

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dptrfs*, *sptrfs* and *zptrfs*. It also exists with a native C interface as *LAPACKE_cptrfs*.

4.9.14 csprfs

csprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine csprfs(UPLO, N, NRHS, AP, AFP, IPIV, B, LDB, X, LDX, FERR, BERR,
                  WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void csprfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *ap,
             const armpl_singlecomplex_t *afp, const armpl_int_t *ipiv,
             const armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_singlecomplex_t *x, const armpl_int_t *ldx, float *ferr,
             float *berr, armpl_singlecomplex_t *work, float *rwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

AFP Input parameter.

AFP is COMPLEX

AFP is an array, dimension (N*(N+1)/2). The factored form of the matrix A. AFP contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by CSPTRF, stored as a packed triangular matrix.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSPTRF.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by CSPTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsprfs*, *ssprfs* and *zsprfs*. It also exists with a native C interface as *LAPACKE_csprfs*.

4.9.15 csyrfs

csyrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine csyrfs(UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X, LDX, FERR,
                  BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void csyrfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *af, const armpl_int_t *ldaf,
             const armpl_int_t *ipiv, const armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *x,
             const armpl_int_t *ldx, float *ferr, float *berr,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by CSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSYTRF.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by CSYTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsyrfs*, *ssyrfs* and *zsyrfs*. It also exists with a native C interface as *LAPACKE_csyrfs*.

4.9.16 csyrfsx

```
CSYRFSX improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric indefinite, and
   provides error bounds and backward error estimates for the
   solution.  In addition to normwise error bound, the code provides
   maximum componentwise error bound if possible.  See comments for
   ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED and S
   below. In this case, the solution and error bounds returned are
   for the original unequilibrated system.                    Some optional␣
↪parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine csyrfsx(UPLO, EQUED, N, NRHS, A, LDA, AF, LDAF, IPIV, S, B, LDB, X,
                   LDX, RCOND, BERR, N_ERR_BNDS, ERR_BNDS_NORM, ERR_BNDS_COMP,
                   NPARAMS, PARAMS, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void csyrfsx_(const char *uplo, const char *equed, const armpl_int_t *n,
              const armpl_int_t *nrhs, const armpl_singlecomplex_t *a,
              const armpl_int_t *lda, const armpl_singlecomplex_t *af,
              const armpl_int_t *ldaf, const armpl_int_t *ipiv,
              const float *s, const armpl_singlecomplex_t *b,
              const armpl_int_t *ldb, armpl_singlecomplex_t *x,
              const armpl_int_t *ldx, float *rcond, float *berr,
              const armpl_int_t *n_err_bnds, float *err_bnds_norm,
              float *err_bnds_comp, const armpl_int_t *nparams, float *params,
              armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
              ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

EQUED Input parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done to A before calling this routine. This is needed to compute the solution and error bounds correctly. = 'N': No equilibration = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). The right hand side B has been changed accordingly.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by SSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSYTRF.

S Input and output parameter.

S is REAL

S is an array, dimension (N). The scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by SGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is REAL

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

Related Information

For this routine in other precisions, please see *dsyrfsx*, *ssyrfsx* and *zsyrfsx*. It also exists with a native C interface as *LAPACKE_csyrfsx*.

4.9.17 ctbrfs

ctbrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix.

The solution matrix X must be computed by CTBTRS or some other means before entering this routine. ctbrfs does not do iterative refinement because doing so cannot improve the backward error.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctbrfs(UPLO, TRANS, DIAG, N, KD, NRHS, AB, LDAB, B, LDB, X, LDX,
                  FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ctbrfs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_int_t *nrhs, const armpl_singlecomplex_t *ab,
             const armpl_int_t *ldab, const armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, const armpl_singlecomplex_t *x,
             const armpl_int_t *ldx, float *ferr, float *berr,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals or subdiagonals of the triangular band matrix A. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first kd+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). The solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

4.9.18 ctprfs

ctprfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix.

The solution matrix X must be computed by CTPTRS or some other means before entering this routine. ctprfs does not do iterative refinement because doing so cannot improve the backward error.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctprfs(UPLO, TRANS, DIAG, N, NRHS, AP, B, LDB, X, LDX, FERR, BERR,
                  WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ctprfs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *ap, const armpl_singlecomplex_t *b,
```

(continues on next page)

(continued from previous page)

```
            const armpl_int_t *ldb, const armpl_singlecomplex_t *x,
            const armpl_int_t *ldx, float *ferr, float *berr,
            armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
            ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). The solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtprfs*, *stprfs* and *ztprfs*. It also exists with a native C interface as *LAPACKE_ctprfs*.

4.9.19 ctrrfs

ctrrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix.

The solution matrix X must be computed by CTRTRS or some other means before entering this routine. ctrrfs does not do iterative refinement because doing so cannot improve the backward error.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctrrfs(UPLO, TRANS, DIAG, N, NRHS, A, LDA, B, LDB, X, LDX, FERR,
                  BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ctrrfs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
```

(continues on next page)

(continued from previous page)

```
                const armpl_singlecomplex_t *b, const armpl_int_t *ldb,
                const armpl_singlecomplex_t *x, const armpl_int_t *ldx,
                float *ferr, float *berr, armpl_singlecomplex_t *work,
                float *rwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). The solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtrrfs*, *strrfs* and *ztrrfs*. It also exists with a native C interface as *LAPACKE_ctrrfs*.

4.9.20 dgbrfs

dgbrfs improves the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgbrfs(TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV, B, LDB,
                  X, LDX, FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgbrfs_(const char *trans, const armpl_int_t *n, const armpl_int_t *kl,
             const armpl_int_t *ku, const armpl_int_t *nrhs, const double *ab,
             const armpl_int_t *ldab, const double *afb,
             const armpl_int_t *ldafb, const armpl_int_t *ipiv,
             const double *b, const armpl_int_t *ldb, double *x,
             const armpl_int_t *ldx, double *ferr, double *berr, double *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). The original band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input parameter.

AFB is DOUBLE PRECISION

AFB is an array, dimension (LDAFB, N). Details of the LU factorization of the band matrix A, as computed by DGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL*KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from DGBTRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by DGBTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgbrfs*, *sgbrfs* and *zgbrfs*. It also exists with a native C interface as *LAPACKE_dgbrfs*.

4.9.21 dgbrfsx

```
DGBRFSX improves the computed solution to a system of linear
   equations and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED, R
   and C below. In this case, the solution and error bounds returned
   are for the original unequilibrated system.                    Some␣
↪optional parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dgbrfsx(TRANS, EQUED, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV,
                   R, C, B, LDB, X, LDX, RCOND, BERR, N_ERR_BNDS,
                   ERR_BNDS_NORM, ERR_BNDS_COMP, NPARAMS, PARAMS, WORK, IWORK,
                   INFO)
```

C specification:

```
#include "armpl.h"

void dgbrfsx_(const char *trans, const char *equed, const armpl_int_t *n,
              const armpl_int_t *kl, const armpl_int_t *ku,
              const armpl_int_t *nrhs, const double *ab,
              const armpl_int_t *ldab, const double *afb,
              const armpl_int_t *ldafb, const armpl_int_t *ipiv,
              const double *r, const double *c, const double *b,
              const armpl_int_t *ldb, double *x, const armpl_int_t *ldx,
              double *rcond, double *berr, const armpl_int_t *n_err_bnds,
              double *err_bnds_norm, double *err_bnds_comp,
              const armpl_int_t *nparams, double *params, double *work,
              armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

EQUED Input parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done to A before calling this routine. This is needed to compute the solution and error bounds correctly. = 'N': No equilibration = 'R': Row equilibration, i.e., A has been

premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). The right hand side B has been changed accordingly.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). The original band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input parameter.

AFB is DOUBLE PRECISION

AFB is an array, dimension (LDAFB, N). Details of the LU factorization of the band matrix A, as computed by DGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL*KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from DGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

R Input and output parameter.

R is DOUBLE PRECISION

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive. If R is output, each element of R is a power of the radix. If R is input, each element of R should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive. If C is output, each element of C is a power of the radix. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by DGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is DOUBLE PRECISION

PARAMS is an array, dimension (NPARAMS). Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0D+0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

4.9.22 dgerfs

dgerfs improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgerfs(TRANS, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X, LDX,
                  FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgerfs_(const char *trans, const armpl_int_t *n, const armpl_int_t *nrhs,
             const double *a, const armpl_int_t *lda, const double *af,
             const armpl_int_t *ldaf, const armpl_int_t *ipiv,
             const double *b, const armpl_int_t *ldb, double *x,
             const armpl_int_t *ldx, double *ferr, double *berr, double *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The original N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by DGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from DGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by DGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgerfs*, *sgerfs* and *zgerfs*. It also exists with a native C interface as *LAPACKE_dgerfs*.

4.9.23 dgerfsx

```
DGERFSX improves the computed solution to a system of linear
   equations and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED, R
   and C below. In this case, the solution and error bounds returned
   are for the original unequilibrated system.                    Some␣
↪optional parameters are bundled in the PARAMS array.  These
```

(continues on next page)

(continued from previous page)

```
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dgerfsx(TRANS, EQUED, N, NRHS, A, LDA, AF, LDAF, IPIV, R, C, B,
                   LDB, X, LDX, RCOND, BERR, N_ERR_BNDS, ERR_BNDS_NORM,
                   ERR_BNDS_COMP, NPARAMS, PARAMS, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgerfsx_(const char *trans, const char *equed, const armpl_int_t *n,
              const armpl_int_t *nrhs, const double *a,
              const armpl_int_t *lda, const double *af,
              const armpl_int_t *ldaf, const armpl_int_t *ipiv,
              const double *r, const double *c, const double *b,
              const armpl_int_t *ldb, double *x, const armpl_int_t *ldx,
              double *rcond, double *berr, const armpl_int_t *n_err_bnds,
              double *err_bnds_norm, double *err_bnds_comp,
              const armpl_int_t *nparams, double *params, double *work,
              armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

EQUED Input parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done to A before calling this routine. This is needed to compute the solution and error bounds correctly. = 'N': No equilibration = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). The right hand side B has been changed accordingly.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The original N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by DGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from DGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

R Input parameter.

R is DOUBLE PRECISION

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. If R is accessed, each element of R should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. If C is accessed, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by DGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is DOUBLE PRECISION

PARAMS is an array, dimension (NPARAMS). Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0D+0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been

completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

4.9.24 dgtrfs

dgtrfs improves the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgtrfs(TRANS, N, NRHS, DL, D, DU, DLF, DF, DUF, DU2, IPIV, B, LDB,
                  X, LDX, FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgtrfs_(const char *trans, const armpl_int_t *n, const armpl_int_t *nrhs,
             const double *dl, const double *d, const double *du,
             const double *dlf, const double *df, const double *duf,
             const double *du2, const armpl_int_t *ipiv, const double *b,
             const armpl_int_t *ldb, double *x, const armpl_int_t *ldx,
             double *ferr, double *berr, double *work, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input parameter.

DL is DOUBLE PRECISION

DL is an array, dimension (N-1). The (n-1) subdiagonal elements of A.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The diagonal elements of A.

DU Input parameter.

DU is DOUBLE PRECISION

DU is an array, dimension (N-1). The (n-1) superdiagonal elements of A.

DLF Input parameter.

DLF is DOUBLE PRECISION

DLF is an array, dimension (N-1). The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by DGTTRF.

DF Input parameter.

DF is DOUBLE PRECISION

DF is an array, dimension (N). The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DUF Input parameter.

DUF is DOUBLE PRECISION

DUF is an array, dimension (N-1). The (n-1) elements of the first superdiagonal of U.

DU2 Input parameter.

DU2 is DOUBLE PRECISION

DU2 is an array, dimension (N-2). The (n-2) elements of the second superdiagonal of U.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by DGTTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgtrfs*, *sgtrfs* and *zgtrfs*. It also exists with a native C interface as *LAPACKE_dgtrfs*.

4.9.25 dpbrfs

dpbrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and banded, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpbrfs(UPLO, N, KD, NRHS, AB, LDAB, AFB, LDAFB, B, LDB, X, LDX,
                  FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dpbrfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_int_t *nrhs, const double *ab,
```

(continues on next page)

(continued from previous page)

```
                const armpl_int_t *ldab, const double *afb,
                const armpl_int_t *ldafb, const double *b,
                const armpl_int_t *ldb, double *x, const armpl_int_t *ldx,
                double *ferr, double *berr, double *work, armpl_int_t *iwork,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). The upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

AFB Input parameter.

AFB is DOUBLE PRECISION

AFB is an array, dimension (LDAFB, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the band matrix A as computed by DPBTRF, in the same storage format as A (see AB).

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= KD+1.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by DPBTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

4.9.26 dporfs

dporfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine dporfs(UPLO, N, NRHS, A, LDA, AF, LDAF, B, LDB, X, LDX, FERR, BERR,
                  WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dporfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const double *a, const armpl_int_t *lda, const double *af,
             const armpl_int_t *ldaf, const double *b, const armpl_int_t *ldb,
             double *x, const armpl_int_t *ldx, double *ferr, double *berr,
             double *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by DPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by DPOTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cporfs*, *sporfs* and *zporfs*. It also exists with a native C interface as *LAPACKE_dporfs*.

4.9.27 dporfsx

```
DPORFSX improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric positive
   definite, and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED and S
   below. In this case, the solution and error bounds returned are
   for the original unequilibrated system.                    Some optional␣
↪parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dporfsx(UPLO, EQUED, N, NRHS, A, LDA, AF, LDAF, S, B, LDB, X, LDX,
                   RCOND, BERR, N_ERR_BNDS, ERR_BNDS_NORM, ERR_BNDS_COMP,
                   NPARAMS, PARAMS, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dporfsx_(const char *uplo, const char *equed, const armpl_int_t *n,
              const armpl_int_t *nrhs, const double *a,
              const armpl_int_t *lda, const double *af,
              const armpl_int_t *ldaf, const double *s, const double *b,
              const armpl_int_t *ldb, double *x, const armpl_int_t *ldx,
              double *rcond, double *berr, const armpl_int_t *n_err_bnds,
              double *err_bnds_norm, double *err_bnds_comp,
              const armpl_int_t *nparams, double *params, double *work,
              armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

EQUED Input parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done to A before calling this routine. This is needed to compute the solution and error bounds correctly. = 'N': No equilibration = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). The right hand side B has been changed accordingly.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by DPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

S Input and output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The row scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by DGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then

ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is DOUBLE PRECISION

PARAMS is an array, dimension (NPARAMS). Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0D+0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only

the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check `ERR_BNDS_NORM` or `ERR_BNDS_COMP`.

Related Information

4.9.28 dpprfs

`dpprfs` improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and packed, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpprfs(UPLO, N, NRHS, AP, AFP, B, LDB, X, LDX, FERR, BERR, WORK,
                  IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dpprfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const double *ap, const double *afp, const double *b,
             const armpl_int_t *ldb, double *x, const armpl_int_t *ldx,
             double *ferr, double *berr, double *work, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

= '`U`': Upper triangle of A is stored; = '`L`': Lower triangle of A is stored.

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0.

NRHS Input parameter.

`NRHS` is `INTEGER`

The number of right hand sides, i.e., the number of columns of the matrices `B` and `X`. `NRHS` >= 0.

AP Input parameter.

`AP` is `DOUBLE PRECISION`

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

AFP Input parameter.

AFP is DOUBLE PRECISION

AFP is an array, dimension (N*(N+1)/2). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by DPPTRF/ZPPTRF, packed columnwise in a linear array in the same format as A (see AP).

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by DPPTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpprfs*, *spprfs* and *zpprfs*. It also exists with a native C interface as *LAPACKE_dpprfs*.

4.9.29 dptrfs

`dptrfs` improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine dptrfs(N, NRHS, D, E, DF, EF, B, LDB, X, LDX, FERR, BERR, WORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dptrfs_(const armpl_int_t *n, const armpl_int_t *nrhs, const double *d,
             const double *e, const double *df, const double *ef,
             const double *b, const armpl_int_t *ldb, double *x,
             const armpl_int_t *ldx, double *ferr, double *berr, double *work,
             armpl_int_t *info);
```

Parameters

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0.

NRHS Input parameter.

`NRHS` is `INTEGER`

The number of right hand sides, i.e., the number of columns of the matrix `B`. `NRHS` >= 0.

D Input parameter.

`D` is `DOUBLE PRECISION`

`D` is an array, dimension (`N`). The n diagonal elements of the tridiagonal matrix A.

E Input parameter.

`E` is `DOUBLE PRECISION`

`E` is an array, dimension (N-1). The (n-1) subdiagonal elements of the tridiagonal matrix A.

DF Input parameter.

`DF` is `DOUBLE PRECISION`

`DF` is an array, dimension (`N`). The n diagonal elements of the diagonal matrix `D` from the factorization computed by DPTTRF.

EF Input parameter.

EF is DOUBLE PRECISION

EF is an array, dimension (N-1). The (n-1) subdiagonal elements of the unit bidiagonal factor L from the factorization computed by DPTTRF.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by DPTTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j).

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cptrfs*, *sptrfs* and *zptrfs*. It also exists with a native C interface as *LAPACKE_dptrfs*.

4.9.30 dsprfs

dsprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsprfs(UPLO, N, NRHS, AP, AFP, IPIV, B, LDB, X, LDX, FERR, BERR,
                  WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsprfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const double *ap, const double *afp, const armpl_int_t *ipiv,
             const double *b, const armpl_int_t *ldb, double *x,
             const armpl_int_t *ldx, double *ferr, double *berr, double *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

AFP Input parameter.

AFP is DOUBLE PRECISION

AFP is an array, dimension (N*(N+1)/2). The factored form of the matrix A. AFP contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by DSPTRF, stored as a packed triangular matrix.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSPTRF.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by DSPTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

4.9.31 dsyrfs

dsyrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsyrfs(UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X, LDX, FERR,
                  BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsyrfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const double *a, const armpl_int_t *lda, const double *af,
             const armpl_int_t *ldaf, const armpl_int_t *ipiv,
             const double *b, const armpl_int_t *ldb, double *x,
             const armpl_int_t *ldx, double *ferr, double *berr, double *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by DSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSYTRF.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by DSYTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

4.9.32 dsyrfsx

```
DSYRFSX improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric indefinite, and
   provides error bounds and backward error estimates for the
   solution.  In addition to normwise error bound, the code provides
   maximum componentwise error bound if possible.  See comments for
   ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED and S
   below. In this case, the solution and error bounds returned are
   for the original unequilibrated system.                    Some optional␣
↪parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dsyrfsx(UPLO, EQUED, N, NRHS, A, LDA, AF, LDAF, IPIV, S, B, LDB, X,
                   LDX, RCOND, BERR, N_ERR_BNDS, ERR_BNDS_NORM, ERR_BNDS_COMP,
                   NPARAMS, PARAMS, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsyrfsx_(const char *uplo, const char *equed, const armpl_int_t *n,
              const armpl_int_t *nrhs, const double *a,
              const armpl_int_t *lda, const double *af,
              const armpl_int_t *ldaf, const armpl_int_t *ipiv,
              const double *s, const double *b, const armpl_int_t *ldb,
              double *x, const armpl_int_t *ldx, double *rcond, double *berr,
              const armpl_int_t *n_err_bnds, double *err_bnds_norm,
              double *err_bnds_comp, const armpl_int_t *nparams,
              double *params, double *work, armpl_int_t *iwork,
              armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

EQUED Input parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done to A before calling this routine. This is needed to compute the solution and error bounds correctly. = 'N': No equilibration = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). The right hand side B has been changed accordingly.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by DSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSYTRF.

S Input and output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by DGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is DOUBLE PRECISION

PARAMS is an array, dimension (NPARAMS). Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0D+0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

4.9.33 dtbrfs

dtbrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix.

The solution matrix X must be computed by DTBTRS or some other means before entering this routine. dtbrfs does not do iterative refinement because doing so cannot improve the backward error.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtbrfs(UPLO, TRANS, DIAG, N, KD, NRHS, AB, LDAB, B, LDB, X, LDX,
                  FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtbrfs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_int_t *nrhs, const double *ab,
             const armpl_int_t *ldab, const double *b, const armpl_int_t *ldb,
             const double *x, const armpl_int_t *ldx, double *ferr,
             double *berr, double *work, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals or subdiagonals of the triangular band matrix A. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first kd+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). The solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctbrfs*, *stbrfs* and *ztbrfs*. It also exists with a native C interface as *LAPACKE_dtbrfs*.

4.9.34 dtprfs

dtprfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix.

The solution matrix X must be computed by DTPTRS or some other means before entering this routine. dtprfs does not do iterative refinement because doing so cannot improve the backward error.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtprfs(UPLO, TRANS, DIAG, N, NRHS, AP, B, LDB, X, LDX, FERR, BERR,
                  WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtprfs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *nrhs, const double *ap,
             const double *b, const armpl_int_t *ldb, const double *x,
             const armpl_int_t *ldx, double *ferr, double *berr, double *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). The solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctprfs*, *stprfs* and *ztprfs*. It also exists with a native C interface as *LAPACKE_dtprfs*.

4.9.35 dtrrfs

dtrrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix.

The solution matrix X must be computed by DTRTRS or some other means before entering this routine. dtrrfs does not do iterative refinement because doing so cannot improve the backward error.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtrrfs(UPLO, TRANS, DIAG, N, NRHS, A, LDA, B, LDB, X, LDX, FERR,
                  BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtrrfs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *nrhs, const double *a,
             const armpl_int_t *lda, const double *b, const armpl_int_t *ldb,
             const double *x, const armpl_int_t *ldx, double *ferr,
             double *berr, double *work, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). The solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

4.9.36 sgbrfs

sgbrfs improves the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgbrfs(TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV, B, LDB,
                  X, LDX, FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgbrfs_(const char *trans, const armpl_int_t *n, const armpl_int_t *kl,
             const armpl_int_t *ku, const armpl_int_t *nrhs, const float *ab,
             const armpl_int_t *ldab, const float *afb,
             const armpl_int_t *ldafb, const armpl_int_t *ipiv,
             const float *b, const armpl_int_t *ldb, float *x,
             const armpl_int_t *ldx, float *ferr, float *berr, float *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). The original band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input parameter.

AFB is REAL

AFB is an array, dimension (LDAFB, N). Details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL*KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from SGBTRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by SGBTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgbrfs*, *dgbrfs* and *zgbrfs*. It also exists with a native C interface as *LAPACKE_sgbrfs*.

4.9.37 sgbrfsx

```
SGBRFSX improves the computed solution to a system of linear
   equations and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED, R
   and C below. In this case, the solution and error bounds returned
   are for the original unequilibrated system.                    Some␣
↪optional parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sgbrfsx(TRANS, EQUED, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV,
                   R, C, B, LDB, X, LDX, RCOND, BERR, N_ERR_BNDS,
                   ERR_BNDS_NORM, ERR_BNDS_COMP, NPARAMS, PARAMS, WORK, IWORK,
                   INFO)
```

C specification:

```
#include "armpl.h"

void sgbrfsx_(const char *trans, const char *equed, const armpl_int_t *n,
              const armpl_int_t *kl, const armpl_int_t *ku,
              const armpl_int_t *nrhs, const float *ab,
              const armpl_int_t *ldab, const float *afb,
              const armpl_int_t *ldafb, const armpl_int_t *ipiv,
              const float *r, const float *c, const float *b,
              const armpl_int_t *ldb, float *x, const armpl_int_t *ldx,
              float *rcond, float *berr, const armpl_int_t *n_err_bnds,
              float *err_bnds_norm, float *err_bnds_comp,
              const armpl_int_t *nparams, float *params, float *work,
              armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

EQUED Input parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done to A before calling this routine. This is needed to compute the solution and error bounds correctly. = 'N': No equilibration = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). The right hand side B has been changed accordingly.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). The original band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input parameter.

AFB is REAL

AFB is an array, dimension (LDAFB, N). Details of the LU factorization of the band matrix A, as computed by DGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL*KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from SGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

R Input and output parameter.

R is REAL

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive. If R is output, each element of R is a power of the radix. If R is input, each element of R should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

C Input and output parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive. If C is output, each element of C is a power of the radix. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by SGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is REAL

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

4.9.38 sgerfs

sgerfs improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgerfs(TRANS, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X, LDX,
                  FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgerfs_(const char *trans, const armpl_int_t *n, const armpl_int_t *nrhs,
             const float *a, const armpl_int_t *lda, const float *af,
             const armpl_int_t *ldaf, const armpl_int_t *ipiv, const float *b,
             const armpl_int_t *ldb, float *x, const armpl_int_t *ldx,
             float *ferr, float *berr, float *work, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The original N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is REAL

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by SGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from SGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by SGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

EQUED Input parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done to A before calling this routine. This is needed to compute the solution and error bounds correctly. = 'N': No equilibration = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). The right hand side B has been changed accordingly.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The original N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is REAL

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by SGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from SGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

R Input parameter.

R is REAL

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. If R is accessed, each element of R should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

C Input parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. If C is accessed, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by SGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is REAL

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

4.9.40 sgtrfs

sgtrfs improves the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgtrfs(TRANS, N, NRHS, DL, D, DU, DLF, DF, DUF, DU2, IPIV, B, LDB,
                  X, LDX, FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgtrfs_(const char *trans, const armpl_int_t *n, const armpl_int_t *nrhs,
             const float *dl, const float *d, const float *du,
             const float *dlf, const float *df, const float *duf,
             const float *du2, const armpl_int_t *ipiv, const float *b,
             const armpl_int_t *ldb, float *x, const armpl_int_t *ldx,
             float *ferr, float *berr, float *work, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input parameter.

DL is REAL

DL is an array, dimension (N-1). The (n-1) subdiagonal elements of A.

D Input parameter.

D is REAL

D is an array, dimension (N). The diagonal elements of A.

DU Input parameter.

DU is REAL

DU is an array, dimension (N-1). The (n-1) superdiagonal elements of A.

DLF Input parameter.

DLF is REAL

DLF is an array, dimension (N-1). The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

DF Input parameter.

DF is REAL

DF is an array, dimension (N). The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DUF Input parameter.

DUF is REAL

DUF is an array, dimension (N-1). The (n-1) elements of the first superdiagonal of U.

DU2 Input parameter.

DU2 is REAL

DU2 is an array, dimension (N-2). The (n-2) elements of the second superdiagonal of U.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by SGTTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgtrfs*, *dgtrfs* and *zgtrfs*. It also exists with a native C interface as *LAPACKE_sgtrfs*.

4.9.41 spbrfs

spbrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and banded, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine spbrfs(UPLO, N, KD, NRHS, AB, LDAB, AFB, LDAFB, B, LDB, X, LDX,
                  FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void spbrfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_int_t *nrhs, const float *ab,
             const armpl_int_t *ldab, const float *afb,
             const armpl_int_t *ldafb, const float *b, const armpl_int_t *ldb,
             float *x, const armpl_int_t *ldx, float *ferr, float *berr,
             float *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). The upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

AFB Input parameter.

AFB is REAL

AFB is an array, dimension (LDAFB, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the band matrix A as computed by SPBTRF, in the same storage format as A (see AB).

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= KD+1.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by SPBTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpbrfs*, *dpbrfs* and *zpbrfs*. It also exists with a native C interface as *LAPACKE_spbrfs*.

4.9.42 sporfs

sporfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine sporfs(UPLO, N, NRHS, A, LDA, AF, LDAF, B, LDB, X, LDX, FERR, BERR,
                  WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sporfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const float *a, const armpl_int_t *lda, const float *af,
             const armpl_int_t *ldaf, const float *b, const armpl_int_t *ldb,
             float *x, const armpl_int_t *ldx, float *ferr, float *berr,
             float *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is REAL

AF is an array, dimension (LDAF, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by SPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by SPOTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cporfs*, *dporfs* and *zporfs*. It also exists with a native C interface as *LAPACKE_sporfs*.

4.9.43 sporfsx

```
SPORFSX improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric positive
   definite, and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED and S
   below. In this case, the solution and error bounds returned are
   for the original unequilibrated system.                          Some optional␣
↪parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sporfsx(UPLO, EQUED, N, NRHS, A, LDA, AF, LDAF, S, B, LDB, X, LDX,
                   RCOND, BERR, N_ERR_BNDS, ERR_BNDS_NORM, ERR_BNDS_COMP,
                   NPARAMS, PARAMS, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sporfsx_(const char *uplo, const char *equed, const armpl_int_t *n,
              const armpl_int_t *nrhs, const float *a, const armpl_int_t *lda,
              const float *af, const armpl_int_t *ldaf, const float *s,
```

(continues on next page)

(continued from previous page)

```
                const float *b, const armpl_int_t *ldb, float *x,
                const armpl_int_t *ldx, float *rcond, float *berr,
                const armpl_int_t *n_err_bnds, float *err_bnds_norm,
                float *err_bnds_comp, const armpl_int_t *nparams, float *params,
                float *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

EQUED Input parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done to A before calling this routine. This is needed to compute the solution and error bounds correctly. = 'N': No equilibration = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). The right hand side B has been changed accordingly.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is REAL

AF is an array, dimension (LDAF, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by SPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

S Input and output parameter.

S is REAL

S is an array, dimension (N). The row scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the

radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by SGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is REAL

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision

refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

Related Information

4.9.44 spprfs

spprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and packed, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine spprfs(UPLO, N, NRHS, AP, AFP, B, LDB, X, LDX, FERR, BERR, WORK,
                  IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void spprfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const float *ap, const float *afp, const float *b,
             const armpl_int_t *ldb, float *x, const armpl_int_t *ldx,
             float *ferr, float *berr, float *work, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

AFP Input parameter.

AFP is REAL

AFP is an array, dimension (N*(N+1)/2). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by SPPTRF/CPPTRF, packed columnwise in a linear array in the same format as A (see AP).

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by SPPTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpprfs*, *dpprfs* and *zpprfs*. It also exists with a native C interface as *LAPACKE_spprfs*.

4.9.45 sptrfs

sptrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine sptrfs(N, NRHS, D, E, DF, EF, B, LDB, X, LDX, FERR, BERR, WORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sptrfs_(const armpl_int_t *n, const armpl_int_t *nrhs, const float *d,
             const float *e, const float *df, const float *ef, const float *b,
             const armpl_int_t *ldb, float *x, const armpl_int_t *ldx,
             float *ferr, float *berr, float *work, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the tridiagonal matrix A.

E Input parameter.

E is REAL

E is an array, dimension (N-1). The (n-1) subdiagonal elements of the tridiagonal matrix A.

DF Input parameter.

DF is REAL

DF is an array, dimension (N). The n diagonal elements of the diagonal matrix D from the factorization computed by SPTTRF.

EF Input parameter.

EF is REAL

EF is an array, dimension (N-1). The (n-1) subdiagonal elements of the unit bidiagonal factor L from the factorization computed by SPTTRF.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by SPTTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j).

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cptrfs*, *dptrfs* and *zptrfs*. It also exists with a native C interface as *LAPACKE_sptrfs*.

4.9.46 ssprfs

ssprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssprfs(UPLO, N, NRHS, AP, AFP, IPIV, B, LDB, X, LDX, FERR, BERR,
                  WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssprfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const float *ap, const float *afp, const armpl_int_t *ipiv,
             const float *b, const armpl_int_t *ldb, float *x,
             const armpl_int_t *ldx, float *ferr, float *berr, float *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

AFP Input parameter.

AFP is REAL

AFP is an array, dimension (N*(N+1)/2). The factored form of the matrix A. AFP contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by SSPTRF, stored as a packed triangular matrix.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSPTRF.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by SSPTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

4.9.47 ssyrfs

ssyrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssyrfs(UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X, LDX, FERR,
                  BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssyrfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const float *a, const armpl_int_t *lda, const float *af,
             const armpl_int_t *ldaf, const armpl_int_t *ipiv, const float *b,
             const armpl_int_t *ldb, float *x, const armpl_int_t *ldx,
             float *ferr, float *berr, float *work, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is REAL

AF is an array, dimension (LDAF, N). The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by SSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSYTRF.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by SSYTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csyrfs*, *dsyrfs* and *zsyrfs*. It also exists with a native C interface as *LAPACKE_ssyrfs*.

4.9.48 ssyrfsx

```
SSYRFSX improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric indefinite, and
   provides error bounds and backward error estimates for the
   solution.  In addition to normwise error bound, the code provides
   maximum componentwise error bound if possible.  See comments for
   ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED and S
   below. In this case, the solution and error bounds returned are
   for the original unequilibrated system.                          Some optional␣
↪parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine ssyrfsx(UPLO, EQUED, N, NRHS, A, LDA, AF, LDAF, IPIV, S, B, LDB, X,
                   LDX, RCOND, BERR, N_ERR_BNDS, ERR_BNDS_NORM, ERR_BNDS_COMP,
                   NPARAMS, PARAMS, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssyrfsx_(const char *uplo, const char *equed, const armpl_int_t *n,
              const armpl_int_t *nrhs, const float *a, const armpl_int_t *lda,
              const float *af, const armpl_int_t *ldaf,
              const armpl_int_t *ipiv, const float *s, const float *b,
```

(continues on next page)

(continued from previous page)

```
                const armpl_int_t *ldb, float *x, const armpl_int_t *ldx,
                float *rcond, float *berr, const armpl_int_t *n_err_bnds,
                float *err_bnds_norm, float *err_bnds_comp,
                const armpl_int_t *nparams, float *params, float *work,
                armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

EQUED Input parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done to A before calling this routine. This is needed to compute the solution and error bounds correctly. = 'N': No equilibration = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). The right hand side B has been changed accordingly.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is REAL

AF is an array, dimension (LDAF, N). The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by SSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSYTRF.

S Input and output parameter.

S is REAL

S is an array, dimension (N). The scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is REAL

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by SGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is REAL

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

4.9.49 stbrfs

stbrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix.

The solution matrix X must be computed by STBTRS or some other means before entering this routine. stbrfs does not do iterative refinement because doing so cannot improve the backward error.

Syntax

Fortran specification:

```
use armpl_library

subroutine stbrfs(UPLO, TRANS, DIAG, N, KD, NRHS, AB, LDAB, B, LDB, X, LDX,
                  FERR, BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void stbrfs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_int_t *nrhs, const float *ab,
             const armpl_int_t *ldab, const float *b, const armpl_int_t *ldb,
             const float *x, const armpl_int_t *ldx, float *ferr, float *berr,
             float *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals or subdiagonals of the triangular band matrix A. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first kd+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input parameter.

X is REAL

X is an array, dimension (LDX, NRHS). The solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctbrfs*, *dtbrfs* and *ztbrfs*. It also exists with a native C interface as *LAPACKE_stbrfs*.

4.9.50 stprfs

stprfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix.

The solution matrix X must be computed by STPTRS or some other means before entering this routine. stprfs does not do iterative refinement because doing so cannot improve the backward error.

Syntax

Fortran specification:

```
use armpl_library

subroutine stprfs(UPLO, TRANS, DIAG, N, NRHS, AP, B, LDB, X, LDX, FERR, BERR,
                  WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void stprfs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *nrhs, const float *ap,
             const float *b, const armpl_int_t *ldb, const float *x,
             const armpl_int_t *ldx, float *ferr, float *berr, float *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input parameter.

X is REAL

X is an array, dimension (LDX, NRHS). The solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctprfs*, *dtprfs* and *ztprfs*. It also exists with a native C interface as *LAPACKE_stprfs*.

4.9.51 strrfs

strrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix.

The solution matrix X must be computed by STRTRS or some other means before entering this routine. strrfs does not do iterative refinement because doing so cannot improve the backward error.

Syntax

Fortran specification:

```
use armpl_library

subroutine strrfs(UPLO, TRANS, DIAG, N, NRHS, A, LDA, B, LDB, X, LDX, FERR,
                  BERR, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void strrfs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *nrhs, const float *a,
             const armpl_int_t *lda, const float *b, const armpl_int_t *ldb,
             const float *x, const armpl_int_t *ldx, float *ferr, float *berr,
             float *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input parameter.

X is REAL

X is an array, dimension (LDX, NRHS). The solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is REAL

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

4.9.52 zgbrfs

zgbrfs improves the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgbrfs(TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV, B, LDB,
                  X, LDX, FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgbrfs_(const char *trans, const armpl_int_t *n, const armpl_int_t *kl,
             const armpl_int_t *ku, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
             const armpl_doublecomplex_t *afb, const armpl_int_t *ldafb,
             const armpl_int_t *ipiv, const armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *x,
             const armpl_int_t *ldx, double *ferr, double *berr,
             armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
             ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). The original band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input parameter.

AFB is COMPLEX*16

AFB is an array, dimension (LDAFB, N). Details of the LU factorization of the band matrix A, as computed by ZGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL*KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from ZGBTRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by ZGBTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgbrfs*, *dgbrfs* and *sgbrfs*. It also exists with a native C interface as *LAPACKE_zgbrfs*.

4.9.53 zgbrfsx

```
ZGBRFSX improves the computed solution to a system of linear
   equations and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED, R
   and C below. In this case, the solution and error bounds returned
   are for the original unequilibrated system.                                Some␣
↪optional parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zgbrfsx(TRANS, EQUED, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV,
                   R, C, B, LDB, X, LDX, RCOND, BERR, N_ERR_BNDS,
                   ERR_BNDS_NORM, ERR_BNDS_COMP, NPARAMS, PARAMS, WORK, RWORK,
                   INFO)
```

C specification:

```
#include "armpl.h"

void zgbrfsx_(const char *trans, const char *equed, const armpl_int_t *n,
              const armpl_int_t *kl, const armpl_int_t *ku,
              const armpl_int_t *nrhs, const armpl_doublecomplex_t *ab,
              const armpl_int_t *ldab, const armpl_doublecomplex_t *afb,
              const armpl_int_t *ldafb, const armpl_int_t *ipiv,
              const double *r, const double *c,
              const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
              armpl_doublecomplex_t *x, const armpl_int_t *ldx, double *rcond,
              double *berr, const armpl_int_t *n_err_bnds,
              double *err_bnds_norm, double *err_bnds_comp,
              const armpl_int_t *nparams, double *params,
              armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
              ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

EQUED Input parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done to A before calling this routine. This is needed to compute the solution and error bounds correctly. = 'N': No equilibration = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). The right hand side B has been changed accordingly.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). The original band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input parameter.

AFB is COMPLEX*16

AFB is an array, dimension (LDAFB, N). Details of the LU factorization of the band matrix A, as computed by DGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL*KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from DGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

R Input and output parameter.

R is DOUBLE PRECISION

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive. If R is output, each element of R is a power of the radix. If R is input, each element of R should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive. If C is output, each element of C is a power of the radix. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by DGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix

Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is DOUBLE PRECISION

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0D+0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

4.9.54 zgerfs

`zgerfs` improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgerfs(TRANS, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X, LDX,
                  FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgerfs_(const char *trans, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *af, const armpl_int_t *ldaf,
             const armpl_int_t *ipiv, const armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *x,
             const armpl_int_t *ldx, double *ferr, double *berr,
             armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
             ... );
```

Parameters

TRANS Input parameter.

`TRANS` is `CHARACTER*1`

Specifies the form of the system of equations: = 'N': `A` * `X` = `B` (No transpose) = 'T': A^T * `X` = `B` (Transpose) = 'C': A^H * `X` = `B` (Conjugate transpose)

N Input parameter.

`N` is `INTEGER`

The order of the matrix `A`. `N` >= 0.

NRHS Input parameter.

`NRHS` is `INTEGER`

The number of right hand sides, i.e., the number of columns of the matrices `B` and `X`. `NRHS` >= 0.

A Input parameter.

`A` is `COMPLEX*16`

`A` is an array, dimension (`LDA`, `N`). The original N-by-N matrix `A`.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `N`).

AF Input parameter.

`AF` is `COMPLEX*16`

`AF` is an array, dimension (`LDAF`, `N`). The factors L and U from the factorization `A` = P*L*U as computed by ZGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from ZGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by ZGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgerfs*, *dgerfs* and *sgerfs*. It also exists with a native C interface as *LAPACKE_zgerfs*.

4.9.55 zgerfsx

```
ZGERFSX improves the computed solution to a system of linear
   equations and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED, R
   and C below. In this case, the solution and error bounds returned
   are for the original unequilibrated system.                    Some␣
↪optional parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zgerfsx(TRANS, EQUED, N, NRHS, A, LDA, AF, LDAF, IPIV, R, C, B,
                   LDB, X, LDX, RCOND, BERR, N_ERR_BNDS, ERR_BNDS_NORM,
                   ERR_BNDS_COMP, NPARAMS, PARAMS, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgerfsx_(const char *trans, const char *equed, const armpl_int_t *n,
              const armpl_int_t *nrhs, const armpl_doublecomplex_t *a,
              const armpl_int_t *lda, const armpl_doublecomplex_t *af,
              const armpl_int_t *ldaf, const armpl_int_t *ipiv,
              const double *r, const double *c,
              const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
              armpl_doublecomplex_t *x, const armpl_int_t *ldx, double *rcond,
              double *berr, const armpl_int_t *n_err_bnds,
              double *err_bnds_norm, double *err_bnds_comp,
              const armpl_int_t *nparams, double *params,
              armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
              ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

EQUED Input parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done to A before calling this routine. This is needed to compute the solution and error bounds correctly. = 'N': No equilibration = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). The right hand side B has been changed accordingly.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The original N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by ZGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from ZGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIV(i).

R Input parameter.

R is DOUBLE PRECISION

R is an array, dimension (N). The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. If R is accessed, each element of R should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. If C is accessed, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by ZGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is DOUBLE PRECISION

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0D+0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

4.9.56 zgtrfs

zgtrfs improves the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgtrfs(TRANS, N, NRHS, DL, D, DU, DLF, DF, DUF, DU2, IPIV, B, LDB,
                  X, LDX, FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgtrfs_(const char *trans, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *dl, const armpl_doublecomplex_t *d,
             const armpl_doublecomplex_t *du,
             const armpl_doublecomplex_t *dlf,
             const armpl_doublecomplex_t *df,
```

(continues on next page)

(continued from previous page)

```
                const armpl_doublecomplex_t *duf,
                const armpl_doublecomplex_t *du2, const armpl_int_t *ipiv,
                const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
                armpl_doublecomplex_t *x, const armpl_int_t *ldx, double *ferr,
                double *berr, armpl_doublecomplex_t *work, double *rwork,
                armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input parameter.

DL is COMPLEX*16

DL is an array, dimension (N-1). The (n-1) subdiagonal elements of A.

D Input parameter.

D is COMPLEX*16

D is an array, dimension (N). The diagonal elements of A.

DU Input parameter.

DU is COMPLEX*16

DU is an array, dimension (N-1). The (n-1) superdiagonal elements of A.

DLF Input parameter.

DLF is COMPLEX*16

DLF is an array, dimension (N-1). The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by ZGTTRF.

DF Input parameter.

DF is COMPLEX*16

DF is an array, dimension (N). The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DUF Input parameter.

DUF is COMPLEX*16

DUF is an array, dimension (N-1). The (n-1) elements of the first superdiagonal of U.

DU2 Input parameter.

DU2 is COMPLEX*16

DU2 is an array, dimension (N-2). The (n-2) elements of the second superdiagonal of U.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by ZGTTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgtrfs*, *dgtrfs* and *sgtrfs*. It also exists with a native C interface as *LAPACKE_zgtrfs*.

4.9.57 zherfs

zherfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine zherfs(UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X, LDX, FERR,
                  BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zherfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *af, const armpl_int_t *ldaf,
             const armpl_int_t *ipiv, const armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *x,
             const armpl_int_t *ldx, double *ferr, double *berr,
             armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^H or A = L*D*L^H as computed by ZHETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZHETRF.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by ZHETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cherfs*. It also exists with a native C interface as *LAPACKE_zherfs*.

4.9.58 zherfsx

```
ZHERFSX improves the computed solution to a system of linear
   equations when the coefficient matrix is Hermitian indefinite, and
   provides error bounds and backward error estimates for the
   solution.  In addition to normwise error bound, the code provides
   maximum componentwise error bound if possible.  See comments for
   ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED and S
   below. In this case, the solution and error bounds returned are
   for the original unequilibrated system.                          Some optional␣
↪parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zherfsx(UPLO, EQUED, N, NRHS, A, LDA, AF, LDAF, IPIV, S, B, LDB, X,
                   LDX, RCOND, BERR, N_ERR_BNDS, ERR_BNDS_NORM, ERR_BNDS_COMP,
                   NPARAMS, PARAMS, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zherfsx_(const char *uplo, const char *equed, const armpl_int_t *n,
              const armpl_int_t *nrhs, const armpl_doublecomplex_t *a,
              const armpl_int_t *lda, const armpl_doublecomplex_t *af,
              const armpl_int_t *ldaf, const armpl_int_t *ipiv,
              const double *s, const armpl_doublecomplex_t *b,
              const armpl_int_t *ldb, armpl_doublecomplex_t *x,
              const armpl_int_t *ldx, double *rcond, double *berr,
              const armpl_int_t *n_err_bnds, double *err_bnds_norm,
              double *err_bnds_comp, const armpl_int_t *nparams,
              double *params, armpl_doublecomplex_t *work, double *rwork,
              armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

EQUED Input parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done to A before calling this routine. This is needed to compute the solution and error bounds correctly. = 'N': No equilibration = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). The right hand side B has been changed accordingly.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by DSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSYTRF.

S Input and output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by DGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is DOUBLE PRECISION

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0D+0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

Related Information

For this routine in other precisions, please see *cherfsx*. It also exists with a native C interface as *LAPACKE_zherfsx*.

4.9.59 zhprfs

zhprfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite and packed, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhprfs(UPLO, N, NRHS, AP, AFP, IPIV, B, LDB, X, LDX, FERR, BERR,
                  WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhprfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *ap,
             const armpl_doublecomplex_t *afp, const armpl_int_t *ipiv,
             const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_doublecomplex_t *x, const armpl_int_t *ldx, double *ferr,
             double *berr, armpl_doublecomplex_t *work, double *rwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

AFP Input parameter.

AFP is COMPLEX*16

AFP is an array, dimension (N*(N+1)/2). The factored form of the matrix A. AFP contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^H or A = L*D*L^H as computed by ZHPTRF, stored as a packed triangular matrix.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZHPTRF.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by ZHPTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *chprfs*. It also exists with a native C interface as *LAPACKE_zhprfs*.

4.9.60 zpbrfs

zpbrfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and banded, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpbrfs(UPLO, N, KD, NRHS, AB, LDAB, AFB, LDAFB, B, LDB, X, LDX,
                  FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zpbrfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_int_t *nrhs, const armpl_doublecomplex_t *ab,
             const armpl_int_t *ldab, const armpl_doublecomplex_t *afb,
             const armpl_int_t *ldafb, const armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *x,
             const armpl_int_t *ldx, double *ferr, double *berr,
             armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). The upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

AFB Input parameter.

AFB is COMPLEX*16

AFB is an array, dimension (LDAFB, N). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the band matrix A as computed by ZPBTRF, in the same storage format as A (see AB).

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= KD+1.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by ZPBTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpbrfs*, *dpbrfs* and *spbrfs*. It also exists with a native C interface as *LAPACKE_zpbrfs*.

4.9.61 zporfs

zporfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine zporfs(UPLO, N, NRHS, A, LDA, AF, LDAF, B, LDB, X, LDX, FERR, BERR,
                  WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zporfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *af, const armpl_int_t *ldaf,
             const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_doublecomplex_t *x, const armpl_int_t *ldx, double *ferr,
```

(continues on next page)

(continued from previous page)

```
                double *berr, armpl_doublecomplex_t *work, double *rwork,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , as computed by ZPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by ZPOTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cporfs*, *dporfs* and *sporfs*. It also exists with a native C interface as *LAPACKE_zporfs*.

4.9.62 zporfsx

```
ZPORFSX improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric positive
   definite, and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED and S
   below. In this case, the solution and error bounds returned are
   for the original unequilibrated system.                          Some optional␣
↪parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zporfsx(UPLO, EQUED, N, NRHS, A, LDA, AF, LDAF, S, B, LDB, X, LDX,
                   RCOND, BERR, N_ERR_BNDS, ERR_BNDS_NORM, ERR_BNDS_COMP,
                   NPARAMS, PARAMS, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zporfsx_(const char *uplo, const char *equed, const armpl_int_t *n,
              const armpl_int_t *nrhs, const armpl_doublecomplex_t *a,
              const armpl_int_t *lda, const armpl_doublecomplex_t *af,
              const armpl_int_t *ldaf, const double *s,
              const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
              armpl_doublecomplex_t *x, const armpl_int_t *ldx, double *rcond,
              double *berr, const armpl_int_t *n_err_bnds,
              double *err_bnds_norm, double *err_bnds_comp,
              const armpl_int_t *nparams, double *params,
              armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
              ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

EQUED Input parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done to A before calling this routine. This is needed to compute the solution and error bounds correctly. = 'N': No equilibration = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). The right hand side B has been changed accordingly.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by DPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

S Input and output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The row scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by DGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is DOUBLE PRECISION

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0D+0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

Related Information

4.9.63 zpprfs

zpprfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and packed, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpprfs(UPLO, N, NRHS, AP, AFP, B, LDB, X, LDX, FERR, BERR, WORK,
                  RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zpprfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *ap,
             const armpl_doublecomplex_t *afp, const armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *x,
             const armpl_int_t *ldx, double *ferr, double *berr,
             armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

AFP Input parameter.

AFP is COMPLEX*16

AFP is an array, dimension (N*(N+1)/2). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , as computed by DPPTRF/ZPPTRF, packed columnwise in a linear array in the same format as A (see AP).

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by ZPPTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpprfs*, *dpprfs* and *spprfs*. It also exists with a native C interface as *LAPACKE_zpprfs*.

4.9.64 zptrfs

zptrfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine zptrfs(UPLO, N, NRHS, D, E, DF, EF, B, LDB, X, LDX, FERR, BERR,
                  WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zptrfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const double *d, const armpl_doublecomplex_t *e,
             const double *df, const armpl_doublecomplex_t *ef,
             const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_doublecomplex_t *x, const armpl_int_t *ldx, double *ferr,
             double *berr, armpl_doublecomplex_t *work, double *rwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and the form of the factorization: = 'U': E is the superdiagonal of A, and A = U^H *D*U; = 'L': E is the subdiagonal of A, and A = L*D*L^H . (The two forms are equivalent if A is real.)

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n real diagonal elements of the tridiagonal matrix A.

E Input parameter.

E is COMPLEX*16

E is an array, dimension (N-1). The (n-1) off-diagonal elements of the tridiagonal matrix A (see UPLO).

DF Input parameter.

DF is DOUBLE PRECISION

DF is an array, dimension (N). The n diagonal elements of the diagonal matrix D from the factorization computed by ZPTTRF.

EF Input parameter.

EF is COMPLEX*16

EF is an array, dimension (N-1). The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by ZPTTRF (see UPLO).

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by ZPTTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j).

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cptrfs*, *dptrfs* and *sptrfs*. It also exists with a native C interface as *LAPACKE_zptrfs*.

4.9.65 zsprfs

zsprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsprfs(UPLO, N, NRHS, AP, AFP, IPIV, B, LDB, X, LDX, FERR, BERR,
                  WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsprfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *ap,
             const armpl_doublecomplex_t *afp, const armpl_int_t *ipiv,
             const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_doublecomplex_t *x, const armpl_int_t *ldx, double *ferr,
             double *berr, armpl_doublecomplex_t *work, double *rwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

AFP Input parameter.

AFP is COMPLEX*16

AFP is an array, dimension (N*(N+1)/2). The factored form of the matrix A. AFP contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by ZSPTRF, stored as a packed triangular matrix.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSPTRF.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by ZSPTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csprfs*, *dsprfs* and *ssprfs*. It also exists with a native C interface as *LAPACKE_zsprfs*.

4.9.66 zsyrfs

zsyrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsyrfs(UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X, LDX, FERR,
                  BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsyrfs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *af, const armpl_int_t *ldaf,
             const armpl_int_t *ipiv, const armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *x,
             const armpl_int_t *ldx, double *ferr, double *berr,
             armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by ZSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSYTRF.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by ZSYTRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csyrfs*, *dsyrfs* and *ssyrfs*. It also exists with a native C interface as *LAPACKE_zsyrfs*.

4.9.67 zsyrfsx

```
ZSYRFSX improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric indefinite, and
   provides error bounds and backward error estimates for the
   solution.  In addition to normwise error bound, the code provides
   maximum componentwise error bound if possible.  See comments for
   ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED and S
   below. In this case, the solution and error bounds returned are
   for the original unequilibrated system.                    Some optional␣
↪parameters are bundled in the PARAMS array.  These
    settings determine how refinement is performed, but often the
    defaults are acceptable.  If the defaults are acceptable, users
    can pass NPARAMS = 0 which prevents the source code from accessing
    the PARAMS argument.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zsyrfsx(UPLO, EQUED, N, NRHS, A, LDA, AF, LDAF, IPIV, S, B, LDB, X,
                   LDX, RCOND, BERR, N_ERR_BNDS, ERR_BNDS_NORM, ERR_BNDS_COMP,
                   NPARAMS, PARAMS, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsyrfsx_(const char *uplo, const char *equed, const armpl_int_t *n,
              const armpl_int_t *nrhs, const armpl_doublecomplex_t *a,
              const armpl_int_t *lda, const armpl_doublecomplex_t *af,
              const armpl_int_t *ldaf, const armpl_int_t *ipiv,
              const double *s, const armpl_doublecomplex_t *b,
              const armpl_int_t *ldb, armpl_doublecomplex_t *x,
              const armpl_int_t *ldx, double *rcond, double *berr,
              const armpl_int_t *n_err_bnds, double *err_bnds_norm,
              double *err_bnds_comp, const armpl_int_t *nparams,
              double *params, armpl_doublecomplex_t *work, double *rwork,
              armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

EQUED Input parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done to A before calling this routine. This is needed to compute the solution and error bounds correctly. = 'N': No equilibration = 'Y': Both row and column equilibration, i.e., A has been replaced by diag(S) * A * diag(S). The right hand side B has been changed accordingly.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U^T or A = L*D*L^T as computed by DSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSYTRF.

S Input and output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A. If EQUED = 'Y', A is multiplied on the left and right by diag(S). S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive. If S is output, each element of S is a power of the radix. If S is input, each element of S should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). On entry, the solution matrix X, as computed by DGETRS. On exit, the improved solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). Componentwise relative backward error. This is the componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

N_ERR_BNDS Input parameter.

N_ERR_BNDS is INTEGER

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See ERR_BNDS_NORM and ERR_BNDS_COMP below.

ERR_BNDS_NORM Output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:, N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * dlamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * dlamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

NPARAMS Input parameter.

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS Input and output parameter.

PARAMS is DOUBLE PRECISION

PARAMS is an array, dimension NPARAMS. Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative refinement or not. Default: 1.0D+0 = 0.0 : No refinement is performed, and no error bounds are computed. = 1.0 : Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (other values are reserved for future use)

PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual computations allowed for refinement. Default: 10 Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code will attempt to find a solution with small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence)

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. The solution to every right-hand side is guaranteed. < 0: If INFO = -i, the i-th argument had an illegal value > 0 and <= N: U(INFO, INFO) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+J: The solution corresponding to the Jth right-hand side is not guaranteed. The solutions corresponding to other right- hand sides K with K > J may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested (PARAMS(3) = 0.0) then the Jth right-hand side is the first with a normwise error bound that is not guaranteed (the smallest J such that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0) the Jth right-hand side is the first with either a normwise or componentwise error bound that is not guaranteed (the smallest J such that either ERR_BNDS_NORM(J,1) = 0.0 or ERR_BNDS_COMP(J,1) = 0.0). See the definition of ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

Related Information

4.9.68 ztbrfs

ztbrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix.

The solution matrix X must be computed by ZTBTRS or some other means before entering this routine. ztbrfs does not do iterative refinement because doing so cannot improve the backward error.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztbrfs(UPLO, TRANS, DIAG, N, KD, NRHS, AB, LDAB, B, LDB, X, LDX,
                  FERR, BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ztbrfs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_int_t *nrhs, const armpl_doublecomplex_t *ab,
             const armpl_int_t *ldab, const armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, const armpl_doublecomplex_t *x,
             const armpl_int_t *ldx, double *ferr, double *berr,
             armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals or subdiagonals of the triangular band matrix A. KD >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first kd+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). The solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctbrfs*, *dtbrfs* and *stbrfs*. It also exists with a native C interface as *LAPACKE_ztbrfs*.

4.9.69 ztprfs

ztprfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix.

The solution matrix X must be computed by ZTPTRS or some other means before entering this routine. ztprfs does not do iterative refinement because doing so cannot improve the backward error.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztprfs(UPLO, TRANS, DIAG, N, NRHS, AP, B, LDB, X, LDX, FERR, BERR,
                  WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ztprfs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *ap, const armpl_doublecomplex_t *b,
```

(continues on next page)

(continued from previous page)

```
            const armpl_int_t *ldb, const armpl_doublecomplex_t *x,
            const armpl_int_t *ldx, double *ferr, double *berr,
            armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
            ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). The solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctprfs*, *dtprfs* and *stprfs*. It also exists with a native C interface as *LAPACKE_ztprfs*.

4.9.70 ztrrfs

ztrrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix.

The solution matrix X must be computed by ZTRTRS or some other means before entering this routine. ztrrfs does not do iterative refinement because doing so cannot improve the backward error.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztrrfs(UPLO, TRANS, DIAG, N, NRHS, A, LDA, B, LDB, X, LDX, FERR,
                  BERR, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ztrrfs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
```

(continues on next page)

(continued from previous page)

```
                const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
                const armpl_doublecomplex_t *x, const armpl_int_t *ldx,
                double *ferr, double *berr, armpl_doublecomplex_t *work,
                double *rwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right hand side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

X Input parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). The solution matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N).

FERR Output parameter.

FERR is DOUBLE PRECISION

FERR is an array, dimension (NRHS). The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrrfs*, *dtrrfs* and *strrfs*. It also exists with a native C interface as *LAPACKE_ztrrfs*.

4.10 LAPACK singular value decompositions routines

4.10.1 cbdsqr

cbdsqr computes the singular values and, optionally, the right and/or left singular vectors from the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B using the implicit zero-shift QR algorithm. The SVD of B has the form

```
B = Q * S * P**H
```

where S is the diagonal matrix of singular values, Q is an orthogonal matrix of left singular vectors, and P is an orthogonal matrix of right singular vectors. If left singular vectors are requested, this subroutine actually returns U*Q instead of Q, and, if right singular vectors are requested, this subroutine returns P^H *VT instead of P^H , for given complex input matrices U and VT. When U and VT are the unitary matrices that reduce a general matrix A to bidiagonal form: A = U*B*VT, as computed by CGEBRD, then

```
A = (U*Q) * S * (P**H*VT)
```

is the SVD of A. Optionally, the subroutine may also compute Q^H *C for a given complex input matrix C.

See "Computing Small Singular Values of Bidiagonal Matrices With Guaranteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Working Note #3 (or SIAM J. Sci. Statist. Comput. vol. 11, no. 5, pp. 873-912, Sept 1990) and "Accurate singular values and differential qd algorithms," by B. Parlett and V. Fernando, Technical Report CPAM-554, Mathematics Department, University of California at Berkeley, July 1992 for a detailed description of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine cbdsqr(UPLO, N, NCVT, NRU, NCC, D, E, VT, LDVT, U, LDU, C, LDC,
                  RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cbdsqr_(const char *uplo, const armpl_int_t *n, const armpl_int_t *ncvt,
             const armpl_int_t *nru, const armpl_int_t *ncc, float *d,
             float *e, armpl_singlecomplex_t *vt, const armpl_int_t *ldvt,
             armpl_singlecomplex_t *u, const armpl_int_t *ldu,
             armpl_singlecomplex_t *c, const armpl_int_t *ldc, float *rwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': B is upper bidiagonal; = 'L': B is lower bidiagonal.

N Input parameter.

N is INTEGER

The order of the matrix B. N >= 0.

NCVT Input parameter.

NCVT is INTEGER

The number of columns of the matrix VT. NCVT >= 0.

NRU Input parameter.

NRU is INTEGER

The number of rows of the matrix U. NRU >= 0.

NCC Input parameter.

NCC is INTEGER

The number of columns of the matrix C. NCC >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B in decreasing order.

E Input and output parameter.

E is REAL

E is an array, dimension (N-1). On entry, the N-1 offdiagonal elements of the bidiagonal matrix B. On exit, if INFO = 0, E is destroyed; if INFO > 0, D and E will contain the diagonal and superdiagonal elements of a bidiagonal matrix orthogonally equivalent to the one given as input.

VT Input and output parameter.

VT is COMPLEX

VT is an array, dimension (LDVT, NCVT). On entry, an N-by-NCVT matrix VT. On exit, VT is overwritten by P^H * VT. Not referenced if NCVT = 0.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= max(1, N) if NCVT > 0; LDVT >= 1 if NCVT = 0.

U Input and output parameter.

U is COMPLEX

U is an array, dimension (LDU, N). On entry, an NRU-by-N matrix U. On exit, U is overwritten by U * Q. Not referenced if NRU = 0.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= max(1, NRU).

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, NCC). On entry, an N-by-NCC matrix C. On exit, C is overwritten by Q^H * C. Not referenced if NCC = 0.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, N) if NCC > 0; LDC >=1 if NCC = 0.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (4*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: If INFO = -i, the i-th argument had an illegal value > 0: the algorithm did not converge; D and E contain the elements of a bidiagonal matrix which is orthogonally similar to the input matrix B; if INFO = i, i elements of E have not converged to zero.

Related Information

For this routine in other precisions, please see *dbdsqr*, *sbdsqr* and *zbdsqr*. It also exists with a native C interface as *LAPACKE_cbdsqr*.

4.10.2 cgbbrd

`cgbbrd` reduces a complex general m-by-n band matrix A to real upper bidiagonal form B by a unitary transformation: Q^H * A * P = B.

The routine computes B, and optionally forms Q or P^H , or computes Q^H *C for a given matrix C.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgbbrd(VECT, M, N, NCC, KL, KU, AB, LDAB, D, E, Q, LDQ, PT, LDPT,
                  C, LDC, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgbbrd_(const char *vect, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *ncc, const armpl_int_t *kl,
             const armpl_int_t *ku, armpl_singlecomplex_t *ab,
             const armpl_int_t *ldab, float *d, float *e,
             armpl_singlecomplex_t *q, const armpl_int_t *ldq,
             armpl_singlecomplex_t *pt, const armpl_int_t *ldpt,
             armpl_singlecomplex_t *c, const armpl_int_t *ldc,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

VECT Input parameter.

`VECT` is `CHARACTER*1`

Specifies whether or not the matrices `Q` and P^H are to be formed. = 'N': do not form `Q` or P^H ; = 'Q': form `Q` only; = 'P': form P^H only; = 'B': form both.

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix A. `M` >= 0.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix A. `N` >= 0.

NCC Input parameter.

`NCC` is `INTEGER`

The number of columns of the matrix `C`. `NCC` >= 0.

KL Input parameter.

`KL` is `INTEGER`

The number of subdiagonals of the matrix A. `KL` >= 0.

KU Input parameter.

`KU` is `INTEGER`

The number of superdiagonals of the matrix A. KU >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the m-by-n band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl). On exit, A is overwritten by values generated during the reduction.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array A. LDAB >= KL+KU+1.

D Output parameter.

D is REAL

D is an array, dimension (min(M, N)). The diagonal elements of the bidiagonal matrix B.

E Output parameter.

E is REAL

E is an array, dimension (min(M, N)-1). The superdiagonal elements of the bidiagonal matrix B.

Q Output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, M). If VECT = 'Q' or 'B', the m-by-m unitary matrix Q. If VECT = 'N' or 'P', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, M) if VECT = 'Q' or 'B'; LDQ >= 1 otherwise.

PT Output parameter.

PT is COMPLEX

PT is an array, dimension (LDPT, N). If VECT = 'P' or 'B', the n-by-n unitary matrix P'. If VECT = 'N' or 'Q', the array PT is not referenced.

LDPT Input parameter.

LDPT is INTEGER

The leading dimension of the array PT. LDPT >= max(1, N) if VECT = 'P' or 'B'; LDPT >= 1 otherwise.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, NCC). On entry, an m-by-ncc matrix C. On exit, C is overwritten by Q^H *C. C is not referenced if NCC = 0.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M) if NCC > 0; LDC >= 1 if NCC = 0.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (max(M, N)) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (max(M, N)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dgbbrd*, *sgbbrd* and *zgbbrd*. It also exists with a native C interface as *LAPACKE_cgbbrd*.

4.10.3 cgebrd

cgebrd reduces a general complex M-by-N matrix A to upper or lower bidiagonal form B by a unitary transformation: $Q^H * A * P = B$.

If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgebrd(M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgebrd_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda, float *d,
             float *e, armpl_singlecomplex_t *tauq,
             armpl_singlecomplex_t *taup, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows in the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns in the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N general matrix to be reduced. On exit, if m >= n, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors; if m < n, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the

unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Output parameter.

D is REAL

D is an array, dimension (min(M, N)). The diagonal elements of the bidiagonal matrix B: D(i) = A(i,i).

E Output parameter.

E is REAL

E is an array, dimension (min(M, N)-1). The off-diagonal elements of the bidiagonal matrix B: if m >= n, E(i) = A(i,i+1) for i = 1,2,...,n-1; if m < n, E(i) = A(i+1,i) for i = 1,2,...,m-1.

TAUQ Output parameter.

TAUQ is COMPLEX

TAUQ is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the unitary matrix Q. See Further Details.

TAUP Output parameter.

TAUP is COMPLEX

TAUP is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the unitary matrix P. See Further Details.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1, M, N). For optimum performance LWORK >= (M+N)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dgebrd*, *sgebrd* and *zgebrd*. It also exists with a native C interface as *LAPACKE_cgebrd*.

4.10.4 cgejsv

cgejsv computes the singular value decomposition (SVD) of a complex M-by-N matrix [A], where M >= N. The SVD of [A] is written as

```
[A] = [U] * [SIGMA] * [V]^*,
```

where [SIGMA] is an N-by-N (M-by-N) matrix which is zero except for its N diagonal elements, [U] is an M-by-N (or M-by-M) unitary matrix, and [V] is an N-by-N unitary matrix. The diagonal elements of [SIGMA] are the singular values of [A]. The columns of [U] and [V] are the left and the right singular vectors of [A], respectively. The matrices [U] and [V] are computed and stored in the arrays U and V, respectively. The diagonal of [SIGMA] is computed and stored in the array SVA.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgejsv(JOBA, JOBU, JOBV, JOBR, JOBT, JOBP, M, N, A, LDA, SVA, U,
                  LDU, V, LDV, CWORK, LWORK, RWORK, LRWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgejsv_(const char *joba, const char *jobu, const char *jobv,
             const char *jobr, const char *jobt, const char *jobp,
             const armpl_int_t *m, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda, float *sva,
             armpl_singlecomplex_t *u, const armpl_int_t *ldu,
             armpl_singlecomplex_t *v, const armpl_int_t *ldv,
             armpl_singlecomplex_t *cwork, const armpl_int_t *lwork,
             float *rwork, const armpl_int_t *lrwork, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

JOBA Input parameter.

JOBA is CHARACTER*1

Specifies the level of accuracy: = 'C': This option works well (high relative accuracy) if A = B * D, with well-conditioned B and arbitrary diagonal matrix D. The accuracy cannot be spoiled by COLUMN scaling. The accuracy of the computed output depends on the condition of B, and the procedure aims at the best theoretical accuracy. The relative error max_{i=1:N}|d sigma_i| / sigma_i is bounded by f(M, N)*epsilon* cond(B), independent of D. The input matrix is preprocessed with the QRF with column pivoting. This initial preprocessing and preconditioning by a rank revealing QR factorization is common for all values of JOBA. Additional actions are specified as follows: = 'E': Computation as with 'C' with an additional estimate of the condition number of B. It provides a realistic error bound. = 'F': If A = D1 * C * D2 with ill-conditioned diagonal scalings D1, D2, and well-conditioned matrix C, this option gives higher accuracy than the 'C' option. If the structure of the input matrix is not known, and relative accuracy is desirable, then this option is advisable. The input matrix A is preprocessed with QR factorization with FULL (row and column) pivoting. = 'G' Computation as with 'F' with an additional estimate of the condition number of B, where A=B*D. If A has heavily weighted rows, then using this condition number gives too pessimistic error bound. = 'A': Small singular values are not well determined by the data and are considered as noisy; the matrix is treated as numerically rank defficient. The error in the computed singular values is bounded by f(m,n)*epsilon*||A||. The computed SVD A = U * S * V^* restores A up to f(m,n)*epsilon*||A||. This gives the procedure the licence to discard (set to zero) all singular values below N*epsilon*||A||. = 'R': Similar as

in ‘A’. Rank revealing property of the initial QR factorization is used do reveal (using triangular factor) a gap sigma_{r+1} < epsilon * sigma_r in which case the numerical RANK is declared to be r. The SVD is computed with absolute error bounds, but more accurately than with ‘A’.

JOBU Input parameter.

JOBU is CHARACTER*1

Specifies whether to compute the columns of U: = ‘U’: N columns of U are returned in the array U. = ‘F’: full set of M left sing. vectors is returned in the array U. = ‘W’: U may be used as workspace of length M*N. See the description of U. = ‘N’: U is not computed.

JOBV Input parameter.

JOBV is CHARACTER*1

Specifies whether to compute the matrix V: = ‘V’: N columns of V are returned in the array V; Jacobi rotations are not explicitly accumulated. = ‘J’: N columns of V are returned in the array V, but they are computed as the product of Jacobi rotations, if JOBT .EQ. ‘N’. = ‘W’: V may be used as workspace of length N*N. See the description of V. = ‘N’: V is not computed.

JOBR Input parameter.

JOBR is CHARACTER*1

Specifies the RANGE for the singular values. Issues the licence to set to zero small positive singular values if they are outside specified range. If A .NE. 0 is scaled so that the largest singular value of c* A is around SQRT(BIG), BIG=SLAMCH(‘O’), then JOBR issues the licence to kill columns of A whose norm in c* A is less than SQRT(SFMIN) (for JOBR.EQ.’R’), or less than SMALL=SFMIN/EPSLN, where SFMIN=SLAMCH(‘S’), EPSLN=SLAMCH(‘E’). = ‘N’: Do not kill small columns of c*A. This option assumes that BLAS and QR factorizations and triangular solvers are implemented to work in that range. If the condition of A is greater than BIG, use CGESVJ. = ‘R’: RESTRICTED range for sigma(c*A) is [SQRT(SFMIN), SQRT(BIG)] (roughly, as described above). This option is recommended. ========== For computing the singular values in the FULL range [SFMIN,BIG] use CGESVJ.

JOBT Input parameter.

JOBT is CHARACTER*1

If the matrix is square then the procedure may determine to use transposed A if A^* seems to be better with respect to convergence. If the matrix is not square, JOBT is ignored. The decision is based on two values of entropy over the adjoint orbit of A^* * A. See the descriptions of WORK(6) and WORK(7). = ‘T’: transpose if entropy test indicates possibly faster convergence of Jacobi process if A^* is taken as input. If A is replaced with A^*, then the row pivoting is included automatically. = ‘N’: do not speculate. The option ‘T’ can be used to compute only the singular values, or the full SVD (U, SIGMA and V). For only one set of singular vectors (U or V), the caller should provide both U and V, as one of the matrices is used as workspace if the matrix A is transposed. The implementer can easily remove this constraint and make the code more complicated. See the descriptions of U and V. In general, this option is considered experimental, and ‘N’; should be preferred. This is subject to changes in the future.

JOBP Input parameter.

JOBP is CHARACTER*1

Issues the licence to introduce structured perturbations to drown denormalized numbers. This licence should be active if the denormals are poorly implemented, causing slow computation, especially in cases of fast convergence (!). For details see [1,2]. For the sake of simplicity, this perturbations are included only when the full SVD or only the singular values are requested. The implementer/user can easily add the perturbation for the cases of computing one set of singular vectors. = ‘P’: introduce perturbation = ‘N’: do not perturb

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. M >= N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

SVA Output parameter.

SVA is REAL

SVA is an array, dimension (N). On exit, - For WORK(1)/WORK(2) = ONE: The singular values of A. During the computation SVA contains Euclidean column norms of the iterated matrices in the array A. - For WORK(1) .NE. WORK(2): The singular values of A are (WORK(1)/WORK(2)) * SVA(1:N). This factored form is used if sigma_max(A) overflows or if small singular values have been saved from underflow by scaling the input matrix A. - If JOBR='R' then some of the singular values may be returned as exact zeros obtained by "set to zero" because they are below the numerical rank threshold or are denormalized numbers.

U Output parameter.

U is COMPLEX

U is an array, dimension (LDU, N) or (LDU, M). If JOBU = 'U', then U contains on exit the M-by-N matrix of the left singular vectors. If JOBU = 'F', then U contains on exit the M-by-M matrix of the left singular vectors, including an ONB of the orthogonal complement of the Range(A). If JOBU = 'W' .AND. (JOBV.EQ.'V' .AND. JOBT.EQ.'T' .AND. M.EQ.N), then U is used as workspace if the procedure replaces A with A^*. In that case, [V] is computed in U as left singular vectors of A^* and then copied back to the V array. This 'W' option is just a reminder to the caller that in this case U is reserved as workspace of length N*N. If JOBU = 'N' U is not referenced, unless JOBT='T'.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U, LDU >= 1. IF JOBU = 'U' or 'F' or 'W', then LDU >= M.

V Output parameter.

V is COMPLEX

V is an array, dimension (LDV, N). If JOBV = 'V', 'J' then V contains on exit the N-by-N matrix of the right singular vectors; If JOBV = 'W', AND (JOBU.EQ.'U' AND JOBT.EQ.'T' AND M.EQ.N), then V is used as workspace if the pprocedure replaces A with A^*. In that case, [U] is computed in V as right singular vectors of A^* and then copied back to the U array. This 'W' option is just a reminder to the caller that in this case V is reserved as workspace of length N*N. If JOBV = 'N' V is not referenced, unless JOBT='T'.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V, LDV >= 1. If JOBV = 'V' or 'J' or 'W', then LDV >= N.

CWORK Output parameter.

CWORK is COMPLEX

CWORK is an array, dimension (MAX(2, LWORK)). If the call to CGEJSV is a workspace query (indicated by LWORK=-1 or LRWORK=-1), then on exit CWORK(1) contains the required length of CWORK for the job parameters used in the call.

LWORK Input parameter.

LWORK is INTEGER

Length of CWORK to confirm proper allocation of workspace. LWORK depends on the job:

1. If only SIGMA is needed (JOBU.EQ.'N', JOBV.EQ.'N') and 1.1 .. no scaled condition estimate required (JOBA.NE.'E'.AND.JOBA.NE.'G'): LWORK >= 2*N+1. This is the minimal requirement. ->> For optimal performance (blocked code) the optimal value is LWORK >= N + (N+1)*NB. Here NB is the optimal block size for CGEQP3 and CGEQRF. In general, optimal LWORK is computed as LWORK >= max(N+LWORK(CGEQP3),N+LWORK(CGEQRF), LWORK(CGESVJ)). 1.2. .. an estimate of the scaled condition number of A is required (JOBA='E', or 'G'). In this case, LWORK the minimal requirement is LWORK >= N* N + 2*N. ->> For optimal performance (blocked code) the optimal value is LWORK >= max(N+(N+1)*NB, N*N+2*N)=N**2+2*N. In general, the optimal length LWORK is computed as LWORK >= max(N+LWORK(CGEQP3),N+LWORK(CGEQRF), LWORK(CGESVJ), N*N+LWORK(CPOCON)). 2. If SIGMA and the right singular vectors are needed (JOBV.EQ.'V'), (JOBU.EQ.'N') 2.1 .. no scaled condition estimate requested (JOBE.EQ.'N'): -> the minimal requirement is LWORK >= 3*N. -> For optimal performance, LWORK >= max(N+(N+1)*NB, 2*N+N*NB)=2*N+N*NB, where NB is the optimal block size for CGEQP3, CGEQRF, CGELQ, CUNMLQ. In general, the optimal length LWORK is computed as LWORK >= max(N+LWORK(CGEQP3), N+LWORK(CGESVJ), N+LWORK(CGELQF), 2*N+LWORK(CGEQRF), N+LWORK(CUNMLQ)). 2.2 .. an estimate of the scaled condition number of A is required (JOBA='E', or 'G'). -> the minimal requirement is LWORK >= 3*N. -> For optimal performance, LWORK >= max(N+(N+1)*NB, 2*N,2*N+N*NB)=2*N+N*NB, where NB is the optimal block size for CGEQP3, CGEQRF, CGELQ, CUNMLQ. In general, the optimal length LWORK is computed as LWORK >= max(N+LWORK(CGEQP3), LWORK(CPOCON), N+LWORK(CGESVJ), N+LWORK(CGELQF), 2*N+LWORK(CGEQRF), N+LWORK(CUNMLQ)). 3. If SIGMA and the left singular vectors are needed 3.1 .. no scaled condition estimate requested (JOBE.EQ.'N'): -> the minimal requirement is LWORK >= 3*N. -> For optimal performance: if JOBU.EQ.'U' :: LWORK >= max(3*N, N+(N+1)*NB, 2*N+N*NB)=2*N+N*NB, where NB is the optimal block size for CGEQP3, CGEQRF, CUNMQR. In general, the optimal length LWORK is computed as LWORK >= max(N+LWORK(CGEQP3), 2*N+LWORK(CGEQRF), N+LWORK(CUNMQR)). 3.2 .. an estimate of the scaled condition number of A is required (JOBA='E', or 'G'). -> the minimal requirement is LWORK >= 3*N. -> For optimal performance: if JOBU.EQ.'U' :: LWORK >= max(3*N, N+(N+1)*NB, 2*N+N*NB)=2*N+N*NB, where NB is the optimal block size for CGEQP3, CGEQRF, CUNMQR. In general, the optimal length LWORK is computed as LWORK >= max(N+LWORK(CGEQP3),N+LWORK(CPOCON), 2*N+LWORK(CGEQRF), N+LWORK(CUNMQR)).

4. If the full SVD is needed: (JOBU.EQ.'U' or JOBU.EQ.'F') and 4.1. if JOBV.EQ.'V' the minimal requirement is LWORK >= 5*N+2*N*N. 4.2. if JOBV.EQ.'J' the minimal requirement is LWORK >= 4*N+N*N. In both cases, the allocated CWORK can accommodate blocked runs of CGEQP3, CGEQRF, CGELQF, CUNMQR, CUNMLQ.

If the call to CGEJSV is a workspace query (indicated by LWORK=-1 or LRWORK=-1), then on exit CWORK(1) contains the optimal and CWORK(2) contains the minimal length of CWORK for the job parameters used in the call.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (MAX(7, LWORK)). On exit, RWORK(1) = Determines the scaling factor SCALE = RWORK(2) / RWORK(1) such that SCALE*SVA(1:N) are the computed singular values of A. (See the description of SVA().) RWORK(2) = See the description of RWORK(1). RWORK(3) = SCONDA is an estimate for the condition number of column equilibrated A. (If JOBA .EQ. 'E' or 'G') SCONDA is an estimate of SQRT(||(R^* * R)^(-1)||_1). It is computed using SPOCON. It holds N^(-1/4) * SCONDA <= ||R^(-1)||_2 <= N^(1/4) * SCONDA where R is the triangular factor from the QRF of A. However, if R is truncated and the numerical rank is determined to be strictly smaller than N, SCONDA is returned as -1, thus indicating that the smallest singular values might be lost.

If full SVD is needed, the following two condition numbers are useful for the analysis of the algorithm. They are provied for a developer/implementer who is familiar with the details of the method.

RWORK(4) = an estimate of the scaled condition number of the triangular factor in the first QR factorization. RWORK(5) = an estimate of the scaled condition number of the triangular factor in the second QR factorization. The following two parameters are computed if JOBT .EQ. 'T'. They are provided for a developer/implementer who is familiar with the details of the method. RWORK(6) = the entropy of A^* * A :: this is the Shannon entropy of diag(A^* * A) / Trace(A^* * A) taken as point in the probability simplex. RWORK(7) = the entropy of A * A^*. (See the description of RWORK(6).) If the call to CGEJSV is a workspace query (indicated by LWORK=-1 or LRWORK=-1), then on exit RWORK(1) contains the required length of RWORK for the job parameters used in the call.

LRWORK Input parameter.

LRWORK is INTEGER

Length of RWORK to confirm proper allocation of workspace. LRWORK depends on the job:

1. If only the singular values are requested i.e. if LSAME(JOBU,'N') .AND. LSAME(JOBV,'N') then: 1.1. If LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G'), then: LRWORK = max(7, 2 * M). 1.2. Otherwise, LRWORK = max(7, N). 2. If singular values with the right singular vectors are requested i.e. if (LSAME(JOBV,'V').OR.LSAME(JOBV,'J')) .AND. .NOT.(LSAME(JOBU,'U').OR.LSAME(JOBU,'F')) then: 2.1. If LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G'), then LRWORK = max(7, 2 * M). 2.2. Otherwise, LRWORK = max(7, N). 3. If singular values with the left singular vectors are requested, i.e. if (LSAME(JOBU,'U').OR.LSAME(JOBU,'F')) .AND. .NOT.(LSAME(JOBV,'V').OR.LSAME(JOBV,'J')) then: 3.1. If LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G'), then LRWORK = max(7, 2 * M). 3.2. Otherwise, LRWORK = max(7, N). 4. If singular values with both the left and the right singular vectors are requested, i.e. if (LSAME(JOBU,'U').OR.LSAME(JOBU,'F')) .AND. (LSAME(JOBV,'V').OR.LSAME(JOBV,'J')) then: 4.1. If LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G'), then LRWORK = max(7, 2 * M). 4.2. Otherwise, LRWORK = max(7, N).

If, on entry, LRWORK = -1 or LWORK=-1, a workspace query is assumed and the length of RWORK is returned in RWORK(1).

IWORK Output parameter.

IWORK is INTEGER array, of dimension at least 4, that further depends

on the job:

1. If only the singular values are requested then: If (LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G')) then the length of IWORK is N+M; otherwise the length of IWORK is N. 2. If the singular values and the right singular vectors are requested then: If (LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G')) then the length of IWORK is N+M; otherwise the length of IWORK is N. 3. If the singular values and the left singular vectors are requested then: If (LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G')) then the length of IWORK is N+M; otherwise the length of IWORK is N. 4. If the singular values with both the left and the right singular vectors are requested, then: 4.1. If LSAME(JOBV,'J') the length of IWORK is determined as follows: If (LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G')) then the length of IWORK is N+M; otherwise the length of IWORK is N. 4.2. If LSAME(JOBV,'V') the length of IWORK is determined as follows: If (LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G')) then the length of IWORK is 2*N+M; otherwise the length of IWORK is 2*N.

On exit, IWORK(1) = the numerical rank determined after the initial QR factorization with pivoting. See the descriptions of JOBA and JOBR. IWORK(2) = the number of the computed nonzero singular values IWORK(3) = if nonzero, a warning message: If IWORK(3).EQ.1 then some of the column norms of A were denormalized floats. The requested high accuracy is not warranted by the data. IWORK(4) = 1 or -1. If IWORK(4) .EQ. 1, then the procedure used A^* to do the job as specified by the JOB parameters. If the call to CGEJSV is a workspace query (indicated by LWORK .EQ. -1 and LRWORK .EQ. -1), then on exit IWORK(1) contains the required length of IWORK for the job parameters used in the call.

INFO Output parameter.

INFO is INTEGER

< 0 : if INFO = -i, then the i-th argument had an illegal value. = 0 : successful exit; > 0 : CGEJSV did not converge in the maximal allowed number of sweeps. The computed values may be inaccurate.

Related Information

For this routine in other precisions, please see *dgejsv*, *sgejsv* and *zgejsv*. It also exists with a native C interface as *LAPACKE_cgejsv*.

4.10.5 cgesdd

`cgesdd` computes the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors, by using divide-and-conquer method. The SVD is written

```
A = U * SIGMA * conjugate-transpose(V)
```

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M unitary matrix, and V is an N-by-N unitary matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns VT = V^H , not V.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgesdd(JOBZ, M, N, A, LDA, S, U, LDU, VT, LDVT, WORK, LWORK, RWORK,
                  IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgesdd_(const char *jobz, const armpl_int_t *m, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda, float *s,
             armpl_singlecomplex_t *u, const armpl_int_t *ldu,
             armpl_singlecomplex_t *vt, const armpl_int_t *ldvt,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             float *rwork, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

`JOBZ` is `CHARACTER*1`

Specifies options for computing all or part of the matrix U: = 'A': all `M` columns of `U` and all `N` rows of V^H are returned in the arrays `U` and VT; = 'S': the first min(`M`, `N`) columns of `U` and the first min(`M`, `N`) rows of V^H are returned in the arrays U and VT; = 'O': If `M` >= `N`, the first `N` columns of `U` are overwritten in the array `A` and all rows of V^H are returned in the array VT; otherwise, all columns of `U` are returned in the array `U` and the first `M` rows of V^H are overwritten in the array A; = '`N`': no columns of `U` or rows of V^H are computed.

M Input parameter.

`M` is `INTEGER`

The number of rows of the input matrix `A`. `M` >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if JOBZ = 'O', A is overwritten with the first N columns of U (the left singular vectors, stored columnwise) if M >= N; A is overwritten with the first M rows of V^H (the right singular vectors, stored rowwise) otherwise. if JOBZ .ne. 'O', the contents of A are destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

S Output parameter.

S is REAL

S is an array, dimension (min(M, N)). The singular values of A, sorted so that S(i) >= S(i+1).

U Output parameter.

U is COMPLEX

U is an array, dimension (LDU,UCOL). UCOL = M if JOBZ = 'A' or JOBZ = 'O' and M < N; UCOL = min(M, N) if JOBZ = 'S'. If JOBZ = 'A' or JOBZ = 'O' and M < N, U contains the M-by-M unitary matrix U; if JOBZ = 'S', U contains the first min(M, N) columns of U (the left singular vectors, stored columnwise); if JOBZ = 'O' and M >= N, or JOBZ = 'N', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= 1; if JOBZ = 'S' or 'A' or JOBZ = 'O' and M < N, LDU >= M.

VT Output parameter.

VT is COMPLEX

VT is an array, dimension (LDVT, N). If JOBZ = 'A' or JOBZ = 'O' and M >= N, VT contains the N-by-N unitary matrix V^H ; if JOBZ = 'S', VT contains the first min(M, N) rows of V^H (the right singular vectors, stored rowwise); if JOBZ = 'O' and M < N, or JOBZ = 'N', VT is not referenced.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= 1; if JOBZ = 'A' or JOBZ = 'O' and M >= N, LDVT >= N; if JOBZ = 'S', LDVT >= min(M, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 1. If LWORK = -1, a workspace query is assumed. The optimal size for the WORK array is calculated and stored in WORK(1), and no other work except argument checking is performed.

Let mx = max(M, N) and mn = min(M, N). If JOBZ = 'N', LWORK >= 2*mn + mx. If JOBZ = 'O', LWORK >= 2*mn*mn + 2*mn + mx. If JOBZ = 'S', LWORK >= mn*mn + 3*mn. If JOBZ = 'A', LWORK >= mn*mn + 2*mn + mx. These are not tight minimums in all cases; see comments inside code. For good performance, LWORK should generally be larger; a query is recommended.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (MAX(1,LRWORK)). Let mx = max(M, N) and mn = min(M, N). If JOBZ = 'N', LRWORK >= 5*mn (LAPACK <= 3.6 needs 7*mn); else if mx >> mn, LRWORK >= 5*mn*mn + 5*mn; else LRWORK >= max(5*mn*mn + 5*mn, 2*mx*mn + 2*mn*mn + mn).

IWORK Output parameter.

IWORK is INTEGER array, dimension (8*min(M, N))

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: The updating process of SBDSDC did not converge.

Related Information

4.10.6 cgesvd

cgesvd computes the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors. The SVD is written

```
A = U * SIGMA * conjugate-transpose(V)
```

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M unitary matrix, and V is an N-by-N unitary matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns V^H , not V.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgesvd(JOBU, JOBVT, M, N, A, LDA, S, U, LDU, VT, LDVT, WORK, LWORK,
                  RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgesvd_(const char *jobu, const char *jobvt, const armpl_int_t *m,
             const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, float *s, armpl_singlecomplex_t *u,
             const armpl_int_t *ldu, armpl_singlecomplex_t *vt,
             const armpl_int_t *ldvt, armpl_singlecomplex_t *work,
```

(continues on next page)

(continued from previous page)

```
            const armpl_int_t *lwork, float *rwork, armpl_int_t *info,
            ... );
```

Parameters

JOBU Input parameter.

JOBU is CHARACTER*1

Specifies options for computing all or part of the matrix U: = 'A': all M columns of U are returned in array U: = 'S': the first min(m,n) columns of U (the left singular vectors) are returned in the array U; = 'O': the first min(m,n) columns of U (the left singular vectors) are overwritten on the array A; = 'N': no columns of U (no left singular vectors) are computed.

JOBVT Input parameter.

JOBVT is CHARACTER*1

Specifies options for computing all or part of the matrix V^H : = 'A': all N rows of V^H are returned in the array VT; = 'S': the first min(m,n) rows of V^H (the right singular vectors) are returned in the array VT; = 'O': the first min(m,n) rows of V^H (the right singular vectors) are overwritten on the array A; = 'N': no rows of V^H (no right singular vectors) are computed.

JOBVT and JOBU cannot both be 'O'.

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if JOBU = 'O', A is overwritten with the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBVT = 'O', A is overwritten with the first min(m,n) rows of V^H (the right singular vectors, stored rowwise); if JOBU .ne. 'O' and JOBVT .ne. 'O', the contents of A are destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

S Output parameter.

S is REAL

S is an array, dimension (min(M, N)). The singular values of A, sorted so that S(i) >= S(i+1).

U Output parameter.

U is COMPLEX

U is an array, dimension (LDU,UCOL). (LDU, M) if JOBU = 'A' or (LDU,min(M, N)) if JOBU = 'S'. If JOBU = 'A', U contains the M-by-M unitary matrix U; if JOBU = 'S', U contains the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBU = 'N' or 'O', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= 1; if JOBU = 'S' or 'A', LDU >= M.

VT Output parameter.

VT is COMPLEX

VT is an array, dimension (LDVT, N). If JOBVT = 'A', VT contains the N-by-N unitary matrix V^H ; if JOBVT = 'S', VT contains the first min(m,n) rows of V^H (the right singular vectors, stored rowwise); if JOBVT = 'N' or 'O', VT is not referenced.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= 1; if JOBVT = 'A', LDVT >= N; if JOBVT = 'S', LDVT >= min(M, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= MAX(1,2*MIN(M, N)+MAX(M, N)). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (5*min(M, N)). On exit, if INFO > 0, RWORK(1:MIN(M, N)-1) contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in S (not necessarily sorted). B satisfies A = U * B * VT, so it has the same singular values as A, and singular vectors related by U and VT.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if CBDSQR did not converge, INFO specifies how many superdiagonals of an intermediate bidiagonal form B did not converge to zero. See the description of RWORK above for details.

4.10.7 cgesvdx

```
CGESVDX computes the singular value decomposition (SVD) of a complex
 M-by-N matrix A, optionally computing the left and/or right singular
 vectors. The SVD is written

     A = U * SIGMA * transpose(V)

 where SIGMA is an M-by-N matrix which is zero except for its
 min(m,n) diagonal elements, U is an M-by-M unitary matrix, and
 V is an N-by-N unitary matrix.  The diagonal elements of SIGMA
 are the singular values of A; they are real and non-negative, and
 are returned in descending order.  The first min(m,n) columns of
 U and V are the left and right singular vectors of A.

 CGESVDX uses an eigenvalue problem for obtaining the SVD, which
 allows for the computation of a subset of singular values and
 vectors. See SBDSVDX for details.

 Note that the routine returns V**T, not V.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cgesvdx(JOBU, JOBVT, RANGE, M, N, A, LDA, VL, VU, IL, IU, NS, S, U,
                   LDU, VT, LDVT, WORK, LWORK, RWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgesvdx_(const char *jobu, const char *jobvt, const char *range,
              const armpl_int_t *m, const armpl_int_t *n,
              armpl_singlecomplex_t *a, const armpl_int_t *lda,
              const float *vl, const float *vu, const armpl_int_t *il,
              const armpl_int_t *iu, armpl_int_t *ns, float *s,
              armpl_singlecomplex_t *u, const armpl_int_t *ldu,
              armpl_singlecomplex_t *vt, const armpl_int_t *ldvt,
              armpl_singlecomplex_t *work, const armpl_int_t *lwork,
              float *rwork, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

JOBU Input parameter.

JOBU is CHARACTER*1

Specifies options for computing all or part of the matrix U: = 'V': the first min(m,n) columns of U (the left singular vectors) or as specified by RANGE are returned in the array U; = 'N': no columns of U (no left singular vectors) are computed.

JOBVT Input parameter.

JOBVT is CHARACTER*1

Specifies options for computing all or part of the matrix V^T : = 'V': the first min(m,n) rows of V^T (the right singular vectors) or as specified by RANGE are returned in the array VT; = 'N': no rows of V^T (no right singular vectors) are computed.

RANGE Input parameter.

RANGE is CHARACTER*1

= ‘A’: all singular values will be found. = ‘V’: all singular values in the half-open interval (VL,VU] will be found. = ‘I’: the IL-th through IU-th singular values will be found.

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the contents of A are destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

VL Input parameter.

VL is REAL

If RANGE=’V’, the lower bound of the interval to be searched for singular values. VU > VL. Not referenced if RANGE = ‘A’ or ‘I’.

VU Input parameter.

VU is REAL

If RANGE=’V’, the upper bound of the interval to be searched for singular values. VU > VL. Not referenced if RANGE = ‘A’ or ‘I’.

IL Input parameter.

IL is INTEGER

If RANGE=’I’, the index of the smallest singular value to be returned. 1 <= IL <= IU <= min(M, N), if min(M, N) > 0. Not referenced if RANGE = ‘A’ or ‘V’.

IU Input parameter.

IU is INTEGER

If RANGE=’I’, the index of the largest singular value to be returned. 1 <= IL <= IU <= min(M, N), if min(M, N) > 0. Not referenced if RANGE = ‘A’ or ‘V’.

NS Output parameter.

NS is INTEGER

The total number of singular values found, 0 <= NS <= min(M, N). If RANGE = ‘A’, NS = min(M, N); if RANGE = ‘I’, NS = IU-IL+1.

S Output parameter.

S is REAL

S is an array, dimension (min(M, N)). The singular values of A, sorted so that S(i) >= S(i+1).

U Output parameter.

U is COMPLEX

U is an array, dimension (LDU,UCOL). If JOBU = 'V', U contains columns of U (the left singular vectors, stored columnwise) as specified by RANGE; if JOBU = 'N', U is not referenced. Note: The user must ensure that UCOL >= NS; if RANGE = 'V', the exact value of NS is not known in advance and an upper bound must be used.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= 1; if JOBU = 'V', LDU >= M.

VT Output parameter.

VT is COMPLEX

VT is an array, dimension (LDVT, N). If JOBVT = 'V', VT contains the rows of V^T (the right singular vectors, stored rowwise) as specified by RANGE; if JOBVT = 'N', VT is not referenced. Note: The user must ensure that LDVT >= NS; if RANGE = 'V', the exact value of NS is not known in advance and an upper bound must be used.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= 1; if JOBVT = 'V', LDVT >= NS (see above).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK;

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= MAX(1,MIN(M, N)*(MIN(M, N)+4)) for the paths (see comments inside the code): - PATH 1 (M much larger than N) - PATH 1t (N much larger than M) LWORK >= MAX(1,MIN(M, N)*2+MAX(M, N)) for the other paths. For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (MAX(1,LRWORK)). LRWORK >= MIN(M, N)*(MIN(M, N)*2+15*MIN(M, N)).

IWORK Output parameter.

IWORK is INTEGER array, dimension (12*MIN(M, N))

If INFO = 0, the first NS elements of IWORK are zero. If INFO > 0, then IWORK contains the indices of the eigenvectors that failed to converge in SBDSVDX/SSTEVX.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge in SBDSVDX/SSTEVX. if INFO = N*2 + 1, an internal error occurred in SBDSVDX

Related Information

For this routine in other precisions, please see *dgesvdx*, *sgesvdx* and *zgesvdx*. It also exists with a native C interface as *LAPACKE_cgesvdx*.

4.10.8 cgesvj

`cgesvj` computes the singular value decomposition (SVD) of a complex M-by-N matrix A, where M >= N. The SVD of A is written as

```
                            [++]   [xx]   [x0]   [xx]
A = U * SIGMA * V^*,  [++] = [xx] * [ox] * [xx]
                            [++]   [xx]
```

where SIGMA is an N-by-N diagonal matrix, U is an M-by-N orthonormal matrix, and V is an N-by-N unitary matrix. The diagonal elements of SIGMA are the singular values of A. The columns of U and V are the left and the right singular vectors of A, respectively.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgesvj(JOBA, JOBU, JOBV, M, N, A, LDA, SVA, MV, V, LDV, CWORK,
                  LWORK, RWORK, LRWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgesvj_(const char *joba, const char *jobu, const char *jobv,
             const armpl_int_t *m, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda, float *sva,
             const armpl_int_t *mv, armpl_singlecomplex_t *v,
             const armpl_int_t *ldv, armpl_singlecomplex_t *cwork,
             const armpl_int_t *lwork, float *rwork,
             const armpl_int_t *lrwork, armpl_int_t *info, ... );
```

Parameters

JOBA Input parameter.

JOBA is CHARACTER*1

Specifies the structure of A. = 'L': The input matrix A is lower triangular; = 'U': The input matrix A is upper triangular; = 'G': The input matrix A is general M-by-N matrix, M >= N.

JOBU Input parameter.

JOBU is CHARACTER*1

Specifies whether to compute the left singular vectors (columns of U): = 'U' or 'F': The left singular vectors corresponding to the nonzero singular values are computed and returned in the leading columns of A. See more details in the description of A. The default numerical orthogonality threshold is set to approximately TOL=CTOL*EPS, CTOL=SQRT(M), EPS=SLAMCH('E'). = 'C': Analogous to JOBU='U', except that user can control the level of numerical orthogonality of the computed left singular vectors. TOL can be set to TOL = CTOL*EPS, where CTOL is given on input in the array WORK. No CTOL smaller than ONE is allowed. CTOL greater than 1 / EPS is meaningless. The option 'C' can be used if M*EPS is satisfactory orthogonality of the computed left singular vectors, so CTOL=M could save few sweeps of Jacobi rotations.

See the descriptions of A and WORK(1). = 'N': The matrix U is not computed. However, see the description of A.

JOBV Input parameter.

JOBV is CHARACTER*1

Specifies whether to compute the right singular vectors, that is, the matrix V: = 'V' or 'J': the matrix V is computed and returned in the array V = 'A' : the Jacobi rotations are applied to the MV-by-N array V. In other words, the right singular vector matrix V is not computed explicitly; instead it is applied to an MV-by-N matrix initially stored in the first MV rows of V. = 'N' : the matrix V is not computed and the array V is not referenced

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. 1/SLAMCH('E') > M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. M >= N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, If JOBU .EQ. 'U' .OR. JOBU .EQ. 'C': If INFO .EQ. 0 : RANKA orthonormal columns of U are returned in the leading RANKA columns of the array A. Here RANKA <= N is the number of computed singular values of A that are above the underflow threshold SLAMCH('S'). The singular vectors corresponding to underflowed or zero singular values are not computed. The value of RANKA is returned in the array RWORK as RANKA=NINT(RWORK(2)). Also see the descriptions of SVA and RWORK. The computed columns of U are mutually numerically orthogonal up to approximately TOL=SQRT(M)*EPS (default); or TOL=CTOL*EPS (JOBU.EQ.'C'), see the description of JOBU. If INFO .GT. 0, the procedure CGESVJ did not converge in the given number of iterations (sweeps). In that case, the computed columns of U may not be orthogonal up to TOL. The output U (stored in A), SIGMA (given by the computed singular values in SVA(1:N)) and V is still a decomposition of the input matrix A in the sense that the residual || A - SCALE * U * SIGMA * V^* ||_2 / ||A||_2 is small. If JOBU .EQ. 'N': If INFO .EQ. 0 : Note that the left singular vectors are 'for free' in the one-sided Jacobi SVD algorithm. However, if only the singular values are needed, the level of numerical orthogonality of U is not an issue and iterations are stopped when the columns of the iterated matrix are numerically orthogonal up to approximately M*EPS. Thus, on exit, A contains the columns of U scaled with the corresponding singular values. If INFO .GT. 0 : the procedure CGESVJ did not converge in the given number of iterations (sweeps).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

SVA Output parameter.

SVA is REAL

SVA is an array, dimension (N). On exit, If INFO .EQ. 0 : depending on the value SCALE = RWORK(1), we have: If SCALE .EQ. ONE: SVA(1:N) contains the computed singular values of A. During the computation SVA contains the Euclidean column norms of the iterated matrices in the array A. If SCALE .NE. ONE: The singular values of A are SCALE*SVA(1:N), and this factored representation is due to the fact that some of the singular values of A might underflow or overflow.

If INFO .GT. 0 : the procedure CGESVJ did not converge in the given number of iterations (sweeps) and SCALE*SVA(1:N) may not be accurate.

MV Input parameter.

MV is INTEGER

If JOBV .EQ. 'A', then the product of Jacobi rotations in CGESVJ is applied to the first MV rows of V. See the description of JOBV.

V Input and output parameter.

V is COMPLEX

V is an array, dimension (LDV, N). If JOBV = 'V', then V contains on exit the N-by-N matrix of the right singular vectors; If JOBV = 'A', then V contains the product of the computed right singular vector matrix and the initial matrix in the array V. If JOBV = 'N', then V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V, LDV .GE. 1. If JOBV .EQ. 'V', then LDV .GE. max(1, N). If JOBV .EQ. 'A', then LDV .GE. max(1, MV) .

CWORK Input and output parameter.

CWORK is COMPLEX

CWORK is an array, dimension (max(1, LWORK)). Used as workspace. If on entry LWORK .EQ. -1, then a workspace query is assumed and no computation is done; CWORK(1) is set to the minial (and optimal) length of CWORK.

LWORK Input parameter.

LWORK is INTEGER.

Length of CWORK, LWORK >= M+N.

RWORK Input and output parameter.

RWORK is REAL

RWORK is an array, dimension (max(6, LRWORK)). On entry, If JOBU .EQ. 'C' : RWORK(1) = CTOL, where CTOL defines the threshold for convergence. The process stops if all columns of A are mutually orthogonal up to CTOL*EPS, EPS=SLAMCH('E'). It is required that CTOL >= ONE, i.e. it is not allowed to force the routine to obtain orthogonality below EPSILON. On exit, RWORK(1) = SCALE is the scaling factor such that SCALE*SVA(1:N) are the computed singular values of A. (See description of SVA().) RWORK(2) = NINT(RWORK(2)) is the number of the computed nonzero singular values. RWORK(3) = NINT(RWORK(3)) is the number of the computed singular values that are larger than the underflow threshold. RWORK(4) = NINT(RWORK(4)) is the number of sweeps of Jacobi rotations needed for numerical convergence. RWORK(5) = max_{i.NE.j} |COS(A(:,i),A(:,j))| in the last sweep. This is useful information in cases when CGESVJ did not converge, as it can be used to estimate whether the output is stil useful and for post festum analysis. RWORK(6) = the largest absolute value over all sines of the Jacobi rotation angles in the last sweep. It can be useful for a post festum analysis. If on entry LRWORK .EQ. -1, then a workspace query is assumed and no computation is done; RWORK(1) is set to the minial (and optimal) length of RWORK.

LRWORK Input parameter.

LRWORK is INTEGER

Length of RWORK, LRWORK >= MAX(6, N).

INFO Output parameter.

INFO is INTEGER

= 0 : successful exit. < 0 : if INFO = -i, then the i-th argument had an illegal value > 0 : CGESVJ did not converge in the maximal allowed number (NSWEEP=30) of sweeps. The output may still be useful. See the description of RWORK.

Related Information

For this routine in other precisions, please see *dgesvj*, *sgesvj* and *zgesvj*. It also exists with a native C interface as *LAPACKE_cgesvj*.

4.10.9 cggsvd3

`cggsvd3` computes the generalized singular value decomposition (GSVD) of an M-by-N complex matrix A and P-by-N complex matrix B:

```
U**H*A*Q = D1*( 0 R ),    V**H*B*Q = D2*( 0 R )
```

where U, V and Q are unitary matrices. Let K+L = the effective numerical rank of the matrix $(A^H, B^H)^H$, then R is a (K+L)-by-(K+L) nonsingular upper triangular matrix, D1 and D2 are M-by-(K+L) and P-by-(K+L) "diagonal" matrices and of the following structures, respectively:

If M-K-L >= 0,

```
                  K  L
     D1 =     K ( I  0 )
              L ( 0  C )
          M-K-L ( 0  0 )

                 K  L
     D2 =   L ( 0  S )
          P-L ( 0  0 )

                N-K-L  K    L
( 0 R ) = K (  0   R11  R12 )
          L (  0    0   R22 )
```

where

```
C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),
S = diag( BETA(K+1),  ... , BETA(K+L) ),
C**2 + S**2 = I.

R is stored in A(1:K+L,N-K-L+1:N) on exit.
```

If M-K-L < 0,

```
                 K M-K K+L-M
     D1 =   K ( I  0    0   )
          M-K ( 0  C    0   )

                   K M-K K+L-M
     D2 =   M-K ( 0  S    0  )
          K+L-M ( 0  0    I  )
            P-L ( 0  0    0  )

                  N-K-L  K   M-K  K+L-M
( 0 R ) =     K ( 0    R11  R12  R13  )
            M-K ( 0     0   R22  R23  )
          K+L-M ( 0     0    0   R33  )
```

where

```
C = diag( ALPHA(K+1), ... , ALPHA(M) ),
S = diag( BETA(K+1),  ... , BETA(M) ),
C**2 + S**2 = I.
```

(continues on next page)

(continued from previous page)

```
(R11 R12 R13 ) is stored in A(1:M, N-K-L+1:N), and R33 is stored
( 0  R22 R23 )
in B(M-K+1:L,N+M-K-L+1:N) on exit.
```

The routine computes C, S, R, and optionally the unitary transformation matrices U, V and Q.

In particular, if B is an N-by-N nonsingular matrix, then the GSVD of A and B implicitly gives the SVD of A*inv(B):

```
A*inv(B) = U*(D1*inv(D2))*V**H.
```

If (A^H ,B^H)^H has orthonormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and B. Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

```
A**H*A x = lambda* B**H*B x.
```

In some literature, the GSVD of A and B is presented in the form

```
U**H*A*X = ( 0 D1 ),   V**H*B*X = ( 0 D2 )
```

where U and V are orthogonal and X is nonsingular, and D1 and D2 are ‘’diagonal’‘. The former GSVD form can be converted to the latter form by taking the nonsingular matrix X as

```
X = Q*(  I   0    )
      (  0 inv(R) )
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cggsvd3(JOBU, JOBV, JOBQ, M, N, P, K, L, A, LDA, B, LDB, ALPHA,
                   BETA, U, LDU, V, LDV, Q, LDQ, WORK, LWORK, RWORK, IWORK,
                   INFO)
```

C specification:

```
#include "armpl.h"

void cggsvd3_(const char *jobu, const char *jobv, const char *jobq,
              const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *p, armpl_int_t *k, armpl_int_t *l,
              armpl_singlecomplex_t *a, const armpl_int_t *lda,
              armpl_singlecomplex_t *b, const armpl_int_t *ldb, float *alpha,
              float *beta, armpl_singlecomplex_t *u, const armpl_int_t *ldu,
              armpl_singlecomplex_t *v, const armpl_int_t *ldv,
              armpl_singlecomplex_t *q, const armpl_int_t *ldq,
              armpl_singlecomplex_t *work, const armpl_int_t *lwork,
              float *rwork, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

JOBU Input parameter.

JOBU is CHARACTER*1

= ‘U’: Unitary matrix U is computed; = ‘N’: U is not computed.

JOBV Input parameter.

JOBV is CHARACTER*1

= 'V': Unitary matrix V is computed; = 'N': V is not computed.

JOBQ Input parameter.

JOBQ is CHARACTER*1

= 'Q': Unitary matrix Q is computed; = 'N': Q is not computed.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. P >= 0.

K Output parameter.

K is INTEGER

L Output parameter.

L is INTEGER

On exit, K and L specify the dimension of the subblocks described in Purpose. K + L = effective numerical rank of $(A^H, B^H)^H$.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A contains the triangular matrix R, or part of R. See Purpose for details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, B contains part of the triangular matrix R if M-K-L < 0. See Purpose for details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

ALPHA Output parameter.

ALPHA is REAL

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is REAL

BETA is an array, dimension (N). On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; ALPHA(1:K) = 1, BETA(1:K) = 0, and if M-K-L >= 0, ALPHA(K+1:K+L) = C, BETA(K+1:K+L) = S, or if M-K-L < 0, ALPHA(K+1:M)=C, ALPHA(M+1:K+L)=0 BETA(K+1:M) =S, BETA(M+1:K+L) =1 and ALPHA(K+L+1:N) = 0 BETA(K+L+1:N) = 0

U Output parameter.

U is COMPLEX

U is an array, dimension (LDU, M). If JOBU = 'U', U contains the M-by-M unitary matrix U. If JOBU = 'N', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= max(1, M) if JOBU = 'U'; LDU >= 1 otherwise.

V Output parameter.

V is COMPLEX

V is an array, dimension (LDV, P). If JOBV = 'V', V contains the P-by-P unitary matrix V. If JOBV = 'N', V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, P) if JOBV = 'V'; LDV >= 1 otherwise.

Q Output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, N). If JOBQ = 'Q', Q contains the N-by-N unitary matrix Q. If JOBQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

On exit, IWORK stores the sorting information. More precisely, the following loop will sort ALPHA for I = K+1, min(M,K+L) swap ALPHA(I) and ALPHA(IWORK(I)) endfor such that ALPHA(1) >= ALPHA(2) >= ... >= ALPHA(N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, the Jacobi-type procedure failed to converge. For further details, see subroutine CTGSJA.

4.10.10 cggsvp3

cggsvp3 computes unitary matrices U, V and Q such that

```
                    N-K-L  K    L
U**H*A*Q =      K ( 0    A12  A13 )  if M-K-L >= 0;
                L ( 0     0   A23 )
            M-K-L ( 0     0    0  )

                 N-K-L  K    L
         =     K ( 0    A12  A13 )  if M-K-L < 0;
             M-K ( 0     0   A23 )

                 N-K-L  K    L
V**H*B*Q =   L ( 0     0   B13 )
             P-L ( 0     0    0  )
```

where the K-by-K matrix A12 and L-by-L matrix B13 are nonsingular upper triangular; A23 is L-by-L upper triangular if M-K-L >= 0, otherwise A23 is (M-K)-by-L upper trapezoidal. K+L = the effective numerical rank of the (M+P)-by-N matrix $(A^H, B^H)^H$.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine CGGSVD3.

Syntax

Fortran specification:

```
use armpl_library

subroutine cggsvp3(JOBU, JOBV, JOBQ, M, P, N, A, LDA, B, LDB, TOLA, TOLB, K,
                   L, U, LDU, V, LDV, Q, LDQ, IWORK, RWORK, TAU, WORK, LWORK,
                   INFO)
```

C specification:

```
#include "armpl.h"

void cggsvp3_(const char *jobu, const char *jobv, const char *jobq,
              const armpl_int_t *m, const armpl_int_t *p,
```

(continues on next page)

(continued from previous page)

                armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
                const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOBU Input parameter.

JOBU is CHARACTER*1

= 'U': Unitary matrix U is computed; = 'N': U is not computed.

JOBV Input parameter.

JOBV is CHARACTER*1

= 'V': Unitary matrix V is computed; = 'N': V is not computed.

JOBQ Input parameter.

JOBQ is CHARACTER*1

= 'Q': Unitary matrix Q is computed; = 'N': Q is not computed.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. P >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A contains the triangular (or trapezoidal) matrix described in the Purpose section.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, B contains the triangular matrix described in the Purpose section.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

TOLA Input parameter.

TOLA is REAL

TOLB Input parameter.

TOLB is REAL

TOLA and TOLB are the thresholds to determine the effective numerical rank of matrix B and a subblock of A. Generally, they are set to TOLA = MAX(M, N)*norm(A)*MACHEPS, TOLB = MAX(P, N)*norm(B)*MACHEPS. The size of TOLA and TOLB may affect the size of backward errors of the decomposition.

K Output parameter.

K is INTEGER

L Output parameter.

L is INTEGER

On exit, K and L specify the dimension of the subblocks described in Purpose section. K + L = effective numerical rank of $(A^H, B^H)^H$.

U Output parameter.

U is COMPLEX

U is an array, dimension (LDU, M). If JOBU = 'U', U contains the unitary matrix U. If JOBU = 'N', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= max(1, M) if JOBU = 'U'; LDU >= 1 otherwise.

V Output parameter.

V is COMPLEX

V is an array, dimension (LDV, P). If JOBV = 'V', V contains the unitary matrix V. If JOBV = 'N', V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, P) if JOBV = 'V'; LDV >= 1 otherwise.

Q Output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, N). If JOBQ = 'Q', Q contains the unitary matrix Q. If JOBQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*N) .

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (N) .

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dggsvp3*, *sggsvp3* and *zggsvp3*. It also exists with a native C interface as *LAPACKE_cggsvp3*.

4.10.11 ctgsja

ctgsja computes the generalized singular value decomposition (GSVD) of two complex upper triangular (or trapezoidal) matrices A and B.

On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine CGGSVP from a general M-by-N matrix A and P-by-N matrix B:

```
           N-K-L  K    L
A =    K ( 0    A12  A13 ) if M-K-L >= 0;
       L ( 0     0   A23 )
   M-K-L ( 0     0    0  )

         N-K-L  K    L
A =  K ( 0    A12  A13 ) if M-K-L < 0;
   M-K ( 0     0   A23 )

         N-K-L  K    L
B =  L ( 0     0   B13 )
   P-L ( 0     0    0  )
```

where the K-by-K matrix A12 and L-by-L matrix B13 are nonsingular upper triangular; A23 is L-by-L upper triangular if M-K-L >= 0, otherwise A23 is (M-K)-by-L upper trapezoidal.

On exit,

```
U**H *A*Q = D1*( 0 R ),     V**H *B*Q = D2*( 0 R ),
```

where U, V and Q are unitary matrices. R is a nonsingular upper triangular matrix, and D1 and D2 are ‘‘diagonal” matrices, which are of the following structures:

If M-K-L >= 0,

```
                    K  L
     D1 =      K ( I  0 )
               L ( 0  C )
             M-K-L ( 0  0 )

                   K  L
     D2 = L    ( 0  S )
          P-L  ( 0  0 )

                N-K-L  K    L
( 0 R ) = K (   0    R11  R12 ) K
          L (   0     0   R22 ) L
```

where

```
 C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),
S = diag( BETA(K+1),  ... , BETA(K+L) ),
C**2 + S**2 = I.

R is stored in A(1:K+L,N-K-L+1:N) on exit.
```

If M-K-L < 0,

```
             K M-K K+L-M
D1 =    K ( I  0    0   )
      M-K ( 0  C    0   )

               K M-K K+L-M
D2 =    M-K ( 0  S    0   )
      K+L-M ( 0  0    I   )
        P-L ( 0  0    0   )

             N-K-L  K   M-K  K+L-M
```

(0 R) = K (0 R11 R12 R13)

```
  M-K ( 0     0    R22  R23  )
K+L-M ( 0     0     0   R33  )
```

where C = diag(ALPHA(K+1), . . . , ALPHA(M)), S = diag(BETA(K+1), . . . , BETA(M)), C**2 + S**2 = I.

R = (R11 R12 R13) is stored in A(1:M, N-K-L+1:N) and R33 is stored

```
(  0  R22 R23 )
```

in B(M-K+1:L,N+M-K-L+1:N) on exit.

The computation of the unitary transformation matrices U, V or Q is optional. These matrices may either be formed explicitly, or they may be postmultiplied into input matrices U1, V1, or Q1.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctgsja(JOBU, JOBV, JOBQ, M, P, N, K, L, A, LDA, B, LDB, TOLA, TOLB,
                  ALPHA, BETA, U, LDU, V, LDV, Q, LDQ, WORK, NCYCLE, INFO)
```

C specification:

```
#include "armpl.h"

void ctgsja_(const char *jobu, const char *jobv, const char *jobq,
             const armpl_int_t *m, const armpl_int_t *p, const armpl_int_t *n,
             const armpl_int_t *k, const armpl_int_t *l,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             const float *tola, const float *tolb, float *alpha, float *beta,
             armpl_singlecomplex_t *u, const armpl_int_t *ldu,
             armpl_singlecomplex_t *v, const armpl_int_t *ldv,
             armpl_singlecomplex_t *q, const armpl_int_t *ldq,
             armpl_singlecomplex_t *work, armpl_int_t *ncycle,
             armpl_int_t *info, ... );
```

Parameters

JOBU Input parameter.

JOBU is CHARACTER*1

= 'U': U must contain a unitary matrix U1 on entry, and the product U1* U is returned; = 'I': U is initialized to the unit matrix, and the unitary matrix U is returned; = 'N': U is not computed.

JOBV Input parameter.

JOBV is CHARACTER*1

= 'V': V must contain a unitary matrix V1 on entry, and the product V1* V is returned; = 'I': V is initialized to the unit matrix, and the unitary matrix V is returned; = 'N': V is not computed.

JOBQ Input parameter.

JOBQ is CHARACTER*1

= 'Q': Q must contain a unitary matrix Q1 on entry, and the product Q1* Q is returned; = 'I': Q is initialized to the unit matrix, and the unitary matrix Q is returned; = 'N': Q is not computed.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. P >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

K Input parameter.

K is INTEGER

L Input parameter.

L is INTEGER

K and L specify the subblocks in the input matrices A and B: A23 = A(K+1:MIN(K+L, M),N-L+1:N) and B13 = B(1:L,,N-L+1:N) of A and B, whose GSVD is going to be computed by CTGSJA. See Further Details.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A(N-K+1:N,1:MIN(K+L, M)) contains the triangular matrix R or part of R. See Purpose for details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, if necessary, B(M-K+1:L,N+M-K-L+1:N) contains a part of R. See Purpose for details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

TOLA Input parameter.

TOLA is REAL

TOLB Input parameter.

TOLB is REAL

TOLA and TOLB are the convergence criteria for the Jacobi- Kogbetliantz iteration procedure. Generally, they are the same as used in the preprocessing step, say TOLA = MAX(M, N)*norm(A)*MACHEPS, TOLB = MAX(P, N)*norm(B)*MACHEPS.

ALPHA Output parameter.

ALPHA is REAL

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is REAL

BETA is an array, dimension (N). On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; ALPHA(1:K) = 1, BETA(1:K) = 0, and if M-K-L >= 0, ALPHA(K+1:K+L) = diag(C), BETA(K+1:K+L) = diag(S), or if M-K-L < 0, ALPHA(K+1:M)= C, ALPHA(M+1:K+L)= 0 BETA(K+1:M) = S, BETA(M+1:K+L) = 1. Furthermore, if K+L < N, ALPHA(K+L+1:N) = 0 BETA(K+L+1:N) = 0.

U Input and output parameter.

U is COMPLEX

U is an array, dimension (LDU, M). On entry, if JOBU = 'U', U must contain a matrix U1 (usually the unitary matrix returned by CGGSVP). On exit, if JOBU = 'I', U contains the unitary matrix U; if JOBU = 'U', U contains the product U1*U. If JOBU = 'N', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= max(1, M) if JOBU = 'U'; LDU >= 1 otherwise.

V Input and output parameter.

V is COMPLEX

V is an array, dimension (LDV, P). On entry, if JOBV = 'V', V must contain a matrix V1 (usually the unitary matrix returned by CGGSVP). On exit, if JOBV = 'I', V contains the unitary matrix V; if JOBV = 'V', V contains the product V1*V. If JOBV = 'N', V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, P) if JOBV = 'V'; LDV >= 1 otherwise.

Q Input and output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, N). On entry, if JOBQ = 'Q', Q must contain a matrix Q1 (usually the unitary matrix returned by CGGSVP). On exit, if JOBQ = 'I', Q contains the unitary matrix Q; if JOBQ = 'Q', Q contains the product Q1*Q. If JOBQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

NCYCLE Output parameter.

NCYCLE is INTEGER

The number of cycles required for convergence.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1: the procedure does not converge after MAXIT cycles.

Related Information

4.10.12 cungbr

cungbr generates one of the complex unitary matrices Q or P^H determined by CGEBRD when reducing a complex matrix A to bidiagonal form: A = Q * B * P^H . Q and P^H are defined as products of elementary reflectors H(i) or G(i) respectively.

If VECT = 'Q', A is assumed to have been an M-by-K matrix, and Q is of order M: if m >= k, Q = H(1) H(2) . . . H(k) and cungbr returns the first n columns of Q, where m >= n >= k; if m < k, Q = H(1) H(2) . . . H(m-1) and cungbr returns Q as an M-by-M matrix.

If VECT = 'P', A is assumed to have been a K-by-N matrix, and P^H is of order N: if k < n, P^H = G(k) . . . G(2) G(1) and cungbr returns the first m rows of P^H , where n >= m >= k; if k >= n, P^H = G(n-1) . . . G(2) G(1) and cungbr returns P^H as an N-by-N matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine cungbr(VECT, M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cungbr_(const char *vect, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *k, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, const armpl_singlecomplex_t *tau,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

Specifies whether the matrix Q or the matrix P^H is required, as defined in the transformation applied by CGEBRD: = 'Q': generate Q; = 'P': generate P^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix Q or P^H to be returned. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q or P^H to be returned. N >= 0. If VECT = 'Q', M >= N >= min(M, K); if VECT = 'P', N >= M >= min(N, K).

K Input parameter.

K is INTEGER

If VECT = 'Q', the number of columns in the original M-by-K matrix reduced by CGEBRD. If VECT = 'P', the number of rows in the original K-by-N matrix reduced by CGEBRD. K >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the vectors which define the elementary reflectors, as returned by CGEBRD. On exit, the M-by-N matrix Q or P^H .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= M.

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension. (min(M, K)) if VECT = 'Q' (min(N, K)) if VECT = 'P' TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i), which determines Q or P^H , as returned by CGEBRD in its array argument TAUQ or TAUP.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,min(M, N)). For optimum performance LWORK >= min(M, N)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zungbr*. It also exists with a native C interface as *LAPACKE_cungbr*.

4.10.13 cunmbr

If VECT = 'Q', cunmbr overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H

If VECT = 'P', cunmbr overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': P * C C * P TRANS = 'C': P^H * C C * P^H

Here Q and P^H are the unitary matrices determined by CGEBRD when reducing a complex matrix A to bidiagonal form: A = Q * B * P^H . Q and P^H are defined as products of elementary reflectors H(i) and G(i) respectively.

Let nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Thus nq is the order of the unitary matrix Q or P^H that is applied.

If VECT = 'Q', A is assumed to have been an NQ-by-K matrix: if nq >= k, Q = H(1) H(2) . . . H(k); if nq < k, Q = H(1) H(2) . . . H(nq-1).

If VECT = 'P', A is assumed to have been a K-by-NQ matrix: if k < nq, P = G(1) G(2) . . . G(k); if k >= nq, P = G(1) G(2) . . . G(nq-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine cunmbr(VECT, SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK,
                  LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cunmbr_(const char *vect, const char *side, const char *trans,
             const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *c,
             const armpl_int_t *ldc, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

= 'Q': apply Q or Q^H ; = 'P': apply P or P^H .

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q, Q^H , P or P^H from the Left; = 'R': apply Q, Q^H , P or P^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q or P; = 'C': Conjugate transpose, apply Q^H or P^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

If VECT = 'Q', the number of columns in the original matrix reduced by CGEBRD. If VECT = 'P', the number of rows in the original matrix reduced by CGEBRD. K >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension. (LDA,min(nq, K)) if VECT = 'Q' (LDA,nq) if VECT = 'P' The vectors which define the elementary reflectors H(i) and G(i), whose products determine the matrices Q and P, as returned by CGEBRD.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If VECT = 'Q', LDA >= max(1,nq); if VECT = 'P', LDA >= max(1,min(nq, K)).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (min(nq, K)). TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i) which determines Q or P, as returned by CGEBRD in the array argument TAUQ or TAUP.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q or P* C or P^H * C or C*P or C*P^H .

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M); if N = 0 or M = 0, LWORK >= 1. For optimum performance LWORK >= max(1,N*NB) if SIDE = 'L', and LWORK >= max(1,M*NB) if SIDE = 'R', where NB is the optimal blocksize. (NB = 0 if M = 0 or N = 0.)

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

For this routine in other precisions, please see *zunmbr*. It also exists with a native C interface as *LAPACKE_cunmbr*.

4.10.14 dbdsdc

dbdsdc computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: B = U * S * VT, using a divide and conquer method, where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and U and VT are orthogonal matrices of left and right singular vectors, respectively. dbdsdc can be used to compute all singular values, and optionally, singular vectors or singular vectors in compact form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See DLASD3 for details.

The code currently calls DLASDQ if singular values only are desired. However, it can be slightly modified to compute singular values using the divide and conquer method.

Syntax

Fortran specification:

```
use armpl_library

subroutine dbdsdc(UPLO, COMPQ, N, D, E, U, LDU, VT, LDVT, Q, IQ, WORK, IWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dbdsdc_(const char *uplo, const char *compq, const armpl_int_t *n,
             double *d, double *e, double *u, const armpl_int_t *ldu,
             double *vt, const armpl_int_t *ldvt, double *q, armpl_int_t *iq,
             double *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': B is upper bidiagonal. = 'L': B is lower bidiagonal.

COMPQ Input parameter.

COMPQ is CHARACTER*1

Specifies whether singular vectors are to be computed as follows: = 'N': Compute singular values only; = 'P': Compute singular values and compute singular vectors in compact form; = 'I': Compute singular values and singular vectors.

N Input parameter.

N is INTEGER

The order of the matrix B. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). On entry, the elements of E contain the offdiagonal elements of the bidiagonal matrix whose SVD is desired. On exit, E has been destroyed.

U Output parameter.

U is DOUBLE PRECISION

U is an array, dimension (LDU, N). If COMPQ = 'I', then: On exit, if INFO = 0, U contains the left singular vectors of the bidiagonal matrix. For other values of COMPQ, U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= 1. If singular vectors are desired, then LDU >= max(1, N).

VT Output parameter.

VT is DOUBLE PRECISION

VT is an array, dimension (LDVT, N). If COMPQ = 'I', then: On exit, if INFO = 0, VT^T contains the right singular vectors of the bidiagonal matrix. For other values of COMPQ, VT is not referenced.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= 1. If singular vectors are desired, then LDVT >= max(1, N).

Q Output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ). If COMPQ = 'P', then: On exit, if INFO = 0, Q and IQ contain the left and right singular vectors in a compact form, requiring O(N log N) space instead of 2*N**2. In particular, Q contains all the DOUBLE PRECISION data in LDQ >= N*(11 + 2*SMLSIZ + 8*INT(LOG_2(N/(SMLSIZ+1)))) words of memory, where SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25). For other values of COMPQ, Q is not referenced.

IQ Output parameter.

IQ is INTEGER array, dimension (LDIQ)

If COMPQ = 'P', then: On exit, if INFO = 0, Q and IQ contain the left and right singular vectors in a compact form, requiring O(N log N) space instead of 2*N**2. In particular, IQ contains all INTEGER data in LDIQ >= N*(3 + 3*INT(LOG_2(N/(SMLSIZ+1)))) words of memory, where SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25). For other values of COMPQ, IQ is not referenced.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)). If COMPQ = 'N' then LWORK >= (4 * N). If COMPQ = 'P' then LWORK >= (6 * N). If COMPQ = 'I' then LWORK >= (3 * N**2 + 4 * N).

IWORK Output parameter.

IWORK is INTEGER array, dimension (8*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: The algorithm failed to compute a singular value. The update process of divide and conquer failed.

Related Information

For this routine in other precisions, please see *sbdsdc*. It also exists with a native C interface as *LAPACKE_dbdsdc*.

4.10.15 dbdsqr

dbdsqr computes the singular values and, optionally, the right and/or left singular vectors from the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B using the implicit zero-shift QR algorithm. The SVD of B has the form

```
B = Q * S * P**T
```

where S is the diagonal matrix of singular values, Q is an orthogonal matrix of left singular vectors, and P is an orthogonal matrix of right singular vectors. If left singular vectors are requested, this subroutine actually returns U*Q instead of Q, and, if right singular vectors are requested, this subroutine returns P^T *VT instead of P^T , for given real input matrices U and VT. When U and VT are the orthogonal matrices that reduce a general matrix A to bidiagonal form: A = U*B*VT, as computed by DGEBRD, then

```
A = (U*Q) * S * (P**T*VT)
```

is the SVD of A. Optionally, the subroutine may also compute Q^T *C for a given real input matrix C.

See "Computing Small Singular Values of Bidiagonal Matrices With Guaranteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Working Note #3 (or SIAM J. Sci. Statist. Comput. vol. 11, no. 5, pp. 873-912, Sept 1990) and "Accurate singular values and differential qd algorithms," by B. Parlett and V. Fernando, Technical Report CPAM-554, Mathematics Department, University of California at Berkeley, July 1992 for a detailed description of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine dbdsqr(UPLO, N, NCVT, NRU, NCC, D, E, VT, LDVT, U, LDU, C, LDC,
                  WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dbdsqr_(const char *uplo, const armpl_int_t *n, const armpl_int_t *ncvt,
             const armpl_int_t *nru, const armpl_int_t *ncc, double *d,
             double *e, double *vt, const armpl_int_t *ldvt, double *u,
             const armpl_int_t *ldu, double *c, const armpl_int_t *ldc,
             double *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': B is upper bidiagonal; = 'L': B is lower bidiagonal.

N Input parameter.

N is INTEGER

The order of the matrix B. N >= 0.

NCVT Input parameter.

NCVT is INTEGER

The number of columns of the matrix VT. NCVT >= 0.

NRU Input parameter.

NRU is INTEGER

The number of rows of the matrix U. NRU >= 0.

NCC Input parameter.

NCC is INTEGER

The number of columns of the matrix C. NCC >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B in decreasing order.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). On entry, the N-1 offdiagonal elements of the bidiagonal matrix B. On exit, if INFO = 0, E is destroyed; if INFO > 0, D and E will contain the diagonal and superdiagonal elements of a bidiagonal matrix orthogonally equivalent to the one given as input.

VT Input and output parameter.

VT is DOUBLE PRECISION

VT is an array, dimension (LDVT, NCVT). On entry, an N-by-NCVT matrix VT. On exit, VT is overwritten by P^T * VT. Not referenced if NCVT = 0.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= max(1, N) if NCVT > 0; LDVT >= 1 if NCVT = 0.

U Input and output parameter.

U is DOUBLE PRECISION

U is an array, dimension (LDU, N). On entry, an NRU-by-N matrix U. On exit, U is overwritten by U * Q. Not referenced if NRU = 0.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= max(1, NRU).

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, NCC). On entry, an N-by-NCC matrix C. On exit, C is overwritten by Q^T * C. Not referenced if NCC = 0.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, N) if NCC > 0; LDC >=1 if NCC = 0.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: If INFO = -i, the i-th argument had an illegal value > 0: if NCVT = NRU = NCC = 0, = 1, a split was marked by a positive value in E = 2, current block of Z not diagonalized after 30*N iterations (in inner while loop) = 3, termination criterion of outer while loop not met (program created more than N unreduced blocks) else NCVT = NRU = NCC = 0, the algorithm did not converge; D and E contain the elements of a bidiagonal matrix which is orthogonally similar to the input matrix B; if INFO = i, i elements of E have not converged to zero.

Related Information

For this routine in other precisions, please see *cbdsqr*, *sbdsqr* and *zbdsqr*. It also exists with a native C interface as *LAPACKE_dbdsqr*.

4.10.16 dbdsvdx

```
DBDSVDX computes the singular value decomposition (SVD) of a real
 N-by-N (upper or lower) bidiagonal matrix B, B = U * S * VT,
 where S is a diagonal matrix with non-negative diagonal elements
 (the singular values of B), and U and VT are orthogonal matrices
 of left and right singular vectors, respectively.

 Given an upper bidiagonal B with diagonal D = [ d_1 d_2 ... d_N ]
 and superdiagonal E = [ e_1 e_2 ... e_N-1 ], DBDSVDX computes the
 singular value decompositon of B through the eigenvalues and
 eigenvectors of the N*2-by-N*2 tridiagonal matrix

       |  0  d_1               |
       | d_1  0  e_1           |
 TGK = |     e_1  0  d_2       |
       |         d_2  .   .    |
       |              .   .   . |

 If (s,u,v) is a singular triplet of B with ||u|| = ||v|| = 1, then
 (+/-s,q), ||q|| = 1, are eigenpairs of TGK, with q = P * ( u' +/-v' ) /
 sqrt(2) = ( v_1 u_1 v_2 u_2 ... v_n u_n ) / sqrt(2), and
 P = [ e_{n+1} e_{1} e_{n+2} e_{2} ... ].

 Given a TGK matrix, one can either a) compute -s,-v and change signs
 so that the singular values (and corresponding vectors) are already in
 descending order (as in DGESVD/DGESDD) or b) compute s,v and reorder
 the values (and corresponding vectors). DBDSVDX implements a) by
 calling DSTEVX (bisection plus inverse iteration, to be replaced
 with a version of the Multiple Relative Robust Representation
 algorithm. (See P. Willems and B. Lang, A framework for the MR^3
 algorithm: theory and implementation, SIAM J. Sci. Comput.,
 35:740-766, 2013.)
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dbdsvdx(UPLO, JOBZ, RANGE, N, D, E, VL, VU, IL, IU, NS, S, Z, LDZ,
                   WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dbdsvdx_(const char *uplo, const char *jobz, const char *range,
              const armpl_int_t *n, const double *d, const double *e,
              const double *vl, const double *vu, const armpl_int_t *il,
              const armpl_int_t *iu, armpl_int_t *ns, double *s, double *z,
              const armpl_int_t *ldz, double *work, armpl_int_t *iwork,
              armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': B is upper bidiagonal; = 'L': B is lower bidiagonal.

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute singular values only; = 'V': Compute singular values and singular vectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all singular values will be found. = 'V': all singular values in the half-open interval [VL, VU) will be found. = 'I': the IL-th through IU-th singular values will be found.

N Input parameter.

N is INTEGER

The order of the bidiagonal matrix. N >= 0.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n diagonal elements of the bidiagonal matrix B.

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (max(1,N-1)). The (n-1) superdiagonal elements of the bidiagonal matrix B in elements 1 to N-1.

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for singular values. VU > VL. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for singular values. VU > VL. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest singular value to be returned. 1 <= IL <= IU <= min(M, N), if min(M, N) > 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest singular value to be returned. 1 <= IL <= IU <= min(M, N), if min(M, N) > 0. Not referenced if RANGE = 'A' or 'V'.

NS Output parameter.

NS is INTEGER

The total number of singular values found. 0 <= NS <= N. If RANGE = 'A', NS = N, and if RANGE = 'I', NS = IU-IL+1.

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The first NS elements contain the selected singular values in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (2*N,K)). If JOBZ = 'V', then if INFO = 0 the first NS columns of Z contain the singular vectors of the matrix B corresponding to the selected singular values, with U in rows 1 to N and V in rows N+1 to N*2, i.e. Z = [U] [V] If JOBZ = 'N', then Z is not referenced. Note: The user must ensure that at least K = NS+1 columns are supplied in the array Z; if RANGE = 'V', the exact value of NS is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(2,N*2).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (14*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (12*N)

If JOBZ = 'V', then if INFO = 0, the first NS elements of IWORK are zero. If INFO > 0, then IWORK contains the indices of the eigenvectors that failed to converge in DSTEVX.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge in DSTEVX. The indices of the eigenvectors (as returned by DSTEVX) are stored in the array IWORK. if INFO = N*2 + 1, an internal error occurred.

Related Information

For this routine in other precisions, please see *sbdsvdx*. It also exists with a native C interface as *LAPACKE_dbdsvdx*.

4.10.17 dgbbrd

dgbbrd reduces a real general m-by-n band matrix A to upper bidiagonal form B by an orthogonal transformation: Q^T * A * P = B.

The routine computes B, and optionally forms Q or P^T , or computes Q^T *C for a given matrix C.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgbbrd(VECT, M, N, NCC, KL, KU, AB, LDAB, D, E, Q, LDQ, PT, LDPT,
                  C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgbbrd_(const char *vect, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *ncc, const armpl_int_t *kl,
             const armpl_int_t *ku, double *ab, const armpl_int_t *ldab,
```

(continues on next page)

(continued from previous page)

```
                double *d, double *e, double *q, const armpl_int_t *ldq,
                double *pt, const armpl_int_t *ldpt, double *c,
                const armpl_int_t *ldc, double *work, armpl_int_t *info, ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

Specifies whether or not the matrices Q and P^T are to be formed. = 'N': do not form Q or P^T ; = 'Q': form Q only; = 'P': form P^T only; = 'B': form both.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NCC Input parameter.

NCC is INTEGER

The number of columns of the matrix C. NCC >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals of the matrix A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals of the matrix A. KU >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the m-by-n band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl). On exit, A is overwritten by values generated during the reduction.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array A. LDAB >= KL+KU+1.

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (min(M, N)). The diagonal elements of the bidiagonal matrix B.

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (min(M, N)-1). The superdiagonal elements of the bidiagonal matrix B.

Q Output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, M). If VECT = 'Q' or 'B', the m-by-m orthogonal matrix Q. If VECT = 'N' or 'P', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, M) if VECT = 'Q' or 'B'; LDQ >= 1 otherwise.

PT Output parameter.

PT is DOUBLE PRECISION

PT is an array, dimension (LDPT, N). If VECT = 'P' or 'B', the n-by-n orthogonal matrix P'. If VECT = 'N' or 'Q', the array PT is not referenced.

LDPT Input parameter.

LDPT is INTEGER

The leading dimension of the array PT. LDPT >= max(1, N) if VECT = 'P' or 'B'; LDPT >= 1 otherwise.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, NCC). On entry, an m-by-ncc matrix C. On exit, C is overwritten by Q^T *C. C is not referenced if NCC = 0.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M) if NCC > 0; LDC >= 1 if NCC = 0.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*max(M, N)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgbbrd*, *sgbbrd* and *zgbbrd*. It also exists with a native C interface as *LAPACKE_dgbbrd*.

4.10.18 dgebrd

dgebrd reduces a general real M-by-N matrix A to upper or lower bidiagonal form B by an orthogonal transformation: Q^T * A * P = B.

If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgebrd(M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgebrd_(const armpl_int_t *m, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, double *d, double *e, double *tauq,
             double *taup, double *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows in the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns in the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N general matrix to be reduced. On exit, if m >= n, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors; if m < n, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (min(M, N)). The diagonal elements of the bidiagonal matrix B: D(i) = A(i,i).

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (min(M, N)-1). The off-diagonal elements of the bidiagonal matrix B: if m >= n, E(i) = A(i,i+1) for i = 1,2,...,n-1; if m < n, E(i) = A(i+1,i) for i = 1,2,...,m-1.

TAUQ Output parameter.

TAUQ is DOUBLE PRECISION

TAUQ is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the orthogonal matrix Q. See Further Details.

TAUP Output parameter.

TAUP is DOUBLE PRECISION

TAUP is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the orthogonal matrix P. See Further Details.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1, M, N). For optimum performance LWORK >= (M+N)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgebrd*, *sgebrd* and *zgebrd*. It also exists with a native C interface as *LAPACKE_dgebrd*.

4.10.19 dgejsv

dgejsv computes the singular value decomposition (SVD) of a real M-by-N matrix [A], where M >= N. The SVD of [A] is written as

```
[A] = [U] * [SIGMA] * [V]^t,
```

where [SIGMA] is an N-by-N (M-by-N) matrix which is zero except for its N diagonal elements, [U] is an M-by-N (or M-by-M) orthonormal matrix, and [V] is an N-by-N orthogonal matrix. The diagonal elements of [SIGMA] are the singular values of [A]. The columns of [U] and [V] are the left and the right singular vectors of [A], respectively. The matrices [U] and [V] are computed and stored in the arrays U and V, respectively. The diagonal of [SIGMA] is computed and stored in the array SVA. dgejsv can sometimes compute tiny singular values and their singular vectors much more accurately than other SVD routines, see below under Further Details.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgejsv(JOBA, JOBU, JOBV, JOBR, JOBT, JOBP, M, N, A, LDA, SVA, U,
                  LDU, V, LDV, WORK, LWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgejsv_(const char *joba, const char *jobu, const char *jobv,
             const char *jobr, const char *jobt, const char *jobp,
             const armpl_int_t *m, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, double *sva, double *u,
             const armpl_int_t *ldu, double *v, const armpl_int_t *ldv,
             double *work, const armpl_int_t *lwork, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

JOBA Input parameter.

JOBA is CHARACTER*1

Specifies the level of accuracy: = 'C': This option works well (high relative accuracy) if A = B * D, with well-conditioned B and arbitrary diagonal matrix D. The accuracy cannot be spoiled by COLUMN scaling. The accuracy of the computed output depends on the condition of B, and the procedure aims at the best theoretical accuracy. The relative error max_{i=1:N}|d sigma_i| / sigma_i is bounded by f(M, N)*epsilon* cond(B), independent of D. The input matrix is preprocessed with the QRF with column pivoting. This initial preprocessing and preconditioning by a rank revealing QR factorization is common for all values of JOBA. Additional actions are specified as follows: = 'E': Computation as with 'C' with an additional estimate of the condition number of B. It provides a realistic error bound. = 'F': If A = D1 * C * D2 with ill-conditioned diagonal scalings D1, D2, and well-conditioned matrix C, this option gives higher accuracy than the 'C' option. If the structure of the input matrix is not known, and relative accuracy is desirable, then this option is advisable. The input matrix A is preprocessed with QR factorization with FULL (row and column) pivoting. = 'G' Computation as with 'F' with an additional estimate of the condition number of B, where A=D*B. If A has heavily weighted rows, then using this condition number gives too pessimistic error bound. = 'A': Small singular values are the noise and the matrix is treated as numerically rank deficient. The error in the computed singular values is bounded by f(m,n)*epsilon*||A||. The computed SVD A = U * S * V^t restores A up to f(m,n)*epsilon*||A||. This gives the procedure the licence to discard (set to zero) all singular values below N*epsilon*||A||. = 'R': Similar as in 'A'. Rank revealing property of the initial QR factorization is used do reveal (using triangular factor) a gap sigma_{r+1} < epsilon * sigma_r in which case the numerical RANK is declared to be r. The SVD is computed with absolute error bounds, but more accurately than with 'A'.

JOBU Input parameter.

JOBU is CHARACTER*1

Specifies whether to compute the columns of U: = 'U': N columns of U are returned in the array U. = 'F': full set of M left sing. vectors is returned in the array U. = 'W': U may be used as workspace of length M*N. See the description of U. = 'N': U is not computed.

JOBV Input parameter.

JOBV is CHARACTER*1

Specifies whether to compute the matrix V: = 'V': N columns of V are returned in the array V; Jacobi rotations are not explicitly accumulated. = 'J': N columns of V are returned in the array V, but they are computed as the product of Jacobi rotations. This option is allowed only if JOBU .NE. 'N', i.e. in computing the full SVD. = 'W': V may be used as workspace of length N*N. See the description of V. = 'N': V is not computed.

JOBR Input parameter.

JOBR is CHARACTER*1

Specifies the RANGE for the singular values. Issues the licence to set to zero small positive singular values if they are outside specified range. If A .NE. 0 is scaled so that the largest singular value of c* A is around DSQRT(BIG), BIG=SLAMCH('O'), then JOBR issues the licence to kill columns of A whose norm in c* A is less than DSQRT(SFMIN) (for JOBR.EQ.'R'), or less than SMALL=SFMIN/EPSLN, where SFMIN=SLAMCH('S'), EPSLN=SLAMCH('E'). = 'N': Do not kill small columns of c*A. This

option assumes that BLAS and QR factorizations and triangular solvers are implemented to work in that range. If the condition of A is greater than BIG, use DGESVJ. = 'R': RESTRICTED range for sigma(c*A) is [DSQRT(SFMIN), DSQRT(BIG)] (roughly, as described above). This option is recommended. ~~~~~~~~~~~~~~~~~~~~~~~~~~~~ For computing the singular values in the FULL range [SFMIN,BIG] use DGESVJ.

JOBT Input parameter.

JOBT is CHARACTER*1

If the matrix is square then the procedure may determine to use transposed A if A^t seems to be better with respect to convergence. If the matrix is not square, JOBT is ignored. This is subject to changes in the future. The decision is based on two values of entropy over the adjoint orbit of A^t * A. See the descriptions of WORK(6) and WORK(7). = 'T': transpose if entropy test indicates possibly faster convergence of Jacobi process if A^t is taken as input. If A is replaced with A^t, then the row pivoting is included automatically. = 'N': do not speculate. This option can be used to compute only the singular values, or the full SVD (U, SIGMA and V). For only one set of singular vectors (U or V), the caller should provide both U and V, as one of the matrices is used as workspace if the matrix A is transposed. The implementer can easily remove this constraint and make the code more complicated. See the descriptions of U and V.

JOBP Input parameter.

JOBP is CHARACTER*1

Issues the licence to introduce structured perturbations to drown denormalized numbers. This licence should be active if the denormals are poorly implemented, causing slow computation, especially in cases of fast convergence (!). For details see [1,2]. For the sake of simplicity, this perturbations are included only when the full SVD or only the singular values are requested. The implementer/user can easily add the perturbation for the cases of computing one set of singular vectors. = 'P': introduce perturbation = 'N': do not perturb

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. M >= N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

SVA Output parameter.

SVA is DOUBLE PRECISION

SVA is an array, dimension (N). On exit, - For WORK(1)/WORK(2) = ONE: The singular values of A. During the computation SVA contains Euclidean column norms of the iterated matrices in the array A. - For WORK(1) .NE. WORK(2): The singular values of A are (WORK(1)/WORK(2)) * SVA(1:N). This factored form is used if sigma_max(A) overflows or if small singular values have been saved from underflow by scaling the input matrix A. - If JOBR='R' then some of the singular values may be returned as exact zeros obtained by "set to zero" because they are below the numerical rank threshold or are denormalized numbers.

U Output parameter.

U is DOUBLE PRECISION

U is an array, dimension (LDU, N). If JOBU = 'U', then U contains on exit the M-by-N matrix of the left singular vectors. If JOBU = 'F', then U contains on exit the M-by-M matrix of the left singular vectors, including an ONB of the orthogonal complement of the Range(A). If JOBU = 'W' .AND. (JOBV.EQ.'V' .AND. JOBT.EQ.'T' .AND. M.EQ.N), then U is used as workspace if the procedure replaces A with A^t. In that case, [V] is computed in U as left singular vectors of A^t and then copied back to the V array. This 'W' option is just a reminder to the caller that in this case U is reserved as workspace of length N*N. If JOBU = 'N' U is not referenced, unless JOBT='T'.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U, LDU >= 1. IF JOBU = 'U' or 'F' or 'W', then LDU >= M.

V Output parameter.

V is DOUBLE PRECISION

V is an array, dimension (LDV, N). If JOBV = 'V', 'J' then V contains on exit the N-by-N matrix of the right singular vectors; If JOBV = 'W', AND (JOBU.EQ.'U' AND JOBT.EQ.'T' AND M.EQ.N), then V is used as workspace if the pprocedure replaces A with A^t. In that case, [U] is computed in V as right singular vectors of A^t and then copied back to the U array. This 'W' option is just a reminder to the caller that in this case V is reserved as workspace of length N*N. If JOBV = 'N' V is not referenced, unless JOBT='T'.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V, LDV >= 1. If JOBV = 'V' or 'J' or 'W', then LDV >= N.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK). On exit, if N.GT.0 .AND. M.GT.0 (else not referenced), WORK(1) = SCALE = WORK(2) / WORK(1) is the scaling factor such that SCALE*SVA(1:N) are the computed singular values of A. (See the description of SVA().) WORK(2) = See the description of WORK(1). WORK(3) = SCONDA is an estimate for the condition number of column equilibrated A. (If JOBA .EQ. 'E' or 'G') SCONDA is an estimate of DSQRT(||(R^t * R)^(-1)||_1). It is computed using DPOCON. It holds N^(-1/4) * SCONDA <= ||R^(-1)||_2 <= N^(1/4) * SCONDA where R is the triangular factor from the QRF of A. However, if R is truncated and the numerical rank is determined to be strictly smaller than N, SCONDA is returned as -1, thus indicating that the smallest singular values might be lost.

If full SVD is needed, the following two condition numbers are useful for the analysis of the algorithm. They are provied for a developer/implementer who is familiar with the details of the method.

WORK(4) = an estimate of the scaled condition number of the triangular factor in the first QR factorization. WORK(5) = an estimate of the scaled condition number of the triangular factor in the second QR factorization. The following two parameters are computed if JOBT .EQ. 'T'. They are provided for a developer/implementer who is familiar with the details of the method.

WORK(6) = the entropy of A^t* A :: this is the Shannon entropy of diag(A^t*A) / Trace(A^t*A) taken as point in the probability simplex. WORK(7) = the entropy of A*A^t.

LWORK Input parameter.

LWORK is INTEGER

Length of WORK to confirm proper allocation of work space. LWORK depends on the job:

If only SIGMA is needed (JOBU.EQ.'N', JOBV.EQ.'N') and -> .. no scaled condition estimate required (JOBE.EQ.'N'): LWORK >= max(2*M+N,4*N+1,7). This is the minimal requirement. ->> For optimal performance (blocked code) the optimal value is LWORK >= max(2*M+N,3*N+(N+1)*NB,7). Here NB is the optimal block size for DGEQP3 and DGEQRF. In general, optimal LWORK is computed as LWORK >= max(2*M+N,N+LWORK(DGEQP3),N+LWORK(DGEQRF), 7). -> .. an estimate of the scaled condition number of A is required (JOBA='E', 'G'). In this case, LWORK is the maximum of the above and N*N+4*N, i.e. LWORK >= max(2*M+N,N*N+4*N,7). ->> For optimal performance (blocked code) the optimal value is LWORK >= max(2*M+N,3*N+(N+1)*NB, N*N+4*N, 7). In general, the optimal

length LWORK is computed as LWORK >= max(2*M+N,N+LWORK(DGEQP3),N+LWORK(DGEQRF), N+N*N+LWORK(DPOCON),7).

If SIGMA and the right singular vectors are needed (JOBV.EQ.'V'), -> the minimal requirement is LWORK >= max(2*M+N,4*N+1,7). -> For optimal performance, LWORK >= max(2*M+N,3*N+(N+1)*NB,7), where NB is the optimal block size for DGEQP3, DGEQRF, DGELQF, DORMLQ. In general, the optimal length LWORK is computed as LWORK >= max(2*M+N,N+LWORK(DGEQP3), N+LWORK(DPOCON), N+LWORK(DGELQF), 2*N+LWORK(DGEQRF), N+LWORK(DORMLQ)).

If SIGMA and the left singular vectors are needed -> the minimal requirement is LWORK >= max(2*M+N,4*N+1,7). -> For optimal performance: if JOBU.EQ.'U' :: LWORK >= max(2*M+N,3*N+(N+1)*NB,7), if JOBU.EQ.'F' :: LWORK >= max(2*M+N,3*N+(N+1)*NB,N+M*NB,7), where NB is the optimal block size for DGEQP3, DGEQRF, DORMQR. In general, the optimal length LWORK is computed as LWORK >= max(2*M+N,N+LWORK(DGEQP3),N+LWORK(DPOCON), 2*N+LWORK(DGEQRF), N+LWORK(DORMQR)). Here LWORK(DORMQR) equals N*NB (for JOBU.EQ.'U') or M*NB (for JOBU.EQ.'F').

If the full SVD is needed: (JOBU.EQ.'U' or JOBU.EQ.'F') and -> if JOBV.EQ.'V' the minimal requirement is LWORK >= max(2*M+N,6*N+2*N*N). -> if JOBV.EQ.'J' the minimal requirement is LWORK >= max(2*M+N, 4*N+N*N,2*N+N*N+6). -> For optimal performance, LWORK should be additionally larger than N+M*NB, where NB is the optimal block size for DORMQR.

IWORK Output parameter.

IWORK is INTEGER array, dimension (M+3*N).

On exit, IWORK(1) = the numerical rank determined after the initial QR factorization with pivoting. See the descriptions of JOBA and JOBR. IWORK(2) = the number of the computed nonzero singular values IWORK(3) = if nonzero, a warning message: If IWORK(3).EQ.1 then some of the column norms of A were denormalized floats. The requested high accuracy is not warranted by the data.

INFO Output parameter.

INFO is INTEGER

< 0 : if INFO = -i, then the i-th argument had an illegal value. = 0 : successful exit; > 0 : DGEJSV did not converge in the maximal allowed number of sweeps. The computed values may be inaccurate.

4.10.20 dgesdd

dgesdd computes the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and right singular vectors. If singular vectors are desired, it uses a divide-and-conquer algorithm.

The SVD is written

```
A = U * SIGMA * transpose(V)
```

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and V is an N-by-N orthogonal matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns VT = V^T , not V.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgesdd(JOBZ, M, N, A, LDA, S, U, LDU, VT, LDVT, WORK, LWORK, IWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dgesdd_(const char *jobz, const armpl_int_t *m, const armpl_int_t *n,
             double *a, const armpl_int_t *lda, double *s, double *u,
             const armpl_int_t *ldu, double *vt, const armpl_int_t *ldvt,
             double *work, const armpl_int_t *lwork, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

Specifies options for computing all or part of the matrix U: = 'A': all M columns of U and all N rows of V^T are returned in the arrays U and VT; = 'S': the first min(M, N) columns of U and the first min(M, N) rows of V^T are returned in the arrays U and VT; = 'O': If M >= N, the first N columns of U are overwritten on the array A and all rows of V^T are returned in the array VT; otherwise, all columns of U are returned in the array U and the first M rows of V^T are overwritten in the array A; = 'N': no columns of U or rows of V^T are computed.

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if JOBZ = 'O', A is overwritten with the first N columns of U (the left singular vectors, stored columnwise) if M >= N; A is overwritten with the first M rows of V^T (the right singular vectors, stored rowwise) otherwise. if JOBZ .ne. 'O', the contents of A are destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (min(M, N)). The singular values of A, sorted so that S(i) >= S(i+1).

U Output parameter.

U is DOUBLE PRECISION

U is an array, dimension (LDU,UCOL). UCOL = M if JOBZ = 'A' or JOBZ = 'O' and M < N; UCOL = min(M, N) if JOBZ = 'S'. If JOBZ = 'A' or JOBZ = 'O' and M < N, U contains the M-by-M orthogonal matrix U; if JOBZ = 'S', U contains the first min(M, N) columns of U (the left singular vectors, stored columnwise); if JOBZ = 'O' and M >= N, or JOBZ = 'N', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= 1; if JOBZ = 'S' or 'A' or JOBZ = 'O' and M < N, LDU >= M.

VT Output parameter.

VT is DOUBLE PRECISION

VT is an array, dimension (LDVT, N). If JOBZ = 'A' or JOBZ = 'O' and M >= N, VT contains the N-by-N orthogonal matrix V^T ; if JOBZ = 'S', VT contains the first min(M, N) rows of V^T (the right singular vectors, stored rowwise); if JOBZ = 'O' and M < N, or JOBZ = 'N', VT is not referenced.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= 1; if JOBZ = 'A' or JOBZ = 'O' and M >= N, LDVT >= N; if JOBZ = 'S', LDVT >= min(M, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK;

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 1. If LWORK = -1, a workspace query is assumed. The optimal size for the WORK array is calculated and stored in WORK(1), and no other work except argument checking is performed.

Let mx = max(M, N) and mn = min(M, N). If JOBZ = 'N', LWORK >= 3*mn + max(mx, 7*mn). If JOBZ = 'O', LWORK >= 3*mn + max(mx, 5*mn*mn + 4*mn). If JOBZ = 'S', LWORK >= 4*mn*mn + 7*mn. If JOBZ = 'A', LWORK >= 4*mn*mn + 6*mn + mx. These are not tight minimums in all cases; see comments inside code. For good performance, LWORK should generally be larger; a query is recommended.

IWORK Output parameter.

IWORK is INTEGER array, dimension (8*min(M, N))

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: DBDSDC did not converge, updating process failed.

Related Information

For this routine in other precisions, please see *cgesdd*, *sgesdd* and *zgesdd*. It also exists with a native C interface as *LAPACKE_dgesdd*.

4.10.21 dgesvd

dgesvd computes the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and/or right singular vectors. The SVD is written

```
A = U * SIGMA * transpose(V)
```

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and V is an N-by-N orthogonal matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns V^T , not V.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgesvd(JOBU, JOBVT, M, N, A, LDA, S, U, LDU, VT, LDVT, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dgesvd_(const char *jobu, const char *jobvt, const armpl_int_t *m,
             const armpl_int_t *n, double *a, const armpl_int_t *lda,
             double *s, double *u, const armpl_int_t *ldu, double *vt,
             const armpl_int_t *ldvt, double *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

JOBU Input parameter.

JOBU is CHARACTER*1

Specifies options for computing all or part of the matrix U: = 'A': all M columns of U are returned in array U: = 'S': the first min(m,n) columns of U (the left singular vectors) are returned in the array U; = 'O': the first min(m,n) columns of U (the left singular vectors) are overwritten on the array A; = 'N': no columns of U (no left singular vectors) are computed.

JOBVT Input parameter.

JOBVT is CHARACTER*1

Specifies options for computing all or part of the matrix V^T : = 'A': all N rows of V^T are returned in the array VT; = 'S': the first min(m,n) rows of V^T (the right singular vectors) are returned in the array VT; = 'O': the first min(m,n) rows of V^T (the right singular vectors) are overwritten on the array A; = 'N': no rows of V^T (no right singular vectors) are computed.

JOBVT and JOBU cannot both be 'O'.

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if JOBU = 'O', A is overwritten with the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBVT = 'O', A is overwritten with the first min(m,n) rows of V^T (the right singular vectors, stored rowwise); if JOBU .ne. 'O' and JOBVT .ne. 'O', the contents of A are destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (min(M, N)). The singular values of A, sorted so that S(i) >= S(i+1).

U Output parameter.

U is DOUBLE PRECISION

U is an array, dimension (LDU,UCOL). (LDU, M) if JOBU = 'A' or (LDU,min(M, N)) if JOBU = 'S'. If JOBU = 'A', U contains the M-by-M orthogonal matrix U; if JOBU = 'S', U contains the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBU = 'N' or 'O', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= 1; if JOBU = 'S' or 'A', LDU >= M.

VT Output parameter.

VT is DOUBLE PRECISION

VT is an array, dimension (LDVT, N). If JOBVT = 'A', VT contains the N-by-N orthogonal matrix V^T ; if JOBVT = 'S', VT contains the first min(m,n) rows of V^T (the right singular vectors, stored rowwise); if JOBVT = 'N' or 'O', VT is not referenced.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= 1; if JOBVT = 'A', LDVT >= N; if JOBVT = 'S', LDVT >= min(M, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK; if INFO > 0, WORK(2:MIN(M, N)) contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in S (not necessarily sorted). B satisfies A = U * B * VT, so it has the same singular values as A, and singular vectors related by U and VT.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= MAX(1,5*MIN(M, N)) for the paths (see comments inside code): - PATH 1 (M much larger than N, JOBU='N') - PATH 1t (N much larger than M, JOBVT='N') LWORK >= MAX(1,3*MIN(M, N) + MAX(M, N),5*MIN(M, N)) for the other paths For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if DBDSQR did not converge, INFO specifies how many superdiagonals of an intermediate bidiagonal form B did not converge to zero. See the description of WORK above for details.

For this routine in other precisions, please see *cgesvd*, *sgesvd* and *zgesvd*. It also exists with a native C interface as *LAPACKE_dgesvd*.

4.10.22 dgesvdx

```
DGESVDX computes the singular value decomposition (SVD) of a real
 M-by-N matrix A, optionally computing the left and/or right singular
 vectors. The SVD is written

     A = U * SIGMA * transpose(V)

 where SIGMA is an M-by-N matrix which is zero except for its
 min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and
 V is an N-by-N orthogonal matrix.  The diagonal elements of SIGMA
 are the singular values of A; they are real and non-negative, and
 are returned in descending order.  The first min(m,n) columns of
 U and V are the left and right singular vectors of A.

 DGESVDX uses an eigenvalue problem for obtaining the SVD, which
 allows for the computation of a subset of singular values and
 vectors. See DBDSVDX for details.

 Note that the routine returns V**T, not V.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dgesvdx(JOBU, JOBVT, RANGE, M, N, A, LDA, VL, VU, IL, IU, NS, S, U,
                   LDU, VT, LDVT, WORK, LWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgesvdx_(const char *jobu, const char *jobvt, const char *range,
              const armpl_int_t *m, const armpl_int_t *n, double *a,
              const armpl_int_t *lda, const double *vl, const double *vu,
              const armpl_int_t *il, const armpl_int_t *iu, armpl_int_t *ns,
              double *s, double *u, const armpl_int_t *ldu, double *vt,
              const armpl_int_t *ldvt, double *work, const armpl_int_t *lwork,
              armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

JOBU Input parameter.

JOBU is CHARACTER*1

Specifies options for computing all or part of the matrix U: = 'V': the first min(m,n) columns of U (the left singular vectors) or as specified by RANGE are returned in the array U; = 'N': no columns of U (no left singular vectors) are computed.

JOBVT Input parameter.

JOBVT is CHARACTER*1

Specifies options for computing all or part of the matrix V^T : = 'V': the first min(m,n) rows of V^T (the right singular vectors) or as specified by RANGE are returned in the array VT; = 'N': no rows of V^T (no right singular vectors) are computed.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all singular values will be found. = 'V': all singular values in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th singular values will be found.

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the contents of A are destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for singular values. VU > VL. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for singular values. VU > VL. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest singular value to be returned. 1 <= IL <= IU <= min(M, N), if min(M, N) > 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest singular value to be returned. 1 <= IL <= IU <= min(M, N), if min(M, N) > 0. Not referenced if RANGE = 'A' or 'V'.

NS Output parameter.

NS is INTEGER

The total number of singular values found, 0 <= NS <= min(M, N). If RANGE = 'A', NS = min(M, N); if RANGE = 'I', NS = IU-IL+1.

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (min(M, N)). The singular values of A, sorted so that S(i) >= S(i+1).

U Output parameter.

U is DOUBLE PRECISION

U is an array, dimension (LDU,UCOL). If JOBU = 'V', U contains columns of U (the left singular vectors, stored columnwise) as specified by RANGE; if JOBU = 'N', U is not referenced. Note: The user must ensure that UCOL >= NS; if RANGE = 'V', the exact value of NS is not known in advance and an upper bound must be used.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= 1; if JOBU = 'V', LDU >= M.

VT Output parameter.

VT is DOUBLE PRECISION

VT is an array, dimension (LDVT, N). If JOBVT = 'V', VT contains the rows of V^T (the right singular vectors, stored rowwise) as specified by RANGE; if JOBVT = 'N', VT is not referenced. Note: The user must ensure that LDVT >= NS; if RANGE = 'V', the exact value of NS is not known in advance and an upper bound must be used.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= 1; if JOBVT = 'V', LDVT >= NS (see above).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK;

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= MAX(1,MIN(M, N)*(MIN(M, N)+4)) for the paths (see comments inside the code): - PATH 1 (M much larger than N) - PATH 1t (N much larger than M) LWORK >= MAX(1,MIN(M, N)*2+MAX(M, N)) for the other paths. For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (12*MIN(M, N))

If INFO = 0, the first NS elements of IWORK are zero. If INFO > 0, then IWORK contains the indices of the eigenvectors that failed to converge in DBDSVDX/DSTEVX.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge in DBDSVDX/DSTEVX. if INFO = N*2 + 1, an internal error occurred in DBDSVDX

Related Information

For this routine in other precisions, please see *cgesvdx*, *sgesvdx* and *zgesvdx*. It also exists with a native C interface as *LAPACKE_dgesvdx*.

4.10.23 dgesvj

dgesvj computes the singular value decomposition (SVD) of a real M-by-N matrix A, where M >= N. The SVD of A is written as

```
                          [++]   [xx]   [x0]   [xx]
A = U * SIGMA * V^t,      [++] = [xx] * [ox] * [xx]
                          [++]   [xx]
```

where SIGMA is an N-by-N diagonal matrix, U is an M-by-N orthonormal matrix, and V is an N-by-N orthogonal matrix. The diagonal elements of SIGMA are the singular values of A. The columns of U and V are the left and the right singular vectors of A, respectively. dgesvj can sometimes compute tiny singular values and their singular vectors much more accurately than other SVD routines, see below under Further Details.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgesvj(JOBA, JOBU, JOBV, M, N, A, LDA, SVA, MV, V, LDV, WORK,
                  LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgesvj_(const char *joba, const char *jobu, const char *jobv,
             const armpl_int_t *m, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, double *sva, const armpl_int_t *mv,
             double *v, const armpl_int_t *ldv, double *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOBA Input parameter.

JOBA is CHARACTER*1

Specifies the structure of A. = 'L': The input matrix A is lower triangular; = 'U': The input matrix A is upper triangular; = 'G': The input matrix A is general M-by-N matrix, M >= N.

JOBU Input parameter.

JOBU is CHARACTER*1

Specifies whether to compute the left singular vectors (columns of U): = 'U': The left singular vectors corresponding to the nonzero singular values are computed and returned in the leading columns of A. See more details in the description of A. The default numerical orthogonality threshold is set to approximately TOL=CTOL*EPS, CTOL=DSQRT(M), EPS=DLAMCH('E'). = 'C': Analogous to JOBU='U', except that user can control the level of numerical orthogonality of the computed left singular vectors. TOL can be set to TOL = CTOL*EPS, where CTOL is given on input in the array WORK. No CTOL smaller than ONE is allowed. CTOL greater than 1 / EPS is meaningless. The option 'C' can be used if M*EPS is satisfactory orthogonality of the computed left singular vectors, so CTOL=M could save few sweeps of Jacobi rotations. See the descriptions of A and WORK(1). = 'N': The matrix U is not computed. However, see the description of A.

JOBV Input parameter.

JOBV is CHARACTER*1

Specifies whether to compute the right singular vectors, that is, the matrix V: = 'V' : the matrix V is computed and returned in the array V = 'A' : the Jacobi rotations are applied to the MV-by-N array V. In other words, the right singular vector matrix V is not computed explicitly, instead it is applied to an MV-by-N matrix initially stored in the first MV rows of V. = 'N' : the matrix V is not computed and the array V is not referenced

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. 1/DLAMCH('E') > M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. M >= N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit : If JOBU .EQ. 'U' .OR. JOBU .EQ. 'C' : If INFO .EQ. 0 : RANKA orthonormal columns of U are returned in the leading RANKA columns of the array A. Here RANKA <= N is the number of computed singular values of A that are above the underflow threshold DLAMCH('S'). The singular vectors corresponding to underflowed or zero singular values are not computed. The value of RANKA is returned in the array WORK as RANKA=NINT(WORK(2)). Also see the descriptions of SVA and WORK. The computed columns of U are mutually numerically orthogonal up to approximately TOL=DSQRT(M)*EPS (default); or TOL=CTOL*EPS (JOBU.EQ.'C'), see the description of JOBU. If INFO .GT. 0 : the procedure DGESVJ did not converge in the given number of iterations (sweeps). In that case, the computed columns of U may not be orthogonal up to TOL. The output U (stored in A), SIGMA (given by the computed singular values in SVA(1:N)) and V is still a decomposition of the input matrix A in the sense that the residual ||A-SCALE*U*SIGMA*V^T||_2 / ||A||_2 is small.

If JOBU .EQ. 'N' : If INFO .EQ. 0 : Note that the left singular vectors are 'for free' in the one-sided Jacobi SVD algorithm. However, if only the singular values are needed, the level of numerical orthogonality of U is not an issue and iterations are stopped when the columns of the iterated matrix are numerically orthogonal up to approximately M*EPS. Thus, on exit, A contains the columns of U scaled with the corresponding singular values. If INFO .GT. 0 : the procedure DGESVJ did not converge in the given number of iterations (sweeps).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

SVA Output parameter.

SVA is DOUBLE PRECISION

SVA is an array, dimension (N). On exit : If INFO .EQ. 0 : depending on the value SCALE = WORK(1), we have: If SCALE .EQ. ONE : SVA(1:N) contains the computed singular values of A. During the computation SVA contains the Euclidean column norms of the iterated matrices in the array A. If SCALE .NE. ONE : The singular values of A are SCALE*SVA(1:N), and this factored representation is due to the fact that some

of the singular values of A might underflow or overflow. If INFO .GT. 0 : the procedure DGESVJ did not converge in the given number of iterations (sweeps) and SCALE*SVA(1:N) may not be accurate.

MV Input parameter.

MV is INTEGER

If JOBV .EQ. 'A', then the product of Jacobi rotations in DGESVJ is applied to the first MV rows of V. See the description of JOBV.

V Input and output parameter.

V is DOUBLE PRECISION

V is an array, dimension (LDV, N). If JOBV = 'V', then V contains on exit the N-by-N matrix of the right singular vectors; If JOBV = 'A', then V contains the product of the computed right singular vector matrix and the initial matrix in the array V. If JOBV = 'N', then V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V, LDV .GE. 1. If JOBV .EQ. 'V', then LDV .GE. max(1, N). If JOBV .EQ. 'A', then LDV .GE. max(1, MV) .

WORK Input and output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK). On entry : If JOBU .EQ. 'C' : WORK(1) = CTOL, where CTOL defines the threshold for convergence. The process stops if all columns of A are mutually orthogonal up to CTOL*EPS, EPS=DLAMCH('E'). It is required that CTOL >= ONE, i.e. it is not allowed to force the routine to obtain orthogonality below EPS. On exit : WORK(1) = SCALE is the scaling factor such that SCALE*SVA(1:N) are the computed singular values of A. (See description of SVA().) WORK(2) = NINT(WORK(2)) is the number of the computed nonzero singular values. WORK(3) = NINT(WORK(3)) is the number of the computed singular values that are larger than the underflow threshold. WORK(4) = NINT(WORK(4)) is the number of sweeps of Jacobi rotations needed for numerical convergence. WORK(5) = max_{i.NE.j} |COS(A(:,i),A(:,j))| in the last sweep. This is useful information in cases when DGESVJ did not converge, as it can be used to estimate whether the output is stil useful and for post festum analysis. WORK(6) = the largest absolute value over all sines of the Jacobi rotation angles in the last sweep. It can be useful for a post festum analysis.

LWORK Input parameter.

LWORK is INTEGER

length of WORK, WORK >= MAX(6,M+N)

INFO Output parameter.

INFO is INTEGER

= 0 : successful exit. < 0 : if INFO = -i, then the i-th argument had an illegal value > 0 : DGESVJ did not converge in the maximal allowed number (30) of sweeps. The output may still be useful. See the description of WORK.

Related Information

For this routine in other precisions, please see *cgesvj*, *sgesvj* and *zgesvj*. It also exists with a native C interface as *LAPACKE_dgesvj*.

4.10.24 dggsvd3

dggsvd3 computes the generalized singular value decomposition (GSVD) of an M-by-N real matrix A and P-by-N real matrix B:

```
U**T*A*Q = D1*( 0 R ),     V**T*B*Q = D2*( 0 R )
```

where U, V and Q are orthogonal matrices. Let K+L = the effective numerical rank of the matrix $(A^T, B^T)^T$, then R is a K+L-by-K+L nonsingular upper triangular matrix, D1 and D2 are M-by-(K+L) and P-by-(K+L) "diagonal" matrices and of the following structures, respectively:

If M-K-L >= 0,

```
                   K  L
     D1 =      K ( I  0 )
               L ( 0  C )
           M-K-L ( 0  0 )

                 K  L
     D2 =    L ( 0  S )
           P-L ( 0  0 )

                N-K-L  K    L
( 0 R ) = K (   0    R11  R12 )
          L (   0     0   R22 )
```

where

```
 C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),
S = diag( BETA(K+1),  ... , BETA(K+L) ),
C**2 + S**2 = I.

R is stored in A(1:K+L,N-K-L+1:N) on exit.
```

If M-K-L < 0,

```
                 K M-K K+L-M
     D1 =    K ( I  0    0   )
           M-K ( 0  C    0   )

                   K M-K K+L-M
     D2 =    M-K ( 0  S    0  )
           K+L-M ( 0  0    I  )
             P-L ( 0  0    0  )

                  N-K-L  K   M-K  K+L-M
( 0 R ) =      K ( 0    R11  R12  R13  )
             M-K ( 0      0   R22  R23  )
           K+L-M ( 0      0    0   R33  )
```

where

```
C = diag( ALPHA(K+1), ... , ALPHA(M) ),
S = diag( BETA(K+1),  ... , BETA(M) ),
C**2 + S**2 = I.

(R11 R12 R13 ) is stored in A(1:M, N-K-L+1:N), and R33 is stored
( 0  R22 R23 )
in B(M-K+1:L,N+M-K-L+1:N) on exit.
```

The routine computes C, S, R, and optionally the orthogonal transformation matrices U, V and Q.

In particular, if B is an N-by-N nonsingular matrix, then the GSVD of A and B implicitly gives the SVD of A*inv(B):

```
A*inv(B) = U*(D1*inv(D2))*V**T.
```

If (A^T ,B^T)^T has orthonormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and B. Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

```
A**T*A x = lambda* B**T*B x.
```

In some literature, the GSVD of A and B is presented in the form

```
U**T*A*X = ( 0 D1 ),   V**T*B*X = ( 0 D2 )
```

where U and V are orthogonal and X is nonsingular, D1 and D2 are ‘’diagonal’‘. The former GSVD form can be converted to the latter form by taking the nonsingular matrix X as

```
X = Q*( I   0    )
      ( 0 inv(R) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dggsvd3(JOBU, JOBV, JOBQ, M, N, P, K, L, A, LDA, B, LDB, ALPHA,
                   BETA, U, LDU, V, LDV, Q, LDQ, WORK, LWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dggsvd3_(const char *jobu, const char *jobv, const char *jobq,
              const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *p, armpl_int_t *k, armpl_int_t *l, double *a,
              const armpl_int_t *lda, double *b, const armpl_int_t *ldb,
              double *alpha, double *beta, double *u, const armpl_int_t *ldu,
              double *v, const armpl_int_t *ldv, double *q,
              const armpl_int_t *ldq, double *work, const armpl_int_t *lwork,
              armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

JOBU Input parameter.

JOBU is CHARACTER*1

= ‘U’: Orthogonal matrix U is computed; = ‘N’: U is not computed.

JOBV Input parameter.

JOBV is CHARACTER*1

= ‘V’: Orthogonal matrix V is computed; = ‘N’: V is not computed.

JOBQ Input parameter.

JOBQ is CHARACTER*1

= ‘Q’: Orthogonal matrix Q is computed; = ‘N’: Q is not computed.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. P >= 0.

K Output parameter.

K is INTEGER

L Output parameter.

L is INTEGER

On exit, K and L specify the dimension of the subblocks described in Purpose. K + L = effective numerical rank of $(A^T, B^T)^T$.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A contains the triangular matrix R, or part of R. See Purpose for details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, B contains the triangular matrix R if M-K-L < 0. See Purpose for details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

ALPHA Output parameter.

ALPHA is DOUBLE PRECISION

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is DOUBLE PRECISION

BETA is an array, dimension (N). On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; ALPHA(1:K) = 1, BETA(1:K) = 0, and if M-K-L >= 0, ALPHA(K+1:K+L) = C, BETA(K+1:K+L) = S, or if M-K-L < 0, ALPHA(K+1:M)=C, ALPHA(M+1:K+L)=0 BETA(K+1:M) =S, BETA(M+1:K+L) =1 and ALPHA(K+L+1:N) = 0 BETA(K+L+1:N) = 0

U Output parameter.

U is DOUBLE PRECISION

U is an array, dimension (LDU, M). If JOBU = 'U', U contains the M-by-M orthogonal matrix U. If JOBU = 'N', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= max(1, M) if JOBU = 'U'; LDU >= 1 otherwise.

V Output parameter.

V is DOUBLE PRECISION

V is an array, dimension (LDV, P). If JOBV = 'V', V contains the P-by-P orthogonal matrix V. If JOBV = 'N', V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, P) if JOBV = 'V'; LDV >= 1 otherwise.

Q Output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). If JOBQ = 'Q', Q contains the N-by-N orthogonal matrix Q. If JOBQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

On exit, IWORK stores the sorting information. More precisely, the following loop will sort ALPHA for I = K+1, min(M,K+L) swap ALPHA(I) and ALPHA(IWORK(I)) endfor such that ALPHA(1) >= ALPHA(2) >= ... >= ALPHA(N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, the Jacobi-type procedure failed to converge. For further details, see subroutine DTGSJA.

Related Information

For this routine in other precisions, please see *cggsvd3*, *sggsvd3* and *zggsvd3*. It also exists with a native C interface as *LAPACKE_dggsvd3*.

4.10.25 dggsvp3

dggsvp3 computes orthogonal matrices U, V and Q such that

```
                   N-K-L  K    L
U**T*A*Q =      K ( 0    A12  A13 )  if M-K-L >= 0;
                L ( 0     0   A23 )
            M-K-L ( 0     0    0  )

                 N-K-L  K    L
        =     K ( 0    A12  A13 )  if M-K-L < 0;
            M-K ( 0     0   A23 )

                 N-K-L  K    L
V**T*B*Q =   L ( 0     0   B13 )
            P-L ( 0     0    0  )
```

where the K-by-K matrix A12 and L-by-L matrix B13 are nonsingular upper triangular; A23 is L-by-L upper triangular if M-K-L >= 0, otherwise A23 is (M-K)-by-L upper trapezoidal. K+L = the effective numerical rank of the (M+P)-by-N matrix $(A^T, B^T)^T$.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine DGGSVD3.

Syntax

Fortran specification:

```
use armpl_library

subroutine dggsvp3(JOBU, JOBV, JOBQ, M, P, N, A, LDA, B, LDB, TOLA, TOLB, K,
                   L, U, LDU, V, LDV, Q, LDQ, IWORK, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dggsvp3_(const char *jobu, const char *jobv, const char *jobq,
              const armpl_int_t *m, const armpl_int_t *p,
              const armpl_int_t *n, double *a, const armpl_int_t *lda,
              double *b, const armpl_int_t *ldb, const double *tola,
              const double *tolb, armpl_int_t *k, armpl_int_t *l, double *u,
              const armpl_int_t *ldu, double *v, const armpl_int_t *ldv,
              double *q, const armpl_int_t *ldq, armpl_int_t *iwork,
              double *tau, double *work, const armpl_int_t *lwork,
              armpl_int_t *info, ... );
```

Parameters

JOBU Input parameter.

JOBU is CHARACTER*1

= 'U': Orthogonal matrix U is computed; = 'N': U is not computed.

JOBV Input parameter.

JOBV is CHARACTER*1

= 'V': Orthogonal matrix V is computed; = 'N': V is not computed.

JOBQ Input parameter.

JOBQ is CHARACTER*1

= 'Q': Orthogonal matrix Q is computed; = 'N': Q is not computed.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. P >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A contains the triangular (or trapezoidal) matrix described in the Purpose section.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, B contains the triangular matrix described in the Purpose section.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

TOLA Input parameter.

TOLA is DOUBLE PRECISION

TOLB Input parameter.

TOLB is DOUBLE PRECISION

TOLA and TOLB are the thresholds to determine the effective numerical rank of matrix B and a subblock of A. Generally, they are set to TOLA = MAX(M, N)*norm(A)*MACHEPS, TOLB = MAX(P, N)*norm(B)*MACHEPS. The size of TOLA and TOLB may affect the size of backward errors of the decomposition.

K Output parameter.

K is INTEGER

L Output parameter.

L is INTEGER

On exit, K and L specify the dimension of the subblocks described in Purpose section. K + L = effective numerical rank of $(A^T, B^T)^T$.

U Output parameter.

U is DOUBLE PRECISION

U is an array, dimension (LDU, M). If JOBU = 'U', U contains the orthogonal matrix U. If JOBU = 'N', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= max(1, M) if JOBU = 'U'; LDU >= 1 otherwise.

V Output parameter.

V is DOUBLE PRECISION

V is an array, dimension (LDV, P). If JOBV = 'V', V contains the orthogonal matrix V. If JOBV = 'N', V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, P) if JOBV = 'V'; LDV >= 1 otherwise.

Q Output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). If JOBQ = 'Q', Q contains the orthogonal matrix Q. If JOBQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (N) .

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

4.10.26 dorgbr

`dorgbr` generates one of the real orthogonal matrices Q or P^T determined by DGEBRD when reducing a real matrix A to bidiagonal form: A = Q * B * P^T . Q and P^T are defined as products of elementary reflectors H(i) or G(i) respectively.

If VECT = 'Q', A is assumed to have been an M-by-K matrix, and Q is of order M: if m >= k, Q = H(1) H(2) . . . H(k) and `dorgbr` returns the first n columns of Q, where m >= n >= k; if m < k, Q = H(1) H(2) . . . H(m-1) and `dorgbr` returns Q as an M-by-M matrix.

If VECT = 'P', A is assumed to have been a K-by-N matrix, and P^T is of order N: if k < n, P^T = G(k) . . . G(2) G(1) and `dorgbr` returns the first m rows of P^T , where n >= m >= k; if k >= n, P^T = G(n-1) . . . G(2) G(1) and `dorgbr` returns P^T as an N-by-N matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine dorgbr(VECT, M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorgbr_(const char *vect, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *k, double *a, const armpl_int_t *lda,
             const double *tau, double *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

VECT Input parameter.

`VECT` is `CHARACTER*1`

Specifies whether the matrix Q or the matrix P^T is required, as defined in the transformation applied by DGEBRD: = 'Q': generate Q; = 'P': generate P^T .

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix Q or P^T to be returned. `M` >= 0.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix Q or P^T to be returned. `N` >= 0. If `VECT` = 'Q', `M` >= `N` >= min(`M`, `K`); if `VECT` = 'P', `N` >= `M` >= min(`N`, `K`).

K Input parameter.

`K` is `INTEGER`

If VECT = 'Q', the number of columns in the original M-by-K matrix reduced by DGEBRD. If VECT = 'P', the number of rows in the original K-by-N matrix reduced by DGEBRD. K >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the vectors which define the elementary reflectors, as returned by DGEBRD. On exit, the M-by-N matrix Q or P^T .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension. (min(M, K)) if VECT = 'Q' (min(N, K)) if VECT = 'P' TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i), which determines Q or P^T , as returned by DGEBRD in its array argument TAUQ or TAUP.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,min(M, N)). For optimum performance LWORK >= min(M, N)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sorgbr*. It also exists with a native C interface as *LAPACKE_dorgbr*.

4.10.27 dormbr

If VECT = 'Q', dormbr overwrites the general real M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T

If VECT = 'P', dormbr overwrites the general real M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': P * C C * P TRANS = 'T': P^T * C C * P^T

Here Q and P^T are the orthogonal matrices determined by DGEBRD when reducing a real matrix A to bidiagonal form: A = Q * B * P^T . Q and P^T are defined as products of elementary reflectors H(i) and G(i) respectively.

Let nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Thus nq is the order of the orthogonal matrix Q or P^T that is applied.

If VECT = 'Q', A is assumed to have been an NQ-by-K matrix: if nq >= k, Q = H(1) H(2) . . . H(k); if nq < k, Q = H(1) H(2) . . . H(nq-1).

If VECT = 'P', A is assumed to have been a K-by-NQ matrix: if k < nq, P = G(1) G(2) . . . G(k); if k >= nq, P = G(1) G(2) . . . G(nq-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine dormbr(VECT, SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK,
                  LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dormbr_(const char *vect, const char *side, const char *trans,
             const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             const double *a, const armpl_int_t *lda, const double *tau,
             double *c, const armpl_int_t *ldc, double *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

= 'Q': apply Q or Q^T ; = 'P': apply P or P^T .

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q, Q^T , P or P^T from the Left; = 'R': apply Q, Q^T , P or P^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q or P; = 'T': Transpose, apply Q^T or P^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

If VECT = 'Q', the number of columns in the original matrix reduced by DGEBRD. If VECT = 'P', the number of rows in the original matrix reduced by DGEBRD. K >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension. (LDA,min(nq, K)) if VECT = 'Q' (LDA,nq) if VECT = 'P' The vectors which define the elementary reflectors H(i) and G(i), whose products determine the matrices Q and P, as returned by DGEBRD.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If VECT = 'Q', LDA >= max(1,nq); if VECT = 'P', LDA >= max(1,min(nq, K)).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (min(nq, K)). TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i) which determines Q or P, as returned by DGEBRD in the array argument TAUQ or TAUP.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q or P* C or P^T * C or C*P or C*P^T .

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sormbr*. It also exists with a native C interface as *LAPACKE_dormbr*.

4.10.28 dtgsja

dtgsja computes the generalized singular value decomposition (GSVD) of two real upper triangular (or trapezoidal) matrices A and B.

On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine DGGSVP from a general M-by-N matrix A and P-by-N matrix B:

```
           N-K-L  K    L
A =    K ( 0    A12  A13 ) if M-K-L >= 0;
       L ( 0     0   A23 )
   M-K-L ( 0     0    0  )

         N-K-L  K    L
A =  K ( 0    A12  A13 ) if M-K-L < 0;
   M-K ( 0     0   A23 )

         N-K-L  K    L
B =  L ( 0     0   B13 )
   P-L ( 0     0    0  )
```

where the K-by-K matrix A12 and L-by-L matrix B13 are nonsingular upper triangular; A23 is L-by-L upper triangular if M-K-L >= 0, otherwise A23 is (M-K)-by-L upper trapezoidal.

On exit,

```
U**T *A*Q = D1*( 0 R ),    V**T *B*Q = D2*( 0 R ),
```

where U, V and Q are orthogonal matrices. R is a nonsingular upper triangular matrix, and D1 and D2 are ‘’diagonal” matrices, which are of the following structures:

If M-K-L >= 0,

```
                 K  L
     D1 =     K ( I  0 )
              L ( 0  C )
            M-K-L ( 0  0 )

                 K  L
     D2 = L    ( 0  S )
            P-L ( 0  0 )

               N-K-L  K    L
( 0 R ) = K (  0   R11  R12 ) K
          L (  0    0   R22 ) L
```

where

```
C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),
S = diag( BETA(K+1),  ... , BETA(K+L) ),
C**2 + S**2 = I.

R is stored in A(1:K+L,N-K-L+1:N) on exit.
```

If M-K-L < 0,

```
             K M-K K+L-M
D1 =   K ( I  0    0   )
     M-K ( 0  C    0   )

               K M-K K+L-M
D2 =   M-K ( 0  S    0   )
     K+L-M ( 0  0    I   )
```

(continues on next page)

(continued from previous page)

```
       P-L ( 0  0    0   )

           N-K-L  K   M-K  K+L-M
```

(0 R) = K (0 R11 R12 R13)

```
  M-K ( 0     0   R22  R23  )
K+L-M ( 0     0    0   R33  )
```

where C = diag(ALPHA(K+1), ... , ALPHA(M)), S = diag(BETA(K+1), ... , BETA(M)), C**2 + S**2 = I.

R = (R11 R12 R13) is stored in A(1:M, N-K-L+1:N) and R33 is stored

```
(  0  R22 R23 )
```

in B(M-K+1:L,N+M-K-L+1:N) on exit.

The computation of the orthogonal transformation matrices U, V or Q is optional. These matrices may either be formed explicitly, or they may be postmultiplied into input matrices U1, V1, or Q1.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtgsja(JOBU, JOBV, JOBQ, M, P, N, K, L, A, LDA, B, LDB, TOLA, TOLB,
                  ALPHA, BETA, U, LDU, V, LDV, Q, LDQ, WORK, NCYCLE, INFO)
```

C specification:

```
#include "armpl.h"

void dtgsja_(const char *jobu, const char *jobv, const char *jobq,
             const armpl_int_t *m, const armpl_int_t *p, const armpl_int_t *n,
             const armpl_int_t *k, const armpl_int_t *l, double *a,
             const armpl_int_t *lda, double *b, const armpl_int_t *ldb,
             const double *tola, const double *tolb, double *alpha,
             double *beta, double *u, const armpl_int_t *ldu, double *v,
             const armpl_int_t *ldv, double *q, const armpl_int_t *ldq,
             double *work, armpl_int_t *ncycle, armpl_int_t *info, ... );
```

Parameters

JOBU Input parameter.

JOBU is CHARACTER*1

= 'U': U must contain an orthogonal matrix U1 on entry, and the product U1* U is returned; = 'I': U is initialized to the unit matrix, and the orthogonal matrix U is returned; = 'N': U is not computed.

JOBV Input parameter.

JOBV is CHARACTER*1

= 'V': V must contain an orthogonal matrix V1 on entry, and the product V1* V is returned; = 'I': V is initialized to the unit matrix, and the orthogonal matrix V is returned; = 'N': V is not computed.

JOBQ Input parameter.

JOBQ is CHARACTER*1

= 'Q': Q must contain an orthogonal matrix Q1 on entry, and the product Q1* Q is returned; = 'I': Q is initialized to the unit matrix, and the orthogonal matrix Q is returned; = 'N': Q is not computed.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. P >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

K Input parameter.

K is INTEGER

L Input parameter.

L is INTEGER

K and L specify the subblocks in the input matrices A and B: A23 = A(K+1:MIN(K+L, M),N-L+1:N) and B13 = B(1:L,N-L+1:N) of A and B, whose GSVD is going to be computed by DTGSJA. See Further Details.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A(N-K+1:N,1:MIN(K+L, M)) contains the triangular matrix R or part of R. See Purpose for details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, if necessary, B(M-K+1:L,N+M-K-L+1:N) contains a part of R. See Purpose for details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

TOLA Input parameter.

TOLA is DOUBLE PRECISION

TOLB Input parameter.

TOLB is DOUBLE PRECISION

TOLA and TOLB are the convergence criteria for the Jacobi- Kogbetliantz iteration procedure. Generally, they are the same as used in the preprocessing step, say TOLA = max(M, N)*norm(A)*MAZHEPS, TOLB = max(P, N)*norm(B)*MAZHEPS.

ALPHA Output parameter.

ALPHA is DOUBLE PRECISION

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is DOUBLE PRECISION

BETA is an array, dimension (N). On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; ALPHA(1:K) = 1, BETA(1:K) = 0, and if M-K-L >= 0, ALPHA(K+1:K+L) = diag(C), BETA(K+1:K+L) = diag(S), or if M-K-L < 0, ALPHA(K+1:M)= C, ALPHA(M+1:K+L)= 0 BETA(K+1:M) = S, BETA(M+1:K+L) = 1. Furthermore, if K+L < N, ALPHA(K+L+1:N) = 0 and BETA(K+L+1:N) = 0.

U Input and output parameter.

U is DOUBLE PRECISION

U is an array, dimension (LDU, M). On entry, if JOBU = 'U', U must contain a matrix U1 (usually the orthogonal matrix returned by DGGSVP). On exit, if JOBU = 'I', U contains the orthogonal matrix U; if JOBU = 'U', U contains the product U1*U. If JOBU = 'N', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= max(1, M) if JOBU = 'U'; LDU >= 1 otherwise.

V Input and output parameter.

V is DOUBLE PRECISION

V is an array, dimension (LDV, P). On entry, if JOBV = 'V', V must contain a matrix V1 (usually the orthogonal matrix returned by DGGSVP). On exit, if JOBV = 'I', V contains the orthogonal matrix V; if JOBV = 'V', V contains the product V1*V. If JOBV = 'N', V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, P) if JOBV = 'V'; LDV >= 1 otherwise.

Q Input and output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). On entry, if JOBQ = 'Q', Q must contain a matrix Q1 (usually the orthogonal matrix returned by DGGSVP). On exit, if JOBQ = 'I', Q contains the orthogonal matrix Q; if JOBQ = 'Q', Q contains the product Q1*Q. If JOBQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N) .

NCYCLE Output parameter.

NCYCLE is INTEGER

The number of cycles required for convergence.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1: the procedure does not converge after MAXIT cycles.

Related Information

4.10.29 sbdsdc

sbdsdc computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: B = U * S * VT, using a divide and conquer method, where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and U and VT are orthogonal matrices of left and right singular vectors, respectively. sbdsdc can be used to compute all singular values, and optionally, singular vectors or singular vectors in compact form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLASD3 for details.

The code currently calls SLASDQ if singular values only are desired. However, it can be slightly modified to compute singular values using the divide and conquer method.

Syntax

Fortran specification:

```
use armpl_library

subroutine sbdsdc(UPLO, COMPQ, N, D, E, U, LDU, VT, LDVT, Q, IQ, WORK, IWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sbdsdc_(const char *uplo, const char *compq, const armpl_int_t *n,
             float *d, float *e, float *u, const armpl_int_t *ldu, float *vt,
             const armpl_int_t *ldvt, float *q, armpl_int_t *iq, float *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': B is upper bidiagonal. = 'L': B is lower bidiagonal.

COMPQ Input parameter.

COMPQ is CHARACTER*1

Specifies whether singular vectors are to be computed as follows: = 'N': Compute singular values only; = 'P': Compute singular values and compute singular vectors in compact form; = 'I': Compute singular values and singular vectors.

N Input parameter.

N is INTEGER

The order of the matrix B. N >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B.

E Input and output parameter.

E is REAL

E is an array, dimension (N-1). On entry, the elements of E contain the offdiagonal elements of the bidiagonal matrix whose SVD is desired. On exit, E has been destroyed.

U Output parameter.

U is REAL

U is an array, dimension (LDU, N). If COMPQ = 'I', then: On exit, if INFO = 0, U contains the left singular vectors of the bidiagonal matrix. For other values of COMPQ, U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= 1. If singular vectors are desired, then LDU >= max(1, N).

VT Output parameter.

VT is REAL

VT is an array, dimension (LDVT, N). If COMPQ = 'I', then: On exit, if INFO = 0, VT^T contains the right singular vectors of the bidiagonal matrix. For other values of COMPQ, VT is not referenced.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= 1. If singular vectors are desired, then LDVT >= max(1, N).

Q Output parameter.

Q is REAL

Q is an array, dimension (LDQ). If COMPQ = 'P', then: On exit, if INFO = 0, Q and IQ contain the left and right singular vectors in a compact form, requiring O(N log N) space instead of 2*N**2. In particular, Q contains all the REAL data in LDQ >= N*(11 + 2*SMLSIZ + 8*INT(LOG_2(N/(SMLSIZ+1)))) words of memory, where SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25). For other values of COMPQ, Q is not referenced.

IQ Output parameter.

IQ is INTEGER array, dimension (LDIQ)

If COMPQ = 'P', then: On exit, if INFO = 0, Q and IQ contain the left and right singular vectors in a compact form, requiring O(N log N) space instead of 2*N**2. In particular, IQ contains all INTEGER data in LDIQ >= N*(3 + 3*INT(LOG_2(N/(SMLSIZ+1)))) words of memory, where SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25). For other values of COMPQ, IQ is not referenced.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)). If COMPQ = 'N' then LWORK >= (4 * N). If COMPQ = 'P' then LWORK >= (6 * N). If COMPQ = 'I' then LWORK >= (3 * N**2 + 4 * N).

IWORK Output parameter.

IWORK is INTEGER array, dimension (8*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: The algorithm failed to compute a singular value. The update process of divide and conquer failed.

Related Information

For this routine in other precisions, please see *dbdsdc*. It also exists with a native C interface as *LAPACKE_sbdsdc*.

4.10.30 sbdsqr

sbdsqr computes the singular values and, optionally, the right and/or left singular vectors from the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B using the implicit zero-shift QR algorithm. The SVD of B has the form

```
B = Q * S * P**T
```

where S is the diagonal matrix of singular values, Q is an orthogonal matrix of left singular vectors, and P is an orthogonal matrix of right singular vectors. If left singular vectors are requested, this subroutine actually returns U*Q instead of Q, and, if right singular vectors are requested, this subroutine returns P^T *VT instead of P^T , for given real input matrices U and VT. When U and VT are the orthogonal matrices that reduce a general matrix A to bidiagonal form: A = U*B*VT, as computed by SGEBRD, then

```
A = (U*Q) * S * (P**T*VT)
```

is the SVD of A. Optionally, the subroutine may also compute Q^T *C for a given real input matrix C.

See "Computing Small Singular Values of Bidiagonal Matrices With Guaranteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Working Note #3 (or SIAM J. Sci. Statist. Comput. vol. 11, no. 5, pp. 873-912, Sept 1990) and "Accurate singular values and differential qd algorithms," by B. Parlett and V. Fernando, Technical Report CPAM-554, Mathematics Department, University of California at Berkeley, July 1992 for a detailed description of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine sbdsqr(UPLO, N, NCVT, NRU, NCC, D, E, VT, LDVT, U, LDU, C, LDC,
                  WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sbdsqr_(const char *uplo, const armpl_int_t *n, const armpl_int_t *ncvt,
             const armpl_int_t *nru, const armpl_int_t *ncc, float *d,
             float *e, float *vt, const armpl_int_t *ldvt, float *u,
             const armpl_int_t *ldu, float *c, const armpl_int_t *ldc,
             float *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': B is upper bidiagonal; = 'L': B is lower bidiagonal.

N Input parameter.

N is INTEGER

The order of the matrix B. N >= 0.

NCVT Input parameter.

NCVT is INTEGER

The number of columns of the matrix VT. NCVT >= 0.

NRU Input parameter.

NRU is INTEGER

The number of rows of the matrix U. NRU >= 0.

NCC Input parameter.

NCC is INTEGER

The number of columns of the matrix C. NCC >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B in decreasing order.

E Input and output parameter.

E is REAL

E is an array, dimension (N-1). On entry, the N-1 offdiagonal elements of the bidiagonal matrix B. On exit, if INFO = 0, E is destroyed; if INFO > 0, D and E will contain the diagonal and superdiagonal elements of a bidiagonal matrix orthogonally equivalent to the one given as input.

VT Input and output parameter.

VT is REAL

VT is an array, dimension (LDVT, NCVT). On entry, an N-by-NCVT matrix VT. On exit, VT is overwritten by P^T * VT. Not referenced if NCVT = 0.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= max(1, N) if NCVT > 0; LDVT >= 1 if NCVT = 0.

U Input and output parameter.

U is REAL

U is an array, dimension (LDU, N). On entry, an NRU-by-N matrix U. On exit, U is overwritten by U * Q. Not referenced if NRU = 0.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= max(1, NRU).

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, NCC). On entry, an N-by-NCC matrix C. On exit, C is overwritten by Q^T * C. Not referenced if NCC = 0.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, N) if NCC > 0; LDC >=1 if NCC = 0.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: If INFO = -i, the i-th argument had an illegal value > 0: if NCVT = NRU = NCC = 0, = 1, a split was marked by a positive value in E = 2, current block of Z not diagonalized after 30*N iterations (in inner while loop) = 3, termination criterion of outer while loop not met (program created more than N unreduced blocks) else NCVT = NRU = NCC = 0, the algorithm did not converge; D and E contain the elements of a bidiagonal matrix which is orthogonally similar to the input matrix B; if INFO = i, i elements of E have not converged to zero.

Related Information

For this routine in other precisions, please see *cbdsqr*, *dbdsqr* and *zbdsqr*. It also exists with a native C interface as *LAPACKE_sbdsqr*.

4.10.31 sbdsvdx

```
SBDSVDX computes the singular value decomposition (SVD) of a real
 N-by-N (upper or lower) bidiagonal matrix B, B = U * S * VT,
 where S is a diagonal matrix with non-negative diagonal elements
 (the singular values of B), and U and VT are orthogonal matrices
 of left and right singular vectors, respectively.

 Given an upper bidiagonal B with diagonal D = [ d_1 d_2 ... d_N ]
 and superdiagonal E = [ e_1 e_2 ... e_N-1 ], SBDSVDX computes the
 singular value decompositon of B through the eigenvalues and
 eigenvectors of the N*2-by-N*2 tridiagonal matrix

       |  0  d_1               |
       | d_1  0  e_1           |
 TGK = |     e_1  0  d_2       |
       |         d_2  .   .    |
       |              .   .  . |

 If (s,u,v) is a singular triplet of B with ||u|| = ||v|| = 1, then
 (+/-s,q), ||q|| = 1, are eigenpairs of TGK, with q = P * ( u' +/-v' ) /
 sqrt(2) = ( v_1 u_1 v_2 u_2 ... v_n u_n ) / sqrt(2), and
 P = [ e_{n+1} e_{1} e_{n+2} e_{2} ... ].

 Given a TGK matrix, one can either a) compute -s,-v and change signs
 so that the singular values (and corresponding vectors) are already in
 descending order (as in SGESVD/SGESDD) or b) compute s,v and reorder
 the values (and corresponding vectors). SBDSVDX implements a) by
 calling SSTEVX (bisection plus inverse iteration, to be replaced
 with a version of the Multiple Relative Robust Representation
 algorithm. (See P. Willems and B. Lang, A framework for the MR^3
 algorithm: theory and implementation, SIAM J. Sci. Comput.,
 35:740-766, 2013.)
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sbdsvdx(UPLO, JOBZ, RANGE, N, D, E, VL, VU, IL, IU, NS, S, Z, LDZ,
                   WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sbdsvdx_(const char *uplo, const char *jobz, const char *range,
              const armpl_int_t *n, const float *d, const float *e,
              const float *vl, const float *vu, const armpl_int_t *il,
              const armpl_int_t *iu, armpl_int_t *ns, float *s, float *z,
              const armpl_int_t *ldz, float *work, armpl_int_t *iwork,
              armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': B is upper bidiagonal; = 'L': B is lower bidiagonal.

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute singular values only; = 'V': Compute singular values and singular vectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all singular values will be found. = 'V': all singular values in the half-open interval [VL, VU) will be found. = 'I': the IL-th through IU-th singular values will be found.

N Input parameter.

N is INTEGER

The order of the bidiagonal matrix. N >= 0.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the bidiagonal matrix B.

E Input parameter.

E is REAL

E is an array, dimension (max(1,N-1)). The (n-1) superdiagonal elements of the bidiagonal matrix B in elements 1 to N-1.

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for singular values. VU > VL. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for singular values. VU > VL. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest singular value to be returned. 1 <= IL <= IU <= min(M, N), if min(M, N) > 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest singular value to be returned. 1 <= IL <= IU <= min(M, N), if min(M, N) > 0. Not referenced if RANGE = 'A' or 'V'.

NS Output parameter.

NS is INTEGER

The total number of singular values found. 0 <= NS <= N. If RANGE = 'A', NS = N, and if RANGE = 'I', NS = IU-IL+1.

S Output parameter.

S is REAL

S is an array, dimension (N). The first NS elements contain the selected singular values in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (2*N,K)). If JOBZ = 'V', then if INFO = 0 the first NS columns of Z contain the singular vectors of the matrix B corresponding to the selected singular values, with U in rows 1 to N and V in rows N+1 to N*2, i.e. Z = [U] [V] If JOBZ = 'N', then Z is not referenced. Note: The user must ensure that at least K = NS+1 columns are supplied in the array Z; if RANGE = 'V', the exact value of NS is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(2,N*2).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (14*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (12*N)

If JOBZ = 'V', then if INFO = 0, the first NS elements of IWORK are zero. If INFO > 0, then IWORK contains the indices of the eigenvectors that failed to converge in DSTEVX.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge in SSTEVX. The indices of the eigenvectors (as returned by SSTEVX) are stored in the array IWORK. if INFO = N*2 + 1, an internal error occurred.

Related Information

For this routine in other precisions, please see *dbdsvdx*. It also exists with a native C interface as *LAPACKE_sbdsvdx*.

4.10.32 sgbbrd

`sgbbrd` reduces a real general m-by-n band matrix A to upper bidiagonal form B by an orthogonal transformation: Q^T * A * P = B.

The routine computes B, and optionally forms Q or P^T , or computes Q^T *C for a given matrix C.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgbbrd(VECT, M, N, NCC, KL, KU, AB, LDAB, D, E, Q, LDQ, PT, LDPT,
                  C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgbbrd_(const char *vect, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *ncc, const armpl_int_t *kl,
             const armpl_int_t *ku, float *ab, const armpl_int_t *ldab,
             float *d, float *e, float *q, const armpl_int_t *ldq, float *pt,
             const armpl_int_t *ldpt, float *c, const armpl_int_t *ldc,
             float *work, armpl_int_t *info, ... );
```

Parameters

VECT Input parameter.

`VECT` is `CHARACTER*1`

Specifies whether or not the matrices `Q` and P^T are to be formed. = 'N': do not form `Q` or P^T ; = 'Q': form `Q` only; = 'P': form P^T only; = 'B': form both.

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix A. `M` >= 0.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix A. `N` >= 0.

NCC Input parameter.

`NCC` is `INTEGER`

The number of columns of the matrix `C`. `NCC` >= 0.

KL Input parameter.

`KL` is `INTEGER`

The number of subdiagonals of the matrix A. `KL` >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals of the matrix A. KU >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the m-by-n band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl). On exit, A is overwritten by values generated during the reduction.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array A. LDAB >= KL+KU+1.

D Output parameter.

D is REAL

D is an array, dimension (min(M, N)). The diagonal elements of the bidiagonal matrix B.

E Output parameter.

E is REAL

E is an array, dimension (min(M, N)-1). The superdiagonal elements of the bidiagonal matrix B.

Q Output parameter.

Q is REAL

Q is an array, dimension (LDQ, M). If VECT = 'Q' or 'B', the m-by-m orthogonal matrix Q. If VECT = 'N' or 'P', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, M) if VECT = 'Q' or 'B'; LDQ >= 1 otherwise.

PT Output parameter.

PT is REAL

PT is an array, dimension (LDPT, N). If VECT = 'P' or 'B', the n-by-n orthogonal matrix P'. If VECT = 'N' or 'Q', the array PT is not referenced.

LDPT Input parameter.

LDPT is INTEGER

The leading dimension of the array PT. LDPT >= max(1, N) if VECT = 'P' or 'B'; LDPT >= 1 otherwise.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, NCC). On entry, an m-by-ncc matrix C. On exit, C is overwritten by Q^T *C. C is not referenced if NCC = 0.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M) if NCC > 0; LDC >= 1 if NCC = 0.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (2*max(M, N)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgbbrd*, *dgbbrd* and *zgbbrd*. It also exists with a native C interface as *LAPACKE_sgbbrd*.

4.10.33 sgebrd

sgebrd reduces a general real M-by-N matrix A to upper or lower bidiagonal form B by an orthogonal transformation: $Q^T * A * P = B$.

If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgebrd(M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgebrd_(const armpl_int_t *m, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, float *d, float *e, float *tauq,
             float *taup, float *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows in the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns in the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N general matrix to be reduced. On exit, if m >= n, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors; if m < n, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Output parameter.

D is REAL

D is an array, dimension (min(M, N)). The diagonal elements of the bidiagonal matrix B: D(i) = A(i,i).

E Output parameter.

E is REAL

E is an array, dimension (min(M, N)-1). The off-diagonal elements of the bidiagonal matrix B: if m >= n, E(i) = A(i,i+1) for i = 1,2,...,n-1; if m < n, E(i) = A(i+1,i) for i = 1,2,...,m-1.

TAUQ Output parameter.

TAUQ is REAL

TAUQ is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the orthogonal matrix Q. See Further Details.

TAUP Output parameter.

TAUP is REAL

TAUP is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the orthogonal matrix P. See Further Details.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1, M, N). For optimum performance LWORK >= (M+N)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgebrd*, *dgebrd* and *zgebrd*. It also exists with a native C interface as *LAPACKE_sgebrd*.

4.10.34 sgejsv

sgejsv computes the singular value decomposition (SVD) of a real M-by-N matrix [A], where M >= N. The SVD of [A] is written as

```
[A] = [U] * [SIGMA] * [V]^t,
```

where [SIGMA] is an N-by-N (M-by-N) matrix which is zero except for its N diagonal elements, [U] is an M-by-N (or M-by-M) orthonormal matrix, and [V] is an N-by-N orthogonal matrix. The diagonal elements of [SIGMA] are the singular values of [A]. The columns of [U] and [V] are the left and the right singular vectors of [A], respectively. The matrices [U] and [V] are computed and stored in the arrays U and V, respectively. The diagonal of [SIGMA] is computed and stored in the array SVA. `sgejsv` can sometimes compute tiny singular values and their singular vectors much more accurately than other SVD routines, see below under Further Details.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgejsv(JOBA, JOBU, JOBV, JOBR, JOBT, JOBP, M, N, A, LDA, SVA, U,
                  LDU, V, LDV, WORK, LWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgejsv_(const char *joba, const char *jobu, const char *jobv,
             const char *jobr, const char *jobt, const char *jobp,
             const armpl_int_t *m, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, float *sva, float *u,
             const armpl_int_t *ldu, float *v, const armpl_int_t *ldv,
             float *work, const armpl_int_t *lwork, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

JOBA Input parameter.

JOBA is CHARACTER*1

Specifies the level of accuracy: = 'C': This option works well (high relative accuracy) if A = B * D, with well-conditioned B and arbitrary diagonal matrix D. The accuracy cannot be spoiled by COLUMN scaling. The accuracy of the computed output depends on the condition of B, and the procedure aims at the best theoretical accuracy. The relative error max_{i=1:N}|d sigma_i| / sigma_i is bounded by f(M, N)*epsilon* cond(B), independent of D. The input matrix is preprocessed with the QRF with column pivoting. This initial preprocessing and preconditioning by a rank revealing QR factorization is common for all values of JOBA. Additional actions are specified as follows: = 'E': Computation as with 'C' with an additional estimate of the condition number of B. It provides a realistic error bound. = 'F': If A = D1 * C * D2 with ill-conditioned diagonal scalings D1, D2, and well-conditioned matrix C, this option gives higher accuracy than the 'C' option. If the structure of the input matrix is not known, and relative accuracy is desirable, then this option is advisable. The input matrix A is preprocessed with QR factorization with FULL (row and column) pivoting. = 'G' Computation as with 'F' with an additional estimate of the condition number of B, where A=D*B. If A has heavily weighted rows, then using this condition number gives too pessimistic error bound. = 'A': Small singular values are the noise and the matrix is treated as numerically rank deficient. The error in the computed singular values is bounded by f(m,n)*epsilon*||A||. The computed SVD A = U * S * V^t restores A up to f(m,n)*epsilon*||A||. This gives the procedure the licence to discard (set to zero) all singular values below N*epsilon*||A||. = 'R': Similar as in 'A'. Rank revealing property of the initial QR factorization is used do reveal (using triangular factor) a gap sigma_{r+1} < epsilon * sigma_r in which case the numerical RANK is declared to be r. The SVD is computed with absolute error bounds, but more accurately than with 'A'.

JOBU Input parameter.

JOBU is CHARACTER*1

Specifies whether to compute the columns of U: = 'U': N columns of U are returned in the array U. = 'F': full set of M left sing. vectors is returned in the array U. = 'W': U may be used as workspace of length M*N. See the description of U. = 'N': U is not computed.

JOBV Input parameter.

JOBV is CHARACTER*1

Specifies whether to compute the matrix V: = 'V': N columns of V are returned in the array V; Jacobi rotations are not explicitly accumulated. = 'J': N columns of V are returned in the array V, but they are computed as the product of Jacobi rotations. This option is allowed only if JOBU .NE. 'N', i.e. in computing the full SVD. = 'W': V may be used as workspace of length N*N. See the description of V. = 'N': V is not computed.

JOBR Input parameter.

JOBR is CHARACTER*1

Specifies the RANGE for the singular values. Issues the licence to set to zero small positive singular values if they are outside specified range. If A .NE. 0 is scaled so that the largest singular value of c* A is around SQRT(BIG), BIG=SLAMCH('O'), then JOBR issues the licence to kill columns of A whose norm in c* A is less than SQRT(SFMIN) (for JOBR.EQ.'R'), or less than SMALL=SFMIN/EPSLN, where SFMIN=SLAMCH('S'), EPSLN=SLAMCH('E'). = 'N': Do not kill small columns of c*A. This option assumes that BLAS and QR factorizations and triangular solvers are implemented to work in that range. If the condition of A is greater than BIG, use SGESVJ. = 'R': RESTRICTED range for sigma(c*A) is [SQRT(SFMIN), SQRT(BIG)] (roughly, as described above). This option is recommended. ========================== For computing the singular values in the FULL range [SFMIN,BIG] use SGESVJ.

JOBT Input parameter.

JOBT is CHARACTER*1

If the matrix is square then the procedure may determine to use transposed A if A^t seems to be better with respect to convergence. If the matrix is not square, JOBT is ignored. This is subject to changes in the future. The decision is based on two values of entropy over the adjoint orbit of A^t * A. See the descriptions of WORK(6) and WORK(7). = 'T': transpose if entropy test indicates possibly faster convergence of Jacobi process if A^t is taken as input. If A is replaced with A^t, then the row pivoting is included automatically. = 'N': do not speculate. This option can be used to compute only the singular values, or the full SVD (U, SIGMA and V). For only one set of singular vectors (U or V), the caller should provide both U and V, as one of the matrices is used as workspace if the matrix A is transposed. The implementer can easily remove this constraint and make the code more complicated. See the descriptions of U and V.

JOBP Input parameter.

JOBP is CHARACTER*1

Issues the licence to introduce structured perturbations to drown denormalized numbers. This licence should be active if the denormals are poorly implemented, causing slow computation, especially in cases of fast convergence (!). For details see [1,2]. For the sake of simplicity, this perturbations are included only when the full SVD or only the singular values are requested. The implementer/user can easily add the perturbation for the cases of computing one set of singular vectors. = 'P': introduce perturbation = 'N': do not perturb

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. M >= N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

SVA Output parameter.

SVA is REAL

SVA is an array, dimension (N). On exit, - For WORK(1)/WORK(2) = ONE: The singular values of A. During the computation SVA contains Euclidean column norms of the iterated matrices in the array A. - For WORK(1) .NE. WORK(2): The singular values of A are (WORK(1)/WORK(2)) * SVA(1:N). This factored form is used if sigma_max(A) overflows or if small singular values have been saved from underflow by scaling the input matrix A. - If JOBR='R' then some of the singular values may be returned as exact zeros obtained by "set to zero" because they are below the numerical rank threshold or are denormalized numbers.

U Output parameter.

U is REAL

U is an array, dimension (LDU, N). If JOBU = 'U', then U contains on exit the M-by-N matrix of the left singular vectors. If JOBU = 'F', then U contains on exit the M-by-M matrix of the left singular vectors, including an ONB of the orthogonal complement of the Range(A). If JOBU = 'W' .AND. (JOBV.EQ.'V' .AND. JOBT.EQ.'T' .AND. M.EQ.N), then U is used as workspace if the procedure replaces A with A^t. In that case, [V] is computed in U as left singular vectors of A^t and then copied back to the V array. This 'W' option is just a reminder to the caller that in this case U is reserved as workspace of length N*N. If JOBU = 'N' U is not referenced, unless JOBT='T'.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U, LDU >= 1. IF JOBU = 'U' or 'F' or 'W', then LDU >= M.

V Output parameter.

V is REAL

V is an array, dimension (LDV, N). If JOBV = 'V', 'J' then V contains on exit the N-by-N matrix of the right singular vectors; If JOBV = 'W', AND (JOBU.EQ.'U' AND JOBT.EQ.'T' AND M.EQ.N), then V is used as workspace if the pprocedure replaces A with A^t. In that case, [U] is computed in V as right singular vectors of A^t and then copied back to the U array. This 'W' option is just a reminder to the caller that in this case V is reserved as workspace of length N*N. If JOBV = 'N' V is not referenced, unless JOBT='T'.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V, LDV >= 1. If JOBV = 'V' or 'J' or 'W', then LDV >= N.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK). On exit, WORK(1) = SCALE = WORK(2) / WORK(1) is the scaling factor such that SCALE*SVA(1:N) are the computed singular values of A. (See the description of SVA().) WORK(2) = See the description of WORK(1). WORK(3) = SCONDA is an estimate for the condition number of column equilibrated A. (If JOBA .EQ. 'E' or 'G') SCONDA is an estimate of SQRT(||(R^t * R)^(-1)||_1). It is computed using SPOCON. It holds N^(-1/4) * SCONDA <= ||R^(-1)||_2 <= N^(1/4) * SCONDA where R is the triangular factor from the QRF of A. However, if R is truncated and the numerical rank is determined to be strictly smaller than N, SCONDA is returned as -1, thus indicating that the smallest singular values might be lost.

If full SVD is needed, the following two condition numbers are useful for the analysis of the algorithm. They are provied for a developer/implementer who is familiar with the details of the method.

WORK(4) = an estimate of the scaled condition number of the triangular factor in the first QR factorization. WORK(5) = an estimate of the scaled condition number of the triangular factor in the second QR factorization.

The following two parameters are computed if JOBT .EQ. 'T'. They are provided for a developer/implementer who is familiar with the details of the method.

WORK(6) = the entropy of A^t* A :: this is the Shannon entropy of diag(A^t*A) / Trace(A^t*A) taken as point in the probability simplex. WORK(7) = the entropy of A*A^t.

LWORK Input parameter.

LWORK is INTEGER

Length of WORK to confirm proper allocation of work space. LWORK depends on the job:

If only SIGMA is needed (JOBU.EQ.'N', JOBV.EQ.'N') and -> .. no scaled condition estimate required (JOBE.EQ.'N'): LWORK >= max(2*M+N,4*N+1,7). This is the minimal requirement. ->> For optimal performance (blocked code) the optimal value is LWORK >= max(2*M+N,3*N+(N+1)*NB,7). Here NB is the optimal block size for DGEQP3 and DGEQRF. In general, optimal LWORK is computed as LWORK >= max(2*M+N,N+LWORK(DGEQP3),N+LWORK(DGEQRF), 7). -> .. an estimate of the scaled condition number of A is required (JOBA='E', 'G'). In this case, LWORK is the maximum of the above and N*N+4*N, i.e. LWORK >= max(2*M+N,N*N+4*N,7). ->> For optimal performance (blocked code) the optimal value is LWORK >= max(2*M+N,3*N+(N+1)*NB, N*N+4*N, 7). In general, the optimal length LWORK is computed as LWORK >= max(2*M+N,N+LWORK(DGEQP3),N+LWORK(DGEQRF), N+N*N+LWORK(DPOCON),7).

If SIGMA and the right singular vectors are needed (JOBV.EQ.'V'), -> the minimal requirement is LWORK >= max(2*M+N,4*N+1,7). -> For optimal performance, LWORK >= max(2*M+N,3*N+(N+1)*NB,7), where NB is the optimal block size for DGEQP3, DGEQRF, DGELQ, DORMLQ. In general, the optimal length LWORK is computed as LWORK >= max(2*M+N,N+LWORK(DGEQP3), N+LWORK(DPOCON), N+LWORK(DGELQ), 2*N+LWORK(DGEQRF), N+LWORK(DORMLQ)).

If SIGMA and the left singular vectors are needed -> the minimal requirement is LWORK >= max(2*M+N,4*N+1,7). -> For optimal performance: if JOBU.EQ.'U' :: LWORK >= max(2*M+N,3*N+(N+1)*NB,7), if JOBU.EQ.'F' :: LWORK >= max(2*M+N,3*N+(N+1)*NB,N+M*NB,7), where NB is the optimal block size for DGEQP3, DGEQRF, DORMQR. In general, the optimal length LWORK is computed as LWORK >= max(2*M+N,N+LWORK(DGEQP3),N+LWORK(DPOCON), 2*N+LWORK(DGEQRF), N+LWORK(DORMQR)). Here LWORK(DORMQR) equals N*NB (for JOBU.EQ.'U') or M*NB (for JOBU.EQ.'F').

If the full SVD is needed: (JOBU.EQ.'U' or JOBU.EQ.'F') and -> if JOBV.EQ.'V' the minimal requirement is LWORK >= max(2*M+N,6*N+2*N*N). -> if JOBV.EQ.'J' the minimal requirement is LWORK >= max(2*M+N, 4*N+N*N,2*N+N*N+6). -> For optimal performance, LWORK should be additionally larger than N+M*NB, where NB is the optimal block size for DORMQR.

IWORK Output parameter.

IWORK is INTEGER array, dimension (M+3*N).

On exit, IWORK(1) = the numerical rank determined after the initial QR factorization with pivoting. See the descriptions of JOBA and JOBR. IWORK(2) = the number of the computed nonzero singular values IWORK(3) = if nonzero, a warning message: If IWORK(3).EQ.1 then some of the column norms of A were denormalized floats. The requested high accuracy is not warranted by the data.

INFO Output parameter.

INFO is INTEGER

< 0 : if INFO = -i, then the i-th argument had an illegal value. = 0 : successful exit; > 0 : SGEJSV did not converge in the maximal allowed number of sweeps. The computed values may be inaccurate.

4.10.35 sgesdd

`sgesdd` computes the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and right singular vectors. If singular vectors are desired, it uses a divide-and-conquer algorithm.

The SVD is written

```
A = U * SIGMA * transpose(V)
```

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and V is an N-by-N orthogonal matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns VT = V^T , not V.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgesdd(JOBZ, M, N, A, LDA, S, U, LDU, VT, LDVT, WORK, LWORK, IWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sgesdd_(const char *jobz, const armpl_int_t *m, const armpl_int_t *n,
             float *a, const armpl_int_t *lda, float *s, float *u,
             const armpl_int_t *ldu, float *vt, const armpl_int_t *ldvt,
             float *work, const armpl_int_t *lwork, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

Specifies options for computing all or part of the matrix U: = 'A': all M columns of U and all N rows of V^T are returned in the arrays U and VT; = 'S': the first min(M, N) columns of U and the first min(M, N) rows of V^T are returned in the arrays U and VT; = 'O': If M >= N, the first N columns of U are overwritten on the array A and all rows of V^T are returned in the array VT; otherwise, all columns of U are returned in the array U and the first M rows of V^T are overwritten in the array A; = 'N': no columns of U or rows of V^T are computed.

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if JOBZ = 'O', A is overwritten with the first N columns of U (the left singular vectors, stored columnwise) if M >= N; A is overwritten with the first M rows of V^T (the right singular vectors, stored rowwise) otherwise. if JOBZ .ne. 'O', the contents of A are destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

S Output parameter.

S is REAL

S is an array, dimension (min(M, N)). The singular values of A, sorted so that S(i) >= S(i+1).

U Output parameter.

U is REAL

U is an array, dimension (LDU,UCOL). UCOL = M if JOBZ = 'A' or JOBZ = 'O' and M < N; UCOL = min(M, N) if JOBZ = 'S'. If JOBZ = 'A' or JOBZ = 'O' and M < N, U contains the M-by-M orthogonal matrix U; if JOBZ = 'S', U contains the first min(M, N) columns of U (the left singular vectors, stored columnwise); if JOBZ = 'O' and M >= N, or JOBZ = 'N', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= 1; if JOBZ = 'S' or 'A' or JOBZ = 'O' and M < N, LDU >= M.

VT Output parameter.

VT is REAL

VT is an array, dimension (LDVT, N). If JOBZ = 'A' or JOBZ = 'O' and M >= N, VT contains the N-by-N orthogonal matrix V^T ; if JOBZ = 'S', VT contains the first min(M, N) rows of V^T (the right singular vectors, stored rowwise); if JOBZ = 'O' and M < N, or JOBZ = 'N', VT is not referenced.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= 1; if JOBZ = 'A' or JOBZ = 'O' and M >= N, LDVT >= N; if JOBZ = 'S', LDVT >= min(M, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK;

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 1. If LWORK = -1, a workspace query is assumed. The optimal size for the WORK array is calculated and stored in WORK(1), and no other work except argument checking is performed.

Let mx = max(M, N) and mn = min(M, N). If JOBZ = 'N', LWORK >= 3*mn + max(mx, 7*mn). If JOBZ = 'O', LWORK >= 3*mn + max(mx, 5*mn*mn + 4*mn). If JOBZ = 'S', LWORK >= 4*mn*mn + 7*mn. If JOBZ = 'A', LWORK >= 4*mn*mn + 6*mn + mx. These are not tight minimums in all cases; see comments inside code. For good performance, LWORK should generally be larger; a query is recommended.

IWORK Output parameter.

IWORK is INTEGER array, dimension (8*min(M, N))

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: SBDSDC did not converge, updating process failed.

Related Information

For this routine in other precisions, please see *cgesdd*, *dgesdd* and *zgesdd*. It also exists with a native C interface as *LAPACKE_sgesdd*.

4.10.36 sgesvd

sgesvd computes the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and/or right singular vectors. The SVD is written

```
A = U * SIGMA * transpose(V)
```

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and V is an N-by-N orthogonal matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns V^T , not V.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgesvd(JOBU, JOBVT, M, N, A, LDA, S, U, LDU, VT, LDVT, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sgesvd_(const char *jobu, const char *jobvt, const armpl_int_t *m,
             const armpl_int_t *n, float *a, const armpl_int_t *lda, float *s,
             float *u, const armpl_int_t *ldu, float *vt,
             const armpl_int_t *ldvt, float *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

JOBU Input parameter.

JOBU is CHARACTER*1

Specifies options for computing all or part of the matrix U: = 'A': all M columns of U are returned in array U: = 'S': the first min(m,n) columns of U (the left singular vectors) are returned in the array U; = 'O': the first min(m,n) columns of U (the left singular vectors) are overwritten on the array A; = 'N': no columns of U (no left singular vectors) are computed.

JOBVT Input parameter.

JOBVT is CHARACTER*1

Specifies options for computing all or part of the matrix V^T : = 'A': all N rows of V^T are returned in the array VT; = 'S': the first min(m,n) rows of V^T (the right singular vectors) are returned in the array VT; = 'O': the first min(m,n) rows of V^T (the right singular vectors) are overwritten on the array A; = 'N': no rows of V^T (no right singular vectors) are computed.

JOBVT and JOBU cannot both be 'O'.

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if JOBU = 'O', A is overwritten with the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBVT = 'O', A is overwritten with the first min(m,n) rows of V^T (the right singular vectors, stored rowwise); if JOBU .ne. 'O' and JOBVT .ne. 'O', the contents of A are destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

S Output parameter.

S is REAL

S is an array, dimension (min(M, N)). The singular values of A, sorted so that S(i) >= S(i+1).

U Output parameter.

U is REAL

U is an array, dimension (LDU,UCOL). (LDU, M) if JOBU = 'A' or (LDU,min(M, N)) if JOBU = 'S'. If JOBU = 'A', U contains the M-by-M orthogonal matrix U; if JOBU = 'S', U contains the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBU = 'N' or 'O', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= 1; if JOBU = 'S' or 'A', LDU >= M.

VT Output parameter.

VT is REAL

VT is an array, dimension (LDVT, N). If JOBVT = 'A', VT contains the N-by-N orthogonal matrix V^T ; if JOBVT = 'S', VT contains the first min(m,n) rows of V^T (the right singular vectors, stored rowwise); if JOBVT = 'N' or 'O', VT is not referenced.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= 1; if JOBVT = 'A', LDVT >= N; if JOBVT = 'S', LDVT >= min(M, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK; if INFO > 0, WORK(2:MIN(M, N)) contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in S (not necessarily sorted). B satisfies A = U * B * VT, so it has the same singular values as A, and singular vectors related by U and VT.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= MAX(1,5*MIN(M, N)) for the paths (see comments inside code): - PATH 1 (M much larger than N, JOBU='N') - PATH 1t (N much larger than M, JOBVT='N') LWORK >= MAX(1,3*MIN(M, N)+MAX(M, N),5*MIN(M, N)) for the other paths For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if SBDSQR did not converge, INFO specifies how many superdiagonals of an intermediate bidiagonal form B did not converge to zero. See the description of WORK above for details.

Related Information

For this routine in other precisions, please see *cgesvd*, *dgesvd* and *zgesvd*. It also exists with a native C interface as *LAPACKE_sgesvd*.

4.10.37 sgesvdx

```
SGESVDX computes the singular value decomposition (SVD) of a real
 M-by-N matrix A, optionally computing the left and/or right singular
 vectors. The SVD is written

     A = U * SIGMA * transpose(V)

 where SIGMA is an M-by-N matrix which is zero except for its
 min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and
 V is an N-by-N orthogonal matrix.  The diagonal elements of SIGMA
 are the singular values of A; they are real and non-negative, and
 are returned in descending order.  The first min(m,n) columns of
 U and V are the left and right singular vectors of A.

 SGESVDX uses an eigenvalue problem for obtaining the SVD, which
 allows for the computation of a subset of singular values and
 vectors. See SBDSVDX for details.

 Note that the routine returns V**T, not V.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sgesvdx(JOBU, JOBVT, RANGE, M, N, A, LDA, VL, VU, IL, IU, NS, S, U,
                   LDU, VT, LDVT, WORK, LWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgesvdx_(const char *jobu, const char *jobvt, const char *range,
              const armpl_int_t *m, const armpl_int_t *n, float *a,
              const armpl_int_t *lda, const float *vl, const float *vu,
              const armpl_int_t *il, const armpl_int_t *iu, armpl_int_t *ns,
              float *s, float *u, const armpl_int_t *ldu, float *vt,
              const armpl_int_t *ldvt, float *work, const armpl_int_t *lwork,
              armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

JOBU Input parameter.

JOBU is CHARACTER*1

Specifies options for computing all or part of the matrix U: = 'V': the first min(m,n) columns of U (the left singular vectors) or as specified by RANGE are returned in the array U; = 'N': no columns of U (no left singular vectors) are computed.

JOBVT Input parameter.

JOBVT is CHARACTER*1

Specifies options for computing all or part of the matrix V^T : = 'V': the first min(m,n) rows of V^T (the right singular vectors) or as specified by RANGE are returned in the array VT; = 'N': no rows of V^T (no right singular vectors) are computed.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all singular values will be found. = 'V': all singular values in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th singular values will be found.

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the contents of A are destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for singular values. VU > VL. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for singular values. VU > VL. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest singular value to be returned. 1 <= IL <= IU <= min(M, N), if min(M, N) > 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest singular value to be returned. 1 <= IL <= IU <= min(M, N), if min(M, N) > 0. Not referenced if RANGE = 'A' or 'V'.

NS Output parameter.

NS is INTEGER

The total number of singular values found, 0 <= NS <= min(M, N). If RANGE = 'A', NS = min(M, N); if RANGE = 'I', NS = IU-IL+1.

S Output parameter.

S is REAL

S is an array, dimension (min(M, N)). The singular values of A, sorted so that S(i) >= S(i+1).

U Output parameter.

U is REAL

U is an array, dimension (LDU,UCOL). If JOBU = 'V', U contains columns of U (the left singular vectors, stored columnwise) as specified by RANGE; if JOBU = 'N', U is not referenced. Note: The user must ensure that UCOL >= NS; if RANGE = 'V', the exact value of NS is not known in advance and an upper bound must be used.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= 1; if JOBU = 'V', LDU >= M.

VT Output parameter.

VT is REAL

VT is an array, dimension (LDVT, N). If JOBVT = 'V', VT contains the rows of V^T (the right singular vectors, stored rowwise) as specified by RANGE; if JOBVT = 'N', VT is not referenced. Note: The user must ensure that LDVT >= NS; if RANGE = 'V', the exact value of NS is not known in advance and an upper bound must be used.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= 1; if JOBVT = 'V', LDVT >= NS (see above).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK;

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= MAX(1,MIN(M, N)*(MIN(M, N)+4)) for the paths (see comments inside the code): - PATH 1 (M much larger than N) - PATH 1t (N much larger than M) LWORK >= MAX(1,MIN(M, N)*2+MAX(M, N)) for the other paths. For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (12*MIN(M, N))

If INFO = 0, the first NS elements of IWORK are zero. If INFO > 0, then IWORK contains the indices of the eigenvectors that failed to converge in SBDSVDX/SSTEVX.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge in SBDSVDX/SSTEVX. if INFO = N*2 + 1, an internal error occurred in SBDSVDX

Related Information

For this routine in other precisions, please see *cgesvdx*, *dgesvdx* and *zgesvdx*. It also exists with a native C interface as *LAPACKE_sgesvdx*.

4.10.38 sgesvj

sgesvj computes the singular value decomposition (SVD) of a real M-by-N matrix A, where M >= N. The SVD of A is written as

```
                        [++]   [xx]   [x0]   [xx]
A = U * SIGMA * V^t,    [++] = [xx] * [ox] * [xx]
                        [++]   [xx]
```

where SIGMA is an N-by-N diagonal matrix, U is an M-by-N orthonormal matrix, and V is an N-by-N orthogonal matrix. The diagonal elements of SIGMA are the singular values of A. The columns of U and V are the left and the right singular vectors of A, respectively. sgesvj can sometimes compute tiny singular values and their singular vectors much more accurately than other SVD routines, see below under Further Details.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgesvj(JOBA, JOBU, JOBV, M, N, A, LDA, SVA, MV, V, LDV, WORK,
                  LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgesvj_(const char *joba, const char *jobu, const char *jobv,
             const armpl_int_t *m, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, float *sva, const armpl_int_t *mv,
             float *v, const armpl_int_t *ldv, float *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOBA Input parameter.

JOBA is CHARACTER*1

Specifies the structure of A. = 'L': The input matrix A is lower triangular; = 'U': The input matrix A is upper triangular; = 'G': The input matrix A is general M-by-N matrix, M >= N.

JOBU Input parameter.

JOBU is CHARACTER*1

Specifies whether to compute the left singular vectors (columns of U): = 'U': The left singular vectors corresponding to the nonzero singular values are computed and returned in the leading columns of A. See more details in the description of A. The default numerical orthogonality threshold is set to approximately TOL=CTOL*EPS, CTOL=SQRT(M), EPS=SLAMCH('E'). = 'C': Analogous to JOBU='U', except that user can control the level of numerical orthogonality of the computed left singular vectors. TOL can be set to TOL = CTOL*EPS, where CTOL is given on input in the array WORK. No CTOL smaller than ONE is allowed. CTOL greater than 1 / EPS is meaningless. The option 'C' can be used if M*EPS is satisfactory orthogonality of the computed left singular vectors, so CTOL=M could save few sweeps of Jacobi rotations. See the descriptions of A and WORK(1). = 'N': The matrix U is not computed. However, see the description of A.

JOBV Input parameter.

JOBV is CHARACTER*1

Specifies whether to compute the right singular vectors, that is, the matrix V: = 'V' : the matrix V is computed and returned in the array V = 'A' : the Jacobi rotations are applied to the MV-by-N array V. In other words, the right singular vector matrix V is not computed explicitly; instead it is applied to an MV-by-N matrix initially stored in the first MV rows of V. = 'N' : the matrix V is not computed and the array V is not referenced

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. 1/SLAMCH('E') > M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. M >= N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, If JOBU .EQ. 'U' .OR. JOBU .EQ. 'C': If INFO .EQ. 0 : RANKA orthonormal columns of U are returned in the leading RANKA columns of the array A. Here RANKA <= N is the number of computed singular values of A that are above the underflow threshold SLAMCH('S'). The singular vectors corresponding to underflowed or zero singular values are not computed. The value of RANKA is returned in the array WORK as RANKA=NINT(WORK(2)). Also see the descriptions of SVA and WORK. The computed columns of U are mutually numerically orthogonal up to approximately TOL=SQRT(M)*EPS (default); or TOL=CTOL*EPS (JOBU.EQ.'C'), see the description of JOBU. If INFO .GT. 0, the procedure SGESVJ did not converge in the given number of iterations (sweeps).

In that case, the computed columns of U may not be orthogonal up to TOL. The output U (stored in A), SIGMA (given by the computed singular values in SVA(1:N)) and V is still a decomposition of the input matrix A in the sense that the residual ||A-SCALE*U*SIGMA*V^T||_2 / ||A||_2 is small. If JOBU .EQ. 'N': If INFO .EQ. 0 : Note that the left singular vectors are 'for free' in the one-sided Jacobi SVD algorithm. However, if only the singular values are needed, the level of numerical orthogonality of U is not an issue and iterations are stopped when the columns of the iterated matrix are numerically orthogonal up to approximately M*EPS. Thus, on exit, A contains the columns of U scaled with the corresponding singular values. If INFO .GT. 0 : the procedure SGESVJ did not converge in the given number of iterations (sweeps).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

SVA Output parameter.

SVA is REAL

SVA is an array, dimension (N). On exit, If INFO .EQ. 0 : depending on the value SCALE = WORK(1), we have: If SCALE .EQ. ONE: SVA(1:N) contains the computed singular values of A. During the computation SVA contains the Euclidean column norms of the iterated matrices in the array A. If SCALE .NE. ONE: The singular values of A are SCALE*SVA(1:N), and this factored representation is due to the fact that some of the singular values of A might underflow or overflow.

If INFO .GT. 0 : the procedure SGESVJ did not converge in the given number of iterations (sweeps) and SCALE*SVA(1:N) may not be accurate.

MV Input parameter.

MV is INTEGER

If JOBV .EQ. 'A', then the product of Jacobi rotations in SGESVJ is applied to the first MV rows of V. See the description of JOBV.

V Input and output parameter.

V is REAL

V is an array, dimension (LDV, N). If JOBV = 'V', then V contains on exit the N-by-N matrix of the right singular vectors; If JOBV = 'A', then V contains the product of the computed right singular vector matrix and the initial matrix in the array V. If JOBV = 'N', then V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V, LDV .GE. 1. If JOBV .EQ. 'V', then LDV .GE. max(1, N). If JOBV .EQ. 'A', then LDV .GE. max(1, MV) .

WORK Input and output parameter.

WORK is REAL

WORK is an array, dimension (LWORK). On entry, If JOBU .EQ. 'C' : WORK(1) = CTOL, where CTOL defines the threshold for convergence. The process stops if all columns of A are mutually orthogonal up to CTOL*EPS, EPS=SLAMCH('E'). It is required that CTOL >= ONE, i.e. it is not allowed to force the routine to obtain orthogonality below EPSILON. On exit, WORK(1) = SCALE is the scaling factor such that SCALE*SVA(1:N) are the computed singular vcalues of A. (See description of SVA().) WORK(2) = NINT(WORK(2)) is the number of the computed nonzero singular values. WORK(3) = NINT(WORK(3)) is the number of the computed singular values that are larger than the underflow threshold. WORK(4) = NINT(WORK(4)) is the number of sweeps of Jacobi rotations needed for numerical convergence. WORK(5) = max_{i.NE.j} |COS(A(:,i),A(:,j))| in the last sweep. This is useful information in cases when SGESVJ did not converge, as it can be used to estimate whether the output is stil useful and for post festum analysis. WORK(6) = the largest absolute value over all sines of the Jacobi rotation angles in the last sweep. It can be useful for a post festum analysis.

LWORK Input parameter.

LWORK is INTEGER

length of WORK, WORK >= MAX(6,M+N)

INFO Output parameter.

INFO is INTEGER

= 0 : successful exit. < 0 : if INFO = -i, then the i-th argument had an illegal value > 0 : SGESVJ did not converge in the maximal allowed number (30) of sweeps. The output may still be useful. See the description of WORK.

Related Information

For this routine in other precisions, please see *cgesvj*, *dgesvj* and *zgesvj*. It also exists with a native C interface as *LAPACKE_sgesvj*.

4.10.39 sggsvd3

sggsvd3 computes the generalized singular value decomposition (GSVD) of an M-by-N real matrix A and P-by-N real matrix B:

```
U**T*A*Q = D1*( 0 R ),    V**T*B*Q = D2*( 0 R )
```

where U, V and Q are orthogonal matrices. Let K+L = the effective numerical rank of the matrix $(A^T, B^T)^T$, then R is a K+L-by-K+L nonsingular upper triangular matrix, D1 and D2 are M-by-(K+L) and P-by-(K+L) "diagonal" matrices and of the following structures, respectively:

If M-K-L >= 0,

```
                  K  L
     D1 =     K ( I  0 )
              L ( 0  C )
          M-K-L ( 0  0 )

                K  L
     D2 =   L ( 0  S )
          P-L ( 0  0 )

                N-K-L  K    L
( 0 R ) = K (  0   R11  R12 )
          L (  0    0   R22 )
```

where

```
C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),
S = diag( BETA(K+1),  ... , BETA(K+L) ),
C**2 + S**2 = I.

R is stored in A(1:K+L,N-K-L+1:N) on exit.
```

If M-K-L < 0,

```
                  K M-K K+L-M
     D1 =   K ( I  0    0   )
          M-K ( 0  C    0   )

                  K M-K K+L-M
     D2 =   M-K ( 0  S    0  )
          K+L-M ( 0  0    I  )
```

(continues on next page)

(continued from previous page)

```
            P-L ( 0  0    0   )

                 N-K-L  K    M-K  K+L-M
( 0 R ) =      K ( 0    R11  R12  R13  )
             M-K ( 0     0   R22  R23  )
           K+L-M ( 0     0    0   R33  )
```

where

```
C = diag( ALPHA(K+1), ... , ALPHA(M) ),
S = diag( BETA(K+1),  ... , BETA(M) ),
C**2 + S**2 = I.

(R11 R12 R13 ) is stored in A(1:M, N-K-L+1:N), and R33 is stored
( 0  R22 R23 )
in B(M-K+1:L,N+M-K-L+1:N) on exit.
```

The routine computes C, S, R, and optionally the orthogonal transformation matrices U, V and Q.

In particular, if B is an N-by-N nonsingular matrix, then the GSVD of A and B implicitly gives the SVD of A*inv(B):

```
A*inv(B) = U*(D1*inv(D2))*V**T.
```

If (A^T ,B^T)^T has orthonormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and B. Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

```
A**T*A x = lambda* B**T*B x.
```

In some literature, the GSVD of A and B is presented in the form

```
U**T*A*X = ( 0 D1 ),   V**T*B*X = ( 0 D2 )
```

where U and V are orthogonal and X is nonsingular, D1 and D2 are ‘’diagonal’‘. The former GSVD form can be converted to the latter form by taking the nonsingular matrix X as

```
X = Q*( I   0    )
      ( 0 inv(R) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sggsvd3(JOBU, JOBV, JOBQ, M, N, P, K, L, A, LDA, B, LDB, ALPHA,
                   BETA, U, LDU, V, LDV, Q, LDQ, WORK, LWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sggsvd3_(const char *jobu, const char *jobv, const char *jobq,
              const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *p, armpl_int_t *k, armpl_int_t *l, float *a,
              const armpl_int_t *lda, float *b, const armpl_int_t *ldb,
              float *alpha, float *beta, float *u, const armpl_int_t *ldu,
              float *v, const armpl_int_t *ldv, float *q,
              const armpl_int_t *ldq, float *work, const armpl_int_t *lwork,
              armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

JOBU Input parameter.

JOBU is CHARACTER*1

= 'U': Orthogonal matrix U is computed; = 'N': U is not computed.

JOBV Input parameter.

JOBV is CHARACTER*1

= 'V': Orthogonal matrix V is computed; = 'N': V is not computed.

JOBQ Input parameter.

JOBQ is CHARACTER*1

= 'Q': Orthogonal matrix Q is computed; = 'N': Q is not computed.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. P >= 0.

K Output parameter.

K is INTEGER

L Output parameter.

L is INTEGER

On exit, K and L specify the dimension of the subblocks described in Purpose. K + L = effective numerical rank of $(A^T, B^T)^T$.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A contains the triangular matrix R, or part of R. See Purpose for details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, B contains the triangular matrix R if M-K-L < 0. See Purpose for details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

ALPHA Output parameter.

ALPHA is REAL

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is REAL

BETA is an array, dimension (N). On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; ALPHA(1:K) = 1, BETA(1:K) = 0, and if M-K-L >= 0, ALPHA(K+1:K+L) = C, BETA(K+1:K+L) = S, or if M-K-L < 0, ALPHA(K+1:M)=C, ALPHA(M+1:K+L)=0 BETA(K+1:M) =S, BETA(M+1:K+L) =1 and ALPHA(K+L+1:N) = 0 BETA(K+L+1:N) = 0

U Output parameter.

U is REAL

U is an array, dimension (LDU, M). If JOBU = 'U', U contains the M-by-M orthogonal matrix U. If JOBU = 'N', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= max(1, M) if JOBU = 'U'; LDU >= 1 otherwise.

V Output parameter.

V is REAL

V is an array, dimension (LDV, P). If JOBV = 'V', V contains the P-by-P orthogonal matrix V. If JOBV = 'N', V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, P) if JOBV = 'V'; LDV >= 1 otherwise.

Q Output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). If JOBQ = 'Q', Q contains the N-by-N orthogonal matrix Q. If JOBQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

On exit, IWORK stores the sorting information. More precisely, the following loop will sort ALPHA for I = K+1, min(M,K+L) swap ALPHA(I) and ALPHA(IWORK(I)) endfor such that ALPHA(1) >= ALPHA(2) >= ... >= ALPHA(N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, the Jacobi-type procedure failed to converge. For further details, see subroutine STGSJA.

Related Information

For this routine in other precisions, please see *cggsvd3*, *dggsvd3* and *zggsvd3*. It also exists with a native C interface as *LAPACKE_sggsvd3*.

4.10.40 sggsvp3

sggsvp3 computes orthogonal matrices U, V and Q such that

```
                   N-K-L  K    L
U**T*A*Q =      K ( 0    A12  A13 )  if M-K-L >= 0;
                L ( 0     0   A23 )
            M-K-L ( 0     0    0  )

                 N-K-L  K    L
       =      K ( 0    A12  A13 )  if M-K-L < 0;
            M-K ( 0     0   A23 )

                 N-K-L  K    L
V**T*B*Q =     L ( 0     0   B13 )
            P-L ( 0     0    0  )
```

where the K-by-K matrix A12 and L-by-L matrix B13 are nonsingular upper triangular; A23 is L-by-L upper triangular if M-K-L >= 0, otherwise A23 is (M-K)-by-L upper trapezoidal. K+L = the effective numerical rank of the (M+P)-by-N matrix $(A^T, B^T)^T$.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine SGGSVD3.

Syntax

Fortran specification:

```
use armpl_library

subroutine sggsvp3(JOBU, JOBV, JOBQ, M, P, N, A, LDA, B, LDB, TOLA, TOLB, K,
                   L, U, LDU, V, LDV, Q, LDQ, IWORK, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sggsvp3_(const char *jobu, const char *jobv, const char *jobq,
              const armpl_int_t *m, const armpl_int_t *p,
              const armpl_int_t *n, float *a, const armpl_int_t *lda,
```

(continues on next page)

(continued from previous page)

```
                float *b, const armpl_int_t *ldb, const float *tola,
                const float *tolb, armpl_int_t *k, armpl_int_t *l, float *u,
                const armpl_int_t *ldu, float *v, const armpl_int_t *ldv,
                float *q, const armpl_int_t *ldq, armpl_int_t *iwork,
                float *tau, float *work, const armpl_int_t *lwork,
                armpl_int_t *info, ... );
```

Parameters

JOBU Input parameter.

JOBU is CHARACTER*1

= 'U': Orthogonal matrix U is computed; = 'N': U is not computed.

JOBV Input parameter.

JOBV is CHARACTER*1

= 'V': Orthogonal matrix V is computed; = 'N': V is not computed.

JOBQ Input parameter.

JOBQ is CHARACTER*1

= 'Q': Orthogonal matrix Q is computed; = 'N': Q is not computed.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. P >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A contains the triangular (or trapezoidal) matrix described in the Purpose section.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, B contains the triangular matrix described in the Purpose section.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

TOLA Input parameter.

TOLA is REAL

TOLB Input parameter.

TOLB is REAL

TOLA and TOLB are the thresholds to determine the effective numerical rank of matrix B and a sub-block of A. Generally, they are set to TOLA = MAX(M, N)*norm(A)*MACHEPS, TOLB = MAX(P, N)*norm(B)*MACHEPS. The size of TOLA and TOLB may affect the size of backward errors of the decomposition.

K Output parameter.

K is INTEGER

L Output parameter.

L is INTEGER

On exit, K and L specify the dimension of the subblocks described in Purpose section. K + L = effective numerical rank of $(A^T, B^T)^T$.

U Output parameter.

U is REAL

U is an array, dimension (LDU, M). If JOBU = 'U', U contains the orthogonal matrix U. If JOBU = 'N', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= max(1, M) if JOBU = 'U'; LDU >= 1 otherwise.

V Output parameter.

V is REAL

V is an array, dimension (LDV, P). If JOBV = 'V', V contains the orthogonal matrix V. If JOBV = 'N', V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, P) if JOBV = 'V'; LDV >= 1 otherwise.

Q Output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). If JOBQ = 'Q', Q contains the orthogonal matrix Q. If JOBQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (N) .

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cggsvp3*, *dggsvp3* and *zggsvp3*. It also exists with a native C interface as *LAPACKE_sggsvp3*.

4.10.41 sorgbr

sorgbr generates one of the real orthogonal matrices Q or P^T determined by SGEBRD when reducing a real matrix A to bidiagonal form: A = Q * B * P^T . Q and P^T are defined as products of elementary reflectors H(i) or G(i) respectively.

If VECT = 'Q', A is assumed to have been an M-by-K matrix, and Q is of order M: if m >= k, Q = H(1) H(2) . . . H(k) and sorgbr returns the first n columns of Q, where m >= n >= k; if m < k, Q = H(1) H(2) . . . H(m-1) and sorgbr returns Q as an M-by-M matrix.

If VECT = 'P', A is assumed to have been a K-by-N matrix, and P^T is of order N: if k < n, P^T = G(k) . . . G(2) G(1) and sorgbr returns the first m rows of P^T , where n >= m >= k; if k >= n, P^T = G(n-1) . . . G(2) G(1) and sorgbr returns P^T as an N-by-N matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine sorgbr(VECT, M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorgbr_(const char *vect, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *k, float *a, const armpl_int_t *lda,
             const float *tau, float *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

Specifies whether the matrix Q or the matrix P^T is required, as defined in the transformation applied by SGEBRD: = 'Q': generate Q; = 'P': generate P^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix Q or P^T to be returned. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q or P^T to be returned. N >= 0. If VECT = 'Q', M >= N >= min(M, K); if VECT = 'P', N >= M >= min(N, K).

K Input parameter.

K is INTEGER

If VECT = 'Q', the number of columns in the original M-by-K matrix reduced by SGEBRD. If VECT = 'P', the number of rows in the original K-by-N matrix reduced by SGEBRD. K >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the vectors which define the elementary reflectors, as returned by SGEBRD. On exit, the M-by-N matrix Q or P^T .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is REAL

TAU is an array, dimension. (min(M, K)) if VECT = 'Q' (min(N, K)) if VECT = 'P' TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i), which determines Q or P^T , as returned by SGEBRD in its array argument TAUQ or TAUP.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,min(M, N)). For optimum performance LWORK >= min(M, N)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dorgbr*. It also exists with a native C interface as *LAPACKE_sorgbr*.

4.10.42 sormbr

If VECT = 'Q', `sormbr` overwrites the general real M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T

If VECT = 'P', `sormbr` overwrites the general real M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': P * C C * P TRANS = 'T': P^T * C C * P^T

Here Q and P^T are the orthogonal matrices determined by SGEBRD when reducing a real matrix A to bidiagonal form: A = Q * B * P^T . Q and P^T are defined as products of elementary reflectors H(i) and G(i) respectively.

Let nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Thus nq is the order of the orthogonal matrix Q or P^T that is applied.

If VECT = 'Q', A is assumed to have been an NQ-by-K matrix: if nq >= k, Q = H(1) H(2) . . . H(k); if nq < k, Q = H(1) H(2) . . . H(nq-1).

If VECT = 'P', A is assumed to have been a K-by-NQ matrix: if k < nq, P = G(1) G(2) . . . G(k); if k >= nq, P = G(1) G(2) . . . G(nq-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine sormbr(VECT, SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK,
                  LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sormbr_(const char *vect, const char *side, const char *trans,
             const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             const float *a, const armpl_int_t *lda, const float *tau,
             float *c, const armpl_int_t *ldc, float *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

= 'Q': apply Q or Q^T ; = 'P': apply P or P^T .

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q, Q^T , P or P^T from the Left; = 'R': apply Q, Q^T , P or P^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q or P; = 'T': Transpose, apply Q^T or P^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

If VECT = 'Q', the number of columns in the original matrix reduced by SGEBRD. If VECT = 'P', the number of rows in the original matrix reduced by SGEBRD. K >= 0.

A Input parameter.

A is REAL

A is an array, dimension. (LDA,min(nq, K)) if VECT = 'Q' (LDA,nq) if VECT = 'P' The vectors which define the elementary reflectors H(i) and G(i), whose products determine the matrices Q and P, as returned by SGEBRD.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If VECT = 'Q', LDA >= max(1,nq); if VECT = 'P', LDA >= max(1,min(nq, K)).

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (min(nq, K)). TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i) which determines Q or P, as returned by SGEBRD in the array argument TAUQ or TAUP.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q or P* C or P^T * C or C*P or C*P^T .

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dormbr*. It also exists with a native C interface as *LAPACKE_sormbr*.

4.10.43 stgsja

stgsja computes the generalized singular value decomposition (GSVD) of two real upper triangular (or trapezoidal) matrices A and B.

On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine SGGSVP from a general M-by-N matrix A and P-by-N matrix B:

```
           N-K-L  K    L
A =    K ( 0    A12  A13 ) if M-K-L >= 0;
       L ( 0     0   A23 )
   M-K-L ( 0     0    0  )

         N-K-L  K    L
A =  K ( 0    A12  A13 ) if M-K-L < 0;
   M-K ( 0     0   A23 )

         N-K-L  K    L
B =  L ( 0     0   B13 )
   P-L ( 0     0    0  )
```

where the K-by-K matrix A12 and L-by-L matrix B13 are nonsingular upper triangular; A23 is L-by-L upper triangular if M-K-L >= 0, otherwise A23 is (M-K)-by-L upper trapezoidal.

On exit,

```
U**T *A*Q = D1*( 0 R ),    V**T *B*Q = D2*( 0 R ),
```

where U, V and Q are orthogonal matrices. R is a nonsingular upper triangular matrix, and D1 and D2 are ‘’diagonal” matrices, which are of the following structures:

If M-K-L >= 0,

```
                  K  L
     D1 =     K ( I  0 )
              L ( 0  C )
            M-K-L ( 0  0 )

                  K  L
     D2 = L   ( 0  S )
            P-L ( 0  0 )

               N-K-L  K    L
( 0 R ) = K (  0   R11  R12 ) K
          L (  0    0   R22 ) L
```

where

```
C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),
S = diag( BETA(K+1),  ... , BETA(K+L) ),
C**2 + S**2 = I.

R is stored in A(1:K+L,N-K-L+1:N) on exit.
```

If M-K-L < 0,

```
            K M-K K+L-M
D1 =   K ( I  0    0   )
     M-K ( 0  C    0   )

              K M-K K+L-M
D2 =   M-K ( 0  S    0   )
     K+L-M ( 0  0    I   )
       P-L ( 0  0    0   )

            N-K-L  K   M-K  K+L-M
```

(0 R) = K (0 R11 R12 R13)

```
  M-K ( 0     0   R22  R23  )
K+L-M ( 0     0    0   R33  )
```

where C = diag(ALPHA(K+1), ... , ALPHA(M)), S = diag(BETA(K+1), ... , BETA(M)), C**2 + S**2 = I.

R = (R11 R12 R13) is stored in A(1:M, N-K-L+1:N) and R33 is stored

```
(  0  R22 R23 )
```

in B(M-K+1:L,N+M-K-L+1:N) on exit.

The computation of the orthogonal transformation matrices U, V or Q is optional. These matrices may either be formed explicitly, or they may be postmultiplied into input matrices U1, V1, or Q1.

Syntax

Fortran specification:

```
use armpl_library

subroutine stgsja(JOBU, JOBV, JOBQ, M, P, N, K, L, A, LDA, B, LDB, TOLA, TOLB,
                  ALPHA, BETA, U, LDU, V, LDV, Q, LDQ, WORK, NCYCLE, INFO)
```

C specification:

```
#include "armpl.h"

void stgsja_(const char *jobu, const char *jobv, const char *jobq,
             const armpl_int_t *m, const armpl_int_t *p, const armpl_int_t *n,
             const armpl_int_t *k, const armpl_int_t *l, float *a,
             const armpl_int_t *lda, float *b, const armpl_int_t *ldb,
             const float *tola, const float *tolb, float *alpha, float *beta,
             float *u, const armpl_int_t *ldu, float *v,
             const armpl_int_t *ldv, float *q, const armpl_int_t *ldq,
             float *work, armpl_int_t *ncycle, armpl_int_t *info, ... );
```

Parameters

JOBU Input parameter.

JOBU is CHARACTER*1

= 'U': U must contain an orthogonal matrix U1 on entry, and the product U1* U is returned; = 'I': U is initialized to the unit matrix, and the orthogonal matrix U is returned; = 'N': U is not computed.

JOBV Input parameter.

JOBV is CHARACTER*1

= 'V': V must contain an orthogonal matrix V1 on entry, and the product V1* V is returned; = 'I': V is initialized to the unit matrix, and the orthogonal matrix V is returned; = 'N': V is not computed.

JOBQ Input parameter.

JOBQ is CHARACTER*1

= 'Q': Q must contain an orthogonal matrix Q1 on entry, and the product Q1* Q is returned; = 'I': Q is initialized to the unit matrix, and the orthogonal matrix Q is returned; = 'N': Q is not computed.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. P >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

K Input parameter.

K is INTEGER

L Input parameter.

L is INTEGER

K and L specify the subblocks in the input matrices A and B: A23 = A(K+1:MIN(K+L, M),N-L+1:N) and B13 = B(1:L,N-L+1:N) of A and B, whose GSVD is going to be computed by STGSJA. See Further Details.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A(N-K+1:N,1:MIN(K+L, M)) contains the triangular matrix R or part of R. See Purpose for details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, if necessary, B(M-K+1:L,N+M-K-L+1:N) contains a part of R. See Purpose for details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

TOLA Input parameter.

TOLA is REAL

TOLB Input parameter.

TOLB is REAL

TOLA and TOLB are the convergence criteria for the Jacobi- Kogbetliantz iteration procedure. Generally, they are the same as used in the preprocessing step, say TOLA = max(M, N)*norm(A)*MACHEPS, TOLB = max(P, N)*norm(B)*MACHEPS.

ALPHA Output parameter.

ALPHA is REAL

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is REAL

BETA is an array, dimension (N). On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; ALPHA(1:K) = 1, BETA(1:K) = 0, and if M-K-L >= 0, ALPHA(K+1:K+L) = diag(C), BETA(K+1:K+L) = diag(S), or if M-K-L < 0, ALPHA(K+1:M)= C, ALPHA(M+1:K+L)= 0 BETA(K+1:M) = S, BETA(M+1:K+L) = 1. Furthermore, if K+L < N, ALPHA(K+L+1:N) = 0 and BETA(K+L+1:N) = 0.

U Input and output parameter.

U is REAL

U is an array, dimension (LDU, M). On entry, if JOBU = 'U', U must contain a matrix U1 (usually the orthogonal matrix returned by SGGSVP). On exit, if JOBU = 'I', U contains the orthogonal matrix U; if JOBU = 'U', U contains the product U1*U. If JOBU = 'N', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= max(1, M) if JOBU = 'U'; LDU >= 1 otherwise.

V Input and output parameter.

V is REAL

V is an array, dimension (LDV, P). On entry, if JOBV = 'V', V must contain a matrix V1 (usually the orthogonal matrix returned by SGGSVP). On exit, if JOBV = 'I', V contains the orthogonal matrix V; if JOBV = 'V', V contains the product V1*V. If JOBV = 'N', V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, P) if JOBV = 'V'; LDV >= 1 otherwise.

Q Input and output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). On entry, if JOBQ = 'Q', Q must contain a matrix Q1 (usually the orthogonal matrix returned by SGGSVP). On exit, if JOBQ = 'I', Q contains the orthogonal matrix Q; if JOBQ = 'Q', Q contains the product Q1*Q. If JOBQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (2*N) .

NCYCLE Output parameter.

NCYCLE is INTEGER

The number of cycles required for convergence.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1: the procedure does not converge after MAXIT cycles.

4.10.44 zbdsqr

zbdsqr computes the singular values and, optionally, the right and/or left singular vectors from the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B using the implicit zero-shift QR algorithm. The SVD of B has the form

```
B = Q * S * P**H
```

where S is the diagonal matrix of singular values, Q is an orthogonal matrix of left singular vectors, and P is an orthogonal matrix of right singular vectors. If left singular vectors are requested, this subroutine actually returns U*Q instead of Q, and, if right singular vectors are requested, this subroutine returns P^H *VT instead of P^H , for given complex input matrices U and VT. When U and VT are the unitary matrices that reduce a general matrix A to bidiagonal form: A = U*B*VT, as computed by ZGEBRD, then

```
A = (U*Q) * S * (P**H*VT)
```

is the SVD of A. Optionally, the subroutine may also compute Q^H *C for a given complex input matrix C.

See "Computing Small Singular Values of Bidiagonal Matrices With Guaranteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Working Note #3 (or SIAM J. Sci. Statist. Comput. vol. 11, no. 5, pp. 873-912, Sept 1990) and "Accurate singular values and differential qd algorithms," by B. Parlett and V. Fernando, Technical Report CPAM-554, Mathematics Department, University of California at Berkeley, July 1992 for a detailed description of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine zbdsqr(UPLO, N, NCVT, NRU, NCC, D, E, VT, LDVT, U, LDU, C, LDC,
                  RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zbdsqr_(const char *uplo, const armpl_int_t *n, const armpl_int_t *ncvt,
             const armpl_int_t *nru, const armpl_int_t *ncc, double *d,
             double *e, armpl_doublecomplex_t *vt, const armpl_int_t *ldvt,
             armpl_doublecomplex_t *u, const armpl_int_t *ldu,
             armpl_doublecomplex_t *c, const armpl_int_t *ldc, double *rwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': B is upper bidiagonal; = 'L': B is lower bidiagonal.

N Input parameter.

N is INTEGER

The order of the matrix B. N >= 0.

NCVT Input parameter.

NCVT is INTEGER

The number of columns of the matrix VT. NCVT >= 0.

NRU Input parameter.

NRU is INTEGER

The number of rows of the matrix U. NRU >= 0.

NCC Input parameter.

NCC is INTEGER

The number of columns of the matrix C. NCC >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B in decreasing order.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). On entry, the N-1 offdiagonal elements of the bidiagonal matrix B. On exit, if INFO = 0, E is destroyed; if INFO > 0, D and E will contain the diagonal and superdiagonal elements of a bidiagonal matrix orthogonally equivalent to the one given as input.

VT Input and output parameter.

VT is COMPLEX*16

VT is an array, dimension (LDVT, NCVT). On entry, an N-by-NCVT matrix VT. On exit, VT is overwritten by P^H * VT. Not referenced if NCVT = 0.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= max(1, N) if NCVT > 0; LDVT >= 1 if NCVT = 0.

U Input and output parameter.

U is COMPLEX*16

U is an array, dimension (LDU, N). On entry, an NRU-by-N matrix U. On exit, U is overwritten by U * Q. Not referenced if NRU = 0.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= max(1, NRU).

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, NCC). On entry, an N-by-NCC matrix C. On exit, C is overwritten by Q^H * C. Not referenced if NCC = 0.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, N) if NCC > 0; LDC >=1 if NCC = 0.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (4*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: If INFO = -i, the i-th argument had an illegal value > 0: the algorithm did not converge; D and E contain the elements of a bidiagonal matrix which is orthogonally similar to the input matrix B; if INFO = i, i elements of E have not converged to zero.

Related Information

For this routine in other precisions, please see *cbdsqr*, *dbdsqr* and *sbdsqr*. It also exists with a native C interface as *LAPACKE_zbdsqr*.

4.10.45 zgbbrd

zgbbrd reduces a complex general m-by-n band matrix A to real upper bidiagonal form B by a unitary transformation: Q^H * A * P = B.

The routine computes B, and optionally forms Q or P^H , or computes Q^H *C for a given matrix C.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgbbrd(VECT, M, N, NCC, KL, KU, AB, LDAB, D, E, Q, LDQ, PT, LDPT,
                  C, LDC, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgbbrd_(const char *vect, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *ncc, const armpl_int_t *kl,
             const armpl_int_t *ku, armpl_doublecomplex_t *ab,
             const armpl_int_t *ldab, double *d, double *e,
             armpl_doublecomplex_t *q, const armpl_int_t *ldq,
             armpl_doublecomplex_t *pt, const armpl_int_t *ldpt,
             armpl_doublecomplex_t *c, const armpl_int_t *ldc,
             armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
             ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

Specifies whether or not the matrices Q and P^H are to be formed. = 'N': do not form Q or P^H ; = 'Q': form Q only; = 'P': form P^H only; = 'B': form both.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NCC Input parameter.

NCC is INTEGER

The number of columns of the matrix C. NCC >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals of the matrix A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals of the matrix A. KU >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the m-by-n band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl). On exit, A is overwritten by values generated during the reduction.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array A. LDAB >= KL+KU+1.

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (min(M, N)). The diagonal elements of the bidiagonal matrix B.

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (min(M, N)-1). The superdiagonal elements of the bidiagonal matrix B.

Q Output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, M). If VECT = 'Q' or 'B', the m-by-m unitary matrix Q. If VECT = 'N' or 'P', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, M) if VECT = 'Q' or 'B'; LDQ >= 1 otherwise.

PT Output parameter.

PT is COMPLEX*16

PT is an array, dimension (LDPT, N). If VECT = 'P' or 'B', the n-by-n unitary matrix P'. If VECT = 'N' or 'Q', the array PT is not referenced.

LDPT Input parameter.

LDPT is INTEGER

The leading dimension of the array PT. LDPT >= max(1, N) if VECT = 'P' or 'B'; LDPT >= 1 otherwise.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, NCC). On entry, an m-by-ncc matrix C. On exit, C is overwritten by Q^H *C. C is not referenced if NCC = 0.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M) if NCC > 0; LDC >= 1 if NCC = 0.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (max(M, N)) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (max(M, N)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

4.10.46 zgebrd

zgebrd reduces a general complex M-by-N matrix A to upper or lower bidiagonal form B by a unitary transformation: Q^H * A * P = B.

If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgebrd(M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgebrd_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda, double *d,
             double *e, armpl_doublecomplex_t *tauq,
             armpl_doublecomplex_t *taup, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows in the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns in the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N general matrix to be reduced. On exit, if m >= n, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors; if m < n, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (min(M, N)). The diagonal elements of the bidiagonal matrix B: D(i) = A(i,i).

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (min(M, N)-1). The off-diagonal elements of the bidiagonal matrix B: if m >= n, E(i) = A(i,i+1) for i = 1,2,...,n-1; if m < n, E(i) = A(i+1,i) for i = 1,2,...,m-1.

TAUQ Output parameter.

TAUQ is COMPLEX*16

TAUQ is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the unitary matrix Q. See Further Details.

TAUP Output parameter.

TAUP is COMPLEX*16

TAUP is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the unitary matrix P. See Further Details.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1, M, N). For optimum performance LWORK >= (M+N)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgebrd*, *dgebrd* and *sgebrd*. It also exists with a native C interface as *LAPACKE_zgebrd*.

4.10.47 zgejsv

zgejsv computes the singular value decomposition (SVD) of a complex M-by-N matrix [A], where M >= N. The SVD of [A] is written as

```
[A] = [U] * [SIGMA] * [V]^*,
```

where [SIGMA] is an N-by-N (M-by-N) matrix which is zero except for its N diagonal elements, [U] is an M-by-N (or M-by-M) unitary matrix, and [V] is an N-by-N unitary matrix. The diagonal elements of [SIGMA] are the singular values of [A]. The columns of [U] and [V] are the left and the right singular vectors of [A], respectively. The matrices [U] and [V] are computed and stored in the arrays U and V, respectively. The diagonal of [SIGMA] is computed and stored in the array SVA.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgejsv(JOBA, JOBU, JOBV, JOBR, JOBT, JOBP, M, N, A, LDA, SVA, U,
                  LDU, V, LDV, CWORK, LWORK, RWORK, LRWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgejsv_(const char *joba, const char *jobu, const char *jobv,
             const char *jobr, const char *jobt, const char *jobp,
             const armpl_int_t *m, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda, double *sva,
             armpl_doublecomplex_t *u, const armpl_int_t *ldu,
             armpl_doublecomplex_t *v, const armpl_int_t *ldv,
             armpl_doublecomplex_t *cwork, const armpl_int_t *lwork,
             double *rwork, const armpl_int_t *lrwork, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

JOBA Input parameter.

JOBA is CHARACTER*1

Specifies the level of accuracy: = 'C': This option works well (high relative accuracy) if A = B * D, with well-conditioned B and arbitrary diagonal matrix D. The accuracy cannot be spoiled by COLUMN scaling. The accuracy of the computed output depends on the condition of B, and the procedure aims at the best theoretical accuracy. The relative error max_{i=1:N}|d sigma_i| / sigma_i is bounded by f(M, N)*epsilon* cond(B), independent of D. The input matrix is preprocessed with the QRF with column pivoting. This initial preprocessing and preconditioning by a rank revealing QR factorization is common for all values of JOBA. Additional actions are specified as follows: = 'E': Computation as with 'C' with an additional estimate of the condition number of B. It provides a realistic error bound. = 'F': If A = D1 * C * D2 with ill-conditioned diagonal scalings D1, D2, and well-conditioned matrix C, this option gives higher accuracy than the 'C' option. If the structure of the input matrix is not known, and relative accuracy is desirable, then this option is advisable. The input matrix A is preprocessed with QR factorization with FULL (row and column) pivoting. = 'G' Computation as with 'F' with an additional estimate of the condition number of B, where A=B*D. If A has heavily weighted rows, then using this condition number gives too pessimistic error bound. = 'A': Small singular values are not well determined by the data and are considered as noisy; the matrix is treated as numerically rank defficient. The error in the computed singular values is bounded by f(m,n)*epsilon*||A||. The computed SVD A = U * S * V^* restores A up to f(m,n)*epsilon*||A||. This gives the procedure the licence to discard (set to zero) all singular values below N*epsilon*||A||. = 'R': Similar as in 'A'. Rank revealing property of the initial QR factorization is used do reveal (using triangular factor) a gap sigma_{r+1} < epsilon * sigma_r in which case the numerical RANK is declared to be r. The SVD is computed with absolute error bounds, but more accurately than with 'A'.

JOBU Input parameter.

JOBU is CHARACTER*1

Specifies whether to compute the columns of U: = 'U': N columns of U are returned in the array U. = 'F': full set of M left sing. vectors is returned in the array U. = 'W': U may be used as workspace of length M*N. See the description of U. = 'N': U is not computed.

JOBV Input parameter.

JOBV is CHARACTER*1

Specifies whether to compute the matrix V: = 'V': N columns of V are returned in the array V; Jacobi rotations are not explicitly accumulated. = 'J': N columns of V are returned in the array V, but they are computed as the product of Jacobi rotations, if JOBT .EQ. 'N'. = 'W': V may be used as workspace of length N*N. See the description of V. = 'N': V is not computed.

JOBR Input parameter.

JOBR is CHARACTER*1

Specifies the RANGE for the singular values. Issues the licence to set to zero small positive singular values if they are outside specified range. If A .NE. 0 is scaled so that the largest singular value of c* A is around SQRT(BIG), BIG=DLAMCH('O'), then JOBR issues the licence to kill columns of A

whose norm in c* A is less than SQRT(SFMIN) (for JOBR.EQ.'R'), or less than SMALL=SFMIN/EPSLN, where SFMIN=DLAMCH('S'), EPSLN=DLAMCH('E'). = 'N': Do not kill small columns of c*A. This option assumes that BLAS and QR factorizations and triangular solvers are implemented to work in that range. If the condition of A is greater than BIG, use ZGESVJ. = 'R': RESTRICTED range for sigma(c*A) is [SQRT(SFMIN), SQRT(BIG)] (roughly, as described above). This option is recommended. ========== For computing the singular values in the FULL range [SFMIN,BIG] use ZGESVJ.

JOBT Input parameter.

JOBT is CHARACTER*1

If the matrix is square then the procedure may determine to use transposed A if A^* seems to be better with respect to convergence. If the matrix is not square, JOBT is ignored. The decision is based on two values of entropy over the adjoint orbit of A^* * A. See the descriptions of WORK(6) and WORK(7). = 'T': transpose if entropy test indicates possibly faster convergence of Jacobi process if A^* is taken as input. If A is replaced with A^*, then the row pivoting is included automatically. = 'N': do not speculate. The option 'T' can be used to compute only the singular values, or the full SVD (U, SIGMA and V). For only one set of singular vectors (U or V), the caller should provide both U and V, as one of the matrices is used as workspace if the matrix A is transposed. The implementer can easily remove this constraint and make the code more complicated. See the descriptions of U and V. In general, this option is considered experimental, and 'N'; should be preferred. This is subject to changes in the future.

JOBP Input parameter.

JOBP is CHARACTER*1

Issues the licence to introduce structured perturbations to drown denormalized numbers. This licence should be active if the denormals are poorly implemented, causing slow computation, especially in cases of fast convergence (!). For details see [1,2]. For the sake of simplicity, this perturbations are included only when the full SVD or only the singular values are requested. The implementer/user can easily add the perturbation for the cases of computing one set of singular vectors. = 'P': introduce perturbation = 'N': do not perturb

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. M >= N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

SVA Output parameter.

SVA is DOUBLE PRECISION

SVA is an array, dimension (N). On exit, - For WORK(1)/WORK(2) = ONE: The singular values of A. During the computation SVA contains Euclidean column norms of the iterated matrices in the array A. - For WORK(1) .NE. WORK(2): The singular values of A are (WORK(1)/WORK(2)) * SVA(1:N). This factored form is used if sigma_max(A) overflows or if small singular values have been saved from underflow by scaling the input matrix A. - If JOBR='R' then some of the singular values may be returned as exact zeros obtained by "set to zero" because they are below the numerical rank threshold or are denormalized numbers.

U Output parameter.

U is COMPLEX*16

U is an array, dimension (LDU, N). If JOBU = 'U', then U contains on exit the M-by-N matrix of the left singular vectors. If JOBU = 'F', then U contains on exit the M-by-M matrix of the left singular vectors, including an ONB of the orthogonal complement of the Range(A). If JOBU = 'W' .AND. (JOBV.EQ.'V' .AND. JOBT.EQ.'T' .AND. M.EQ.N), then U is used as workspace if the procedure replaces A with A^*. In that case, [V] is computed in U as left singular vectors of A^* and then copied back to the V array. This 'W' option is just a reminder to the caller that in this case U is reserved as workspace of length N*N. If JOBU = 'N' U is not referenced, unless JOBT='T'.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U, LDU >= 1. IF JOBU = 'U' or 'F' or 'W', then LDU >= M.

V Output parameter.

V is COMPLEX*16

V is an array, dimension (LDV, N). If JOBV = 'V', 'J' then V contains on exit the N-by-N matrix of the right singular vectors; If JOBV = 'W', AND (JOBU.EQ.'U' AND JOBT.EQ.'T' AND M.EQ.N), then V is used as workspace if the pprocedure replaces A with A^*. In that case, [U] is computed in V as right singular vectors of A^* and then copied back to the U array. This 'W' option is just a reminder to the caller that in this case V is reserved as workspace of length N*N. If JOBV = 'N' V is not referenced, unless JOBT='T'.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V, LDV >= 1. If JOBV = 'V' or 'J' or 'W', then LDV >= N.

CWORK Output parameter.

CWORK is COMPLEX*16

CWORK is an array, dimension (MAX(2, LWORK)). If the call to ZGEJSV is a workspace query (indicated by LWORK=-1 or LRWORK=-1), then on exit CWORK(1) contains the required length of CWORK for the job parameters used in the call.

LWORK Input parameter.

LWORK is INTEGER

Length of CWORK to confirm proper allocation of workspace. LWORK depends on the job:

1. If only SIGMA is needed (JOBU.EQ.'N', JOBV.EQ.'N') and 1.1 .. no scaled condition estimate required (JOBA.NE.'E'.AND.JOBA.NE.'G'): LWORK >= 2*N+1. This is the minimal requirement. ->> For optimal performance (blocked code) the optimal value is LWORK >= N + (N+1)*NB. Here NB is the optimal block size for ZGEQP3 and ZGEQRF. In general, optimal LWORK is computed as LWORK >= max(N+LWORK(ZGEQP3),N+LWORK(ZGEQRF), LWORK(ZGESVJ)). 1.2. .. an estimate of the scaled condition number of A is required (JOBA='E', or 'G'). In this case, LWORK the minimal requirement is LWORK >= N* N + 2*N. ->> For optimal performance (blocked code) the optimal value is LWORK >= max(N+(N+1)*NB, N*N+2*N)=N**2+2*N. In general, the optimal length LWORK is computed as LWORK >= max(N+LWORK(ZGEQP3),N+LWORK(ZGEQRF), LWORK(ZGESVJ), N*N+LWORK(ZPOCON)). 2. If SIGMA and the right singular vectors are needed (JOBV.EQ.'V'), (JOBU.EQ.'N') 2.1 .. no scaled condition estimate requested (JOBE.EQ.'N'): -> the minimal requirement is LWORK >= 3*N. -> For optimal performance, LWORK >= max(N+(N+1)*NB, 2*N+N*NB)=2*N+N*NB, where NB is the optimal block size for ZGEQP3, ZGEQRF, ZGELQ, ZUNMLQ. In general, the optimal length LWORK is computed as LWORK >= max(N+LWORK(ZGEQP3), N+LWORK(ZGESVJ), N+LWORK(ZGELQF), 2*N+LWORK(ZGEQRF), N+LWORK(ZUNMLQ)). 2.2 .. an estimate of the scaled condition number of A is required (JOBA='E', or 'G'). -> the minimal requirement is LWORK >= 3*N. -> For optimal performance, LWORK >= max(N+(N+1)*NB, 2*N,2*N+N*NB)=2*N+N*NB, where NB is the optimal block size for ZGEQP3, ZGEQRF, ZGELQ, ZUNMLQ. In general, the optimal length LWORK is computed as LWORK >= max(N+LWORK(ZGEQP3), LWORK(ZPOCON), N+LWORK(ZGESVJ),

N+LWORK(ZGELQF), 2*N+LWORK(ZGEQRF), N+LWORK(ZUNMLQ)). 3. If SIGMA and the left singular vectors are needed 3.1 .. no scaled condition estimate requested (JOBE.EQ.'N'): -> the minimal requirement is LWORK >= 3*N. -> For optimal performance: if JOBU.EQ.'U' :: LWORK >= max(3*N, N+(N+1)*NB, 2*N+N*NB)=2*N+N*NB, where NB is the optimal block size for ZGEQP3, ZGEQRF, ZUNMQR. In general, the optimal length LWORK is computed as LWORK >= max(N+LWORK(ZGEQP3), 2*N+LWORK(ZGEQRF), N+LWORK(ZUNMQR)). 3.2 .. an estimate of the scaled condition number of A is required (JOBA='E', or 'G'). -> the minimal requirement is LWORK >= 3*N. -> For optimal performance: if JOBU.EQ.'U' :: LWORK >= max(3*N, N+(N+1)*NB, 2*N+N*NB)=2*N+N*NB, where NB is the optimal block size for ZGEQP3, ZGEQRF, ZUNMQR. In general, the optimal length LWORK is computed as LWORK >= max(N+LWORK(ZGEQP3),N+LWORK(ZPOCON), 2*N+LWORK(ZGEQRF), N+LWORK(ZUNMQR)). 4. If the full SVD is needed: (JOBU.EQ.'U' or JOBU.EQ.'F') and 4.1. if JOBV.EQ.'V' the minimal requirement is LWORK >= 5*N+2*N*N. 4.2. if JOBV.EQ.'J' the minimal requirement is LWORK >= 4*N+N*N. In both cases, the allocated CWORK can accommodate blocked runs of ZGEQP3, ZGEQRF, ZGELQF, SUNMQR, ZUNMLQ.

If the call to ZGEJSV is a workspace query (indicated by LWORK=-1 or LRWORK=-1), then on exit CWORK(1) contains the optimal and CWORK(2) contains the minimal length of CWORK for the job parameters used in the call.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (MAX(7, LWORK)). On exit, RWORK(1) = Determines the scaling factor SCALE = RWORK(2) / RWORK(1) such that SCALE*SVA(1:N) are the computed singular values of A. (See the description of SVA().) RWORK(2) = See the description of RWORK(1). RWORK(3) = SCONDA is an estimate for the condition number of column equilibrated A. (If JOBA .EQ. 'E' or 'G') SCONDA is an estimate of SQRT(||(R^* * R)^(-1)||_1). It is computed using SPOCON. It holds N^(-1/4) * SCONDA <= ||R^(-1)||_2 <= N^(1/4) * SCONDA where R is the triangular factor from the QRF of A. However, if R is truncated and the numerical rank is determined to be strictly smaller than N, SCONDA is returned as -1, thus indicating that the smallest singular values might be lost.

If full SVD is needed, the following two condition numbers are useful for the analysis of the algorithm. They are provied for a developer/implementer who is familiar with the details of the method.

RWORK(4) = an estimate of the scaled condition number of the triangular factor in the first QR factorization. RWORK(5) = an estimate of the scaled condition number of the triangular factor in the second QR factorization. The following two parameters are computed if JOBT .EQ. 'T'. They are provided for a developer/implementer who is familiar with the details of the method. RWORK(6) = the entropy of A^* * A :: this is the Shannon entropy of diag(A^* * A) / Trace(A^* * A) taken as point in the probability simplex. RWORK(7) = the entropy of A * A^*. (See the description of RWORK(6).) If the call to ZGEJSV is a workspace query (indicated by LWORK=-1 or LRWORK=-1), then on exit RWORK(1) contains the required length of RWORK for the job parameters used in the call.

LRWORK Input parameter.

LRWORK is INTEGER

Length of RWORK to confirm proper allocation of workspace. LRWORK depends on the job:

1. If only the singular values are requested i.e. if LSAME(JOBU,'N') .AND. LSAME(JOBV,'N') then: 1.1. If LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G'), then: LRWORK = max(7, 2 * M). 1.2. Otherwise, LRWORK = max(7, N). 2. If singular values with the right singular vectors are requested i.e. if (LSAME(JOBV,'V').OR.LSAME(JOBV,'J')) .AND. .NOT.(LSAME(JOBU,'U').OR.LSAME(JOBU,'F')) then: 2.1. If LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G'), then LRWORK = max(7, 2 * M). 2.2. Otherwise, LRWORK = max(7, N). 3. If singular values with the left singular vectors are requested, i.e. if (LSAME(JOBU,'U').OR.LSAME(JOBU,'F')) .AND. .NOT.(LSAME(JOBV,'V').OR.LSAME(JOBV,'J')) then: 3.1. If LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G'), then LRWORK = max(7, 2 * M). 3.2. Otherwise, LRWORK = max(7, N). 4. If singular values with both the left and the right singular vectors are requested, i.e. if (LSAME(JOBU,'U').OR.LSAME(JOBU,'F')) .AND. (LSAME(JOBV,'V').OR.LSAME(JOBV,'J')) then: 4.1. If LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G'), then LRWORK = max(7, 2 * M). 4.2. Otherwise, LRWORK = max(7, N).

If, on entry, LRWORK = -1 or LWORK=-1, a workspace query is assumed and the length of RWORK is returned in RWORK(1).

IWORK Output parameter.

IWORK is INTEGER array, of dimension at least 4, that further depends

on the job:

1. If only the singular values are requested then: If (LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G')) then the length of IWORK is N+M; otherwise the length of IWORK is N. 2. If the singular values and the right singular vectors are requested then: If (LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G')) then the length of IWORK is N+M; otherwise the length of IWORK is N. 3. If the singular values and the left singular vectors are requested then: If (LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G')) then the length of IWORK is N+M; otherwise the length of IWORK is N. 4. If the singular values with both the left and the right singular vectors are requested, then: 4.1. If LSAME(JOBV,'J') the length of IWORK is determined as follows: If (LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G')) then the length of IWORK is N+M; otherwise the length of IWORK is N. 4.2. If LSAME(JOBV,'V') the length of IWORK is determined as follows: If (LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G')) then the length of IWORK is 2*N+M; otherwise the length of IWORK is 2*N.

On exit, IWORK(1) = the numerical rank determined after the initial QR factorization with pivoting. See the descriptions of JOBA and JOBR. IWORK(2) = the number of the computed nonzero singular values IWORK(3) = if nonzero, a warning message: If IWORK(3).EQ.1 then some of the column norms of A were denormalized floats. The requested high accuracy is not warranted by the data. IWORK(4) = 1 or -1. If IWORK(4) .EQ. 1, then the procedure used A^* to do the job as specified by the JOB parameters. If the call to ZGEJSV is a workspace query (indicated by LWORK .EQ. -1 or LRWORK .EQ. -1), then on exit IWORK(1) contains the required length of IWORK for the job parameters used in the call.

INFO Output parameter.

INFO is INTEGER

< 0 : if INFO = -i, then the i-th argument had an illegal value. = 0 : successful exit; > 0 : ZGEJSV did not converge in the maximal allowed number of sweeps. The computed values may be inaccurate.

Related Information

For this routine in other precisions, please see *cgejsv*, *dgejsv* and *sgejsv*. It also exists with a native C interface as *LAPACKE_zgejsv*.

4.10.48 zgesdd

zgesdd computes the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors, by using divide-and-conquer method. The SVD is written

```
A = U * SIGMA * conjugate-transpose(V)
```

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M unitary matrix, and V is an N-by-N unitary matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns VT = V^H , not V.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgesdd(JOBZ, M, N, A, LDA, S, U, LDU, VT, LDVT, WORK, LWORK, RWORK,
                  IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgesdd_(const char *jobz, const armpl_int_t *m, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda, double *s,
             armpl_doublecomplex_t *u, const armpl_int_t *ldu,
             armpl_doublecomplex_t *vt, const armpl_int_t *ldvt,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             double *rwork, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

Specifies options for computing all or part of the matrix U: = 'A': all M columns of U and all N rows of V^H are returned in the arrays U and VT; = 'S': the first min(M, N) columns of U and the first min(M, N) rows of V^H are returned in the arrays U and VT; = 'O': If M >= N, the first N columns of U are overwritten in the array A and all rows of V^H are returned in the array VT; otherwise, all columns of U are returned in the array U and the first M rows of V^H are overwritten in the array A; = 'N': no columns of U or rows of V^H are computed.

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if JOBZ = 'O', A is overwritten with the first N columns of U (the left singular vectors, stored columnwise) if M >= N; A is overwritten with the first M rows of V^H (the right singular vectors, stored rowwise) otherwise. if JOBZ .ne. 'O', the contents of A are destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (min(M, N)). The singular values of A, sorted so that S(i) >= S(i+1).

U Output parameter.

U is COMPLEX*16

U is an array, dimension (LDU,UCOL). UCOL = M if JOBZ = 'A' or JOBZ = 'O' and M < N; UCOL = min(M, N) if JOBZ = 'S'. If JOBZ = 'A' or JOBZ = 'O' and M < N, U contains the M-by-M unitary matrix U; if JOBZ = 'S', U contains the first min(M, N) columns of U (the left singular vectors, stored columnwise); if JOBZ = 'O' and M >= N, or JOBZ = 'N', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= 1; if JOBZ = 'S' or 'A' or JOBZ = 'O' and M < N, LDU >= M.

VT Output parameter.

VT is COMPLEX*16

VT is an array, dimension (LDVT, N). If JOBZ = 'A' or JOBZ = 'O' and M >= N, VT contains the N-by-N unitary matrix V^H ; if JOBZ = 'S', VT contains the first min(M, N) rows of V^H (the right singular vectors, stored rowwise); if JOBZ = 'O' and M < N, or JOBZ = 'N', VT is not referenced.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= 1; if JOBZ = 'A' or JOBZ = 'O' and M >= N, LDVT >= N; if JOBZ = 'S', LDVT >= min(M, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 1. If LWORK = -1, a workspace query is assumed. The optimal size for the WORK array is calculated and stored in WORK(1), and no other work except argument checking is performed.

Let mx = max(M, N) and mn = min(M, N). If JOBZ = 'N', LWORK >= 2*mn + mx. If JOBZ = 'O', LWORK >= 2*mn*mn + 2*mn + mx. If JOBZ = 'S', LWORK >= mn*mn + 3*mn. If JOBZ = 'A', LWORK >= mn*mn + 2*mn + mx. These are not tight minimums in all cases; see comments inside code. For good performance, LWORK should generally be larger; a query is recommended.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (MAX(1,LRWORK)). Let mx = max(M, N) and mn = min(M, N). If JOBZ = 'N', LRWORK >= 5*mn (LAPACK <= 3.6 needs 7*mn); else if mx >> mn, LRWORK >= 5*mn*mn + 5*mn; else LRWORK >= max(5*mn*mn + 5*mn, 2*mx*mn + 2*mn*mn + mn).

IWORK Output parameter.

IWORK is INTEGER array, dimension (8*min(M, N))

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: The updating process of DBDSDC did not converge.

4.10.49 zgesvd

`zgesvd` computes the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors. The SVD is written

```
A = U * SIGMA * conjugate-transpose(V)
```

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M unitary matrix, and V is an N-by-N unitary matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns V^H , not V.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgesvd(JOBU, JOBVT, M, N, A, LDA, S, U, LDU, VT, LDVT, WORK, LWORK,
                  RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgesvd_(const char *jobu, const char *jobvt, const armpl_int_t *m,
             const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, double *s, armpl_doublecomplex_t *u,
             const armpl_int_t *ldu, armpl_doublecomplex_t *vt,
             const armpl_int_t *ldvt, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, double *rwork, armpl_int_t *info,
             ... );
```

Parameters

JOBU Input parameter.

`JOBU` is `CHARACTER*1`

Specifies options for computing all or part of the matrix U: = 'A': all `M` columns of `U` are returned in array U: = 'S': the first min(m,n) columns of `U` (the left singular vectors) are returned in the array U; = 'O': the first min(m,n) columns of `U` (the left singular vectors) are overwritten on the array A; = '`N`': no columns of `U` (no left singular vectors) are computed.

JOBVT Input parameter.

`JOBVT` is `CHARACTER*1`

Specifies options for computing all or part of the matrix V^H : = 'A': all `N` rows of V^H are returned in the array VT; = 'S': the first min(m,n) rows of V^H (the right singular vectors) are returned in the array VT; = 'O': the first min(m,n) rows of V^H (the right singular vectors) are overwritten on the array A; = '`N`': no rows of V^H (no right singular vectors) are computed.

`JOBVT` and `JOBU` cannot both be 'O'.

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, if JOBU = 'O', A is overwritten with the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBVT = 'O', A is overwritten with the first min(m,n) rows of V^H (the right singular vectors, stored rowwise); if JOBU .ne. 'O' and JOBVT .ne. 'O', the contents of A are destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (min(M, N)). The singular values of A, sorted so that S(i) >= S(i+1).

U Output parameter.

U is COMPLEX*16

U is an array, dimension (LDU,UCOL). (LDU, M) if JOBU = 'A' or (LDU,min(M, N)) if JOBU = 'S'. If JOBU = 'A', U contains the M-by-M unitary matrix U; if JOBU = 'S', U contains the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBU = 'N' or 'O', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= 1; if JOBU = 'S' or 'A', LDU >= M.

VT Output parameter.

VT is COMPLEX*16

VT is an array, dimension (LDVT, N). If JOBVT = 'A', VT contains the N-by-N unitary matrix V^H ; if JOBVT = 'S', VT contains the first min(m,n) rows of V^H (the right singular vectors, stored rowwise); if JOBVT = 'N' or 'O', VT is not referenced.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= 1; if JOBVT = 'A', LDVT >= N; if JOBVT = 'S', LDVT >= min(M, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= MAX(1,2*MIN(M, N)+MAX(M, N)). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (5*min(M, N)). On exit, if INFO > 0, RWORK(1:MIN(M, N)-1) contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in S (not necessarily sorted). B satisfies A = U * B * VT, so it has the same singular values as A, and singular vectors related by U and VT.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if ZBDSQR did not converge, INFO specifies how many superdiagonals of an intermediate bidiagonal form B did not converge to zero. See the description of RWORK above for details.

4.10.50 zgesvdx

```
ZGESVDX computes the singular value decomposition (SVD) of a complex
 M-by-N matrix A, optionally computing the left and/or right singular
 vectors. The SVD is written

     A = U * SIGMA * transpose(V)

 where SIGMA is an M-by-N matrix which is zero except for its
 min(m,n) diagonal elements, U is an M-by-M unitary matrix, and
 V is an N-by-N unitary matrix.  The diagonal elements of SIGMA
 are the singular values of A; they are real and non-negative, and
 are returned in descending order.  The first min(m,n) columns of
 U and V are the left and right singular vectors of A.

 ZGESVDX uses an eigenvalue problem for obtaining the SVD, which
 allows for the computation of a subset of singular values and
 vectors. See DBDSVDX for details.

 Note that the routine returns V**T, not V.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zgesvdx(JOBU, JOBVT, RANGE, M, N, A, LDA, VL, VU, IL, IU, NS, S, U,
                   LDU, VT, LDVT, WORK, LWORK, RWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgesvdx_(const char *jobu, const char *jobvt, const char *range,
              const armpl_int_t *m, const armpl_int_t *n,
              armpl_doublecomplex_t *a, const armpl_int_t *lda,
              const double *vl, const double *vu, const armpl_int_t *il,
              const armpl_int_t *iu, armpl_int_t *ns, double *s,
              armpl_doublecomplex_t *u, const armpl_int_t *ldu,
              armpl_doublecomplex_t *vt, const armpl_int_t *ldvt,
              armpl_doublecomplex_t *work, const armpl_int_t *lwork,
              double *rwork, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

JOBU Input parameter.

JOBU is CHARACTER*1

Specifies options for computing all or part of the matrix U: = 'V': the first min(m,n) columns of U (the left singular vectors) or as specified by RANGE are returned in the array U; = 'N': no columns of U (no left singular vectors) are computed.

JOBVT Input parameter.

JOBVT is CHARACTER*1

Specifies options for computing all or part of the matrix V^T : = 'V': the first min(m,n) rows of V^T (the right singular vectors) or as specified by RANGE are returned in the array VT; = 'N': no rows of V^T (no right singular vectors) are computed.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all singular values will be found. = 'V': all singular values in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th singular values will be found.

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the contents of A are destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for singular values. VU > VL. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for singular values. VU > VL. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest singular value to be returned. 1 <= IL <= IU <= min(M, N), if min(M, N) > 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest singular value to be returned. 1 <= IL <= IU <= min(M, N), if min(M, N) > 0. Not referenced if RANGE = 'A' or 'V'.

NS Output parameter.

NS is INTEGER

The total number of singular values found, 0 <= NS <= min(M, N). If RANGE = 'A', NS = min(M, N); if RANGE = 'I', NS = IU-IL+1.

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (min(M, N)). The singular values of A, sorted so that S(i) >= S(i+1).

U Output parameter.

U is COMPLEX*16

U is an array, dimension (LDU,UCOL). If JOBU = 'V', U contains columns of U (the left singular vectors, stored columnwise) as specified by RANGE; if JOBU = 'N', U is not referenced. Note: The user must ensure that UCOL >= NS; if RANGE = 'V', the exact value of NS is not known in advance and an upper bound must be used.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= 1; if JOBU = 'V', LDU >= M.

VT Output parameter.

VT is COMPLEX*16

VT is an array, dimension (LDVT, N). If JOBVT = 'V', VT contains the rows of V^T (the right singular vectors, stored rowwise) as specified by RANGE; if JOBVT = 'N', VT is not referenced. Note: The user must ensure that LDVT >= NS; if RANGE = 'V', the exact value of NS is not known in advance and an upper bound must be used.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= 1; if JOBVT = 'V', LDVT >= NS (see above).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK;

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= MAX(1,MIN(M, N)*(MIN(M, N)+4)) for the paths (see comments inside the code): - PATH 1 (M much larger than N) - PATH 1t (N much larger than M) LWORK >= MAX(1,MIN(M, N)*2+MAX(M, N)) for the other paths. For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (MAX(1,LRWORK)). LRWORK >= MIN(M, N)*(MIN(M, N)*2+15*MIN(M, N)).

IWORK Output parameter.

IWORK is INTEGER array, dimension (12*MIN(M, N))

If INFO = 0, the first NS elements of IWORK are zero. If INFO > 0, then IWORK contains the indices of the eigenvectors that failed to converge in DBDSVDX/DSTEVX.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge in DBDSVDX/DSTEVX. if INFO = N*2 + 1, an internal error occurred in DBDSVDX

Related Information

4.10.51 zgesvj

zgesvj computes the singular value decomposition (SVD) of a complex M-by-N matrix A, where M >= N. The SVD of A is written as

```
                        [++]   [xx]   [x0]   [xx]
A = U * SIGMA * V^*,    [++] = [xx] * [ox] * [xx]
                        [++]   [xx]
```

where SIGMA is an N-by-N diagonal matrix, U is an M-by-N orthonormal matrix, and V is an N-by-N unitary matrix. The diagonal elements of SIGMA are the singular values of A. The columns of U and V are the left and the right singular vectors of A, respectively.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgesvj(JOBA, JOBU, JOBV, M, N, A, LDA, SVA, MV, V, LDV, CWORK,
                  LWORK, RWORK, LRWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgesvj_(const char *joba, const char *jobu, const char *jobv,
             const armpl_int_t *m, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda, double *sva,
             const armpl_int_t *mv, armpl_doublecomplex_t *v,
             const armpl_int_t *ldv, armpl_doublecomplex_t *cwork,
             const armpl_int_t *lwork, double *rwork,
             const armpl_int_t *lrwork, armpl_int_t *info, ... );
```

Parameters

JOBA Input parameter.

JOBA is CHARACTER*1

Specifies the structure of A. = 'L': The input matrix A is lower triangular; = 'U': The input matrix A is upper triangular; = 'G': The input matrix A is general M-by-N matrix, M >= N.

JOBU Input parameter.

JOBU is CHARACTER*1

Specifies whether to compute the left singular vectors (columns of U): = 'U' or 'F': The left singular vectors corresponding to the nonzero singular values are computed and returned in the leading columns of A. See more details in the description of A. The default numerical orthogonality threshold is set to approximately TOL=CTOL*EPS, CTOL=SQRT(M), EPS=DLAMCH('E'). = 'C': Analogous to JOBU='U', except that user can control the level of numerical orthogonality of the computed left singular vectors. TOL can be set to TOL = CTOL*EPS, where CTOL is given on input in the array WORK. No CTOL smaller than ONE is allowed. CTOL greater than 1 / EPS is meaningless. The option 'C' can be used if M*EPS is satisfactory orthogonality of the computed left singular vectors, so CTOL=M could save few sweeps of Jacobi rotations. See the descriptions of A and WORK(1). = 'N': The matrix U is not computed. However, see the description of A.

JOBV Input parameter.

JOBV is CHARACTER*1

Specifies whether to compute the right singular vectors, that is, the matrix V: = 'V' or 'J': the matrix V is computed and returned in the array V = 'A' : the Jacobi rotations are applied to the MV-by-N array V. In other words, the right singular vector matrix V is not computed explicitly; instead it is applied to an MV-by-N matrix initially stored in the first MV rows of V. = 'N' : the matrix V is not computed and the array V is not referenced

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. 1/DLAMCH('E') > M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. M >= N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, If JOBU .EQ. 'U' .OR. JOBU .EQ. 'C': If INFO .EQ. 0 : RANKA orthonormal columns of U are returned in the leading RANKA columns of the array A. Here RANKA <= N is the number of computed singular values of A that are above the underflow threshold DLAMCH('S'). The singular vectors corresponding to underflowed or zero singular values are not computed. The value of RANKA is returned in the array RWORK as RANKA=NINT(RWORK(2)). Also see the descriptions of SVA and RWORK. The computed columns of U are mutually numerically orthogonal up to

approximately TOL=SQRT(M)*EPS (default); or TOL=CTOL*EPS (JOBU.EQ.'C'), see the description of JOBU. If INFO .GT. 0, the procedure ZGESVJ did not converge in the given number of iterations (sweeps). In that case, the computed columns of U may not be orthogonal up to TOL. The output U (stored in A), SIGMA (given by the computed singular values in SVA(1:N)) and V is still a decomposition of the input matrix A in the sense that the residual || A - SCALE * U * SIGMA * V^* ||_2 / ||A||_2 is small. If JOBU .EQ. 'N': If INFO .EQ. 0 : Note that the left singular vectors are 'for free' in the one-sided Jacobi SVD algorithm. However, if only the singular values are needed, the level of numerical orthogonality of U is not an issue and iterations are stopped when the columns of the iterated matrix are numerically orthogonal up to approximately M*EPS. Thus, on exit, A contains the columns of U scaled with the corresponding singular values. If INFO .GT. 0 : the procedure ZGESVJ did not converge in the given number of iterations (sweeps).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

SVA Output parameter.

SVA is DOUBLE PRECISION

SVA is an array, dimension (N). On exit, If INFO .EQ. 0 : depending on the value SCALE = RWORK(1), we have: If SCALE .EQ. ONE: SVA(1:N) contains the computed singular values of A. During the computation SVA contains the Euclidean column norms of the iterated matrices in the array A. If SCALE .NE. ONE: The singular values of A are SCALE*SVA(1:N), and this factored representation is due to the fact that some of the singular values of A might underflow or overflow.

If INFO .GT. 0 : the procedure ZGESVJ did not converge in the given number of iterations (sweeps) and SCALE*SVA(1:N) may not be accurate.

MV Input parameter.

MV is INTEGER

If JOBV .EQ. 'A', then the product of Jacobi rotations in ZGESVJ is applied to the first MV rows of V. See the description of JOBV.

V Input and output parameter.

V is COMPLEX*16

V is an array, dimension (LDV, N). If JOBV = 'V', then V contains on exit the N-by-N matrix of the right singular vectors; If JOBV = 'A', then V contains the product of the computed right singular vector matrix and the initial matrix in the array V. If JOBV = 'N', then V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V, LDV .GE. 1. If JOBV .EQ. 'V', then LDV .GE. max(1, N). If JOBV .EQ. 'A', then LDV .GE. max(1, MV) .

CWORK Input and output parameter.

CWORK is COMPLEX*16

CWORK is an array, dimension (max(1, LWORK)). Used as workspace. If on entry LWORK .EQ. -1, then a workspace query is assumed and no computation is done; CWORK(1) is set to the minial (and optimal) length of CWORK.

LWORK Input parameter.

LWORK is INTEGER.

Length of CWORK, LWORK >= M+N.

RWORK Input and output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (max(6, LRWORK)). On entry, If JOBU .EQ. 'C' : RWORK(1) = CTOL, where CTOL defines the threshold for convergence. The process stops if all columns of A are mutually orthogonal up to CTOL*EPS, EPS=DLAMCH('E'). It is required that CTOL >= ONE, i.e. it is not allowed to force the routine to obtain orthogonality below EPSILON. On exit, RWORK(1) = SCALE is the scaling factor such that SCALE*SVA(1:N) are the computed singular values of A. (See description of SVA().) RWORK(2) = NINT(RWORK(2)) is the number of the computed nonzero singular values. RWORK(3) = NINT(RWORK(3)) is the number of the computed singular values that are larger than the underflow threshold. RWORK(4) = NINT(RWORK(4)) is the number of sweeps of Jacobi rotations needed for numerical convergence. RWORK(5) = max_{i.NE.j} |COS(A(:,i),A(:,j))| in the last sweep. This is useful information in cases when ZGESVJ did not converge, as it can be used to estimate whether the output is stil useful and for post festum analysis. RWORK(6) = the largest absolute value over all sines of the Jacobi rotation angles in the last sweep. It can be useful for a post festum analysis. If on entry LRWORK .EQ. -1, then a workspace query is assumed and no computation is done; RWORK(1) is set to the minial (and optimal) length of RWORK.

LRWORK Input parameter.

LRWORK is INTEGER

Length of RWORK, LRWORK >= MAX(6, N).

INFO Output parameter.

INFO is INTEGER

= 0 : successful exit. < 0 : if INFO = -i, then the i-th argument had an illegal value > 0 : ZGESVJ did not converge in the maximal allowed number (NSWEEP=30) of sweeps. The output may still be useful. See the description of RWORK.

Related Information

For this routine in other precisions, please see *cgesvj*, *dgesvj* and *sgesvj*. It also exists with a native C interface as *LAPACKE_zgesvj*.

4.10.52 zggsvd3

zggsvd3 computes the generalized singular value decomposition (GSVD) of an M-by-N complex matrix A and P-by-N complex matrix B:

```
U**H*A*Q = D1*( 0 R ),     V**H*B*Q = D2*( 0 R )
```

where U, V and Q are unitary matrices. Let K+L = the effective numerical rank of the matrix $(A^H, B^H)^H$, then R is a (K+L)-by-(K+L) nonsingular upper triangular matrix, D1 and D2 are M-by-(K+L) and P-by-(K+L) "diagonal" matrices and of the following structures, respectively:

If M-K-L >= 0,

```
                   K  L
     D1 =      K ( I  0 )
               L ( 0  C )
           M-K-L ( 0  0 )

                 K  L
     D2 =    L ( 0  S )
           P-L ( 0  0 )

                 N-K-L  K     L
( 0 R ) = K (    0    R11   R12 )
          L (    0     0    R22 )
```

where

```
 C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),
S = diag( BETA(K+1),  ... , BETA(K+L) ),
C**2 + S**2 = I.

R is stored in A(1:K+L,N-K-L+1:N) on exit.
```

If M-K-L < 0,

```
                 K M-K K+L-M
     D1 =   K ( I  0    0   )
          M-K ( 0  C    0   )

                   K M-K K+L-M
     D2 =   M-K ( 0  S    0  )
          K+L-M ( 0  0    I  )
            P-L ( 0  0    0  )

                  N-K-L  K   M-K  K+L-M
( 0 R ) =     K ( 0    R11  R12  R13  )
            M-K ( 0     0   R22  R23  )
          K+L-M ( 0     0    0   R33  )
```

where

```
C = diag( ALPHA(K+1), ... , ALPHA(M) ),
S = diag( BETA(K+1),  ... , BETA(M) ),
C**2 + S**2 = I.

(R11 R12 R13 ) is stored in A(1:M, N-K-L+1:N), and R33 is stored
( 0  R22 R23 )
in B(M-K+1:L,N+M-K-L+1:N) on exit.
```

The routine computes C, S, R, and optionally the unitary transformation matrices U, V and Q.

In particular, if B is an N-by-N nonsingular matrix, then the GSVD of A and B implicitly gives the SVD of A*inv(B):

```
A*inv(B) = U*(D1*inv(D2))*V**H.
```

If $(A^H , B^H)^H$ has orthonormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and B. Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

```
A**H*A x = lambda* B**H*B x.
```

In some literature, the GSVD of A and B is presented in the form

```
U**H*A*X = ( 0 D1 ),   V**H*B*X = ( 0 D2 )
```

where U and V are orthogonal and X is nonsingular, and D1 and D2 are ‘’diagonal’‘. The former GSVD form can be converted to the latter form by taking the nonsingular matrix X as

```
X = Q*(  I   0    )
     (  0 inv(R) )
```

```

Parameters

JOBU Input parameter.

JOBU is CHARACTER*1

= 'U': Unitary matrix U is computed; = 'N': U is not computed.

JOBV Input parameter.

JOBV is CHARACTER*1

= 'V': Unitary matrix V is computed; = 'N': V is not computed.

JOBQ Input parameter.

JOBQ is CHARACTER*1

= 'Q': Unitary matrix Q is computed; = 'N': Q is not computed.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. P >= 0.

K Output parameter.

K is INTEGER

L Output parameter.

L is INTEGER

On exit, K and L specify the dimension of the subblocks described in Purpose. K + L = effective numerical rank of $(A^H, B^H)^H$.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A contains the triangular matrix R, or part of R. See Purpose for details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, B contains part of the triangular matrix R if M-K-L < 0. See Purpose for details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

ALPHA Output parameter.

ALPHA is DOUBLE PRECISION

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is DOUBLE PRECISION

BETA is an array, dimension (N). On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; ALPHA(1:K) = 1, BETA(1:K) = 0, and if M-K-L >= 0, ALPHA(K+1:K+L) = C, BETA(K+1:K+L) = S, or if M-K-L < 0, ALPHA(K+1:M)=C, ALPHA(M+1:K+L)=0 BETA(K+1:M) =S, BETA(M+1:K+L) =1 and ALPHA(K+L+1:N) = 0 BETA(K+L+1:N) = 0

U Output parameter.

U is COMPLEX*16

U is an array, dimension (LDU, M). If JOBU = 'U', U contains the M-by-M unitary matrix U. If JOBU = 'N', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= max(1, M) if JOBU = 'U'; LDU >= 1 otherwise.

V Output parameter.

V is COMPLEX*16

V is an array, dimension (LDV, P). If JOBV = 'V', V contains the P-by-P unitary matrix V. If JOBV = 'N', V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, P) if JOBV = 'V'; LDV >= 1 otherwise.

Q Output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, N). If JOBQ = 'Q', Q contains the N-by-N unitary matrix Q. If JOBQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

On exit, IWORK stores the sorting information. More precisely, the following loop will sort ALPHA for I = K+1, min(M,K+L) swap ALPHA(I) and ALPHA(IWORK(I)) endfor such that ALPHA(1) >= ALPHA(2) >= ... >= ALPHA(N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, the Jacobi-type procedure failed to converge. For further details, see subroutine ZTGSJA.

4.10.53 zggsvp3

zggsvp3 computes unitary matrices U, V and Q such that

```
                    N-K-L  K    L
U**H*A*Q =      K ( 0    A12  A13 )  if M-K-L >= 0;
                L ( 0     0   A23 )
            M-K-L ( 0     0    0  )

                 N-K-L  K    L
        =     K ( 0    A12  A13 )  if M-K-L < 0;
            M-K ( 0     0   A23 )

                 N-K-L  K    L
V**H*B*Q =   L ( 0     0   B13 )
           P-L ( 0     0    0  )
```

where the K-by-K matrix A12 and L-by-L matrix B13 are nonsingular upper triangular; A23 is L-by-L upper triangular if M-K-L >= 0, otherwise A23 is (M-K)-by-L upper trapezoidal. K+L = the effective numerical rank of the (M+P)-by-N matrix $(A^H, B^H)^H$.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine ZGGSVD3.

Syntax

Fortran specification:

```
use armpl_library

subroutine zggsvp3(JOBU, JOBV, JOBQ, M, P, N, A, LDA, B, LDB, TOLA, TOLB, K,
                   L, U, LDU, V, LDV, Q, LDQ, IWORK, RWORK, TAU, WORK, LWORK,
                   INFO)
```

C specification:

```
#include "armpl.h"

void zggsvp3_(const char *jobu, const char *jobv, const char *jobq,
              const armpl_int_t *m, const armpl_int_t *p,
              const armpl_int_t *n, armpl_doublecomplex_t *a,
              const armpl_int_t *lda, armpl_doublecomplex_t *b,
              const armpl_int_t *ldb, const double *tola, const double *tolb,
              armpl_int_t *k, armpl_int_t *l, armpl_doublecomplex_t *u,
              const armpl_int_t *ldu, armpl_doublecomplex_t *v,
              const armpl_int_t *ldv, armpl_doublecomplex_t *q,
              const armpl_int_t *ldq, armpl_int_t *iwork, double *rwork,
              armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
              const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOBU Input parameter.

JOBU is CHARACTER*1

= 'U': Unitary matrix U is computed; = 'N': U is not computed.

JOBV Input parameter.

JOBV is CHARACTER*1

= 'V': Unitary matrix V is computed; = 'N': V is not computed.

JOBQ Input parameter.

JOBQ is CHARACTER*1

= 'Q': Unitary matrix Q is computed; = 'N': Q is not computed.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. P >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A contains the triangular (or trapezoidal) matrix described in the Purpose section.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, B contains the triangular matrix described in the Purpose section.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

TOLA Input parameter.

TOLA is DOUBLE PRECISION

TOLB Input parameter.

TOLB is DOUBLE PRECISION

TOLA and TOLB are the thresholds to determine the effective numerical rank of matrix B and a subblock of A. Generally, they are set to TOLA = MAX(M, N)*norm(A)*MAZHEPS, TOLB = MAX(P, N)*norm(B)*MAZHEPS. The size of TOLA and TOLB may affect the size of backward errors of the decomposition.

K Output parameter.

K is INTEGER

L Output parameter.

L is INTEGER

On exit, K and L specify the dimension of the subblocks described in Purpose section. K + L = effective numerical rank of $(A^H, B^H)^H$.

U Output parameter.

U is COMPLEX*16

U is an array, dimension (LDU, M). If JOBU = 'U', U contains the unitary matrix U. If JOBU = 'N', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= max(1, M) if JOBU = 'U'; LDU >= 1 otherwise.

V Output parameter.

V is COMPLEX*16

V is an array, dimension (LDV, P). If JOBV = 'V', V contains the unitary matrix V. If JOBV = 'N', V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, P) if JOBV = 'V'; LDV >= 1 otherwise.

Q Output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, N). If JOBQ = 'Q', Q contains the unitary matrix Q. If JOBQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*N) .

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (N) .

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cggsvp3*, *dggsvp3* and *sggsvp3*. It also exists with a native C interface as *LAPACKE_zggsvp3*.

4.10.54 ztgsja

ztgsja computes the generalized singular value decomposition (GSVD) of two complex upper triangular (or trapezoidal) matrices A and B.

On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine ZGGSVP from a general M-by-N matrix A and P-by-N matrix B:

```
             N-K-L  K    L
A =    K ( 0    A12  A13 ) if M-K-L >= 0;
       L ( 0     0   A23 )
   M-K-L ( 0     0    0  )

            N-K-L  K    L
A =  K ( 0    A12  A13 ) if M-K-L < 0;
   M-K ( 0     0   A23 )

            N-K-L  K    L
B =  L ( 0     0   B13 )
   P-L ( 0     0    0  )
```

where the K-by-K matrix A12 and L-by-L matrix B13 are nonsingular upper triangular; A23 is L-by-L upper triangular if M-K-L >= 0, otherwise A23 is (M-K)-by-L upper trapezoidal.

On exit,

```
U**H *A*Q = D1*( 0 R ),    V**H *B*Q = D2*( 0 R ),
```

where U, V and Q are unitary matrices. R is a nonsingular upper triangular matrix, and D1 and D2 are ‘‘diagonal” matrices, which are of the following structures:

If M-K-L >= 0,

```
                  K  L
     D1 =     K ( I  0 )
              L ( 0  C )
          M-K-L ( 0  0 )

                 K  L
     D2 = L    ( 0  S )
          P-L  ( 0  0 )

               N-K-L  K    L
( 0 R ) = K (  0   R11  R12 ) K
          L (  0    0   R22 ) L
```

where

```
C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),
S = diag( BETA(K+1),  ... , BETA(K+L) ),
C**2 + S**2 = I.

R is stored in A(1:K+L,N-K-L+1:N) on exit.
```

If M-K-L < 0,

```
            K M-K K+L-M
D1 =   K ( I  0    0   )
     M-K ( 0  C    0   )

              K M-K K+L-M
D2 =   M-K ( 0  S    0   )
     K+L-M ( 0  0    I   )
       P-L ( 0  0    0   )

             N-K-L  K   M-K  K+L-M
```

(0 R) = K (0 R11 R12 R13)

```
   M-K ( 0     0    R22  R23  )
K+L-M ( 0     0    0   R33  )
```

where C = diag(ALPHA(K+1), ... , ALPHA(M)), S = diag(BETA(K+1), ... , BETA(M)), C**2 + S**2 = I.

R = (R11 R12 R13) is stored in A(1:M, N-K-L+1:N) and R33 is stored

```
(  0  R22 R23 )
```

in B(M-K+1:L,N+M-K-L+1:N) on exit.

The computation of the unitary transformation matrices U, V or Q is optional. These matrices may either be formed explicitly, or they may be postmultiplied into input matrices U1, V1, or Q1.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztgsja(JOBU, JOBV, JOBQ, M, P, N, K, L, A, LDA, B, LDB, TOLA, TOLB,
                  ALPHA, BETA, U, LDU, V, LDV, Q, LDQ, WORK, NCYCLE, INFO)
```

C specification:

```
#include "armpl.h"

void ztgsja_(const char *jobu, const char *jobv, const char *jobq,
             const armpl_int_t *m, const armpl_int_t *p, const armpl_int_t *n,
             const armpl_int_t *k, const armpl_int_t *l,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             const double *tola, const double *tolb, double *alpha,
             double *beta, armpl_doublecomplex_t *u, const armpl_int_t *ldu,
             armpl_doublecomplex_t *v, const armpl_int_t *ldv,
             armpl_doublecomplex_t *q, const armpl_int_t *ldq,
             armpl_doublecomplex_t *work, armpl_int_t *ncycle,
             armpl_int_t *info, ... );
```

Parameters

JOBU Input parameter.

JOBU is CHARACTER*1

= 'U': U must contain a unitary matrix U1 on entry, and the product U1* U is returned; = 'I': U is initialized to the unit matrix, and the unitary matrix U is returned; = 'N': U is not computed.

JOBV Input parameter.

JOBV is CHARACTER*1

= 'V': V must contain a unitary matrix V1 on entry, and the product V1* V is returned; = 'I': V is initialized to the unit matrix, and the unitary matrix V is returned; = 'N': V is not computed.

JOBQ Input parameter.

JOBQ is CHARACTER*1

= 'Q': Q must contain a unitary matrix Q1 on entry, and the product Q1* Q is returned; = 'I': Q is initialized to the unit matrix, and the unitary matrix Q is returned; = 'N': Q is not computed.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

P Input parameter.

P is INTEGER

The number of rows of the matrix B. P >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrices A and B. N >= 0.

K Input parameter.

K is INTEGER

L Input parameter.

L is INTEGER

K and L specify the subblocks in the input matrices A and B: A23 = A(K+1:MIN(K+L, M),N-L+1:N) and B13 = B(1:L,,N-L+1:N) of A and B, whose GSVD is going to be computed by ZTGSJA. See Further Details.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A(N-K+1:N,1:MIN(K+L, M)) contains the triangular matrix R or part of R. See Purpose for details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the P-by-N matrix B. On exit, if necessary, B(M-K+1:L,N+M-K-L+1:N) contains a part of R. See Purpose for details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, P).

TOLA Input parameter.

TOLA is DOUBLE PRECISION

TOLB Input parameter.

TOLB is DOUBLE PRECISION

TOLA and TOLB are the convergence criteria for the Jacobi- Kogbetliantz iteration procedure. Generally, they are the same as used in the preprocessing step, say TOLA = MAX(M, N)*norm(A)*MAZHEPS, TOLB = MAX(P, N)*norm(B)*MAZHEPS.

ALPHA Output parameter.

ALPHA is DOUBLE PRECISION

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is DOUBLE PRECISION

BETA is an array, dimension (N). On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; ALPHA(1:K) = 1, BETA(1:K) = 0, and if M-K-L >= 0, ALPHA(K+1:K+L) = diag(C), BETA(K+1:K+L) = diag(S), or if M-K-L < 0, ALPHA(K+1:M)= C, ALPHA(M+1:K+L)= 0 BETA(K+1:M) = S, BETA(M+1:K+L) = 1. Furthermore, if K+L < N, ALPHA(K+L+1:N) = 0 and BETA(K+L+1:N) = 0.

U Input and output parameter.

U is COMPLEX*16

U is an array, dimension (LDU, M). On entry, if JOBU = 'U', U must contain a matrix U1 (usually the unitary matrix returned by ZGGSVP). On exit, if JOBU = 'I', U contains the unitary matrix U; if JOBU = 'U', U contains the product U1*U. If JOBU = 'N', U is not referenced.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= max(1, M) if JOBU = 'U'; LDU >= 1 otherwise.

V Input and output parameter.

V is COMPLEX*16

V is an array, dimension (LDV, P). On entry, if JOBV = 'V', V must contain a matrix V1 (usually the unitary matrix returned by ZGGSVP). On exit, if JOBV = 'I', V contains the unitary matrix V; if JOBV = 'V', V contains the product V1*V. If JOBV = 'N', V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, P) if JOBV = 'V'; LDV >= 1 otherwise.

Q Input and output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, N). On entry, if JOBQ = 'Q', Q must contain a matrix Q1 (usually the unitary matrix returned by ZGGSVP). On exit, if JOBQ = 'I', Q contains the unitary matrix Q; if JOBQ = 'Q', Q contains the product Q1*Q. If JOBQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

NCYCLE Output parameter.

NCYCLE is INTEGER

The number of cycles required for convergence.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1: the procedure does not converge after MAXIT cycles.

4.10.55 zungbr

zungbr generates one of the complex unitary matrices Q or P^H determined by ZGEBRD when reducing a complex matrix A to bidiagonal form: A = Q * B * P^H . Q and P^H are defined as products of elementary reflectors H(i) or G(i) respectively.

If VECT = 'Q', A is assumed to have been an M-by-K matrix, and Q is of order M: if m >= k, Q = H(1) H(2) . . . H(k) and zungbr returns the first n columns of Q, where m >= n >= k; if m < k, Q = H(1) H(2) . . . H(m-1) and zungbr returns Q as an M-by-M matrix.

If VECT = 'P', A is assumed to have been a K-by-N matrix, and P^H is of order N: if k < n, P^H = G(k) . . . G(2) G(1) and zungbr returns the first m rows of P^H , where n >= m >= k; if k >= n, P^H = G(n-1) . . . G(2) G(1) and zungbr returns P^H as an N-by-N matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine zungbr(VECT, M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zungbr_(const char *vect, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *k, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, const armpl_doublecomplex_t *tau,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

Specifies whether the matrix Q or the matrix P^H is required, as defined in the transformation applied by ZGEBRD: = 'Q': generate Q; = 'P': generate P^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix Q or P^H to be returned. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q or P^H to be returned. N >= 0. If VECT = 'Q', M >= N >= min(M, K); if VECT = 'P', N >= M >= min(N, K).

K Input parameter.

K is INTEGER

If VECT = 'Q', the number of columns in the original M-by-K matrix reduced by ZGEBRD. If VECT = 'P', the number of rows in the original K-by-N matrix reduced by ZGEBRD. K >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the vectors which define the elementary reflectors, as returned by ZGEBRD. On exit, the M-by-N matrix Q or P^H .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= M.

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension. (min(M, K)) if VECT = 'Q' (min(N, K)) if VECT = 'P' TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i), which determines Q or P^H , as returned by ZGEBRD in its array argument TAUQ or TAUP.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,min(M, N)). For optimum performance LWORK >= min(M, N)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cungbr*. It also exists with a native C interface as *LAPACKE_zungbr*.

4.10.56 zunmbr

If VECT = 'Q', zunmbr overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H

If VECT = 'P', zunmbr overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': P * C C * P TRANS = 'C': P^H * C C * P^H

Here Q and P^H are the unitary matrices determined by ZGEBRD when reducing a complex matrix A to bidiagonal form: A = Q * B * P^H . Q and P^H are defined as products of elementary reflectors H(i) and G(i) respectively.

Let nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Thus nq is the order of the unitary matrix Q or P^H that is applied.

If VECT = 'Q', A is assumed to have been an NQ-by-K matrix: if nq >= k, Q = H(1) H(2) . . . H(k); if nq < k, Q = H(1) H(2) . . . H(nq-1).

If VECT = 'P', A is assumed to have been a K-by-NQ matrix: if k < nq, P = G(1) G(2) . . . G(k); if k >= nq, P = G(1) G(2) . . . G(nq-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine zunmbr(VECT, SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK,
                  LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zunmbr_(const char *vect, const char *side, const char *trans,
             const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

= 'Q': apply Q or Q^H ; = 'P': apply P or P^H .

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q, Q^H , P or P^H from the Left; = 'R': apply Q, Q^H , P or P^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q or P; = 'C': Conjugate transpose, apply Q^H or P^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

If VECT = 'Q', the number of columns in the original matrix reduced by ZGEBRD. If VECT = 'P', the number of rows in the original matrix reduced by ZGEBRD. K >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension. (LDA,min(nq, K)) if VECT = 'Q' (LDA,nq) if VECT = 'P' The vectors which define the elementary reflectors H(i) and G(i), whose products determine the matrices Q and P, as returned by ZGEBRD.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If VECT = 'Q', LDA >= max(1,nq); if VECT = 'P', LDA >= max(1,min(nq, K)).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (min(nq, K)). TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i) which determines Q or P, as returned by ZGEBRD in the array argument TAUQ or TAUP.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q or P* C or P^H * C or C*P or C*P^H .

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M); if N = 0 or M = 0, LWORK >= 1. For optimum performance LWORK >= max(1,N*NB) if SIDE = 'L', and LWORK >= max(1,M*NB) if SIDE = 'R', where NB is the optimal blocksize. (NB = 0 if M = 0 or N = 0.)

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cunmbr*. It also exists with a native C interface as *LAPACKE_zunmbr*.

4.11 LAPACK symmetric eigenvalues routines

4.11.1 chbev

chbev computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A.

Syntax

Fortran specification:

```
use armpl_library

subroutine chbev(JOBZ, UPLO, N, KD, AB, LDAB, W, Z, LDZ, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chbev_(const char *jobz, const char *uplo, const armpl_int_t *n,
            const armpl_int_t *kd, armpl_singlecomplex_t *ab,
            const armpl_int_t *ldab, float *w, armpl_singlecomplex_t *z,
            const armpl_int_t *ldz, armpl_singlecomplex_t *work, float *rwork,
            armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (max(1,3*N-2)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *zhbev*. It also exists with a native C interface as *LAPACKE_chbev*.

4.11.2 chbevd

chbevd computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine chbevd(JOBZ, UPLO, N, KD, AB, LDAB, W, Z, LDZ, WORK, LWORK, RWORK,
                  LRWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chbevd_(const char *jobz, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *kd, armpl_singlecomplex_t *ab,
             const armpl_int_t *ldab, float *w, armpl_singlecomplex_t *z,
             const armpl_int_t *ldz, armpl_singlecomplex_t *work,
```

(continues on next page)

(continued from previous page)

```
                const armpl_int_t *lwork, float *rwork,
                const armpl_int_t *lrwork, armpl_int_t *iwork,
                const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least N. If JOBZ = 'V' and N > 1, LWORK must be at least 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array,. dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of array RWORK. If N <= 1, LRWORK must be at least 1. If JOBZ = 'N' and N > 1, LRWORK must be at least N. If JOBZ = 'V' and N > 1, LRWORK must be at least 1 + 5* N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of array IWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5* N .

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *zhbevd*. It also exists with a native C interface as *LAPACKE_chbevd*.

4.11.3 chbevx

chbevx computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine chbevx(JOBZ, RANGE, UPLO, N, KD, AB, LDAB, Q, LDQ, VL, VU, IL, IU,
                  ABSTOL, M, W, Z, LDZ, WORK, RWORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void chbevx_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, const armpl_int_t *kd,
             armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
             armpl_singlecomplex_t *q, const armpl_int_t *ldq,
             const float *vl, const float *vu, const armpl_int_t *il,
             const armpl_int_t *iu, const float *abstol, armpl_int_t *m,
             float *w, armpl_singlecomplex_t *z, const armpl_int_t *ldz,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *iwork,
             armpl_int_t *ifail, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found; = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

Q Output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, N). If JOBZ = 'V', the N-by-N unitary matrix used in the reduction to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. If JOBZ = 'V', then LDQ >= max(1, N).

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AB to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *zhbevx*. It also exists with a native C interface as *LAPACKE_chbevx*.

4.11.4 chbtrd

chbtrd reduces a complex Hermitian band matrix A to real symmetric tridiagonal form T by a unitary similarity transformation: $Q^H * A * Q = T$.

Syntax

Fortran specification:

```
use armpl_library

subroutine chbtrd(VECT, UPLO, N, KD, AB, LDAB, D, E, Q, LDQ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void chbtrd_(const char *vect, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *kd, armpl_singlecomplex_t *ab,
             const armpl_int_t *ldab, float *d, float *e,
             armpl_singlecomplex_t *q, const armpl_int_t *ldq,
             armpl_singlecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

= 'N': do not form Q; = 'V': form Q; = 'U': update a matrix X, by forming X*Q.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). On exit, the diagonal elements of AB are overwritten by the diagonal elements of the tridiagonal matrix T; if KD > 0, the elements on the first superdiagonal (if UPLO = 'U') or the first subdiagonal (if UPLO = 'L') are overwritten by the off-diagonal elements of T; the rest of AB is overwritten by values generated during the reduction.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

D Output parameter.

D is REAL

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T.

E Output parameter.

E is REAL

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T: E(i) = T(i,i+1) if UPLO = 'U'; E(i) = T(i+1,i) if UPLO = 'L'.

Q Input and output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, N). On entry, if VECT = 'U', then Q must contain an N-by-N matrix X; if VECT = 'N' or 'V', then Q need not be set.

On exit: if VECT = 'V', Q contains the N-by-N unitary matrix Q; if VECT = 'U', Q contains the product X*Q; if VECT = 'N', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1, and LDQ >= N if VECT = 'V' or 'U'.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zhbtrd*. It also exists with a native C interface as *LAPACKE_chbtrd*.

4.11.5 cheev

cheev computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A.

Syntax

Fortran specification:

```
use armpl_library

subroutine cheev(JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cheev_(const char *jobz, const char *uplo, const armpl_int_t *n,
            armpl_singlecomplex_t *a, const armpl_int_t *lda, float *w,
            armpl_singlecomplex_t *work, const armpl_int_t *lwork,
            float *rwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1,2*N-1). For optimal efficiency, LWORK >= (NB+1)*N, where NB is the blocksize for CHETRD returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (max(1, 3*N-2)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *zheev*. It also exists with a native C interface as *LAPACKE_cheev*.

4.11.6 cheevd

`cheevd` computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine cheevd(JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, RWORK, LRWORK, IWORK,
                  LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cheevd_(const char *jobz, const char *uplo, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda, float *w,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             float *rwork, const armpl_int_t *lrwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least N + 1. If JOBZ = 'V' and N > 1, LWORK must be at least 2* N + N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array,. dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of the array RWORK. If N <= 1, LRWORK must be at least 1. If JOBZ = 'N' and N > 1, LRWORK must be at least N. If JOBZ = 'V' and N > 1, LRWORK must be at least 1 + 5* N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If N <= 1, LIWORK must be at least 1. If JOBZ = 'N' and N > 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i and JOBZ = 'N', then the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; if INFO = i and JOBZ = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

Related Information

For this routine in other precisions, please see *zheevd*. It also exists with a native C interface as *LAPACKE_cheevd*.

4.11.7 cheevr

`cheevr` computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

`cheevr` first reduces the matrix A to tridiagonal form T with a call to CHETRD. Then, whenever possible, `cheevr` calls CSTEMR to compute the eigenspectrum using Relatively Robust Representations. CSTEMR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" L D L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows.

For each unreduced block (submatrix) of T,

```
(a) Compute T - sigma I  = L D L^T, so that L and D
     define all the wanted eigenvalues to high relative accuracy.
     This means that small relative changes in the entries of D and L
     cause only small relative changes in the eigenvalues and
     eigenvectors. The standard (unfactored) representation of the
     tridiagonal matrix T does not have this property in general.
 (b) Compute the eigenvalues to suitable accuracy.
     If the eigenvectors are desired, the algorithm attains full
     accuracy of the computed eigenvalues only right before
     the corresponding vectors have to be computed, see steps c) and d).
 (c) For each cluster of close eigenvalues, select a new
     shift close to the cluster, find a new factorization, and refine
     the shifted eigenvalues to suitable accuracy.
 (d) For each eigenvalue with a large enough relative separation compute
     the corresponding eigenvector by forming a rank revealing twisted
     factorization. Go back to (c) for any clusters that remain.
```

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see DSTEMR's documentation and: - Inderjit S. Dhillon and Beresford N. Parlett: "Multiple representations

```
 to compute orthogonal eigenvectors of symmetric tridiagonal matrices,"
Linear Algebra and its Applications, 387(1), pp. 1-28, August 2004.
```

- Inderjit Dhillon and Beresford Parlett: "Orthogonal Eigenvectors and

```
 Relative Gaps," SIAM Journal on Matrix Analysis and Applications, Vol. 25,
2004.  Also LAPACK Working Note 154.
```

- Inderjit Dhillon: "A new O(n^2) algorithm for the symmetric

```
 tridiagonal eigenvalue/eigenvector problem",
Computer Science Division Technical Report No. UCB/CSD-97-971,
UC Berkeley, May 1997.
```

Note 1 : `cheevr` calls CSTEMR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. `cheevr` calls SSTEBZ and CSTEIN on non-ieee machines and when partial spectrum requests are made.

Normal execution of CSTEMR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

Syntax

Fortran specification:

```
use armpl_library

subroutine cheevr(JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU, ABSTOL, M, W,
                  Z, LDZ, ISUPPZ, WORK, LWORK, RWORK, LRWORK, IWORK, LIWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void cheevr_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, const float *vl, const float *vu,
             const armpl_int_t *il, const armpl_int_t *iu,
             const float *abstol, armpl_int_t *m, float *w,
             armpl_singlecomplex_t *z, const armpl_int_t *ldz,
             armpl_int_t *isuppz, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, float *rwork,
             const armpl_int_t *lrwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found. For RANGE = 'V' or 'I' and IU - IL < N - 1, SSTEBZ and CSTEIN are called

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to SLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but furutre releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i). This is an output of CSTEMR (tridiagonal matrix). The support of the eigenvectors of A is typically 1:N because of the unitary transformations applied by CUNMTR. Implemented only for RANGE = 'A' or 'I' and IU - IL = N - 1

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1,2*N). For optimal efficiency, LWORK >= (NB+1)*N, where NB is the max of the blocksize for CHETRD and for CUNMTR as returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (MAX(1, LRWORK)). On exit, if INFO = 0, RWORK(1) returns the optimal (and minimal) LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The length of the array RWORK. LRWORK >= max(1,24*N).

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal (and minimal) LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= max(1,10*N).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: Internal error

Related Information

For this routine in other precisions, please see *zheevr*. It also exists with a native C interface as *LAPACKE_cheevr*.

4.11.8 cheevx

`cheevx` computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine cheevx(JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU, ABSTOL, M, W,
                  Z, LDZ, WORK, LWORK, RWORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void cheevx_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, const float *vl, const float *vu,
             const armpl_int_t *il, const armpl_int_t *iu,
             const float *abstol, armpl_int_t *m, float *w,
             armpl_singlecomplex_t *z, const armpl_int_t *ldz,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             float *rwork, armpl_int_t *iwork, armpl_int_t *ifail,
             armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise 2*N. For optimal efficiency, LWORK >= (NB+1)*N, where NB is the max of the blocksize for CHETRD and for CUNMTR as returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *zheevx*. It also exists with a native C interface as *LAPACKE_cheevx*.

4.11.9 chetrd

chetrd reduces a complex Hermitian matrix A to real symmetric tridiagonal form T by a unitary similarity transformation: $Q^H * A * Q = T$.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetrd(UPLO, N, A, LDA, D, E, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chetrd_(const char *uplo, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, float *d, float *e,
             armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are over- written by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

D Output parameter.

D is REAL

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E Output parameter.

E is REAL

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T: E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 1. For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zhetrd*. It also exists with a native C interface as *LAPACKE_chetrd*.

4.11.10 chpev

chpev computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix in packed storage.

Syntax

Fortran specification:

```
use armpl_library

subroutine chpev(JOBZ, UPLO, N, AP, W, Z, LDZ, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chpev_(const char *jobz, const char *uplo, const armpl_int_t *n,
            armpl_singlecomplex_t *ap, float *w, armpl_singlecomplex_t *z,
            const armpl_int_t *ldz, armpl_singlecomplex_t *work, float *rwork,
            armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (max(1, 2*N-1)) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (max(1, 3*N-2)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *zhpev*. It also exists with a native C interface as *LAPACKE_chpev*.

4.11.11 chpevd

chpevd computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like

the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine chpevd(JOBZ, UPLO, N, AP, W, Z, LDZ, WORK, LWORK, RWORK, LRWORK,
                  IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chpevd_(const char *jobz, const char *uplo, const armpl_int_t *n,
             armpl_singlecomplex_t *ap, float *w, armpl_singlecomplex_t *z,
             const armpl_int_t *ldz, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, float *rwork,
             const armpl_int_t *lrwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the required LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least N. If JOBZ = 'V' and N > 1, LWORK must be at least 2*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (MAX(1, LRWORK)). On exit, if INFO = 0, RWORK(1) returns the required LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of array RWORK. If N <= 1, LRWORK must be at least 1. If JOBZ = 'N' and N > 1, LRWORK must be at least N. If JOBZ = 'V' and N > 1, LRWORK must be at least 1 + 5* N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the required LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of array IWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *zhpevd*. It also exists with a native C interface as *LAPACKE_chpevd*.

4.11.12 chpevx

chpevx computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage. Eigenvalues/vectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine chpevx(JOBZ, RANGE, UPLO, N, AP, VL, VU, IL, IU, ABSTOL, M, W, Z,
                  LDZ, WORK, RWORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void chpevx_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, armpl_singlecomplex_t *ap, const float *vl,
             const float *vu, const armpl_int_t *il, const armpl_int_t *iu,
             const float *abstol, armpl_int_t *m, float *w,
             armpl_singlecomplex_t *z, const armpl_int_t *ldz,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *iwork,
             armpl_int_t *ifail, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found; = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *zhpevx*. It also exists with a native C interface as *LAPACKE_chpevx*.

4.11.13 chptrd

chptrd reduces a complex Hermitian matrix A stored in packed form to real symmetric tridiagonal form T by a unitary similarity transformation: $Q^H * A * Q = T$.

Syntax

Fortran specification:

```
use armpl_library

subroutine chptrd(UPLO, N, AP, D, E, TAU, INFO)
```

C specification:

```
#include "armpl.h"

void chptrd_(const char *uplo, const armpl_int_t *n,
             armpl_singlecomplex_t *ap, float *d, float *e,
             armpl_singlecomplex_t *tau, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are over- written by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

D Output parameter.

D is REAL

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E Output parameter.

E is REAL

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T: E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zhptrd*. It also exists with a native C interface as *LAPACKE_chptrd*.

4.11.14 cpteqr

`cpteqr` computes all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF and then calling CBDSQR to compute the singular values of the bidiagonal factor.

This routine computes the eigenvalues of the positive definite tridiagonal matrix to high relative accuracy. This means that if the eigenvalues range over many orders of magnitude in size, then the small eigenvalues and corresponding eigenvectors will be computed more accurately than, for example, with the standard QR method.

The eigenvectors of a full or band positive definite Hermitian matrix can also be found if CHETRD, CHPTRD, or CHBTRD has been used to reduce this matrix to tridiagonal form. (The reduction to tridiagonal form, however, may preclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix, if these eigenvalues range over many orders of magnitude.)

Syntax

Fortran specification:

```
use armpl_library

subroutine cpteqr(COMPZ, N, D, E, Z, LDZ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cpteqr_(const char *compz, const armpl_int_t *n, float *d, float *e,
             armpl_singlecomplex_t *z, const armpl_int_t *ldz, float *work,
             armpl_int_t *info, ... );
```

Parameters

COMPZ Input parameter.

`COMPZ` is `CHARACTER*1`

= 'N': Compute eigenvalues only. = 'V': Compute eigenvectors of original Hermitian matrix also. Array `Z` contains the unitary matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvectors of tridiagonal matrix also.

N Input parameter.

`N` is `INTEGER`

The order of the matrix. `N` >= 0.

D Input and output parameter.

`D` is `REAL`

`D` is an array, dimension (`N`). On entry, the n diagonal elements of the tridiagonal matrix. On normal exit, `D` contains the eigenvalues, in descending order.

E Input and output parameter.

`E` is `REAL`

`E` is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, `E` has been destroyed.

Z Input and output parameter.

`Z` is `COMPLEX`

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', the unitary matrix used in the reduction to tridiagonal form. On exit, if COMPZ = 'V', the orthonormal eigenvectors of the original Hermitian matrix; if COMPZ = 'I', the orthonormal eigenvectors of the tridiagonal matrix. If INFO > 0 on exit, Z contains the eigenvectors associated with only the stored eigenvalues. If COMPZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if COMPZ = 'V' or 'I', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, and i is: <= N the Cholesky factorization of the matrix could not be performed because the i-th principal minor was not positive definite. > N the SVD algorithm failed to converge; if INFO = N+i, i off-diagonal elements of the bidiagonal factor did not converge to zero.

Related Information

For this routine in other precisions, please see *dpteqr*, *spteqr* and *zpteqr*. It also exists with a native C interface as *LAPACKE_cpteqr*.

4.11.15 cstedc

cstedc computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band complex Hermitian matrix can also be found if CHETRD or CHPTRD or CHBTRD has been used to reduce this matrix to tridiagonal form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLAED3 for details.

Syntax

Fortran specification:

```
use armpl_library

subroutine cstedc(COMPZ, N, D, E, Z, LDZ, WORK, LWORK, RWORK, LRWORK, IWORK,
                  LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cstedc_(const char *compz, const armpl_int_t *n, float *d, float *e,
             armpl_singlecomplex_t *z, const armpl_int_t *ldz,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             float *rwork, const armpl_int_t *lrwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': Compute eigenvalues only. = 'I': Compute eigenvectors of tridiagonal matrix also. = 'V': Compute eigenvectors of original Hermitian matrix also. On entry, Z contains the unitary matrix used to reduce the original matrix to tridiagonal form.

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E Input and output parameter.

E is REAL

E is an array, dimension (N-1). On entry, the subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z Input and output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', then Z contains the unitary matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ = 'V', Z contains the orthonormal eigenvectors of the original Hermitian matrix, and if COMPZ = 'I', Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1. If eigenvectors are desired, then LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If COMPZ = 'N' or 'I', or N <= 1, LWORK must be at least 1. If COMPZ = 'V' and N > 1, LWORK must be at least N*N. Note that for COMPZ = 'V', then if N is less than or equal to the minimum divide size, usually 25, then LWORK need only be 1.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (MAX(1, LRWORK)). On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of the array RWORK. If COMPZ = 'N' or N <= 1, LRWORK must be at least 1. If COMPZ = 'V' and N > 1, LRWORK must be at least 1 + 3* N + 2*N*lg N + 4*N**2 , where lg(N) = smallest integer k such that 2**k >= N. If COMPZ = 'I' and N > 1, LRWORK must be at least 1 + 4* N + 2*N**2 . Note that for COMPZ = 'I' or 'V', then if N is less than or equal to the minimum divide size, usually 25, then LRWORK need only be max(1,2*(N-1)).

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If COMPZ = 'N' or N <= 1, LIWORK must be at least 1. If COMPZ = 'V' or N > 1, LIWORK must be at least 6 + 6* N + 5*N*lg N. If COMPZ = 'I' or N > 1, LIWORK must be at least 3 + 5* N . Note that for COMPZ = 'I' or 'V', then if N is less than or equal to the minimum divide size, usually 25, then LIWORK need only be 1.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: The algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

4.11.16 cstegr

cstegr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T. Any such unreduced matrix has a well defined set of pairwise different real eigenvalues, the corresponding real eigenvectors are pairwise orthogonal.

The spectrum may be computed either completely or partially by specifying either an interval (VL,VU] or a range of indices IL:IU for the desired eigenvalues.

cstegr is a compatibility wrapper around the improved CSTEMR routine. See SSTEMR for further details.

One important change is that the ABSTOL parameter no longer provides any benefit and hence is no longer used.

Note : cstegr and CSTEMR work only on machines which follow IEEE-754 floating-point standard in their handling of infinities and NaNs. Normal execution may create these exceptiona values and hence may abort due to a floating point exception in environments which do not conform to the IEEE-754 standard.

Syntax

Fortran specification:

```
use armpl_library

subroutine cstegr(JOBZ, RANGE, N, D, E, VL, VU, IL, IU, ABSTOL, M, W, Z, LDZ,
                  ISUPPZ, WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cstegr_(const char *jobz, const char *range, const armpl_int_t *n,
             float *d, float *e, const float *vl, const float *vu,
             const armpl_int_t *il, const armpl_int_t *iu,
             const float *abstol, armpl_int_t *m, float *w,
             armpl_singlecomplex_t *z, const armpl_int_t *ldz,
             armpl_int_t *isuppz, float *work, const armpl_int_t *lwork,
             armpl_int_t *iwork, const armpl_int_t *liwork, armpl_int_t *info,
             ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the N diagonal elements of the tridiagonal matrix T. On exit, D is overwritten.

E Input and output parameter.

E is REAL

E is an array, dimension (N). On entry, the (N-1) subdiagonal elements of the tridiagonal matrix T in elements 1 to N-1 of E. E(N) need not be set on input, but is used internally as workspace. On exit, E is overwritten.

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

Unused. Was the absolute error tolerance for the eigenvalues/eigenvectors in previous versions.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', and if INFO = 0, then the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used. Supplying N columns is always safe.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', then LDZ >= max(1, N).

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th computed eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i). This is relevant in the case when the matrix is split. ISUPPZ is only accessed when JOBZ is 'V' and N > 0.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,18*N) if JOBZ = 'V', and LWORK >= max(1,12*N) if JOBZ = 'N'. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size

of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (LIWORK)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= max(1,10*N) if the eigenvectors are desired, and LIWORK >= max(1,8*N) if only the eigenvalues are to be computed. If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

On exit, INFO = 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = 1X, internal error in SLARRE, if INFO = 2X, internal error in CLARRV. Here, the digit X = ABS(IINFO) < 10, where IINFO is the nonzero error code returned by SLARRE or CLARRV, respectively.

Related Information

For this routine in other precisions, please see *dstegr*, *sstegr* and *zstegr*. It also exists with a native C interface as *LAPACKE_cstegr*.

4.11.17 cstein

cstein computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter MAXITS (currently set to 5).

Although the eigenvectors are real, they are stored in a complex array, which may be passed to CUNMTR or CUPMTR for back transformation to the eigenvectors of a complex Hermitian matrix which was reduced to tridiagonal form.

Syntax

Fortran specification:

```
use armpl_library

subroutine cstein(N, D, E, M, W, IBLOCK, ISPLIT, Z, LDZ, WORK, IWORK, IFAIL,
                  INFO)
```

C specification:

```
#include "armpl.h"

void cstein_(const armpl_int_t *n, const float *d, const float *e,
             const armpl_int_t *m, const float *w, const armpl_int_t *iblock,
             const armpl_int_t *isplit, armpl_singlecomplex_t *z,
             const armpl_int_t *ldz, float *work, armpl_int_t *iwork,
             armpl_int_t *ifail, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the tridiagonal matrix T.

E Input parameter.

E is REAL

E is an array, dimension (N-1). The (n-1) subdiagonal elements of the tridiagonal matrix T, stored in elements 1 to N-1.

M Input parameter.

M is INTEGER

The number of eigenvectors to be found. 0 <= M <= N.

W Input parameter.

W is REAL

W is an array, dimension (N). The first M elements of W contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array W from SSTEBZ with ORDER = 'B' is expected here.)

IBLOCK Input parameter.

IBLOCK is INTEGER array, dimension (N)

The submatrix indices associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first submatrix from the top, =2 if W(i) belongs to the second submatrix, etc. (The output array IBLOCK from SSTEBZ is expected here.)

ISPLIT Input parameter.

ISPLIT is INTEGER array, dimension (N)

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc. (The output array ISPLIT from SSTEBZ is expected here.)

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, M). The computed eigenvectors. The eigenvector associated with the eigenvalue W(i) is stored in the i-th column of Z. Any vector which fails to converge is set to its current iterate after MAXITS iterations. The imaginary parts of the eigenvectors are set to zero.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (5*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (M)

On normal exit, all elements of IFAIL are zero. If one or more eigenvectors fail to converge after MAXITS iterations, then their indices are stored in array IFAIL.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge in MAXITS iterations. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *dstein*, *sstein* and *zstein*. It also exists with a native C interface as *LAPACKE_cstein*.

4.11.18 cstemr

cstemr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T. Any such unreduced matrix has a well defined set of pairwise different real eigenvalues, the corresponding real eigenvectors are pairwise orthogonal.

The spectrum may be computed either completely or partially by specifying either an interval (VL,VU] or a range of indices IL:IU for the desired eigenvalues.

Depending on the number of desired eigenvalues, these are computed either by bisection or the dqds algorithm. Numerically orthogonal eigenvectors are computed by the use of various suitable L D L^T factorizations near clusters of close eigenvalues (referred to as RRRs, Relatively Robust Representations). An informal sketch of the algorithm follows.

For each unreduced block (submatrix) of T,

```
(a) Compute T - sigma I  = L D L^T, so that L and D
     define all the wanted eigenvalues to high relative accuracy.
     This means that small relative changes in the entries of D and L
     cause only small relative changes in the eigenvalues and
     eigenvectors. The standard (unfactored) representation of the
     tridiagonal matrix T does not have this property in general.
 (b) Compute the eigenvalues to suitable accuracy.
     If the eigenvectors are desired, the algorithm attains full
     accuracy of the computed eigenvalues only right before
     the corresponding vectors have to be computed, see steps c) and d).
 (c) For each cluster of close eigenvalues, select a new
     shift close to the cluster, find a new factorization, and refine
     the shifted eigenvalues to suitable accuracy.
 (d) For each eigenvalue with a large enough relative separation compute
     the corresponding eigenvector by forming a rank revealing twisted
     factorization. Go back to (c) for any clusters that remain.
```

For more details, see: - Inderjit S. Dhillon and Beresford N. Parlett: “Multiple representations

```
 to compute orthogonal eigenvectors of symmetric tridiagonal matrices,"
Linear Algebra and its Applications, 387(1), pp. 1-28, August 2004.
```

- Inderjit Dhillon and Beresford Parlett: “Orthogonal Eigenvectors and

```
 Relative Gaps," SIAM Journal on Matrix Analysis and Applications, Vol. 25,
2004.  Also LAPACK Working Note 154.
```

- Inderjit Dhillon: “A new O(n^2) algorithm for the symmetric

```
 tridiagonal eigenvalue/eigenvector problem",
Computer Science Division Technical Report No. UCB/CSD-97-971,
UC Berkeley, May 1997.
```

Further Details 1.‘‘cstemr‘‘ works only on machines which follow IEEE-754 floating-point standard in their handling of infinities and NaNs. This permits the use of efficient inner loops avoiding a check for zero divisors.

2. LAPACK routines can be used to reduce a complex Hermitean matrix to real symmetric tridiagonal form.

(Any complex Hermitean tridiagonal matrix has real values on its diagonal and potentially complex numbers on its off-diagonals. By applying a similarity transform with an appropriate diagonal matrix diag(1,e^{i phy_1}, … , e^{i phy_{n-1}}), the complex Hermitean matrix can be transformed into a real symmetric matrix and complex arithmetic can be entirely avoided.)

While the eigenvectors of the real symmetric tridiagonal matrix are real, the eigenvectors of original complex Hermitean matrix have complex entries in general. Since LAPACK drivers overwrite the matrix data with the eigenvectors, `cstemr` accepts complex workspace to facilitate interoperability with CUNMTR or CUPMTR.

Syntax

Fortran specification:

```
use armpl_library

subroutine cstemr(JOBZ, RANGE, N, D, E, VL, VU, IL, IU, M, W, Z, LDZ, NZC,
                  ISUPPZ, TRYRAC, WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cstemr_(const char *jobz, const char *range, const armpl_int_t *n,
             float *d, float *e, const float *vl, const float *vu,
             const armpl_int_t *il, const armpl_int_t *iu, armpl_int_t *m,
             float *w, armpl_singlecomplex_t *z, const armpl_int_t *ldz,
             const armpl_int_t *nzc, armpl_int_t *isuppz, armpl_int_t *tryrac,
             float *work, const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= ‘N’: Compute eigenvalues only; = ‘V’: Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= ‘A’: all eigenvalues will be found. = ‘V’: all eigenvalues in the half-open interval (VL,VU] will be found. = ‘I’: the IL-th through IU-th eigenvalues will be found.

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the N diagonal elements of the tridiagonal matrix T. On exit, D is overwritten.

E Input and output parameter.

E is REAL

E is an array, dimension (N). On entry, the (N-1) subdiagonal elements of the tridiagonal matrix T in elements 1 to N-1 of E. E(N) need not be set on input, but is used internally as workspace. On exit, E is overwritten.

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0. Not referenced if RANGE = 'A' or 'V'.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', and if INFO = 0, then the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and can be computed with a workspace query by setting NZC = -1, see below.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', then LDZ >= max(1, N).

NZC Input parameter.

NZC is INTEGER

The number of eigenvectors to be held in the array Z. If RANGE = 'A', then NZC >= max(1, N). If RANGE = 'V', then NZC >= the number of eigenvalues in (VL,VU]. If RANGE = 'I', then NZC >= IU-IL+1. If NZC =

-1, then a workspace query is assumed; the routine calculates the number of columns of the array Z that are needed to hold the eigenvectors. This value is returned as the first entry of the Z array, and no error message related to NZC is issued by XERBLA.

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th computed eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i). This is relevant in the case when the matrix is split. ISUPPZ is only accessed when JOBZ is 'V' and N > 0.

TRYRAC Input and output parameter.

TRYRAC is LOGICAL

If TRYRAC.EQ..TRUE., indicates that the code should check whether the tridiagonal matrix defines its eigenvalues to high relative accuracy. If so, the code uses relative-accuracy preserving algorithms that might be (a bit) slower depending on the matrix. If the matrix does not define its eigenvalues to high relative accuracy, the code can uses possibly faster algorithms. If TRYRAC.EQ..FALSE., the code is not required to guarantee relatively accurate eigenvalues and can use the fastest possible techniques. On exit, a .TRUE. TRYRAC will be set to .FALSE. if the matrix does not define its eigenvalues to high relative accuracy.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,18*N) if JOBZ = 'V', and LWORK >= max(1,12*N) if JOBZ = 'N'. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (LIWORK)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= max(1,10*N) if the eigenvectors are desired, and LIWORK >= max(1,8*N) if only the eigenvalues are to be computed. If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

On exit, INFO = 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = 1X, internal error in SLARRE, if INFO = 2X, internal error in CLARRV. Here, the digit X = ABS(IINFO) < 10, where IINFO is the nonzero error code returned by SLARRE or CLARRV, respectively.

Related Information

For this routine in other precisions, please see *dstemr*, *sstemr* and *zstemr*. It also exists with a native C interface as *LAPACKE_cstemr*.

4.11.19 csteqr

csteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. The eigenvectors of a full or band complex Hermitian matrix can also be found if CHETRD or CHPTRD or CHBTRD has been used to reduce this matrix to tridiagonal form.

Syntax

Fortran specification:

```
use armpl_library

subroutine csteqr(COMPZ, N, D, E, Z, LDZ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void csteqr_(const char *compz, const armpl_int_t *n, float *d, float *e,
             armpl_singlecomplex_t *z, const armpl_int_t *ldz, float *work,
             armpl_int_t *info, ... );
```

Parameters

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': Compute eigenvalues only. = 'V': Compute eigenvalues and eigenvectors of the original Hermitian matrix. On entry, Z must contain the unitary matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvalues and eigenvectors of the tridiagonal matrix. Z is initialized to the identity matrix.

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E Input and output parameter.

E is REAL

E is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z Input and output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', then Z contains the unitary matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ = 'V', Z contains the orthonormal eigenvectors of the original Hermitian matrix, and if COMPZ = 'I', Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if eigenvectors are desired, then LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (max(1,2*N-2)). If COMPZ = 'N', then WORK is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: the algorithm has failed to find all the eigenvalues in a total of 30* N iterations; if INFO = i, then i elements of E have not converged to zero; on exit, D and E contain the elements of a symmetric tridiagonal matrix which is unitarily similar to the original matrix.

Related Information

For this routine in other precisions, please see *dsteqr*, *ssteqr* and *zsteqr*. It also exists with a native C interface as *LAPACKE_csteqr*.

4.11.20 cungtr

cungtr generates a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by CHETRD:

if UPLO = 'U', Q = H(n-1) . . . H(2) H(1),

if UPLO = 'L', Q = H(1) H(2) . . . H(n-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine cungtr(UPLO, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cungtr_(const char *uplo, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, const armpl_singlecomplex_t *tau,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A contains elementary reflectors from CHETRD; = 'L': Lower triangle of A contains elementary reflectors from CHETRD.

N Input parameter.

N is INTEGER

The order of the matrix Q. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the vectors which define the elementary reflectors, as returned by CHETRD. On exit, the N-by-N unitary matrix Q.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= N.

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (N-1). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CHETRD.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= N-1. For optimum performance LWORK >= (N-1)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zungtr*. It also exists with a native C interface as *LAPACKE_cungtr*.

4.11.21 cunm22

```
CUNM22 overwrites the general complex M-by-N matrix C with

                 SIDE = 'L'     SIDE = 'R'
 TRANS = 'N':      Q * C          C * Q
 TRANS = 'C':      Q**H * C       C * Q**H

 where Q is a complex unitary matrix of order NQ, with NQ = M if
 SIDE = 'L' and NQ = N if SIDE = 'R'.
 The unitary matrix Q processes a 2-by-2 block structure

        [  Q11  Q12  ]
    Q = [            ]
        [  Q21  Q22  ],

 where Q12 is an N1-by-N1 lower triangular matrix and Q21 is an
 N2-by-N2 upper triangular matrix.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cunm22(SIDE, TRANS, M, N, N1, N2, Q, LDQ, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void cunm22_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *n1,
             const armpl_int_t *n2, const armpl_singlecomplex_t *q,
             const armpl_int_t *ldq, armpl_singlecomplex_t *c,
             const armpl_int_t *ldc, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose); = 'C': apply Q^H (Conjugate transpose).

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

N1 Input parameter.

N2 Input parameter.

N1 is INTEGER

N2 is INTEGER The dimension of Q12 and Q21, respectively. N1, N2 >= 0. The following requirement must be satisfied: N1 + N2 = M if SIDE = 'L' and N1 + N2 = N if SIDE = 'R'.

Q Input parameter.

Q is COMPLEX

Q is an array, dimension. (LDQ, M) if SIDE = 'L' (LDQ, N) if SIDE = 'R'

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, M) if SIDE = 'L'; LDQ >= max(1, N) if SIDE = 'R'.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For optimum performance LWORK >= M*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zunm22*.

4.11.22 cunmtr

cunmtr overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H

where Q is a complex unitary matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of nq-1 elementary reflectors, as returned by CHETRD:

if UPLO = 'U', Q = H(nq-1) . . . H(2) H(1);

if UPLO = 'L', Q = H(1) H(2) . . . H(nq-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine cunmtr(SIDE, UPLO, TRANS, M, N, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void cunmtr_(const char *side, const char *uplo, const char *trans,
             const armpl_int_t *m, const armpl_int_t *n,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *c,
             const armpl_int_t *ldc, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A contains elementary reflectors from CHETRD; = 'L': Lower triangle of A contains elementary reflectors from CHETRD.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Conjugate transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension. (LDA, M) if SIDE = 'L' (LDA, N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by CHETRD.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M) if SIDE = 'L'; LDA >= max(1, N) if SIDE = 'R'.

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension. (M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CHETRD.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >=M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zunmtr*. It also exists with a native C interface as *LAPACKE_cunmtr*.

4.11.23 cupgtr

cupgtr generates a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by CHPTRD using packed storage:

if UPLO = 'U', Q = H(n-1) . . . H(2) H(1),

if UPLO = 'L', Q = H(1) H(2) . . . H(n-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine cupgtr(UPLO, N, AP, TAU, Q, LDQ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cupgtr_(const char *uplo, const armpl_int_t *n,
             const armpl_singlecomplex_t *ap,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *q,
             const armpl_int_t *ldq, armpl_singlecomplex_t *work,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular packed storage used in previous call to CHPTRD; = 'L': Lower triangular packed storage used in previous call to CHPTRD.

N Input parameter.

N is INTEGER

The order of the matrix Q. N >= 0.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). The vectors which define the elementary reflectors, as returned by CHPTRD.

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (N-1). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CHPTRD.

Q Output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, N). The N-by-N unitary matrix Q.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N-1) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zupgtr*. It also exists with a native C interface as *LAPACKE_cupgtr*.

4.11.24 cupmtr

cupmtr overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H

where Q is a complex unitary matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of nq-1 elementary reflectors, as returned by CHPTRD using packed storage:

if UPLO = 'U', Q = H(nq-1) . . . H(2) H(1);

if UPLO = 'L', Q = H(1) H(2) . . . H(nq-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine cupmtr(SIDE, UPLO, TRANS, M, N, AP, TAU, C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cupmtr_(const char *side, const char *uplo, const char *trans,
             const armpl_int_t *m, const armpl_int_t *n,
             const armpl_singlecomplex_t *ap,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *c,
             const armpl_int_t *ldc, armpl_singlecomplex_t *work,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular packed storage used in previous call to CHPTRD; = 'L': Lower triangular packed storage used in previous call to CHPTRD.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Conjugate transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension. (M*(M+1)/2) if SIDE = 'L' (N*(N+1)/2) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by CHPTRD. AP is modified by the routine but restored on exit.

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (M-1) if SIDE = 'L'. or (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CHPTRD.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension. (N) if SIDE = 'L' (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zupmtr*. It also exists with a native C interface as *LAPACKE_cupmtr*.

4.11.25 ddisna

ddisna computes the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m-by-n matrix. The reciprocal condition number is the 'gap' between the corresponding eigenvalue or singular value and the nearest other one.

The bound on the error, measured by angle in radians, in the I-th computed vector is given by

```
DLAMCH( 'E' ) * ( ANORM / SEP( I ) )
```

where ANORM = 2-norm(A) = max(abs(D(j))). SEP(I) is not allowed to be smaller than DLAMCH('E')*ANORM in order to limit the size of the error bound.

ddisna may also be used to compute error bounds for eigenvectors of the generalized symmetric definite eigenproblem.

Syntax

Fortran specification:

```
use armpl_library

subroutine ddisna(JOB, M, N, D, SEP, INFO)
```

C specification:

```
#include "armpl.h"

void ddisna_(const char *job, const armpl_int_t *m, const armpl_int_t *n,
             const double *d, double *sep, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies for which problem the reciprocal condition numbers should be computed: = 'E': the eigenvectors of a symmetric/Hermitian matrix; = 'L': the left singular vectors of a general matrix; = 'R': the right singular vectors of a general matrix.

M Input parameter.

M is INTEGER

The number of rows of the matrix. M >= 0.

N Input parameter.

N is INTEGER

If JOB = 'L' or 'R', the number of columns of the matrix, in which case N >= 0. Ignored if JOB = 'E'.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (M) if JOB = 'E'. dimension (min(M, N)) if JOB = 'L' or 'R' The eigenvalues (if JOB = 'E') or singular values (if JOB = 'L' or 'R') of the matrix, in either increasing or decreasing order. If singular values, they must be non-negative.

SEP Output parameter.

SEP is DOUBLE PRECISION

SEP is an array, dimension (M) if JOB = 'E'. dimension (min(M, N)) if JOB = 'L' or 'R' The reciprocal condition numbers of the vectors.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *sdisna*. It also exists with a native C interface as *LAPACKE_ddisna*.

4.11.26 dopgtr

dopgtr generates a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by DSPTRD using packed storage:

if UPLO = 'U', Q = H(n-1) . . . H(2) H(1),

if UPLO = 'L', Q = H(1) H(2) . . . H(n-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine dopgtr(UPLO, N, AP, TAU, Q, LDQ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dopgtr_(const char *uplo, const armpl_int_t *n, const double *ap,
             const double *tau, double *q, const armpl_int_t *ldq,
             double *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular packed storage used in previous call to DSPTRD; = 'L': Lower triangular packed storage used in previous call to DSPTRD.

N Input parameter.

N is INTEGER

The order of the matrix Q. N >= 0.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). The vectors which define the elementary reflectors, as returned by DSPTRD.

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (N-1). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DSPTRD.

Q Output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). The N-by-N orthogonal matrix Q.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N-1) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sopgtr*. It also exists with a native C interface as *LAPACKE_dopgtr*.

4.11.27 dopmtr

dopmtr overwrites the general real M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T

where Q is a real orthogonal matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of nq-1 elementary reflectors, as returned by DSPTRD using packed storage:

if UPLO = 'U', Q = H(nq-1) . . . H(2) H(1);

if UPLO = 'L', Q = H(1) H(2) . . . H(nq-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine dopmtr(SIDE, UPLO, TRANS, M, N, AP, TAU, C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dopmtr_(const char *side, const char *uplo, const char *trans,
             const armpl_int_t *m, const armpl_int_t *n, const double *ap,
             const double *tau, double *c, const armpl_int_t *ldc,
             double *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular packed storage used in previous call to DSPTRD; = 'L': Lower triangular packed storage used in previous call to DSPTRD.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension. (M*(M+1)/2) if SIDE = 'L' (N*(N+1)/2) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by DSPTRD. AP is modified by the routine but restored on exit.

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (M-1) if SIDE = 'L'. or (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DSPTRD.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension. (N) if SIDE = 'L' (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sopmtr*. It also exists with a native C interface as *LAPACKE_dopmtr*.

4.11.28 dorgtr

dorgtr generates a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by DSYTRD:

if UPLO = 'U', Q = H(n-1) . . . H(2) H(1),

if UPLO = 'L', Q = H(1) H(2) . . . H(n-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine dorgtr(UPLO, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorgtr_(const char *uplo, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, const double *tau, double *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A contains elementary reflectors from DSYTRD; = 'L': Lower triangle of A contains elementary reflectors from DSYTRD.

N Input parameter.

N is INTEGER

The order of the matrix Q. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the vectors which define the elementary reflectors, as returned by DSYTRD. On exit, the N-by-N orthogonal matrix Q.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (N-1). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DSYTRD.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,N-1). For optimum performance LWORK >= (N-1)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sorgtr*. It also exists with a native C interface as *LAPACKE_dorgtr*.

4.11.29 dorm22

```
DORM22 overwrites the general real M-by-N matrix C with

                 SIDE = 'L'     SIDE = 'R'
 TRANS = 'N':      Q * C          C * Q
 TRANS = 'T':      Q**T * C       C * Q**T

 where Q is a real orthogonal matrix of order NQ, with NQ = M if
 SIDE = 'L' and NQ = N if SIDE = 'R'.
 The orthogonal matrix Q processes a 2-by-2 block structure

        [  Q11  Q12  ]
    Q = [            ]
        [  Q21  Q22  ],

 where Q12 is an N1-by-N1 lower triangular matrix and Q21 is an
 N2-by-N2 upper triangular matrix.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dorm22(SIDE, TRANS, M, N, N1, N2, Q, LDQ, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dorm22_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *n1,
             const armpl_int_t *n2, const double *q, const armpl_int_t *ldq,
             double *c, const armpl_int_t *ldc, double *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose); = 'C': apply Q^T (Conjugate transpose).

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

N1 Input parameter.

N2 Input parameter.

N1 is INTEGER

N2 is INTEGER The dimension of Q12 and Q21, respectively. N1, N2 >= 0. The following requirement must be satisfied: N1 + N2 = M if SIDE = 'L' and N1 + N2 = N if SIDE = 'R'.

Q Input parameter.

Q is DOUBLE PRECISION

Q is an array, dimension. (LDQ, M) if SIDE = 'L' (LDQ, N) if SIDE = 'R'

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, M) if SIDE = 'L'; LDQ >= max(1, N) if SIDE = 'R'.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For optimum performance LWORK >= M*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sorm22*.

4.11.30 dormtr

dormtr overwrites the general real M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T

where Q is a real orthogonal matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of nq-1 elementary reflectors, as returned by DSYTRD:

if UPLO = 'U', Q = H(nq-1) . . . H(2) H(1);

if UPLO = 'L', Q = H(1) H(2) . . . H(nq-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine dormtr(SIDE, UPLO, TRANS, M, N, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dormtr_(const char *side, const char *uplo, const char *trans,
             const armpl_int_t *m, const armpl_int_t *n, const double *a,
             const armpl_int_t *lda, const double *tau, double *c,
             const armpl_int_t *ldc, double *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A contains elementary reflectors from DSYTRD; = 'L': Lower triangle of A contains elementary reflectors from DSYTRD.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension. (LDA, M) if SIDE = 'L' (LDA, N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by DSYTRD.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M) if SIDE = 'L'; LDA >= max(1, N) if SIDE = 'R'.

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension. (M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DSYTRD.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sormtr*. It also exists with a native C interface as *LAPACKE_dormtr*.

4.11.31 dpteqr

dpteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using DPTTRF, and then calling DBDSQR to compute the singular values of the bidiagonal factor.

This routine computes the eigenvalues of the positive definite tridiagonal matrix to high relative accuracy. This means that if the eigenvalues range over many orders of magnitude in size, then the small eigenvalues and corresponding eigenvectors will be computed more accurately than, for example, with the standard QR method.

The eigenvectors of a full or band symmetric positive definite matrix can also be found if DSYTRD, DSPTRD, or DSBTRD has been used to reduce this matrix to tridiagonal form. (The reduction to tridiagonal form, however,

may preclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix, if these eigenvalues range over many orders of magnitude.)

Syntax

Fortran specification:

```
use armpl_library

subroutine dpteqr(COMPZ, N, D, E, Z, LDZ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dpteqr_(const char *compz, const armpl_int_t *n, double *d, double *e,
             double *z, const armpl_int_t *ldz, double *work,
             armpl_int_t *info, ... );
```

Parameters

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': Compute eigenvalues only. = 'V': Compute eigenvectors of original symmetric matrix also. Array Z contains the orthogonal matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvectors of tridiagonal matrix also.

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the n diagonal elements of the tridiagonal matrix. On normal exit, D contains the eigenvalues, in descending order.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', the orthogonal matrix used in the reduction to tridiagonal form. On exit, if COMPZ = 'V', the orthonormal eigenvectors of the original symmetric matrix; if COMPZ = 'I', the orthonormal eigenvectors of the tridiagonal matrix. If INFO > 0 on exit, Z contains the eigenvectors associated with only the stored eigenvalues. If COMPZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if COMPZ = 'V' or 'I', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, and i is: <= N the Cholesky factorization of the matrix could not be performed because the i-th principal minor was not positive definite. > N the SVD algorithm failed to converge; if INFO = N+i, i off-diagonal elements of the bidiagonal factor did not converge to zero.

Related Information

For this routine in other precisions, please see *cpteqr*, *spteqr* and *zpteqr*. It also exists with a native C interface as *LAPACKE_dpteqr*.

4.11.32 dsbev

dsbev computes all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsbev(JOBZ, UPLO, N, KD, AB, LDAB, W, Z, LDZ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsbev_(const char *jobz, const char *uplo, const armpl_int_t *n,
            const armpl_int_t *kd, double *ab, const armpl_int_t *ldab,
            double *w, double *z, const armpl_int_t *ldz, double *work,
            armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (max(1,3*N-2)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *ssbev*. It also exists with a native C interface as *LAPACKE_dsbev*.

4.11.33 dsbevd

dsbevd computes all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsbevd(JOBZ, UPLO, N, KD, AB, LDAB, W, Z, LDZ, WORK, LWORK, IWORK,
                  LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsbevd_(const char *jobz, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *kd, double *ab, const armpl_int_t *ldab,
             double *w, double *z, const armpl_int_t *ldz, double *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array,. dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. IF N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 2, LWORK must be at least 2*N. If JOBZ = 'V' and N > 2, LWORK must be at least (1 + 5* N + 2*N**2).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 2, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *ssbevd*. It also exists with a native C interface as *LAPACKE_dsbevd*.

4.11.34 dsbevx

dsbevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsbevx(JOBZ, RANGE, UPLO, N, KD, AB, LDAB, Q, LDQ, VL, VU, IL, IU,
                  ABSTOL, M, W, Z, LDZ, WORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void dsbevx_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, const armpl_int_t *kd, double *ab,
             const armpl_int_t *ldab, double *q, const armpl_int_t *ldq,
             const double *vl, const double *vu, const armpl_int_t *il,
             const armpl_int_t *iu, const double *abstol, armpl_int_t *m,
             double *w, double *z, const armpl_int_t *ldz, double *work,
             armpl_int_t *iwork, armpl_int_t *ifail, armpl_int_t *info,
             ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found; = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

Q Output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). If JOBZ = 'V', the N-by-N orthogonal matrix used in the reduction to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. If JOBZ = 'V', then LDQ >= max(1, N).

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AB to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*DLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *ssbevx*. It also exists with a native C interface as *LAPACKE_dsbevx*.

4.11.35 dsbtrd

dsbtrd reduces a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: Q^T * A * Q = T.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsbtrd(VECT, UPLO, N, KD, AB, LDAB, D, E, Q, LDQ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsbtrd_(const char *vect, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *kd, double *ab, const armpl_int_t *ldab,
             double *d, double *e, double *q, const armpl_int_t *ldq,
             double *work, armpl_int_t *info, ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

= 'N': do not form Q; = 'V': form Q; = 'U': update a matrix X, by forming X*Q.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). On exit, the diagonal elements of AB are overwritten by the diagonal elements of the tridiagonal matrix T; if KD > 0, the elements on the first superdiagonal (if UPLO = 'U') or the first subdiagonal (if UPLO = 'L') are overwritten by the off-diagonal elements of T; the rest of AB is overwritten by values generated during the reduction.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T.

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T: E(i) = T(i,i+1) if UPLO = 'U'; E(i) = T(i+1,i) if UPLO = 'L'.

Q Input and output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). On entry, if VECT = 'U', then Q must contain an N-by-N matrix X; if VECT = 'N' or 'V', then Q need not be set.

On exit: if VECT = 'V', Q contains the N-by-N orthogonal matrix Q; if VECT = 'U', Q contains the product X*Q; if VECT = 'N', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1, and LDQ >= N if VECT = 'V' or 'U'.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ssbtrd*. It also exists with a native C interface as *LAPACKE_dsbtrd*.

4.11.36 dspev

dspev computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage.

Syntax

Fortran specification:

```
use armpl_library

subroutine dspev(JOBZ, UPLO, N, AP, W, Z, LDZ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dspev_(const char *jobz, const char *uplo, const armpl_int_t *n,
            double *ap, double *w, double *z, const armpl_int_t *ldz,
            double *work, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *sspev*. It also exists with a native C interface as *LAPACKE_dspev*.

4.11.37 dspevd

dspevd computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine dspevd(JOBZ, UPLO, N, AP, W, Z, LDZ, WORK, LWORK, IWORK, LIWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dspevd_(const char *jobz, const char *uplo, const armpl_int_t *n,
             double *ap, double *w, double *z, const armpl_int_t *ldz,
             double *work, const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the required LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least 2*N. If JOBZ = 'V' and N > 1, LWORK must be at least 1 + 6* N + N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the required LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *sspevd*. It also exists with a native C interface as *LAPACKE_dspevd*.

4.11.38 dspevx

dspevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage. Eigenvalues/vectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine dspevx(JOBZ, RANGE, UPLO, N, AP, VL, VU, IL, IU, ABSTOL, M, W, Z,
                  LDZ, WORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void dspevx_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, double *ap, const double *vl,
             const double *vu, const armpl_int_t *il, const armpl_int_t *iu,
             const double *abstol, armpl_int_t *m, double *w, double *z,
             const armpl_int_t *ldz, double *work, armpl_int_t *iwork,
             armpl_int_t *ifail, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found; = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*DLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the selected eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (8*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *sspevx*. It also exists with a native C interface as *LAPACKE_dspevx*.

4.11.39 dsptrd

dsptrd reduces a real symmetric matrix A stored in packed form to symmetric tridiagonal form T by an orthogonal similarity transformation: $Q^T * A * Q = T$.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsptrd(UPLO, N, AP, D, E, TAU, INFO)
```

C specification:

```
#include "armpl.h"

void dsptrd_(const char *uplo, const armpl_int_t *n, double *ap, double *d,
             double *e, double *tau, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are over- written by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T: E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ssptrd*. It also exists with a native C interface as *LAPACKE_dsptrd*.

4.11.40 dstebz

dstebz computes the eigenvalues of a symmetric tridiagonal matrix T. The user may ask for all eigenvalues, all eigenvalues in the half-open interval (VL, VU], or the IL-th through IU-th eigenvalues.

To avoid overflow, the matrix must be scaled so that its largest element is no greater than overflow**(1/2) * underflow**(1/4) in absolute value, and for greatest accuracy, it should not be much smaller than that.

See W. Kahan "Accurate Eigenvalues of a Symmetric Tridiagonal Matrix", Report CS41, Computer Science Dept., Stanford University, July 21, 1966.

Syntax

Fortran specification:

```
use armpl_library

subroutine dstebz(RANGE, ORDER, N, VL, VU, IL, IU, ABSTOL, D, E, M, NSPLIT, W,
                  IBLOCK, ISPLIT, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dstebz_(const char *range, const char *order, const armpl_int_t *n,
             const double *vl, const double *vu, const armpl_int_t *il,
             const armpl_int_t *iu, const double *abstol, const double *d,
             const double *e, armpl_int_t *m, armpl_int_t *nsplit, double *w,
             armpl_int_t *iblock, armpl_int_t *isplit, double *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': ("All") all eigenvalues will be found. = 'V': ("Value") all eigenvalues in the half-open interval (VL, VU] will be found. = 'I': ("Index") the IL-th through IU-th eigenvalues (of the entire matrix) will be found.

ORDER Input parameter.

ORDER is CHARACTER*1

= 'B': ("By Block") the eigenvalues will be grouped by split-off block (see IBLOCK, ISPLIT) and ordered from smallest to largest within the block. = 'E': ("Entire matrix") the eigenvalues for the entire matrix will be ordered from smallest to largest.

N Input parameter.

N is INTEGER

The order of the tridiagonal matrix T. N >= 0.

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. Eigenvalues less than or equal to VL, or greater than VU, will not be returned. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. Eigenvalues less than or equal to VL, or greater than VU, will not be returned. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute tolerance for the eigenvalues. An eigenvalue (or cluster) is considered to be located if it has been determined to lie in an interval whose width is ABSTOL or less. If ABSTOL is less than or equal to zero, then ULP*|T| will be used, where |T| means the 1-norm of T.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH('S'), not zero.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n diagonal elements of the tridiagonal matrix T.

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The (n-1) off-diagonal elements of the tridiagonal matrix T.

M Output parameter.

M is INTEGER

The actual number of eigenvalues found. 0 <= M <= N. (See also the description of INFO=2,3.)

NSPLIT Output parameter.

NSPLIT is INTEGER

The number of diagonal blocks in the matrix T. 1 <= NSPLIT <= N.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). On exit, the first M elements of W will contain the eigenvalues. (DSTEBZ may use the remaining N-M elements as workspace.)

IBLOCK Output parameter.

IBLOCK is INTEGER array, dimension (N)

At each row/column j where E(j) is zero or small, the matrix T is considered to split into a block diagonal matrix. On exit, if INFO = 0, IBLOCK(i) specifies to which block (from 1 to the number of blocks) the eigenvalue W(i) belongs. (DSTEBZ may use the remaining N-M elements as workspace.)

ISPLIT Output parameter.

ISPLIT is INTEGER array, dimension (N)

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc., and the NSPLIT-th consists of rows/columns ISPLIT(NSPLIT-1)+1 through ISPLIT(NSPLIT)=N. (Only the first NSPLIT elements will actually be used, but since the user cannot know a priori what value NSPLIT will have, N words must be reserved for ISPLIT.)

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (3*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: some or all of the eigenvalues failed to converge or were not computed: =1 or 3: Bisection failed to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances. This is generally caused by unexpectedly inaccurate arithmetic. =2 or 3: RANGE='I' only: Not all of the eigenvalues IL:IU were found. Effect: M < IU+1-IL Cause: non-monotonic arithmetic, causing the Sturm sequence to be non-monotonic. Cure: recalculate, using RANGE='A', and pick out eigenvalues IL:IU. In some cases, increasing the PARAMETER "FUDGE" may make things work. = 4: RANGE='I', and the Gershgorin interval initially used was too small. No eigenvalues were computed. Probable cause: your machine has sloppy floating-point arithmetic. Cure: Increase the PARAMETER "FUDGE", recompile, and try again.

Related Information

For this routine in other precisions, please see *sstebz*. It also exists with a native C interface as *LAPACKE_dstebz*.

4.11.41 dstedc

`dstedc` computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band real symmetric matrix can also be found if DSYTRD or DSPTRD or DSBTRD has been used to reduce this matrix to tridiagonal form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See DLAED3 for details.

Syntax

Fortran specification:

```
use armpl_library

subroutine dstedc(COMPZ, N, D, E, Z, LDZ, WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dstedc_(const char *compz, const armpl_int_t *n, double *d, double *e,
             double *z, const armpl_int_t *ldz, double *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

COMPZ Input parameter.

`COMPZ` is `CHARACTER*1`

= 'N': Compute eigenvalues only. = 'I': Compute eigenvectors of tridiagonal matrix also. = 'V': Compute eigenvectors of original dense symmetric matrix also. On entry, `Z` contains the orthogonal matrix used to reduce the original matrix to tridiagonal form.

N Input parameter.

`N` is `INTEGER`

The dimension of the symmetric tridiagonal matrix. `N` >= 0.

D Input and output parameter.

`D` is `DOUBLE PRECISION`

`D` is an array, dimension (`N`). On entry, the diagonal elements of the tridiagonal matrix. On exit, if `INFO` = 0, the eigenvalues in ascending order.

E Input and output parameter.

`E` is `DOUBLE PRECISION`

`E` is an array, dimension (N-1). On entry, the subdiagonal elements of the tridiagonal matrix. On exit, `E` has been destroyed.

Z Input and output parameter.

`Z` is `DOUBLE PRECISION`

`Z` is an array, dimension (`LDZ`, `N`). On entry, if `COMPZ` = 'V', then `Z` contains the orthogonal matrix used in the reduction to tridiagonal form. On exit, if `INFO` = 0, then if `COMPZ` = 'V', `Z` contains the orthonormal

eigenvectors of the original symmetric matrix, and if COMPZ = 'I', Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1. If eigenvectors are desired, then LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If COMPZ = 'N' or N <= 1 then LWORK must be at least 1. If COMPZ = 'V' and N > 1 then LWORK must be at least (1 + 3* N + 2*N*lg N + 4*N**2), where lg(N) = smallest integer k such that 2**k >= N. If COMPZ = 'I' and N > 1 then LWORK must be at least (1 + 4* N + N**2). Note that for COMPZ = 'I' or 'V', then if N is less than or equal to the minimum divide size, usually 25, then LWORK need only be max(1,2*(N-1)).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If COMPZ = 'N' or N <= 1 then LIWORK must be at least 1. If COMPZ = 'V' and N > 1 then LIWORK must be at least (6 + 6* N + 5*N*lg N). If COMPZ = 'I' and N > 1 then LIWORK must be at least (3 + 5* N). Note that for COMPZ = 'I' or 'V', then if N is less than or equal to the minimum divide size, usually 25, then LIWORK need only be 1.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: The algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

Related Information

For this routine in other precisions, please see *cstedc*, *sstedc* and *zstedc*. It also exists with a native C interface as *LAPACKE_dstedc*.

4.11.42 dstegr

dstegr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T. Any such unreduced matrix has a well defined set of pairwise different real eigenvalues, the corresponding real eigenvectors are pairwise orthogonal.

The spectrum may be computed either completely or partially by specifying either an interval (VL,VU] or a range of indices IL:IU for the desired eigenvalues.

dstegr is a compatibility wrapper around the improved DSTEMR routine. See DSTEMR for further details.

One important change is that the ABSTOL parameter no longer provides any benefit and hence is no longer used.

Note : dstegr and DSTEMR work only on machines which follow IEEE-754 floating-point standard in their handling of infinities and NaNs. Normal execution may create these exceptiona values and hence may abort due to a floating point exception in environments which do not conform to the IEEE-754 standard.

Syntax

Fortran specification:

```
use armpl_library

subroutine dstegr(JOBZ, RANGE, N, D, E, VL, VU, IL, IU, ABSTOL, M, W, Z, LDZ,
                  ISUPPZ, WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dstegr_(const char *jobz, const char *range, const armpl_int_t *n,
             double *d, double *e, const double *vl, const double *vu,
             const armpl_int_t *il, const armpl_int_t *iu,
             const double *abstol, armpl_int_t *m, double *w, double *z,
             const armpl_int_t *ldz, armpl_int_t *isuppz, double *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the N diagonal elements of the tridiagonal matrix T. On exit, D is overwritten.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). On entry, the (N-1) subdiagonal elements of the tridiagonal matrix T in elements 1 to N-1 of E. E(N) need not be set on input, but is used internally as workspace. On exit, E is overwritten.

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

Unused. Was the absolute error tolerance for the eigenvalues/eigenvectors in previous versions.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', and if INFO = 0, then the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used. Supplying N columns is always safe.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', then LDZ >= max(1, N).

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th computed eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i). This is relevant in the case when the matrix is split. ISUPPZ is only accessed when JOBZ is 'V' and N > 0.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,18*N) if JOBZ = 'V', and LWORK >= max(1,12*N) if JOBZ = 'N'. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (LIWORK)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= max(1,10*N) if the eigenvectors are desired, and LIWORK >= max(1,8*N) if only the eigenvalues are to be computed. If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

On exit, INFO = 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = 1X, internal error in DLARRE, if INFO = 2X, internal error in DLARRV. Here, the digit X = ABS(IINFO) < 10, where IINFO is the nonzero error code returned by DLARRE or DLARRV, respectively.

Related Information

For this routine in other precisions, please see *cstegr*, *sstegr* and *zstegr*. It also exists with a native C interface as *LAPACKE_dstegr*.

4.11.43 dstein

dstein computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter MAXITS (currently set to 5).

Syntax

Fortran specification:

```
use armpl_library

subroutine dstein(N, D, E, M, W, IBLOCK, ISPLIT, Z, LDZ, WORK, IWORK, IFAIL,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dstein_(const armpl_int_t *n, const double *d, const double *e,
             const armpl_int_t *m, const double *w, const armpl_int_t *iblock,
             const armpl_int_t *isplit, double *z, const armpl_int_t *ldz,
             double *work, armpl_int_t *iwork, armpl_int_t *ifail,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n diagonal elements of the tridiagonal matrix T.

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The (n-1) subdiagonal elements of the tridiagonal matrix T, in elements 1 to N-1.

M Input parameter.

M is INTEGER

The number of eigenvectors to be found. 0 <= M <= N.

W Input parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements of W contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array W from DSTEBZ with ORDER = 'B' is expected here.)

IBLOCK Input parameter.

IBLOCK is INTEGER array, dimension (N)

The submatrix indices associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first submatrix from the top, =2 if W(i) belongs to the second submatrix, etc. (The output array IBLOCK from DSTEBZ is expected here.)

ISPLIT Input parameter.

ISPLIT is INTEGER array, dimension (N)

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc. (The output array ISPLIT from DSTEBZ is expected here.)

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, M). The computed eigenvectors. The eigenvector associated with the eigenvalue W(i) is stored in the i-th column of Z. Any vector which fails to converge is set to its current iterate after MAXITS iterations.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (5*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (M)

On normal exit, all elements of IFAIL are zero. If one or more eigenvectors fail to converge after MAXITS iterations, then their indices are stored in array IFAIL.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge in MAXITS iterations. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *cstein*, *sstein* and *zstein*. It also exists with a native C interface as *LAPACKE_dstein*.

4.11.44 dstemr

dstemr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T. Any such unreduced matrix has a well defined set of pairwise different real eigenvalues, the corresponding real eigenvectors are pairwise orthogonal.

The spectrum may be computed either completely or partially by specifying either an interval (VL,VU] or a range of indices IL:IU for the desired eigenvalues.

Depending on the number of desired eigenvalues, these are computed either by bisection or the dqds algorithm. Numerically orthogonal eigenvectors are computed by the use of various suitable L D L^T factorizations near clusters of close eigenvalues (referred to as RRRs, Relatively Robust Representations). An informal sketch of the algorithm follows.

For each unreduced block (submatrix) of T,

```
(a) Compute T - sigma I  = L D L^T, so that L and D
    define all the wanted eigenvalues to high relative accuracy.
    This means that small relative changes in the entries of D and L
    cause only small relative changes in the eigenvalues and
    eigenvectors. The standard (unfactored) representation of the
    tridiagonal matrix T does not have this property in general.
(b) Compute the eigenvalues to suitable accuracy.
    If the eigenvectors are desired, the algorithm attains full
    accuracy of the computed eigenvalues only right before
    the corresponding vectors have to be computed, see steps c) and d).
(c) For each cluster of close eigenvalues, select a new
    shift close to the cluster, find a new factorization, and refine
    the shifted eigenvalues to suitable accuracy.
(d) For each eigenvalue with a large enough relative separation compute
```

(continues on next page)

(continued from previous page)

```
    the corresponding eigenvector by forming a rank revealing twisted
    factorization. Go back to (c) for any clusters that remain.
```

For more details, see: - Inderjit S. Dhillon and Beresford N. Parlett: “Multiple representations

```
 to compute orthogonal eigenvectors of symmetric tridiagonal matrices,"
Linear Algebra and its Applications, 387(1), pp. 1-28, August 2004.
```

- Inderjit Dhillon and Beresford Parlett: “Orthogonal Eigenvectors and

```
 Relative Gaps," SIAM Journal on Matrix Analysis and Applications, Vol. 25,
2004.  Also LAPACK Working Note 154.
```

```
 tridiagonal eigenvalue/eigenvector problem",
Computer Science Division Technical Report No. UCB/CSD-97-971,
UC Berkeley, May 1997.
```

Further Details 1.‘‘dstemr‘‘ works only on machines which follow IEEE-754 floating-point standard in their handling of infinities and NaNs. This permits the use of efficient inner loops avoiding a check for zero divisors.

Syntax

Fortran specification:

```
use armpl_library

subroutine dstemr(JOBZ, RANGE, N, D, E, VL, VU, IL, IU, M, W, Z, LDZ, NZC,
                  ISUPPZ, TRYRAC, WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dstemr_(const char *jobz, const char *range, const armpl_int_t *n,
             double *d, double *e, const double *vl, const double *vu,
             const armpl_int_t *il, const armpl_int_t *iu, armpl_int_t *m,
             double *w, double *z, const armpl_int_t *ldz,
             const armpl_int_t *nzc, armpl_int_t *isuppz, armpl_int_t *tryrac,
             double *work, const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= ‘N’: Compute eigenvalues only; = ‘V’: Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= ‘A’: all eigenvalues will be found. = ‘V’: all eigenvalues in the half-open interval (VL,VU] will be found. = ‘I’: the IL-th through IU-th eigenvalues will be found.

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the N diagonal elements of the tridiagonal matrix T. On exit, D is overwritten.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). On entry, the (N-1) subdiagonal elements of the tridiagonal matrix T in elements 1 to N-1 of E. E(N) need not be set on input, but is used internally as workspace. On exit, E is overwritten.

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0. Not referenced if RANGE = 'A' or 'V'.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', and if INFO = 0, then the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and can be computed with a workspace query by setting NZC = -1, see below.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', then LDZ >= max(1, N).

NZC Input parameter.

NZC is INTEGER

The number of eigenvectors to be held in the array Z. If RANGE = 'A', then NZC >= max(1, N). If RANGE = 'V', then NZC >= the number of eigenvalues in (VL,VU]. If RANGE = 'I', then NZC >= IU-IL+1. If NZC = -1, then a workspace query is assumed; the routine calculates the number of columns of the array Z that are needed to hold the eigenvectors. This value is returned as the first entry of the Z array, and no error message related to NZC is issued by XERBLA.

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th computed eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i). This is relevant in the case when the matrix is split. ISUPPZ is only accessed when JOBZ is 'V' and N > 0.

TRYRAC Input and output parameter.

TRYRAC is LOGICAL

If TRYRAC.EQ..TRUE., indicates that the code should check whether the tridiagonal matrix defines its eigenvalues to high relative accuracy. If so, the code uses relative-accuracy preserving algorithms that might be (a bit) slower depending on the matrix. If the matrix does not define its eigenvalues to high relative accuracy, the code can uses possibly faster algorithms. If TRYRAC.EQ..FALSE., the code is not required to guarantee relatively accurate eigenvalues and can use the fastest possible techniques. On exit, a .TRUE. TRYRAC will be set to .FALSE. if the matrix does not define its eigenvalues to high relative accuracy.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,18*N) if JOBZ = 'V', and LWORK >= max(1,12*N) if JOBZ = 'N'. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (LIWORK)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= max(1,10*N) if the eigenvectors are desired, and LIWORK >= max(1,8*N) if only the eigenvalues are to be computed. If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

On exit, INFO = 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = 1X, internal error in DLARRE, if INFO = 2X, internal error in DLARRV. Here, the digit X = ABS(IINFO) < 10, where IINFO is the nonzero error code returned by DLARRE or DLARRV, respectively.

Related Information

For this routine in other precisions, please see *cstemr*, *sstemr* and *zstemr*. It also exists with a native C interface as *LAPACKE_dstemr*.

4.11.45 dsteqr

dsteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. The eigenvectors of a full or band symmetric matrix can also be found if DSYTRD or DSPTRD or DSBTRD has been used to reduce this matrix to tridiagonal form.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsteqr(COMPZ, N, D, E, Z, LDZ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsteqr_(const char *compz, const armpl_int_t *n, double *d, double *e,
             double *z, const armpl_int_t *ldz, double *work,
             armpl_int_t *info, ... );
```

Parameters

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': Compute eigenvalues only. = 'V': Compute eigenvalues and eigenvectors of the original symmetric matrix. On entry, Z must contain the orthogonal matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvalues and eigenvectors of the tridiagonal matrix. Z is initialized to the identity matrix.

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', then Z contains the orthogonal matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ = 'V', Z contains the orthonormal

eigenvectors of the original symmetric matrix, and if COMPZ = 'I', Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if eigenvectors are desired, then LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (max(1,2*N-2)). If COMPZ = 'N', then WORK is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: the algorithm has failed to find all the eigenvalues in a total of 30* N iterations; if INFO = i, then i elements of E have not converged to zero; on exit, D and E contain the elements of a symmetric tridiagonal matrix which is orthogonally similar to the original matrix.

Related Information

For this routine in other precisions, please see *csteqr*, *ssteqr* and *zsteqr*. It also exists with a native C interface as *LAPACKE_dsteqr*.

4.11.46 dsterf

dsterf computes all eigenvalues of a symmetric tridiagonal matrix using the Pal-Walker-Kahan variant of the QL or QR algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsterf(N, D, E, INFO)
```

C specification:

```
#include "armpl.h"

void dsterf_(const armpl_int_t *n, double *d, double *e, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the n diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: the algorithm failed to find all of the eigenvalues in a total of 30* N iterations; if INFO = i, then i elements of E have not converged to zero.

Related Information

For this routine in other precisions, please see *ssterf*. It also exists with a native C interface as *LAPACKE_dsterf*.

4.11.47 dstev

dstev computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A.

Syntax

Fortran specification:

```
use armpl_library

subroutine dstev(JOBZ, N, D, E, Z, LDZ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dstev_(const char *jobz, const armpl_int_t *n, double *d, double *e,
            double *z, const armpl_int_t *ldz, double *work,
            armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the n diagonal elements of the tridiagonal matrix A. On exit, if INFO = 0, the eigenvalues in ascending order.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A, stored in elements 1 to N-1 of E. On exit, the contents of E are destroyed.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with D(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (max(1,2*N-2)). If JOBZ = 'N', WORK is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of E did not converge to zero.

Related Information

For this routine in other precisions, please see *sstev*. It also exists with a native C interface as *LAPACKE_dstev*.

4.11.48 dstevd

dstevd computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine dstevd(JOBZ, N, D, E, Z, LDZ, WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dstevd_(const char *jobz, const armpl_int_t *n, double *d, double *e,
             double *z, const armpl_int_t *ldz, double *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the n diagonal elements of the tridiagonal matrix A. On exit, if INFO = 0, the eigenvalues in ascending order.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A, stored in elements 1 to N-1 of E. On exit, the contents of E are destroyed.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with D(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array,. dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If JOBZ = 'N' or N <= 1 then LWORK must be at least 1. If JOBZ = 'V' and N > 1 then LWORK must be at least (1 + 4* N + N**2).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If JOBZ = 'N' or N <= 1 then LIWORK must be at least 1. If JOBZ = 'V' and N > 1 then LIWORK must be at least 3+5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of E did not converge to zero.

Related Information

For this routine in other precisions, please see *sstevd*. It also exists with a native C interface as *LAPACKE_dstevd*.

4.11.49 dstevr

dstevr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, dstevr calls DSTEMR to compute the eigenspectrum using Relatively Robust Representations. DSTEMR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" L D L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i-th unreduced block of T,

```
(a) Compute T - sigma_i = L_i D_i L_i^T, such that L_i D_i L_i^T
     is a relatively robust representation,
(b) Compute the eigenvalues, lambda_j, of L_i D_i L_i^T to high
    relative accuracy by the dqds algorithm,
(c) If there is a cluster of close eigenvalues, "choose" sigma_i
    close to the cluster, and go to step (a),
(d) Given the approximate eigenvalue lambda_j of L_i D_i L_i^T,
    compute the corresponding eigenvector by forming a
    rank-revealing twisted factorization.
```

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new O(n^2) algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB//CSD-97-971, UC Berkeley, May 1997.

Note 1 : dstevr calls DSTEMR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. dstevr calls DSTEBZ and DSTEIN on non-ieee machines and when partial spectrum requests are made.

Normal execution of DSTEMR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

Syntax

Fortran specification:

```
use armpl_library

subroutine dstevr(JOBZ, RANGE, N, D, E, VL, VU, IL, IU, ABSTOL, M, W, Z, LDZ,
                  ISUPPZ, WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dstevr_(const char *jobz, const char *range, const armpl_int_t *n,
             double *d, double *e, const double *vl, const double *vu,
             const armpl_int_t *il, const armpl_int_t *iu,
             const double *abstol, armpl_int_t *m, double *w, double *z,
             const armpl_int_t *ldz, armpl_int_t *isuppz, double *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found. For RANGE = 'V' or 'I' and IU - IL < N - 1, DSTEBZ and DSTEIN are called

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the n diagonal elements of the tridiagonal matrix A. On exit, D may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (max(1,N-1)). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A in elements 1 to N-1 of E. On exit, E may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to DLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i). Implemented only for RANGE = 'A' or 'I' and IU - IL = N - 1

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,20*N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal (and minimal) LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= max(1,10*N).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: Internal error

Related Information

For this routine in other precisions, please see *sstevr*. It also exists with a native C interface as *LAPACKE_dstevr*.

4.11.50 dstevx

dstevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine dstevx(JOBZ, RANGE, N, D, E, VL, VU, IL, IU, ABSTOL, M, W, Z, LDZ,
                  WORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void dstevx_(const char *jobz, const char *range, const armpl_int_t *n,
             double *d, double *e, const double *vl, const double *vu,
             const armpl_int_t *il, const armpl_int_t *iu,
             const double *abstol, armpl_int_t *m, double *w, double *z,
             const armpl_int_t *ldz, double *work, armpl_int_t *iwork,
             armpl_int_t *ifail, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the n diagonal elements of the tridiagonal matrix A. On exit, D may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (max(1,N-1)). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A in elements 1 to N-1 of E. On exit, E may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*DLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge (INFO > 0), then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (5*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *sstevx*. It also exists with a native C interface as *LAPACKE_dstevx*.

4.11.51 dsyev

`dsyev` computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsyev(JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsyev_(const char *jobz, const char *uplo, const armpl_int_t *n,
            double *a, const armpl_int_t *lda, double *w, double *work,
            const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1,3*N-1). For optimal efficiency, LWORK >= (NB+2)*N, where NB is the blocksize for DSYTRD returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *ssyev*. It also exists with a native C interface as *LAPACKE_dsyev*.

4.11.52 dsyevd

dsyevd computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Because of large use of BLAS of level 3, dsyevd needs N**2 more workspace than DSYEVX.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsyevd(JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsyevd_(const char *jobz, const char *uplo, const armpl_int_t *n,
             double *a, const armpl_int_t *lda, double *w, double *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array,. dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least 2*N+1. If JOBZ = 'V' and N > 1, LWORK must be at least 1 + 6* N + 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If N <= 1, LIWORK must be at least 1. If JOBZ = 'N' and N > 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i and JOBZ = 'N', then the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not

converge to zero; if INFO = i and JOBZ = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

Related Information

For this routine in other precisions, please see *ssyevd*. It also exists with a native C interface as *LAPACKE_dsyevd*.

4.11.53 dsyevr

dsyevr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

dsyevr first reduces the matrix A to tridiagonal form T with a call to DSYTRD. Then, whenever possible, dsyevr calls DSTEMR to compute the eigenspectrum using Relatively Robust Representations. DSTEMR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" L D L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows.

For each unreduced block (submatrix) of T,

```
 (a) Compute T - sigma I  = L D L^T, so that L and D
     define all the wanted eigenvalues to high relative accuracy.
     This means that small relative changes in the entries of D and L
     cause only small relative changes in the eigenvalues and
     eigenvectors. The standard (unfactored) representation of the
     tridiagonal matrix T does not have this property in general.
(b) Compute the eigenvalues to suitable accuracy.
     If the eigenvectors are desired, the algorithm attains full
     accuracy of the computed eigenvalues only right before
     the corresponding vectors have to be computed, see steps c) and d).
(c) For each cluster of close eigenvalues, select a new
     shift close to the cluster, find a new factorization, and refine
     the shifted eigenvalues to suitable accuracy.
(d) For each eigenvalue with a large enough relative separation compute
     the corresponding eigenvector by forming a rank revealing twisted
     factorization. Go back to (c) for any clusters that remain.
```

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see DSTEMR's documentation and: - Inderjit S. Dhillon and Beresford N. Parlett: "Multiple representations

```
 to compute orthogonal eigenvectors of symmetric tridiagonal matrices,"
Linear Algebra and its Applications, 387(1), pp. 1-28, August 2004.
```

```
 Relative Gaps," SIAM Journal on Matrix Analysis and Applications, Vol. 25,
2004.  Also LAPACK Working Note 154.
```

- Inderjit Dhillon: "A new O(n^2) algorithm for the symmetric

```
 tridiagonal eigenvalue/eigenvector problem",
Computer Science Division Technical Report No. UCB/CSD-97-971,
UC Berkeley, May 1997.
```

Note 1 : dsyevr calls DSTEMR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. dsyevr calls DSTEBZ and DSTEIN on non-ieee machines and when partial spectrum requests are made.

Normal execution of DSTEMR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsyevr(JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU, ABSTOL, M, W,
                  Z, LDZ, ISUPPZ, WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsyevr_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, double *a, const armpl_int_t *lda,
             const double *vl, const double *vu, const armpl_int_t *il,
             const armpl_int_t *iu, const double *abstol, armpl_int_t *m,
             double *w, double *z, const armpl_int_t *ldz,
             armpl_int_t *isuppz, double *work, const armpl_int_t *lwork,
             armpl_int_t *iwork, const armpl_int_t *liwork, armpl_int_t *info,
             ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found. For RANGE = 'V' or 'I' and IU - IL < N - 1, DSTEBZ and DSTEIN are called

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to DLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used. Supplying N columns is always safe.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i). This is an output of DSTEMR (tridiagonal matrix). The support of the eigenvectors of A is typically 1:N because of the orthogonal transformations applied by DORMTR. Implemented only for RANGE = 'A' or 'I' and IU - IL = N - 1

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,26*N). For optimal efficiency, LWORK >= (NB+6)*N, where NB is the max of the blocksize for DSYTRD and DORMTR returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= max(1,10*N).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: Internal error

Related Information

For this routine in other precisions, please see *ssyevr*. It also exists with a native C interface as *LAPACKE_dsyevr*.

4.11.54 dsyevx

dsyevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsyevx(JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU, ABSTOL, M, W,
                  Z, LDZ, WORK, LWORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void dsyevx_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, double *a, const armpl_int_t *lda,
             const double *vl, const double *vu, const armpl_int_t *il,
             const armpl_int_t *iu, const double *abstol, armpl_int_t *m,
             double *w, double *z, const armpl_int_t *ldz, double *work,
             const armpl_int_t *lwork, armpl_int_t *iwork, armpl_int_t *ifail,
             armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*DLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise 8*N. For optimal efficiency, LWORK >= (NB+3)*N, where NB is the max of the blocksize for DSYTRD and DORMTR returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *ssyevx*. It also exists with a native C interface as *LAPACKE_dsyevx*.

4.11.55 dsytrd

dsytrd reduces a real symmetric matrix A to real symmetric tridiagonal form T by an orthogonal similarity transformation: $Q^T * A * Q = T$.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytrd(UPLO, N, A, LDA, D, E, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsytrd_(const char *uplo, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, double *d, double *e, double *tau,
             double *work, const armpl_int_t *lwork, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are over- written by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T: E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 1. For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ssytrd*. It also exists with a native C interface as *LAPACKE_dsytrd*.

4.11.56 sdisna

sdisna computes the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m-by-n matrix. The reciprocal condition number is the 'gap' between the corresponding eigenvalue or singular value and the nearest other one.

The bound on the error, measured by angle in radians, in the I-th computed vector is given by

```
SLAMCH( 'E' ) * ( ANORM / SEP( I ) )
```

where ANORM = 2-norm(A) = max(abs(D(j))). SEP(I) is not allowed to be smaller than SLAMCH('E')*ANORM in order to limit the size of the error bound.

sdisna may also be used to compute error bounds for eigenvectors of the generalized symmetric definite eigenproblem.

Syntax

Fortran specification:

```
use armpl_library

subroutine sdisna(JOB, M, N, D, SEP, INFO)
```

C specification:

```
#include "armpl.h"

void sdisna_(const char *job, const armpl_int_t *m, const armpl_int_t *n,
             const float *d, float *sep, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies for which problem the reciprocal condition numbers should be computed: = 'E': the eigenvectors of a symmetric/Hermitian matrix; = 'L': the left singular vectors of a general matrix; = 'R': the right singular vectors of a general matrix.

M Input parameter.

M is INTEGER

The number of rows of the matrix. M >= 0.

N Input parameter.

N is INTEGER

If JOB = 'L' or 'R', the number of columns of the matrix, in which case N >= 0. Ignored if JOB = 'E'.

D Input parameter.

D is REAL

D is an array, dimension (M) if JOB = 'E'. dimension (min(M, N)) if JOB = 'L' or 'R' The eigenvalues (if JOB = 'E') or singular values (if JOB = 'L' or 'R') of the matrix, in either increasing or decreasing order. If singular values, they must be non-negative.

SEP Output parameter.

SEP is REAL

SEP is an array, dimension (M) if JOB = 'E'. dimension (min(M, N)) if JOB = 'L' or 'R' The reciprocal condition numbers of the vectors.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *ddisna*. It also exists with a native C interface as *LAPACKE_sdisna*.

4.11.57 sopgtr

sopgtr generates a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by SSPTRD using packed storage:

if UPLO = 'U', Q = H(n-1) . . . H(2) H(1),

if UPLO = 'L', Q = H(1) H(2) . . . H(n-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine sopgtr(UPLO, N, AP, TAU, Q, LDQ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sopgtr_(const char *uplo, const armpl_int_t *n, const float *ap,
             const float *tau, float *q, const armpl_int_t *ldq, float *work,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular packed storage used in previous call to SSPTRD; = 'L': Lower triangular packed storage used in previous call to SSPTRD.

N Input parameter.

N is INTEGER

The order of the matrix Q. N >= 0.

AP Input parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). The vectors which define the elementary reflectors, as returned by SSPTRD.

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (N-1). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SSPTRD.

Q Output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). The N-by-N orthogonal matrix Q.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N-1) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dopgtr*. It also exists with a native C interface as *LAPACKE_sopgtr*.

4.11.58 sopmtr

sopmtr overwrites the general real M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T

where Q is a real orthogonal matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of nq-1 elementary reflectors, as returned by SSPTRD using packed storage:

if UPLO = 'U', Q = H(nq-1) . . . H(2) H(1);

if UPLO = 'L', Q = H(1) H(2) . . . H(nq-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine sopmtr(SIDE, UPLO, TRANS, M, N, AP, TAU, C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sopmtr_(const char *side, const char *uplo, const char *trans,
             const armpl_int_t *m, const armpl_int_t *n, const float *ap,
             const float *tau, float *c, const armpl_int_t *ldc, float *work,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular packed storage used in previous call to SSPTRD; = 'L': Lower triangular packed storage used in previous call to SSPTRD.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

AP Input parameter.

AP is REAL

AP is an array, dimension. (M*(M+1)/2) if SIDE = 'L' (N*(N+1)/2) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by SSPTRD. AP is modified by the routine but restored on exit.

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (M-1) if SIDE = 'L'. or (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SSPTRD.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension. (N) if SIDE = 'L' (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dopmtr*. It also exists with a native C interface as *LAPACKE_sopmtr*.

4.11.59 sorgtr

sorgtr generates a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by SSYTRD:

if UPLO = 'U', Q = H(n-1) . . . H(2) H(1),

if UPLO = 'L', Q = H(1) H(2) . . . H(n-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine sorgtr(UPLO, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorgtr_(const char *uplo, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, const float *tau, float *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A contains elementary reflectors from SSYTRD; = 'L': Lower triangle of A contains elementary reflectors from SSYTRD.

N Input parameter.

N is INTEGER

The order of the matrix Q. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the vectors which define the elementary reflectors, as returned by SSYTRD. On exit, the N-by-N orthogonal matrix Q.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (N-1). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SSYTRD.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,N-1). For optimum performance LWORK >= (N-1)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dorgtr*. It also exists with a native C interface as *LAPACKE_sorgtr*.

4.11.60 sorm22

```
SORM22 overwrites the general real M-by-N matrix C with

                 SIDE = 'L'     SIDE = 'R'
 TRANS = 'N':      Q * C          C * Q
 TRANS = 'T':      Q**T * C       C * Q**T

 where Q is a real orthogonal matrix of order NQ, with NQ = M if
 SIDE = 'L' and NQ = N if SIDE = 'R'.
 The orthogonal matrix Q processes a 2-by-2 block structure

        [  Q11  Q12  ]
    Q = [            ]
        [  Q21  Q22  ],

 where Q12 is an N1-by-N1 lower triangular matrix and Q21 is an
 N2-by-N2 upper triangular matrix.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sorm22(SIDE, TRANS, M, N, N1, N2, Q, LDQ, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sorm22_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *n1,
             const armpl_int_t *n2, const float *q, const armpl_int_t *ldq,
             float *c, const armpl_int_t *ldc, float *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose); = 'C': apply Q^T (Conjugate transpose).

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

N1 Input parameter.

N2 Input parameter.

N1 is INTEGER

N2 is INTEGER The dimension of Q12 and Q21, respectively. N1, N2 >= 0. The following requirement must be satisfied: N1 + N2 = M if SIDE = 'L' and N1 + N2 = N if SIDE = 'R'.

Q Input parameter.

Q is REAL

Q is an array, dimension. (LDQ, M) if SIDE = 'L' (LDQ, N) if SIDE = 'R'

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, M) if SIDE = 'L'; LDQ >= max(1, N) if SIDE = 'R'.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For optimum performance LWORK >= M*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dorm22*.

4.11.61 sormtr

sormtr overwrites the general real M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T

where Q is a real orthogonal matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of nq-1 elementary reflectors, as returned by SSYTRD:

if UPLO = 'U', Q = H(nq-1) . . . H(2) H(1);

if UPLO = 'L', Q = H(1) H(2) . . . H(nq-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine sormtr(SIDE, UPLO, TRANS, M, N, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sormtr_(const char *side, const char *uplo, const char *trans,
             const armpl_int_t *m, const armpl_int_t *n, const float *a,
             const armpl_int_t *lda, const float *tau, float *c,
             const armpl_int_t *ldc, float *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A contains elementary reflectors from SSYTRD; = 'L': Lower triangle of A contains elementary reflectors from SSYTRD.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension. (LDA, M) if SIDE = 'L' (LDA, N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by SSYTRD.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M) if SIDE = 'L'; LDA >= max(1, N) if SIDE = 'R'.

TAU Input parameter.

TAU is REAL

TAU is an array, dimension. (M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SSYTRD.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

4.11.62 spteqr

spteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF, and then calling SBDSQR to compute the singular values of the bidiagonal factor.

This routine computes the eigenvalues of the positive definite tridiagonal matrix to high relative accuracy. This means that if the eigenvalues range over many orders of magnitude in size, then the small eigenvalues and corresponding eigenvectors will be computed more accurately than, for example, with the standard QR method.

The eigenvectors of a full or band symmetric positive definite matrix can also be found if SSYTRD, SSPTRD, or SSBTRD has been used to reduce this matrix to tridiagonal form. (The reduction to tridiagonal form, however, may preclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix, if these eigenvalues range over many orders of magnitude.)

Syntax

Fortran specification:

```
use armpl_library

subroutine spteqr(COMPZ, N, D, E, Z, LDZ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void spteqr_(const char *compz, const armpl_int_t *n, float *d, float *e,
             float *z, const armpl_int_t *ldz, float *work, armpl_int_t *info,
             ... );
```

Parameters

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': Compute eigenvalues only. = 'V': Compute eigenvectors of original symmetric matrix also. Array Z contains the orthogonal matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvectors of tridiagonal matrix also.

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the n diagonal elements of the tridiagonal matrix. On normal exit, D contains the eigenvalues, in descending order.

E Input and output parameter.

E is REAL

E is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z Input and output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', the orthogonal matrix used in the reduction to tridiagonal form. On exit, if COMPZ = 'V', the orthonormal eigenvectors of the original symmetric matrix; if COMPZ = 'I', the orthonormal eigenvectors of the tridiagonal matrix. If INFO > 0 on exit, Z contains the eigenvectors associated with only the stored eigenvalues. If COMPZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if COMPZ = 'V' or 'I', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, and i is: <= N the Cholesky factorization of the matrix could not be performed because the i-th principal minor was not positive definite. > N the SVD algorithm failed to converge; if INFO = N+i, i off-diagonal elements of the bidiagonal factor did not converge to zero.

Related Information

For this routine in other precisions, please see *cpteqr*, *dpteqr* and *zpteqr*. It also exists with a native C interface as *LAPACKE_spteqr*.

4.11.63 ssbev

`ssbev` computes all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssbev(JOBZ, UPLO, N, KD, AB, LDAB, W, Z, LDZ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssbev_(const char *jobz, const char *uplo, const armpl_int_t *n,
            const armpl_int_t *kd, float *ab, const armpl_int_t *ldab,
            float *w, float *z, const armpl_int_t *ldz, float *work,
            armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

`JOBZ` is `CHARACTER*1`

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0.

KD Input parameter.

`KD` is `INTEGER`

The number of superdiagonals of the matrix A if `UPLO` = 'U', or the number of subdiagonals if `UPLO` = 'L'. `KD` >= 0.

AB Input and output parameter.

`AB` is `REAL`

`AB` is an array, dimension (`LDAB`, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if `UPLO` = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if `UPLO` = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (max(1,3*N-2)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *dsbev*. It also exists with a native C interface as *LAPACKE_ssbev*.

4.11.64 ssbevd

ssbevd computes all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssbevd(JOBZ, UPLO, N, KD, AB, LDAB, W, Z, LDZ, WORK, LWORK, IWORK,
                  LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssbevd_(const char *jobz, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *kd, float *ab, const armpl_int_t *ldab,
             float *w, float *z, const armpl_int_t *ldz, float *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array,. dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. IF N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 2, LWORK must be at least 2*N. If JOBZ = 'V' and N > 2, LWORK must be at least (1 + 5* N + 2*N**2).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 2, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *dsbevd*. It also exists with a native C interface as *LAPACKE_ssbevd*.

4.11.65 ssbevx

ssbevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssbevx(JOBZ, RANGE, UPLO, N, KD, AB, LDAB, Q, LDQ, VL, VU, IL, IU,
                  ABSTOL, M, W, Z, LDZ, WORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void ssbevx_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, const armpl_int_t *kd, float *ab,
             const armpl_int_t *ldab, float *q, const armpl_int_t *ldq,
             const float *vl, const float *vu, const armpl_int_t *il,
             const armpl_int_t *iu, const float *abstol, armpl_int_t *m,
             float *w, float *z, const armpl_int_t *ldz, float *work,
             armpl_int_t *iwork, armpl_int_t *ifail, armpl_int_t *info,
             ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found; = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

Q Output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). If JOBZ = 'V', the N-by-N orthogonal matrix used in the reduction to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. If JOBZ = 'V', then LDQ >= max(1, N).

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AB to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *dsbevx*. It also exists with a native C interface as *LAPACKE_ssbevx*.

4.11.66 ssbtrd

ssbtrd reduces a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $Q^T * A * Q = T$.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssbtrd(VECT, UPLO, N, KD, AB, LDAB, D, E, Q, LDQ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssbtrd_(const char *vect, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *kd, float *ab, const armpl_int_t *ldab,
             float *d, float *e, float *q, const armpl_int_t *ldq,
             float *work, armpl_int_t *info, ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

= 'N': do not form Q; = 'V': form Q; = 'U': update a matrix X, by forming X*Q.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). On exit, the diagonal elements of AB are overwritten by the diagonal elements of the tridiagonal matrix T; if KD > 0, the elements on the first superdiagonal (if UPLO = 'U') or the first subdiagonal (if UPLO = 'L') are overwritten by the off-diagonal elements of T; the rest of AB is overwritten by values generated during the reduction.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

D Output parameter.

D is REAL

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T.

E Output parameter.

E is REAL

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T: E(i) = T(i,i+1) if UPLO = 'U'; E(i) = T(i+1,i) if UPLO = 'L'.

Q Input and output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). On entry, if VECT = 'U', then Q must contain an N-by-N matrix X; if VECT = 'N' or 'V', then Q need not be set.

On exit: if VECT = 'V', Q contains the N-by-N orthogonal matrix Q; if VECT = 'U', Q contains the product X*Q; if VECT = 'N', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1, and LDQ >= N if VECT = 'V' or 'U'.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsbtrd*. It also exists with a native C interface as *LAPACKE_ssbtrd*.

4.11.67 sspev

sspev computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage.

Syntax

Fortran specification:

```
use armpl_library

subroutine sspev(JOBZ, UPLO, N, AP, W, Z, LDZ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sspev_(const char *jobz, const char *uplo, const armpl_int_t *n,
            float *ap, float *w, float *z, const armpl_int_t *ldz,
            float *work, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *dspev*. It also exists with a native C interface as *LAPACKE_sspev*.

4.11.68 sspevd

sspevd computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine sspevd(JOBZ, UPLO, N, AP, W, Z, LDZ, WORK, LWORK, IWORK, LIWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sspevd_(const char *jobz, const char *uplo, const armpl_int_t *n,
             float *ap, float *w, float *z, const armpl_int_t *ldz,
             float *work, const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the required LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least 2*N. If JOBZ = 'V' and N > 1, LWORK must be at least 1 + 6* N + N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the required LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *dspevd*. It also exists with a native C interface as *LAPACKE_sspevd*.

4.11.69 sspevx

sspevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage. Eigenvalues/vectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine sspevx(JOBZ, RANGE, UPLO, N, AP, VL, VU, IL, IU, ABSTOL, M, W, Z,
                  LDZ, WORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void sspevx_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, float *ap, const float *vl,
             const float *vu, const armpl_int_t *il, const armpl_int_t *iu,
             const float *abstol, armpl_int_t *m, float *w, float *z,
             const armpl_int_t *ldz, float *work, armpl_int_t *iwork,
             armpl_int_t *ifail, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found; = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the selected eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (8*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *dspevx*. It also exists with a native C interface as *LAPACKE_sspevx*.

4.11.70 ssptrd

`ssptrd` reduces a real symmetric matrix A stored in packed form to symmetric tridiagonal form T by an orthogonal similarity transformation: Q^T * A * Q = T.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssptrd(UPLO, N, AP, D, E, TAU, INFO)
```

C specification:

```
#include "armpl.h"

void ssptrd_(const char *uplo, const armpl_int_t *n, float *ap, float *d,
             float *e, float *tau, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are over- written by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

D Output parameter.

D is REAL

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E Output parameter.

E is REAL

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T: E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsptrd*. It also exists with a native C interface as *LAPACKE_ssptrd*.

4.11.71 sstebz

sstebz computes the eigenvalues of a symmetric tridiagonal matrix T. The user may ask for all eigenvalues, all eigenvalues in the half-open interval (VL, VU], or the IL-th through IU-th eigenvalues.

To avoid overflow, the matrix must be scaled so that its largest element is no greater than overflow**(1/2) * underflow**(1/4) in absolute value, and for greatest accuracy, it should not be much smaller than that.

See W. Kahan "Accurate Eigenvalues of a Symmetric Tridiagonal Matrix", Report CS41, Computer Science Dept., Stanford University, July 21, 1966.

Syntax

Fortran specification:

```
use armpl_library

subroutine sstebz(RANGE, ORDER, N, VL, VU, IL, IU, ABSTOL, D, E, M, NSPLIT, W,
                  IBLOCK, ISPLIT, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sstebz_(const char *range, const char *order, const armpl_int_t *n,
             const float *vl, const float *vu, const armpl_int_t *il,
             const armpl_int_t *iu, const float *abstol, const float *d,
             const float *e, armpl_int_t *m, armpl_int_t *nsplit, float *w,
             armpl_int_t *iblock, armpl_int_t *isplit, float *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': ("All") all eigenvalues will be found. = 'V': ("Value") all eigenvalues in the half-open interval (VL, VU] will be found. = 'I': ("Index") the IL-th through IU-th eigenvalues (of the entire matrix) will be found.

ORDER Input parameter.

ORDER is CHARACTER*1

= 'B': ("By Block") the eigenvalues will be grouped by split-off block (see IBLOCK, ISPLIT) and ordered from smallest to largest within the block. = 'E': ("Entire matrix") the eigenvalues for the entire matrix will be ordered from smallest to largest.

N Input parameter.

N is INTEGER

The order of the tridiagonal matrix T. N >= 0.

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. Eigenvalues less than or equal to VL, or greater than VU, will not be returned. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. Eigenvalues less than or equal to VL, or greater than VU, will not be returned. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute tolerance for the eigenvalues. An eigenvalue (or cluster) is considered to be located if it has been determined to lie in an interval whose width is ABSTOL or less. If ABSTOL is less than or equal to zero, then ULP*|T| will be used, where |T| means the 1-norm of T.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the tridiagonal matrix T.

E Input parameter.

E is REAL

E is an array, dimension (N-1). The (n-1) off-diagonal elements of the tridiagonal matrix T.

M Output parameter.

M is INTEGER

The actual number of eigenvalues found. 0 <= M <= N. (See also the description of INFO=2,3.)

NSPLIT Output parameter.

NSPLIT is INTEGER

The number of diagonal blocks in the matrix T. 1 <= NSPLIT <= N.

W Output parameter.

W is REAL

W is an array, dimension (N). On exit, the first M elements of W will contain the eigenvalues. (SSTEBZ may use the remaining N-M elements as workspace.)

IBLOCK Output parameter.

IBLOCK is INTEGER array, dimension (N)

At each row/column j where E(j) is zero or small, the matrix T is considered to split into a block diagonal matrix. On exit, if INFO = 0, IBLOCK(i) specifies to which block (from 1 to the number of blocks) the eigenvalue W(i) belongs. (SSTEBZ may use the remaining N-M elements as workspace.)

ISPLIT Output parameter.

ISPLIT is INTEGER array, dimension (N)

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc., and the NSPLIT-th consists of rows/columns ISPLIT(NSPLIT-1)+1 through ISPLIT(NSPLIT)=N. (Only the first NSPLIT elements will actually be used, but since the user cannot know a priori what value NSPLIT will have, N words must be reserved for ISPLIT.)

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (3*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: some or all of the eigenvalues failed to converge or were not computed: =1 or 3: Bisection failed to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances. This is generally caused by unexpectedly inaccurate arithmetic. =2 or 3: RANGE='I' only: Not all of the eigenvalues IL:IU were found. Effect: M < IU+1-IL Cause: non-monotonic arithmetic, causing the Sturm sequence to be non-monotonic. Cure: recalculate, using RANGE='A', and pick out eigenvalues IL:IU. In some cases, increasing the PARAMETER "FUDGE" may make things work. = 4: RANGE='I', and the Gershgorin interval initially used was too small. No eigenvalues were computed. Probable cause: your machine has sloppy floating-point arithmetic. Cure: Increase the PARAMETER "FUDGE", recompile, and try again.

Related Information

For this routine in other precisions, please see *dstebz*. It also exists with a native C interface as *LAPACKE_sstebz*.

4.11.72 sstedc

sstedc computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band real symmetric matrix can also be found if SSYTRD or SSPTRD or SSBTRD has been used to reduce this matrix to tridiagonal form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLAED3 for details.

Syntax

Fortran specification:

```
use armpl_library

subroutine sstedc(COMPZ, N, D, E, Z, LDZ, WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sstedc_(const char *compz, const armpl_int_t *n, float *d, float *e,
             float *z, const armpl_int_t *ldz, float *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': Compute eigenvalues only. = 'I': Compute eigenvectors of tridiagonal matrix also. = 'V': Compute eigenvectors of original dense symmetric matrix also. On entry, Z contains the orthogonal matrix used to reduce the original matrix to tridiagonal form.

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E Input and output parameter.

E is REAL

E is an array, dimension (N-1). On entry, the subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z Input and output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', then Z contains the orthogonal matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ = 'V', Z contains the orthonormal eigenvectors of the original symmetric matrix, and if COMPZ = 'I', Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1. If eigenvectors are desired, then LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If COMPZ = 'N' or N <= 1 then LWORK must be at least 1. If COMPZ = 'V' and N > 1 then LWORK must be at least (1 + 3* N + 2*N*lg N + 4*N**2), where lg(N) = smallest integer k such that 2**k >= N. If COMPZ = 'I' and N > 1 then LWORK must be at least (1 + 4* N + N**2). Note that for COMPZ = 'I' or 'V', then if N is less than or equal to the minimum divide size, usually 25, then LWORK need only be max(1,2*(N-1)).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If COMPZ = 'N' or N <= 1 then LIWORK must be at least 1. If COMPZ = 'V' and N > 1 then LIWORK must be at least (6 + 6* N + 5*N*lg N). If COMPZ = 'I' and N > 1 then LIWORK must be at least (3 + 5* N). Note that for COMPZ = 'I' or 'V', then if N is less than or equal to the minimum divide size, usually 25, then LIWORK need only be 1.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: The algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

Related Information

For this routine in other precisions, please see *cstedc*, *dstedc* and *zstedc*. It also exists with a native C interface as *LAPACKE_sstedc*.

4.11.73 sstegr

sstegr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T. Any such unreduced matrix has a well defined set of pairwise different real eigenvalues, the corresponding real eigenvectors are pairwise orthogonal.

The spectrum may be computed either completely or partially by specifying either an interval (VL,VU] or a range of indices IL:IU for the desired eigenvalues.

sstegr is a compatibility wrapper around the improved SSTEMR routine. See SSTEMR for further details.

One important change is that the ABSTOL parameter no longer provides any benefit and hence is no longer used.

Note : sstegr and SSTEMR work only on machines which follow IEEE-754 floating-point standard in their handling of infinities and NaNs. Normal execution may create these exceptiona values and hence may abort due to a floating point exception in environments which do not conform to the IEEE-754 standard.

Syntax

Fortran specification:

```
use armpl_library

subroutine sstegr(JOBZ, RANGE, N, D, E, VL, VU, IL, IU, ABSTOL, M, W, Z, LDZ,
                  ISUPPZ, WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sstegr_(const char *jobz, const char *range, const armpl_int_t *n,
             float *d, float *e, const float *vl, const float *vu,
             const armpl_int_t *il, const armpl_int_t *iu,
             const float *abstol, armpl_int_t *m, float *w, float *z,
             const armpl_int_t *ldz, armpl_int_t *isuppz, float *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the N diagonal elements of the tridiagonal matrix T. On exit, D is overwritten.

E Input and output parameter.

E is REAL

E is an array, dimension (N). On entry, the (N-1) subdiagonal elements of the tridiagonal matrix T in elements 1 to N-1 of E. E(N) need not be set on input, but is used internally as workspace. On exit, E is overwritten.

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

Unused. Was the absolute error tolerance for the eigenvalues/eigenvectors in previous versions.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', and if INFO = 0, then the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used. Supplying N columns is always safe.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', then LDZ >= max(1, N).

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th computed eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i). This is relevant in the case when the matrix is split. ISUPPZ is only accessed when JOBZ is 'V' and N > 0.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,18*N) if JOBZ = 'V', and LWORK >= max(1,12*N) if JOBZ = 'N'. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (LIWORK)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= max(1,10*N) if the eigenvectors are desired, and LIWORK >= max(1,8*N) if only the eigenvalues are to be computed. If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

On exit, INFO = 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = 1X, internal error in SLARRE, if INFO = 2X, internal error in SLARRV. Here, the digit X = ABS(IINFO) < 10, where IINFO is the nonzero error code returned by SLARRE or SLARRV, respectively.

Related Information

For this routine in other precisions, please see *cstegr*, *dstegr* and *zstegr*. It also exists with a native C interface as *LAPACKE_sstegr*.

4.11.74 sstein

sstein computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter MAXITS (currently set to 5).

Syntax

Fortran specification:

```
use armpl_library

subroutine sstein(N, D, E, M, W, IBLOCK, ISPLIT, Z, LDZ, WORK, IWORK, IFAIL,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sstein_(const armpl_int_t *n, const float *d, const float *e,
             const armpl_int_t *m, const float *w, const armpl_int_t *iblock,
             const armpl_int_t *isplit, float *z, const armpl_int_t *ldz,
             float *work, armpl_int_t *iwork, armpl_int_t *ifail,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the tridiagonal matrix T.

E Input parameter.

E is REAL

E is an array, dimension (N-1). The (n-1) subdiagonal elements of the tridiagonal matrix T, in elements 1 to N-1.

M Input parameter.

M is INTEGER

The number of eigenvectors to be found. 0 <= M <= N.

W Input parameter.

W is REAL

W is an array, dimension (N). The first M elements of W contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array W from SSTEBZ with ORDER = 'B' is expected here.)

IBLOCK Input parameter.

IBLOCK is INTEGER array, dimension (N)

The submatrix indices associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first submatrix from the top, =2 if W(i) belongs to the second submatrix, etc. (The output array IBLOCK from SSTEBZ is expected here.)

ISPLIT Input parameter.

ISPLIT is INTEGER array, dimension (N)

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc. (The output array ISPLIT from SSTEBZ is expected here.)

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, M). The computed eigenvectors. The eigenvector associated with the eigenvalue W(i) is stored in the i-th column of Z. Any vector which fails to converge is set to its current iterate after MAXITS iterations.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (5*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (M)

On normal exit, all elements of IFAIL are zero. If one or more eigenvectors fail to converge after MAXITS iterations, then their indices are stored in array IFAIL.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge in MAXITS iterations. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *cstein*, *dstein* and *zstein*. It also exists with a native C interface as *LAPACKE_sstein*.

4.11.75 sstemr

sstemr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T. Any such unreduced matrix has a well defined set of pairwise different real eigenvalues, the corresponding real eigenvectors are pairwise orthogonal.

The spectrum may be computed either completely or partially by specifying either an interval (VL,VU] or a range of indices IL:IU for the desired eigenvalues.

Depending on the number of desired eigenvalues, these are computed either by bisection or the dqds algorithm. Numerically orthogonal eigenvectors are computed by the use of various suitable L D L^T factorizations near clusters of close eigenvalues (referred to as RRRs, Relatively Robust Representations). An informal sketch of the algorithm follows.

For each unreduced block (submatrix) of T,

```
(a) Compute T - sigma I  = L D L^T, so that L and D
    define all the wanted eigenvalues to high relative accuracy.
    This means that small relative changes in the entries of D and L
    cause only small relative changes in the eigenvalues and
    eigenvectors. The standard (unfactored) representation of the
    tridiagonal matrix T does not have this property in general.
(b) Compute the eigenvalues to suitable accuracy.
    If the eigenvectors are desired, the algorithm attains full
    accuracy of the computed eigenvalues only right before
    the corresponding vectors have to be computed, see steps c) and d).
(c) For each cluster of close eigenvalues, select a new
    shift close to the cluster, find a new factorization, and refine
    the shifted eigenvalues to suitable accuracy.
(d) For each eigenvalue with a large enough relative separation compute
    the corresponding eigenvector by forming a rank revealing twisted
    factorization. Go back to (c) for any clusters that remain.
```

For more details, see: - Inderjit S. Dhillon and Beresford N. Parlett: “Multiple representations

```
 to compute orthogonal eigenvectors of symmetric tridiagonal matrices,"
Linear Algebra and its Applications, 387(1), pp. 1-28, August 2004.
```

- Inderjit Dhillon and Beresford Parlett: “Orthogonal Eigenvectors and

```
 Relative Gaps," SIAM Journal on Matrix Analysis and Applications, Vol. 25,
2004.  Also LAPACK Working Note 154.
```

- Inderjit Dhillon: “A new O(n^2) algorithm for the symmetric

```
 tridiagonal eigenvalue/eigenvector problem",
Computer Science Division Technical Report No. UCB/CSD-97-971,
UC Berkeley, May 1997.
```

Further Details 1.‘‘sstemr‘‘ works only on machines which follow IEEE-754 floating-point standard in their handling of infinities and NaNs. This permits the use of efficient inner loops avoiding a check for zero divisors.

Syntax

Fortran specification:

```
use armpl_library

subroutine sstemr(JOBZ, RANGE, N, D, E, VL, VU, IL, IU, M, W, Z, LDZ, NZC,
                  ISUPPZ, TRYRAC, WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sstemr_(const char *jobz, const char *range, const armpl_int_t *n,
             float *d, float *e, const float *vl, const float *vu,
             const armpl_int_t *il, const armpl_int_t *iu, armpl_int_t *m,
             float *w, float *z, const armpl_int_t *ldz,
             const armpl_int_t *nzc, armpl_int_t *isuppz, armpl_int_t *tryrac,
             float *work, const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= ‘N’: Compute eigenvalues only; = ‘V’: Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= ‘A’: all eigenvalues will be found. = ‘V’: all eigenvalues in the half-open interval (VL,VU] will be found. = ‘I’: the IL-th through IU-th eigenvalues will be found.

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the N diagonal elements of the tridiagonal matrix T. On exit, D is overwritten.

E Input and output parameter.

E is REAL

E is an array, dimension (N). On entry, the (N-1) subdiagonal elements of the tridiagonal matrix T in elements 1 to N-1 of E. E(N) need not be set on input, but is used internally as workspace. On exit, E is overwritten.

VL Input parameter.

VL is REAL

If RANGE=’V’, the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = ‘A’ or ‘I’.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0. Not referenced if RANGE = 'A' or 'V'.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', and if INFO = 0, then the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and can be computed with a workspace query by setting NZC = -1, see below.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', then LDZ >= max(1, N).

NZC Input parameter.

NZC is INTEGER

The number of eigenvectors to be held in the array Z. If RANGE = 'A', then NZC >= max(1, N). If RANGE = 'V', then NZC >= the number of eigenvalues in (VL,VU]. If RANGE = 'I', then NZC >= IU-IL+1. If NZC = -1, then a workspace query is assumed; the routine calculates the number of columns of the array Z that are needed to hold the eigenvectors. This value is returned as the first entry of the Z array, and no error message related to NZC is issued by XERBLA.

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th computed eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i). This is relevant in the case when the matrix is split. ISUPPZ is only accessed when JOBZ is 'V' and N > 0.

TRYRAC Input and output parameter.

TRYRAC is LOGICAL

If TRYRAC.EQ..TRUE., indicates that the code should check whether the tridiagonal matrix defines its eigenvalues to high relative accuracy. If so, the code uses relative-accuracy preserving algorithms that might be (a bit) slower depending on the matrix. If the matrix does not define its eigenvalues to high relative accuracy, the code can uses possibly faster algorithms. If TRYRAC.EQ..FALSE., the code is not required to guarantee relatively accurate eigenvalues and can use the fastest possible techniques. On exit, a .TRUE. TRYRAC will be set to .FALSE. if the matrix does not define its eigenvalues to high relative accuracy.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,18*N) if JOBZ = 'V', and LWORK >= max(1,12*N) if JOBZ = 'N'. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (LIWORK)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= max(1,10*N) if the eigenvectors are desired, and LIWORK >= max(1,8*N) if only the eigenvalues are to be computed. If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

On exit, INFO = 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = 1X, internal error in SLARRE, if INFO = 2X, internal error in SLARRV. Here, the digit X = ABS(IINFO) < 10, where IINFO is the nonzero error code returned by SLARRE or SLARRV, respectively.

Related Information

For this routine in other precisions, please see *cstemr*, *dstemr* and *zstemr*. It also exists with a native C interface as *LAPACKE_sstemr*.

4.11.76 ssteqr

ssteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. The eigenvectors of a full or band symmetric matrix can also be found if SSYTRD or SSPTRD or SSBTRD has been used to reduce this matrix to tridiagonal form.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssteqr(COMPZ, N, D, E, Z, LDZ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssteqr_(const char *compz, const armpl_int_t *n, float *d, float *e,
             float *z, const armpl_int_t *ldz, float *work, armpl_int_t *info,
             ... );
```

Parameters

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': Compute eigenvalues only. = 'V': Compute eigenvalues and eigenvectors of the original symmetric matrix. On entry, Z must contain the orthogonal matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvalues and eigenvectors of the tridiagonal matrix. Z is initialized to the identity matrix.

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E Input and output parameter.

E is REAL

E is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z Input and output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', then Z contains the orthogonal matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ = 'V', Z contains the orthonormal eigenvectors of the original symmetric matrix, and if COMPZ = 'I', Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if eigenvectors are desired, then LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (max(1,2*N-2)). If COMPZ = 'N', then WORK is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: the algorithm has failed to find all the eigenvalues in a total of 30* N iterations; if INFO = i, then i elements of E have not converged to

zero; on exit, D and E contain the elements of a symmetric tridiagonal matrix which is orthogonally similar to the original matrix.

Related Information

For this routine in other precisions, please see *csteqr*, *dsteqr* and *zsteqr*. It also exists with a native C interface as *LAPACKE_ssteqr*.

4.11.77 ssterf

ssterf computes all eigenvalues of a symmetric tridiagonal matrix using the Pal-Walker-Kahan variant of the QL or QR algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssterf(N, D, E, INFO)
```

C specification:

```
#include "armpl.h"

void ssterf_(const armpl_int_t *n, float *d, float *e, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the n diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E Input and output parameter.

E is REAL

E is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: the algorithm failed to find all of the eigenvalues in a total of 30* N iterations; if INFO = i, then i elements of E have not converged to zero.

Related Information

For this routine in other precisions, please see *dsterf*. It also exists with a native C interface as *LAPACKE_ssterf*.

4.11.78 sstev

`sstev` computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A.

Syntax

Fortran specification:

```
use armpl_library

subroutine sstev(JOBZ, N, D, E, Z, LDZ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sstev_(const char *jobz, const armpl_int_t *n, float *d, float *e,
            float *z, const armpl_int_t *ldz, float *work, armpl_int_t *info,
            ... );
```

Parameters

JOBZ Input parameter.

`JOBZ` is `CHARACTER*1`

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

N Input parameter.

`N` is `INTEGER`

The order of the matrix. `N` >= 0.

D Input and output parameter.

`D` is `REAL`

`D` is an array, dimension (`N`). On entry, the n diagonal elements of the tridiagonal matrix A. On exit, if `INFO` = 0, the eigenvalues in ascending order.

E Input and output parameter.

`E` is `REAL`

`E` is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A, stored in elements 1 to N-1 of `E`. On exit, the contents of `E` are destroyed.

Z Output parameter.

`Z` is `REAL`

`Z` is an array, dimension (`LDZ`, N). If `JOBZ` = 'V', then if `INFO` = 0, `Z` contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with D(i). If `JOBZ` = 'N', then `Z` is not referenced.

LDZ Input parameter.

`LDZ` is `INTEGER`

The leading dimension of the array `Z`. `LDZ` >= 1, and if `JOBZ` = 'V', `LDZ` >= max(1, `N`).

WORK Output parameter.

`WORK` is `REAL`

`WORK` is an array, dimension (max(1,2*N-2)). If `JOBZ` = 'N', `WORK` is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of E did not converge to zero.

Related Information

For this routine in other precisions, please see *dstev*. It also exists with a native C interface as *LAPACKE_sstev*.

4.11.79 sstevd

sstevd computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine sstevd(JOBZ, N, D, E, Z, LDZ, WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sstevd_(const char *jobz, const armpl_int_t *n, float *d, float *e,
             float *z, const armpl_int_t *ldz, float *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the n diagonal elements of the tridiagonal matrix A. On exit, if INFO = 0, the eigenvalues in ascending order.

E Input and output parameter.

E is REAL

E is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A, stored in elements 1 to N-1 of E. On exit, the contents of E are destroyed.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with D(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array,. dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If JOBZ = 'N' or N <= 1 then LWORK must be at least 1. If JOBZ = 'V' and N > 1 then LWORK must be at least (1 + 4* N + N**2).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If JOBZ = 'N' or N <= 1 then LIWORK must be at least 1. If JOBZ = 'V' and N > 1 then LIWORK must be at least 3+5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of E did not converge to zero.

Related Information

For this routine in other precisions, please see *dstevd*. It also exists with a native C interface as *LAPACKE_sstevd*.

4.11.80 sstevr

sstevr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, sstevr calls SSTEMR to compute the eigenspectrum using Relatively Robust Representations. SSTEMR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" L D L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i-th unreduced block of T,

```
(a) Compute T - sigma_i = L_i D_i L_i^T, such that L_i D_i L_i^T
     is a relatively robust representation,
(b) Compute the eigenvalues, lambda_j, of L_i D_i L_i^T to high
    relative accuracy by the dqds algorithm,
(c) If there is a cluster of close eigenvalues, "choose" sigma_i
    close to the cluster, and go to step (a),
(d) Given the approximate eigenvalue lambda_j of L_i D_i L_i^T,
    compute the corresponding eigenvector by forming a
    rank-revealing twisted factorization.
```

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new O(n^2) algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB//CSD-97-971, UC Berkeley, May 1997.

Note 1 : sstevr calls SSTEMR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. sstevr calls SSTEBZ and SSTEIN on non-ieee machines and when partial spectrum requests are made.

Normal execution of SSTEMR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

Syntax

Fortran specification:

```
use armpl_library

subroutine sstevr(JOBZ, RANGE, N, D, E, VL, VU, IL, IU, ABSTOL, M, W, Z, LDZ,
                  ISUPPZ, WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sstevr_(const char *jobz, const char *range, const armpl_int_t *n,
             float *d, float *e, const float *vl, const float *vu,
             const armpl_int_t *il, const armpl_int_t *iu,
             const float *abstol, armpl_int_t *m, float *w, float *z,
             const armpl_int_t *ldz, armpl_int_t *isuppz, float *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found. For RANGE = 'V' or 'I' and IU - IL < N - 1, SSTEBZ and SSTEIN are called

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the n diagonal elements of the tridiagonal matrix A. On exit, D may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

E Input and output parameter.

E is REAL

E is an array, dimension (max(1,N-1)). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A in elements 1 to N-1 of E. On exit, E may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to SLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i). Implemented only for RANGE = 'A' or 'I' and IU - IL = N - 1

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 20*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal (and minimal) LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= 10*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: Internal error

Related Information

For this routine in other precisions, please see *dstevr*. It also exists with a native C interface as *LAPACKE_sstevr*.

4.11.81 sstevx

sstevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine sstevx(JOBZ, RANGE, N, D, E, VL, VU, IL, IU, ABSTOL, M, W, Z, LDZ,
                  WORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void sstevx_(const char *jobz, const char *range, const armpl_int_t *n,
             float *d, float *e, const float *vl, const float *vu,
             const armpl_int_t *il, const armpl_int_t *iu,
             const float *abstol, armpl_int_t *m, float *w, float *z,
             const armpl_int_t *ldz, float *work, armpl_int_t *iwork,
             armpl_int_t *ifail, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the n diagonal elements of the tridiagonal matrix A. On exit, D may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

E Input and output parameter.

E is REAL

E is an array, dimension (max(1,N-1)). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A in elements 1 to N-1 of E. On exit, E may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge (INFO > 0), then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (5*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *dstevx*. It also exists with a native C interface as *LAPACKE_sstevx*.

4.11.82 ssyev

ssyev computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssyev(JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssyev_(const char *jobz, const char *uplo, const armpl_int_t *n,
            float *a, const armpl_int_t *lda, float *w, float *work,
            const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1,3*N-1). For optimal efficiency, LWORK >= (NB+2)*N, where NB is the blocksize for SSYTRD returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *dsyev*. It also exists with a native C interface as *LAPACKE_ssyev*.

4.11.83 ssyevd

ssyevd computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Because of large use of BLAS of level 3, ssyevd needs N**2 more workspace than SSYEVX.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssyevd(JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssyevd_(const char *jobz, const char *uplo, const armpl_int_t *n,
             float *a, const armpl_int_t *lda, float *w, float *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading

N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is REAL

WORK is an array,. dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least 2*N+1. If JOBZ = 'V' and N > 1, LWORK must be at least 1 + 6* N + 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If N <= 1, LIWORK must be at least 1. If JOBZ = 'N' and N > 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i and JOBZ = 'N', then the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; if INFO = i and JOBZ = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

Related Information

For this routine in other precisions, please see *dsyevd*. It also exists with a native C interface as *LAPACKE_ssyevd*.

4.11.84 ssyevr

ssyevr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ssyevr first reduces the matrix A to tridiagonal form T with a call to SSYTRD. Then, whenever possible, ssyevr calls SSTEMR to compute the eigenspectrum using Relatively Robust Representations. SSTEMR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" L D L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows.

For each unreduced block (submatrix) of T,

```
(a) Compute T - sigma I  = L D L^T, so that L and D
    define all the wanted eigenvalues to high relative accuracy.
    This means that small relative changes in the entries of D and L
    cause only small relative changes in the eigenvalues and
    eigenvectors. The standard (unfactored) representation of the
    tridiagonal matrix T does not have this property in general.
(b) Compute the eigenvalues to suitable accuracy.
    If the eigenvectors are desired, the algorithm attains full
    accuracy of the computed eigenvalues only right before
    the corresponding vectors have to be computed, see steps c) and d).
(c) For each cluster of close eigenvalues, select a new
    shift close to the cluster, find a new factorization, and refine
    the shifted eigenvalues to suitable accuracy.
(d) For each eigenvalue with a large enough relative separation compute
    the corresponding eigenvector by forming a rank revealing twisted
    factorization. Go back to (c) for any clusters that remain.
```

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see SSTEMR's documentation and: - Inderjit S. Dhillon and Beresford N. Parlett: "Multiple representations

```
 to compute orthogonal eigenvectors of symmetric tridiagonal matrices,"
Linear Algebra and its Applications, 387(1), pp. 1-28, August 2004.
```

- Inderjit Dhillon and Beresford Parlett: "Orthogonal Eigenvectors and

```
 Relative Gaps," SIAM Journal on Matrix Analysis and Applications, Vol. 25,
2004.  Also LAPACK Working Note 154.
```

- Inderjit Dhillon: "A new O(n^2) algorithm for the symmetric

```
 tridiagonal eigenvalue/eigenvector problem",
Computer Science Division Technical Report No. UCB/CSD-97-971,
UC Berkeley, May 1997.
```

Note 1 : ssyevr calls SSTEMR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. ssyevr calls SSTEBZ and SSTEIN on non-ieee machines and when partial spectrum requests are made.

Normal execution of SSTEMR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssyevr(JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU, ABSTOL, M, W,
                  Z, LDZ, ISUPPZ, WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssyevr_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, float *a, const armpl_int_t *lda,
             const float *vl, const float *vu, const armpl_int_t *il,
             const armpl_int_t *iu, const float *abstol, armpl_int_t *m,
             float *w, float *z, const armpl_int_t *ldz, armpl_int_t *isuppz,
             float *work, const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found. For RANGE = 'V' or 'I' and IU - IL < N - 1, SSTEBZ and SSTEIN are called

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to SLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used. Supplying N columns is always safe.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i). This is an output of SSTEMR (tridiagonal matrix). The support of the eigenvectors of A is typically 1:N because of the orthogonal transformations applied by SORMTR. Implemented only for RANGE = 'A' or 'I' and IU - IL = N - 1

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,26*N). For optimal efficiency, LWORK >= (NB+6)*N, where NB is the max of the blocksize for SSYTRD and SORMTR returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= max(1,10*N).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: Internal error

4.11.85 ssyevx

ssyevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssyevx(JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU, ABSTOL, M, W,
                  Z, LDZ, WORK, LWORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void ssyevx_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, float *a, const armpl_int_t *lda,
```

(continues on next page)

(continued from previous page)

```
                const float *vl, const float *vu, const armpl_int_t *il,
                const armpl_int_t *iu, const float *abstol, armpl_int_t *m,
                float *w, float *z, const armpl_int_t *ldz, float *work,
                const armpl_int_t *lwork, armpl_int_t *iwork, armpl_int_t *ifail,
                armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise 8*N. For optimal efficiency, LWORK >= (NB+3)*N, where NB is the max of the blocksize for SSYTRD and SORMTR returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *dsyevx*. It also exists with a native C interface as *LAPACKE_ssyevx*.

4.11.86 ssytrd

ssytrd reduces a real symmetric matrix A to real symmetric tridiagonal form T by an orthogonal similarity transformation: $Q^T * A * Q = T$.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytrd(UPLO, N, A, LDA, D, E, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssytrd_(const char *uplo, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, float *d, float *e, float *tau,
             float *work, const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are over- written by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

D Output parameter.

D is REAL

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E Output parameter.

E is REAL

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T: E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 1. For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsytrd*. It also exists with a native C interface as *LAPACKE_ssytrd*.

4.11.87 zhbev

zhbev computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhbev(JOBZ, UPLO, N, KD, AB, LDAB, W, Z, LDZ, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhbev_(const char *jobz, const char *uplo, const armpl_int_t *n,
            const armpl_int_t *kd, armpl_doublecomplex_t *ab,
            const armpl_int_t *ldab, double *w, armpl_doublecomplex_t *z,
            const armpl_int_t *ldz, armpl_doublecomplex_t *work,
            double *rwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (max(1,3*N-2)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *chbev*. It also exists with a native C interface as *LAPACKE_zhbev*.

4.11.88 zhbevd

zhbevd computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhbevd(JOBZ, UPLO, N, KD, AB, LDAB, W, Z, LDZ, WORK, LWORK, RWORK,
                  LRWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhbevd_(const char *jobz, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *kd, armpl_doublecomplex_t *ab,
             const armpl_int_t *ldab, double *w, armpl_doublecomplex_t *z,
             const armpl_int_t *ldz, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, double *rwork,
             const armpl_int_t *lrwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least N. If JOBZ = 'V' and N > 1, LWORK must be at least 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array,. dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of array RWORK. If N <= 1, LRWORK must be at least 1. If JOBZ = 'N' and N > 1, LRWORK must be at least N. If JOBZ = 'V' and N > 1, LRWORK must be at least 1 + 5* N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of array IWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5* N .

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *chbevd*. It also exists with a native C interface as *LAPACKE_zhbevd*.

4.11.89 zhbevx

zhbevx computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhbevx(JOBZ, RANGE, UPLO, N, KD, AB, LDAB, Q, LDQ, VL, VU, IL, IU,
                  ABSTOL, M, W, Z, LDZ, WORK, RWORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void zhbevx_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, const armpl_int_t *kd,
             armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
             armpl_doublecomplex_t *q, const armpl_int_t *ldq,
             const double *vl, const double *vu, const armpl_int_t *il,
             const armpl_int_t *iu, const double *abstol, armpl_int_t *m,
             double *w, armpl_doublecomplex_t *z, const armpl_int_t *ldz,
             armpl_doublecomplex_t *work, double *rwork, armpl_int_t *iwork,
             armpl_int_t *ifail, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found; = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

Q Output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, N). If JOBZ = 'V', the N-by-N unitary matrix used in the reduction to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. If JOBZ = 'V', then LDQ >= max(1, N).

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AB to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*DLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

4.11.90 zhbtrd

zhbtrd reduces a complex Hermitian band matrix A to real symmetric tridiagonal form T by a unitary similarity transformation: $Q^H * A * Q = T$.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhbtrd(VECT, UPLO, N, KD, AB, LDAB, D, E, Q, LDQ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhbtrd_(const char *vect, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *kd, armpl_doublecomplex_t *ab,
             const armpl_int_t *ldab, double *d, double *e,
             armpl_doublecomplex_t *q, const armpl_int_t *ldq,
             armpl_doublecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

= 'N': do not form Q; = 'V': form Q; = 'U': update a matrix X, by forming X*Q.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). On exit, the diagonal elements of AB are overwritten by the diagonal elements of the tridiagonal matrix T; if KD > 0, the elements on the first superdiagonal (if UPLO = 'U') or the first subdiagonal (if UPLO = 'L') are overwritten by the off-diagonal elements of T; the rest of AB is overwritten by values generated during the reduction.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T.

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T: E(i) = T(i,i+1) if UPLO = 'U'; E(i) = T(i+1,i) if UPLO = 'L'.

Q Input and output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, N). On entry, if VECT = 'U', then Q must contain an N-by-N matrix X; if VECT = 'N' or 'V', then Q need not be set.

On exit: if VECT = 'V', Q contains the N-by-N unitary matrix Q; if VECT = 'U', Q contains the product X*Q; if VECT = 'N', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1, and LDQ >= N if VECT = 'V' or 'U'.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *chbtrd*. It also exists with a native C interface as *LAPACKE_zhbtrd*.

4.11.91 zheev

zheev computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A.

Syntax

Fortran specification:

```
use armpl_library

subroutine zheev(JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zheev_(const char *jobz, const char *uplo, const armpl_int_t *n,
            armpl_doublecomplex_t *a, const armpl_int_t *lda, double *w,
```

(continues on next page)

(continued from previous page)

```
            armpl_doublecomplex_t *work, const armpl_int_t *lwork,
            double *rwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1,2*N-1). For optimal efficiency, LWORK >= (NB+1)*N, where NB is the blocksize for ZHETRD returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (max(1, 3*N-2)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *cheev*. It also exists with a native C interface as *LAPACKE_zheev*.

4.11.92 zheevd

zheevd computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine zheevd(JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, RWORK, LRWORK, IWORK,
                  LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zheevd_(const char *jobz, const char *uplo, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda, double *w,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             double *rwork, const armpl_int_t *lrwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least N + 1. If JOBZ = 'V' and N > 1, LWORK must be at least 2* N + N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array,. dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of the array RWORK. If N <= 1, LRWORK must be at least 1. If JOBZ = 'N' and N > 1, LRWORK must be at least N. If JOBZ = 'V' and N > 1, LRWORK must be at least 1 + 5* N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If N <= 1, LIWORK must be at least 1. If JOBZ = 'N' and N > 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i and JOBZ = 'N', then the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; if INFO = i and JOBZ = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

Related Information

For this routine in other precisions, please see *cheevd*. It also exists with a native C interface as *LAPACKE_zheevd*.

4.11.93 zheevr

zheevr computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

zheevr first reduces the matrix A to tridiagonal form T with a call to ZHETRD. Then, whenever possible, zheevr calls ZSTEMR to compute eigenspectrum using Relatively Robust Representations. ZSTEMR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" L D L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows.

For each unreduced block (submatrix) of T,

```
(a) Compute T - sigma I  = L D L^T, so that L and D
    define all the wanted eigenvalues to high relative accuracy.
    This means that small relative changes in the entries of D and L
    cause only small relative changes in the eigenvalues and
    eigenvectors. The standard (unfactored) representation of the
    tridiagonal matrix T does not have this property in general.
(b) Compute the eigenvalues to suitable accuracy.
    If the eigenvectors are desired, the algorithm attains full
    accuracy of the computed eigenvalues only right before
    the corresponding vectors have to be computed, see steps c) and d).
(c) For each cluster of close eigenvalues, select a new
    shift close to the cluster, find a new factorization, and refine
    the shifted eigenvalues to suitable accuracy.
(d) For each eigenvalue with a large enough relative separation compute
    the corresponding eigenvector by forming a rank revealing twisted
    factorization. Go back to (c) for any clusters that remain.
```

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see DSTEMR's documentation and: - Inderjit S. Dhillon and Beresford N. Parlett: "Multiple representations

```
 to compute orthogonal eigenvectors of symmetric tridiagonal matrices,"
Linear Algebra and its Applications, 387(1), pp. 1-28, August 2004.
```

- Inderjit Dhillon and Beresford Parlett: "Orthogonal Eigenvectors and

```
 Relative Gaps," SIAM Journal on Matrix Analysis and Applications, Vol. 25,
2004.  Also LAPACK Working Note 154.
```

- Inderjit Dhillon: "A new O(n^2) algorithm for the symmetric

```
 tridiagonal eigenvalue/eigenvector problem",
Computer Science Division Technical Report No. UCB/CSD-97-971,
UC Berkeley, May 1997.
```

Note 1 : zheevr calls ZSTEMR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. zheevr calls DSTEBZ and ZSTEIN on non-ieee machines and when partial spectrum requests are made.

Normal execution of ZSTEMR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

Syntax

Fortran specification:

```
use armpl_library

subroutine zheevr(JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU, ABSTOL, M, W,
                  Z, LDZ, ISUPPZ, WORK, LWORK, RWORK, LRWORK, IWORK, LIWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zheevr_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, const double *vl, const double *vu,
             const armpl_int_t *il, const armpl_int_t *iu,
             const double *abstol, armpl_int_t *m, double *w,
             armpl_doublecomplex_t *z, const armpl_int_t *ldz,
             armpl_int_t *isuppz, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, double *rwork,
             const armpl_int_t *lrwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found. For RANGE = 'V' or 'I' and IU - IL < N - 1, DSTEBZ and ZSTEIN are called

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to DLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but furutre releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i). This is an output of ZSTEMR (tridiagonal matrix). The support of the eigenvectors of A is typically 1:N because of the unitary transformations applied by ZUNMTR. Implemented only for RANGE = 'A' or 'I' and IU - IL = N - 1

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1,2*N). For optimal efficiency, LWORK >= (NB+1)*N, where NB is the max of the blocksize for ZHETRD and for ZUNMTR as returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (MAX(1, LRWORK)). On exit, if INFO = 0, RWORK(1) returns the optimal (and minimal) LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The length of the array RWORK. LRWORK >= max(1,24*N).

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal (and minimal) LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= max(1,10*N).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: Internal error

Related Information

For this routine in other precisions, please see *cheevr*. It also exists with a native C interface as *LAPACKE_zheevr*.

4.11.94 zheevx

zheevx computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine zheevx(JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU, ABSTOL, M, W,
                  Z, LDZ, WORK, LWORK, RWORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void zheevx_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, const double *vl, const double *vu,
             const armpl_int_t *il, const armpl_int_t *iu,
             const double *abstol, armpl_int_t *m, double *w,
             armpl_doublecomplex_t *z, const armpl_int_t *ldz,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             double *rwork, armpl_int_t *iwork, armpl_int_t *ifail,
             armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= ‘A’: all eigenvalues will be found. = ‘V’: all eigenvalues in the half-open interval (VL,VU] will be found. = ‘I’: the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= ‘U’: Upper triangle of A is stored; = ‘L’: Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = ‘U’, the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = ‘L’, the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO=’L’) or the upper triangle (if UPLO=’U’) of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE=’V’, the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = ‘A’ or ‘I’.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE=’V’, the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = ‘A’ or ‘I’.

IL Input parameter.

IL is INTEGER

If RANGE=’I’, the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = ‘A’ or ‘V’.

IU Input parameter.

IU is INTEGER

If RANGE=’I’, the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = ‘A’ or ‘V’.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH(‘S’), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*DLAMCH(‘S’).

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise 2*N. For optimal efficiency, LWORK >= (NB+1)*N, where NB is the max of the blocksize for ZHETRD and for ZUNMTR as returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

4.11.95 zhetrd

zhetrd reduces a complex Hermitian matrix A to real symmetric tridiagonal form T by a unitary similarity transformation: $Q^H * A * Q = T$.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetrd(UPLO, N, A, LDA, D, E, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhetrd_(const char *uplo, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, double *d, double *e,
             armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are over- written by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T: E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 1. For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *chetrd*. It also exists with a native C interface as *LAPACKE_zhetrd*.

4.11.96 zhpev

zhpev computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix in packed storage.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhpev(JOBZ, UPLO, N, AP, W, Z, LDZ, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhpev_(const char *jobz, const char *uplo, const armpl_int_t *n,
            armpl_doublecomplex_t *ap, double *w, armpl_doublecomplex_t *z,
            const armpl_int_t *ldz, armpl_doublecomplex_t *work,
            double *rwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (max(1, 2*N-1)) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (max(1, 3*N-2)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *chpev*. It also exists with a native C interface as *LAPACKE_zhpev*.

4.11.97 zhpevd

zhpevd computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhpevd(JOBZ, UPLO, N, AP, W, Z, LDZ, WORK, LWORK, RWORK, LRWORK,
                  IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhpevd_(const char *jobz, const char *uplo, const armpl_int_t *n,
             armpl_doublecomplex_t *ap, double *w, armpl_doublecomplex_t *z,
             const armpl_int_t *ldz, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, double *rwork,
             const armpl_int_t *lrwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the required LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least N. If JOBZ = 'V' and N > 1, LWORK must be at least 2*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (MAX(1, LRWORK)). On exit, if INFO = 0, RWORK(1) returns the required LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of array RWORK. If N <= 1, LRWORK must be at least 1. If JOBZ = 'N' and N > 1, LRWORK must be at least N. If JOBZ = 'V' and N > 1, LRWORK must be at least 1 + 5* N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the required LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of array IWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *chpevd*. It also exists with a native C interface as *LAPACKE_zhpevd*.

4.11.98 zhpevx

zhpevx computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage. Eigenvalues/vectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhpevx(JOBZ, RANGE, UPLO, N, AP, VL, VU, IL, IU, ABSTOL, M, W, Z,
                  LDZ, WORK, RWORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void zhpevx_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, armpl_doublecomplex_t *ap,
             const double *vl, const double *vu, const armpl_int_t *il,
             const armpl_int_t *iu, const double *abstol, armpl_int_t *m,
             double *w, armpl_doublecomplex_t *z, const armpl_int_t *ldz,
             armpl_doublecomplex_t *work, double *rwork, armpl_int_t *iwork,
             armpl_int_t *ifail, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= ‘A’: all eigenvalues will be found; = ‘V’: all eigenvalues in the half-open interval (VL,VU] will be found; = ‘I’: the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= ‘U’: Upper triangle of A is stored; = ‘L’: Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = ‘U’, AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = ‘L’, AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = ‘U’, the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = ‘L’, the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE=’V’, the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = ‘A’ or ‘I’.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE=’V’, the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = ‘A’ or ‘I’.

IL Input parameter.

IL is INTEGER

If RANGE=’I’, the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = ‘A’ or ‘V’.

IU Input parameter.

IU is INTEGER

If RANGE=’I’, the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = ‘A’ or ‘V’.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH(‘S’), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*DLAMCH(‘S’).

See “Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy,” by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *chpevx*. It also exists with a native C interface as *LAPACKE_zhpevx*.

4.11.99 zhptrd

zhptrd reduces a complex Hermitian matrix A stored in packed form to real symmetric tridiagonal form T by a unitary similarity transformation: $Q^H * A * Q = T$.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhptrd(UPLO, N, AP, D, E, TAU, INFO)
```

C specification:

```
#include "armpl.h"

void zhptrd_(const char *uplo, const armpl_int_t *n,
             armpl_doublecomplex_t *ap, double *d, double *e,
             armpl_doublecomplex_t *tau, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are over- written by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T: E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *chptrd*. It also exists with a native C interface as *LAPACKE_zhptrd*.

4.11.100 zpteqr

`zpteqr` computes all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using DPTTRF and then calling ZBDSQR to compute the singular values of the bidiagonal factor.

This routine computes the eigenvalues of the positive definite tridiagonal matrix to high relative accuracy. This means that if the eigenvalues range over many orders of magnitude in size, then the small eigenvalues and corresponding eigenvectors will be computed more accurately than, for example, with the standard QR method.

The eigenvectors of a full or band positive definite Hermitian matrix can also be found if ZHETRD, ZHPTRD, or ZHBTRD has been used to reduce this matrix to tridiagonal form. (The reduction to tridiagonal form, however, may preclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix, if these eigenvalues range over many orders of magnitude.)

Syntax

Fortran specification:

```
use armpl_library

subroutine zpteqr(COMPZ, N, D, E, Z, LDZ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zpteqr_(const char *compz, const armpl_int_t *n, double *d, double *e,
             armpl_doublecomplex_t *z, const armpl_int_t *ldz, double *work,
             armpl_int_t *info, ... );
```

Parameters

COMPZ Input parameter.

`COMPZ` is `CHARACTER*1`

= 'N': Compute eigenvalues only. = 'V': Compute eigenvectors of original Hermitian matrix also. Array `Z` contains the unitary matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvectors of tridiagonal matrix also.

N Input parameter.

`N` is `INTEGER`

The order of the matrix. `N` >= 0.

D Input and output parameter.

`D` is `DOUBLE PRECISION`

`D` is an array, dimension (`N`). On entry, the n diagonal elements of the tridiagonal matrix. On normal exit, `D` contains the eigenvalues, in descending order.

E Input and output parameter.

`E` is `DOUBLE PRECISION`

E is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z Input and output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', the unitary matrix used in the reduction to tridiagonal form. On exit, if COMPZ = 'V', the orthonormal eigenvectors of the original Hermitian matrix; if COMPZ = 'I', the orthonormal eigenvectors of the tridiagonal matrix. If INFO > 0 on exit, Z contains the eigenvectors associated with only the stored eigenvalues. If COMPZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if COMPZ = 'V' or 'I', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, and i is: <= N the Cholesky factorization of the matrix could not be performed because the i-th principal minor was not positive definite. > N the SVD algorithm failed to converge; if INFO = N+i, i off-diagonal elements of the bidiagonal factor did not converge to zero.

Related Information

For this routine in other precisions, please see *cpteqr*, *dpteqr* and *spteqr*. It also exists with a native C interface as *LAPACKE_zpteqr*.

4.11.101 zstedc

zstedc computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band complex Hermitian matrix can also be found if ZHETRD or ZHPTRD or ZHBTRD has been used to reduce this matrix to tridiagonal form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See DLAED3 for details.

Syntax

Fortran specification:

```
use armpl_library

subroutine zstedc(COMPZ, N, D, E, Z, LDZ, WORK, LWORK, RWORK, LRWORK, IWORK,
                  LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zstedc_(const char *compz, const armpl_int_t *n, double *d, double *e,
             armpl_doublecomplex_t *z, const armpl_int_t *ldz,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             double *rwork, const armpl_int_t *lrwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': Compute eigenvalues only. = 'I': Compute eigenvectors of tridiagonal matrix also. = 'V': Compute eigenvectors of original Hermitian matrix also. On entry, Z contains the unitary matrix used to reduce the original matrix to tridiagonal form.

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). On entry, the subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z Input and output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', then Z contains the unitary matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ = 'V', Z contains the orthonormal eigenvectors of the original Hermitian matrix, and if COMPZ = 'I', Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1. If eigenvectors are desired, then LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If COMPZ = 'N' or 'I', or N <= 1, LWORK must be at least 1. If COMPZ = 'V' and N > 1, LWORK must be at least N*N. Note that for COMPZ = 'V', then if N is less than or equal to the minimum divide size, usually 25, then LWORK need only be 1.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (MAX(1, LRWORK)). On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of the array RWORK. If COMPZ = 'N' or N <= 1, LRWORK must be at least 1. If COMPZ = 'V' and N > 1, LRWORK must be at least 1 + 3* N + 2*N*lg N + 4*N**2 , where lg(N) = smallest integer k such that 2**k >= N. If COMPZ = 'I' and N > 1, LRWORK must be at least 1 + 4* N + 2*N**2 . Note that for COMPZ = 'I' or 'V', then if N is less than or equal to the minimum divide size, usually 25, then LRWORK need only be max(1,2*(N-1)).

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If COMPZ = 'N' or N <= 1, LIWORK must be at least 1. If COMPZ = 'V' or N > 1, LIWORK must be at least 6 + 6* N + 5*N*lg N. If COMPZ = 'I' or N > 1, LIWORK must be at least 3 + 5* N . Note that for COMPZ = 'I' or 'V', then if N is less than or equal to the minimum divide size, usually 25, then LIWORK need only be 1.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: The algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

Related Information

4.11.102 zstegr

zstegr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T. Any such unreduced matrix has a well defined set of pairwise different real eigenvalues, the corresponding real eigenvectors are pairwise orthogonal.

The spectrum may be computed either completely or partially by specifying either an interval (VL,VU] or a range of indices IL:IU for the desired eigenvalues.

zstegr is a compatibility wrapper around the improved ZSTEMR routine. See DSTEMR for further details.

One important change is that the ABSTOL parameter no longer provides any benefit and hence is no longer used.

Note : zstegr and ZSTEMR work only on machines which follow IEEE-754 floating-point standard in their handling of infinities and NaNs. Normal execution may create these exceptiona values and hence may abort due to a floating point exception in environments which do not conform to the IEEE-754 standard.

Syntax

Fortran specification:

```
use armpl_library

subroutine zstegr(JOBZ, RANGE, N, D, E, VL, VU, IL, IU, ABSTOL, M, W, Z, LDZ,
                  ISUPPZ, WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zstegr_(const char *jobz, const char *range, const armpl_int_t *n,
             double *d, double *e, const double *vl, const double *vu,
             const armpl_int_t *il, const armpl_int_t *iu,
             const double *abstol, armpl_int_t *m, double *w,
             armpl_doublecomplex_t *z, const armpl_int_t *ldz,
             armpl_int_t *isuppz, double *work, const armpl_int_t *lwork,
             armpl_int_t *iwork, const armpl_int_t *liwork, armpl_int_t *info,
             ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the N diagonal elements of the tridiagonal matrix T. On exit, D is overwritten.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). On entry, the (N-1) subdiagonal elements of the tridiagonal matrix T in elements 1 to N-1 of E. E(N) need not be set on input, but is used internally as workspace. On exit, E is overwritten.

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

Unused. Was the absolute error tolerance for the eigenvalues/eigenvectors in previous versions.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', and if INFO = 0, then the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used. Supplying N columns is always safe.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', then LDZ >= max(1, N).

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th computed eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i). This is relevant in the case when the matrix is split. ISUPPZ is only accessed when JOBZ is 'V' and N > 0.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,18*N) if JOBZ = 'V', and LWORK >= max(1,12*N) if JOBZ = 'N'. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (LIWORK)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= max(1,10*N) if the eigenvectors are desired, and LIWORK >= max(1,8*N) if only the eigenvalues are to be computed. If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

On exit, INFO = 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = 1X, internal error in DLARRE, if INFO = 2X, internal error in ZLARRV. Here, the digit X = ABS(IINFO) < 10, where IINFO is the nonzero error code returned by DLARRE or ZLARRV, respectively.

Related Information

For this routine in other precisions, please see *cstegr*, *dstegr* and *sstegr*. It also exists with a native C interface as *LAPACKE_zstegr*.

4.11.103 zstein

zstein computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter MAXITS (currently set to 5).

Although the eigenvectors are real, they are stored in a complex array, which may be passed to ZUNMTR or ZUPMTR for back transformation to the eigenvectors of a complex Hermitian matrix which was reduced to tridiagonal form.

Syntax

Fortran specification:

```
use armpl_library

subroutine zstein(N, D, E, M, W, IBLOCK, ISPLIT, Z, LDZ, WORK, IWORK, IFAIL,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zstein_(const armpl_int_t *n, const double *d, const double *e,
             const armpl_int_t *m, const double *w, const armpl_int_t *iblock,
             const armpl_int_t *isplit, armpl_doublecomplex_t *z,
             const armpl_int_t *ldz, double *work, armpl_int_t *iwork,
             armpl_int_t *ifail, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n diagonal elements of the tridiagonal matrix T.

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The (n-1) subdiagonal elements of the tridiagonal matrix T, stored in elements 1 to N-1.

M Input parameter.

M is INTEGER

The number of eigenvectors to be found. 0 <= M <= N.

W Input parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements of W contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array W from DSTEBZ with ORDER = 'B' is expected here.)

IBLOCK Input parameter.

IBLOCK is INTEGER array, dimension (N)

The submatrix indices associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first submatrix from the top, =2 if W(i) belongs to the second submatrix, etc. (The output array IBLOCK from DSTEBZ is expected here.)

ISPLIT Input parameter.

ISPLIT is INTEGER array, dimension (N)

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc. (The output array ISPLIT from DSTEBZ is expected here.)

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, M). The computed eigenvectors. The eigenvector associated with the eigenvalue W(i) is stored in the i-th column of Z. Any vector which fails to converge is set to its current iterate after MAXITS iterations. The imaginary parts of the eigenvectors are set to zero.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (5*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (M)

On normal exit, all elements of IFAIL are zero. If one or more eigenvectors fail to converge after MAXITS iterations, then their indices are stored in array IFAIL.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge in MAXITS iterations. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *cstein*, *dstein* and *sstein*. It also exists with a native C interface as *LAPACKE_zstein*.

4.11.104 zstemr

zstemr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T. Any such unreduced matrix has a well defined set of pairwise different real eigenvalues, the corresponding real eigenvectors are pairwise orthogonal.

The spectrum may be computed either completely or partially by specifying either an interval (VL,VU] or a range of indices IL:IU for the desired eigenvalues.

Depending on the number of desired eigenvalues, these are computed either by bisection or the dqds algorithm. Numerically orthogonal eigenvectors are computed by the use of various suitable L D L^T factorizations near clusters of close eigenvalues (referred to as RRRs, Relatively Robust Representations). An informal sketch of the algorithm follows.

For each unreduced block (submatrix) of T,

```
(a) Compute T - sigma I  = L D L^T, so that L and D
    define all the wanted eigenvalues to high relative accuracy.
    This means that small relative changes in the entries of D and L
    cause only small relative changes in the eigenvalues and
    eigenvectors. The standard (unfactored) representation of the
    tridiagonal matrix T does not have this property in general.
(b) Compute the eigenvalues to suitable accuracy.
    If the eigenvectors are desired, the algorithm attains full
    accuracy of the computed eigenvalues only right before
    the corresponding vectors have to be computed, see steps c) and d).
(c) For each cluster of close eigenvalues, select a new
    shift close to the cluster, find a new factorization, and refine
    the shifted eigenvalues to suitable accuracy.
(d) For each eigenvalue with a large enough relative separation compute
```

(continues on next page)

(continued from previous page)

```
    the corresponding eigenvector by forming a rank revealing twisted
    factorization. Go back to (c) for any clusters that remain.
```

```
 tridiagonal eigenvalue/eigenvector problem",
Computer Science Division Technical Report No. UCB/CSD-97-971,
UC Berkeley, May 1997.
```

Further Details 1.‘‘zstemr‘‘ works only on machines which follow IEEE-754 floating-point standard in their handling of infinities and NaNs. This permits the use of efficient inner loops avoiding a check for zero divisors.

2. LAPACK routines can be used to reduce a complex Hermitean matrix to real symmetric tridiagonal form.

(Any complex Hermitean tridiagonal matrix has real values on its diagonal and potentially complex numbers on its off-diagonals. By applying a similarity transform with an appropriate diagonal matrix diag(1,e^{i phy_1}, … , e^{i phy_{n-1}}), the complex Hermitean matrix can be transformed into a real symmetric matrix and complex arithmetic can be entirely avoided.)

While the eigenvectors of the real symmetric tridiagonal matrix are real, the eigenvectors of original complex Hermitean matrix have complex entries in general. Since LAPACK drivers overwrite the matrix data with the eigenvectors, `zstemr` accepts complex workspace to facilitate interoperability with ZUNMTR or ZUPMTR.

Syntax

Fortran specification:

```
use armpl_library

subroutine zstemr(JOBZ, RANGE, N, D, E, VL, VU, IL, IU, M, W, Z, LDZ, NZC,
                  ISUPPZ, TRYRAC, WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zstemr_(const char *jobz, const char *range, const armpl_int_t *n,
             double *d, double *e, const double *vl, const double *vu,
             const armpl_int_t *il, const armpl_int_t *iu, armpl_int_t *m,
             double *w, armpl_doublecomplex_t *z, const armpl_int_t *ldz,
             const armpl_int_t *nzc, armpl_int_t *isuppz, armpl_int_t *tryrac,
             double *work, const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

`JOBZ` is `CHARACTER*1`

= ‘`N`’: Compute eigenvalues only; = ‘V’: Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the N diagonal elements of the tridiagonal matrix T. On exit, D is overwritten.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). On entry, the (N-1) subdiagonal elements of the tridiagonal matrix T in elements 1 to N-1 of E. E(N) need not be set on input, but is used internally as workspace. On exit, E is overwritten.

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0. Not referenced if RANGE = 'A' or 'V'.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', and if INFO = 0, then the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th

column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and can be computed with a workspace query by setting NZC = -1, see below.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', then LDZ >= max(1, N).

NZC Input parameter.

NZC is INTEGER

The number of eigenvectors to be held in the array Z. If RANGE = 'A', then NZC >= max(1, N). If RANGE = 'V', then NZC >= the number of eigenvalues in (VL,VU]. If RANGE = 'I', then NZC >= IU-IL+1. If NZC = -1, then a workspace query is assumed; the routine calculates the number of columns of the array Z that are needed to hold the eigenvectors. This value is returned as the first entry of the Z array, and no error message related to NZC is issued by XERBLA.

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th computed eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i). This is relevant in the case when the matrix is split. ISUPPZ is only accessed when JOBZ is 'V' and N > 0.

TRYRAC Input and output parameter.

TRYRAC is LOGICAL

If TRYRAC.EQ..TRUE., indicates that the code should check whether the tridiagonal matrix defines its eigenvalues to high relative accuracy. If so, the code uses relative-accuracy preserving algorithms that might be (a bit) slower depending on the matrix. If the matrix does not define its eigenvalues to high relative accuracy, the code can uses possibly faster algorithms. If TRYRAC.EQ..FALSE., the code is not required to guarantee relatively accurate eigenvalues and can use the fastest possible techniques. On exit, a .TRUE. TRYRAC will be set to .FALSE. if the matrix does not define its eigenvalues to high relative accuracy.
